11. MAB authentication and Web authentication succeed. The user can access the Web resources normally.

RADIUS Accounting for 802.1X and MAB

> **NOTE:**
>
> RADIUS accounting applies only to 802.1X and MAB authentication procedures.

Enterprises or carriers need to charge users who are accessing different enterprise or carrier services such as Internet to be able to accurately and effectively calculate billing information for their customers

When a user gets online, the switch will send accounting start message to the AAA server when authentication is passed and starts accounting; When the user gets offline by either MAC aged out or be deleted, the switch will send accounting stop packet to the AAA server to stop accounting. In the accounting stop packet, the attribute Acct-Session-Time carries the amount of time the user was online.

Users can use the **set protocols dot1x aaa radius accounting disable** <**true | false**> command to enable or disable accounting function for 802.1X and MAB.

AAA server records the packet consumption, you can use the command **run show dot1x dynamic/downloadable filter** to check the counter result. For example,

```
admin@Xorplus# run show  dot1x downloadable filter
  ------------------------------------------------------------
  Downloadable Filter Name : abc
  Applied Interface              : ge-1/1/25
  Applied Client MAC             : 00:00:00:00:11:22
  Downloadable Filter Rule : sequence 500 from destination-address-ipv4  192.168.2.0/24
                             sequence 500 then action forward
  Downloadable Rule Counter: sequence 500       match counter: 115595648 packets
```

```
admin@Xorplus# run show dot1x dynamic filter
==========================================================================
    Filter: f6
      Description     :
      ------------------------------------------------------------
      Sequence        : 50
      Description     :
      Match counter   : 60544 packets
      Match Condition : Destination MAC     : 00:00:00:88:88:88
      Action          : Forward
      ------------------------------------------------------------
      Applied Clients : ge-1/1/25    00:00:00:00:11:22
```

Change of Authorization (CoA)

Server initiated Change of Authorization allows the administrator to modify the authorization of the already authorized users through the CoA messages from the AAA server.

The AAA server sends CoA messages to the PICA8 switch when the authorization information of an authorized user is changed by the administrator. The switch initiates a new authorization of the client when it receives a CoA messages. For example, if the administrator configures to disable the host port on the AAA server, the AAA server will send a CoA-Request message with disable-host-port field to the switch to disable the port connecting to the host.

CoA involves two parties: Dynamic Authorization Server (DAS) and Dynamic Authorization Client (DAC):

- DAS: The component that resides on the NAS (switch) that processes and replies to the Change-of-Authorization (CoA) Request and Disconnect messages.
- DAC: The component that sends CoA-Request and Disconnect messages to the Dynamic Authorization Server. This component often resides on the RADIUS server. For details, please refer to RFC5176.

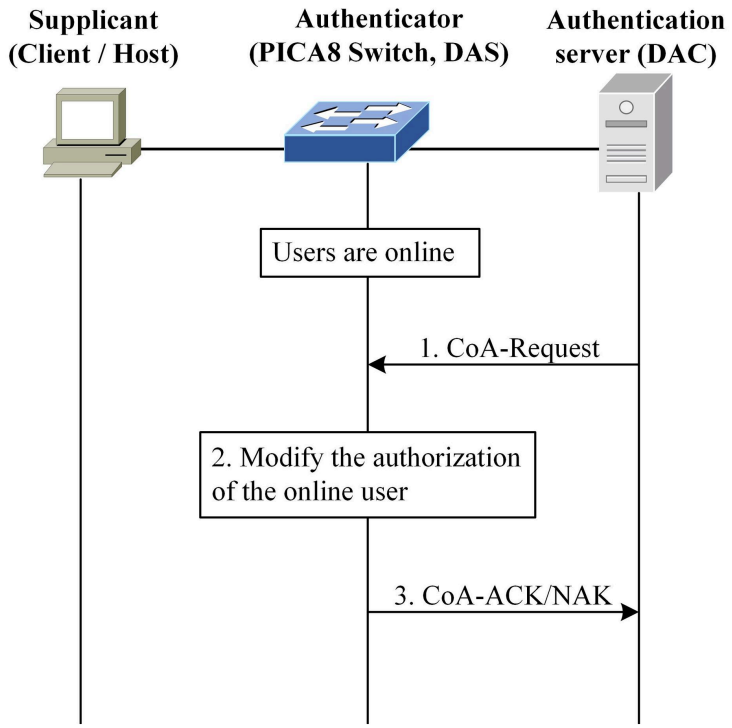
> **NOTE:**

- The CoA feature provides network administrators the flexibility to remotely control authorization changes of clients.
- FreeRADIUS server does not support DAC function. To support DAC function, user needs to connect to an AAA platform that supports DAC of CoA function, such as PacketFence.
- PICOS supports to configure a maximum of 20 CoA dynamic authorization clients.

CoA includes two types of message flows: Disconnect and Change-of-Authorization (CoA) processes. Disconnect message terminates a user session immediately whereas CoA message modifies the user session authorization attributes.

Figure 3 illustrates a CoA message exchange between an 802.1X-enabled client, a switch operating as Authenticator (DAS), and a RADIUS server operating as an Authentication Server (DAC).

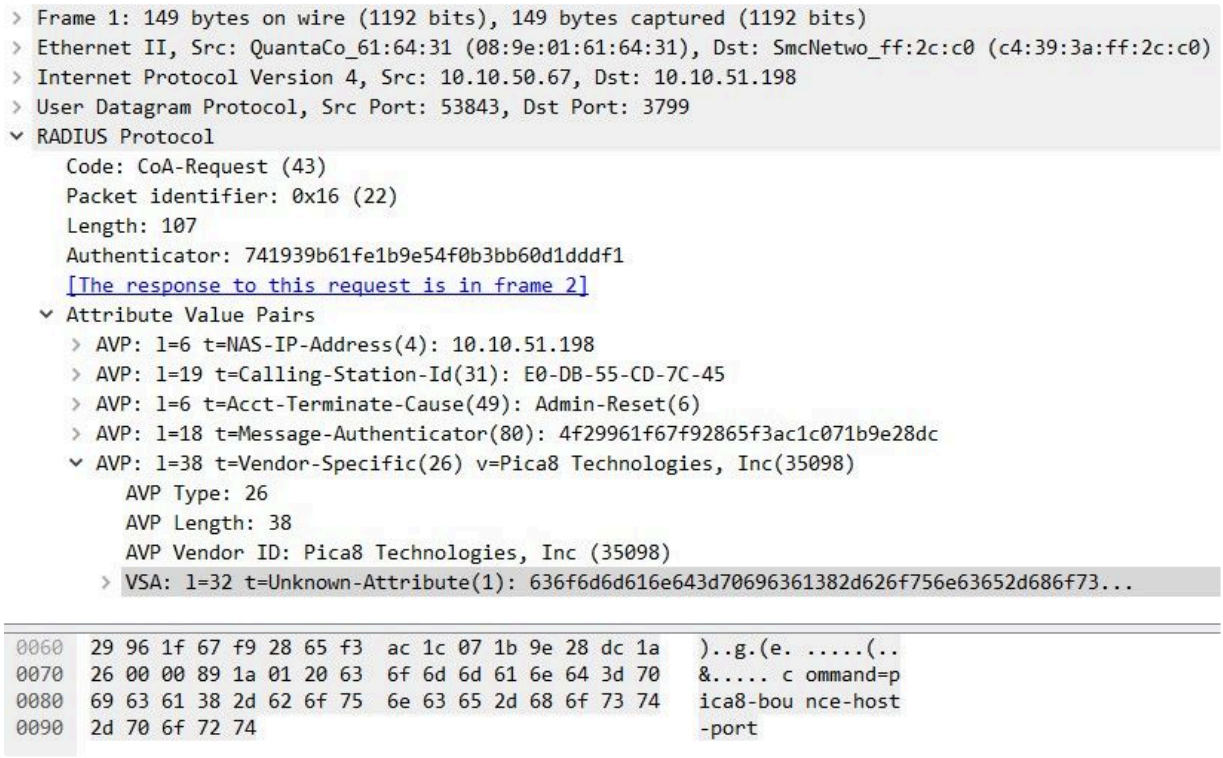
Figure 3. Message Exchange during CoA Process



The AAA server sends a CoA-Request packet to the switch to request to change the user authorization attribute. The packet may include one of the four authorization attributes supported by PICOS: Disconnect, Re-authenticate, Bounce-host-port and Disable-host-port, as shown in Figure 3.

- **Disconnect**: When the switch receives the Disconnect message, it terminates the user session immediately.
- **Re-authenticate**: When the switch receives the re-authenticate CoA Request message from the AAA server, the switch sends an EAP Request message to the supplicant to initiate re-authentication.
- **Bounce-host-port**: The CoA-Request message with bounce-host-port attribute brings the interface down and then up immediately.
- **Disable-host-port**: The CoA-Request message with disable-host-port attribute brings the interface down. The interface cannot be used after this operation. If you want to enable this interface, use the **set interface gigabit-ethernet**<*port*> **disable false** CLI command.

Figure 4. Bounce-host-port Attribute in CoA-Request Message



1. DAS performs the action according to the authorization attribute in the CoA-Request packet.

2. DAS replies with a CoA-ACK/NAK message. While sending the CoA-ACK/NAK, the source port in the CoA-Request packet is used as the destination port whereas the destination port of 3799 in the CoA-Request packet is used as the source port.

- If DAS successfully applies the action in the CoA Request packet it will reply with a CoA-ACK message. DAS replies with a CoA-ACK message.
- If for some reason the DAS is unable to carry out the action requested in the CoA Request packet, the DAS replies with a CoA-NAK message.

Downloadable ACL

The downloadable ACL is a dynamic packet filtering function that is implemented by the AAA server and the firewall filter module of the switch. To use downloadable ACL, users have to configure the ACL name and the detailed ACL rules on the AAA server; the switch only has to enable 802.1X authentication or MAB authentication locally.

After the 802.1X authentication or MAB authentication has succeeded, the AAA server sends the ACL to the switch in the Access-Accept message. The switch parses the received downloadable ACL field and implements packet filtering through the packet matching rules and processing operations. The downloadable ACL is delivered to a specific MAB or 802.1X user and is delivered only when the respective authentications are passed successfully.

For downloadable ACL, PICA8 has defined two vendor-specific-attributes (VSAs) on the AAA server. First one is the **Pica8-IP-Downloadable-ACL-Name**, the attribute ID number is 3, and **Pica8-IP-Downloadable-ACL-Rule**, the attribute ID number is 2 in the PICA8 RADIUS dictionary. To use these VSAs the users have to import the PICA8 RADIUS dictionary to the AAA server. For details about how to import PICA8 RADIUS dictionary, please refer to the document How to Import PICA8 RADIUS Dictionary.

The values for **Pica8-IP-Downloadable-ACL-Rule** attribute are implemented based on the firewall filter module. The template of supported matching conditions/actions are as follows.

Template of Downloadable ACL:

```
sequence [0..9999] from destination-address-ipv4 <IPv4Net>
```

sequence [0..9999] from source-address-ipv4 <IPv4Net>

sequence [0..9999] from destination-address-ipv6 <IPv6Net>

sequence [0..9999] from source-address-ipv6 <IPv6Net>

sequence [0..9999] from destination-port <uintrange>

sequence [0..9999] from source-port <uintrange>

sequence [0..9999] from ether-type [1501..65535]

sequence [0..9999] from protocol icmp

sequence [0..9999] from protocol icmp [type|code] [0..254]

sequence [0..9999] from protocol igmp

sequence [0..9999] from protocol ip

sequence [0..9999] from protocol tcp

sequence [0..9999] from protocol ospf

sequence [0..9999] from protocol others [0..255]

sequence [0..9999] then action [discard|forward]

and is the logical operator between the matching fields with the same sequence number, that is, to be considered to match a firewall filter rule and included in a class, the packets must match all of the matching fields with the same sequence number. NOTE that there is a drop rule for each firewall filter rule by default.

To reduce the size of Access-Accept message, PICOS supports parsing the abbreviation downloadable ACLs. The following table shows the supported abbreviation styles.

Full keywords	Abbreviation
sequence	s, se, seq
destination-address-ipv4	dip4
destination-address-ipv6	dip6
destination-port	dp, dport
source-address-ipv4	sip4
source-address-ipv6	sip6
source-port	sp, sport
protocol	pro
then	t, th
from	f, fr
action	a, ac, act
discard	di, dis, disc
forward	fo, for, forw
ether-type	etyp

It is also supported to merge multiple **from** statements and **action** statements of the same sequence number into one single line.

For example,

For the following downloadable ACL rules.

```
sequence 100 from protocol tcp
sequence 100 from source-port 443
sequence 100 from destination-address-ipv4 63.18.0.0/16
sequence 100 then action forward
```

The equivalent ACL rule to that is:

```
sequence 100 from protocol tcp from source-port 443 from destination-address-ipv4 63.18.0.0/16 then action forward
```

or

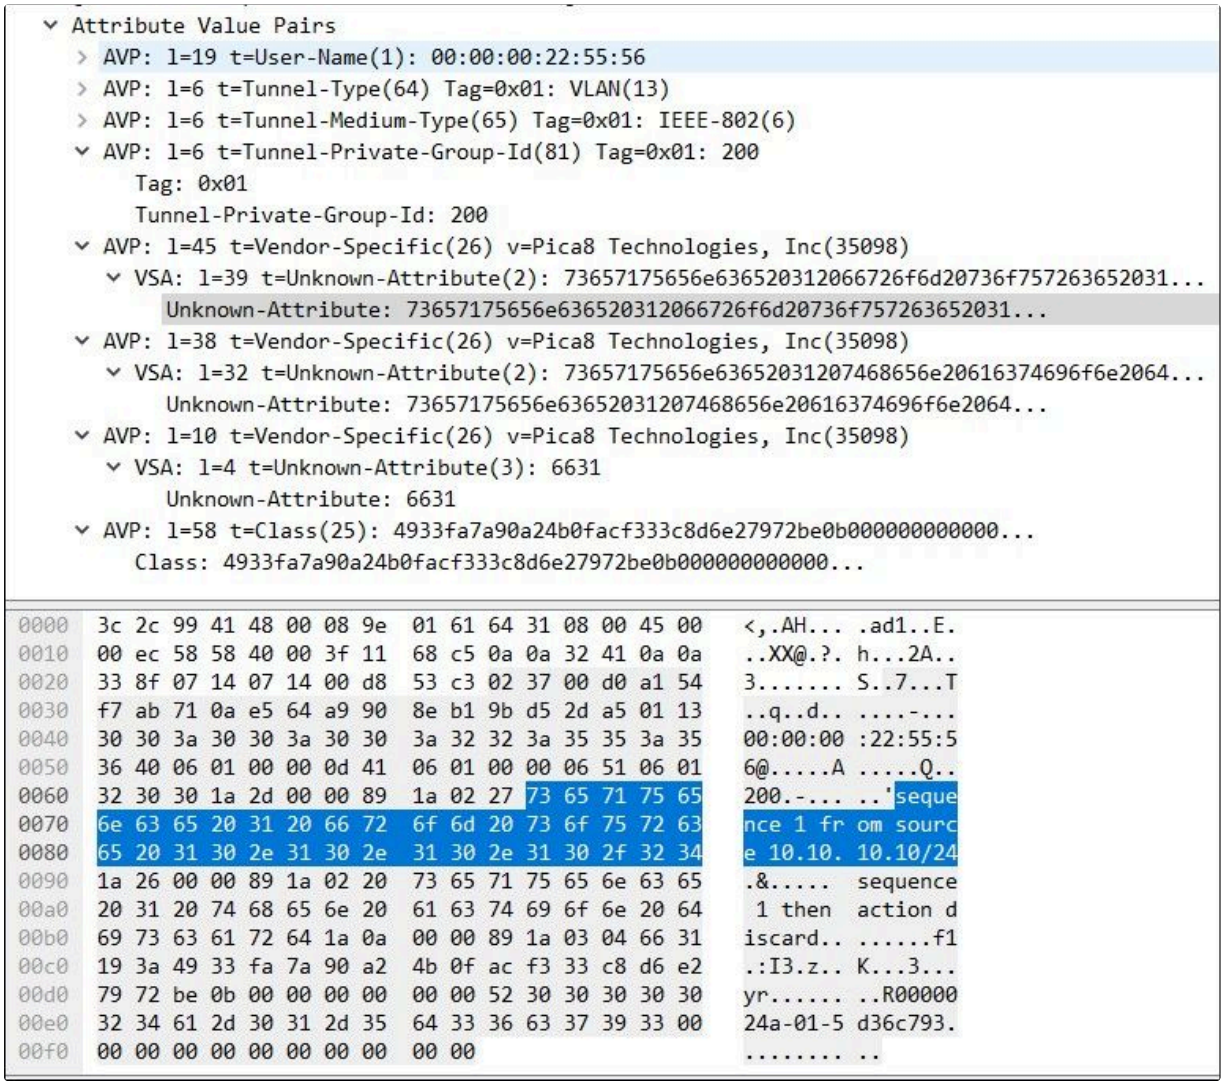
```
s 100 f pro tcp f sp 443 f dip4 63.18.0.0/16 t a fo
```

This equivalent ACL greatly reduces the size of the Access-Accept message.

NOTE:

- If the format or the content of the downloadable ACL do not meet the template conditions mentioned above, the ACL rule fails to be parsed and applied to the hardware.
- On the AAA server, make sure you use only one Pica8-IP-Downloadable-ACL-Name attribute which carries the downloadable ACL name, but you can have multiple Pica8-IP-Downloadable-ACL-Rule attributes.

The following image shows the format of the downloadable ACL in the Access-Accept message which is sent from the AAA server to the switch:



On the switch, you can use the **run show dot1x interface** and **run show dot1x downloadable filter** commands to view the detailed information about the downloadable ACL delivered by the interface.

For example,

```
admin@Xorplus# run show dot1x interface gigabit-ethernet ge-1/1/48
Interface ge-1/1/48:
============================================================
Client MAC                              : 00:00:00:11:11:11
Status                                      : authorized
Success Auth Method             : MAB
Last Success Time                   : Sun Mar 20 21:08:11 2022
Traffic Class                             : Other
Downloadable Filter Name     : pica-dacl-mab (active)
============================================================

admin@Xorplus# run show dot1x downloadable filter
=============================================
Filter: pica-dacl-mab
Description     :
---------------------------------------------------------------------
Sequence        : 1
Description     :
Match counter   : 0 packets
```

```
Match Condition : L4 Destination Port  : 67..67
                  L4 Source Port       : 68..68
                  Protocol             : udp
                  Action               : Forward
```

The employment of the downloadable ACL and the configuration examples on the ClearPass/Cisco ISE and the switch are detailed in the document Configuring Dynamic and Downloadable ACL for ClearPass and Configuring Dynamic and Downloadable ACL on Cisco ISE in Typical Configuration of NAC.

NOTE:

- PICOS supports configuring ACL rules based on firewall filter for ports on which dynamic/downloadable ACLs of NAC are already configured. If both types of ACL rules are configured, the matching rules are as follows:

  The priority of the firewall filter-based ACL rule is higher than that of the NAC dynamic/downloadable ACL. However, in the case when the message hits an ACL rule of discard action, the discard rule has the highest priority, that is to say, the message will be discarded, regardless of whether the rule is a firewall filter-based ACL rule or the dynamic/downloadable ACL of NAC.

- When matching ACL rules, the system processes IPv6 rules (**destination-address-ipv6/source-address-ipv6**) with higher priority than other ACL rules. Even if the sequence number of IPv6 rule is larger than the other rules', the IPv6 rule will be processed first.
  For example, confider the ACL rules shown below. The **destination-address-ipv6** rule will be processed first then all the other rules will be processed.

  admin@XorPlus# set dot1x filter MyFilter sequence 100 from source-port 332
  admin@XorPlus# set dot1x filter MyFilter sequence 100 then action discard
  admin@XorPlus# set dot1x filter MyFilter sequence 200 from destination-address-ipv6 2001::1/128
  admin@XorPlus# set dot1x filter MyFilter sequence 200 then action forward

  Therefore, when planning ACL rules, it is recommended to configure IPv6 source/destination rules with smaller sequence numbers. If not then it is highly stressed to keep this exception in mind while trying to achieve the desired effect.

- IPv6 ACL rules cannot be configured with the following rules at the same time:
  - Configuration with ether-type or destination-port is not supported on the ingress port.
  - Configuration with ether-type is not supported on the egress port.

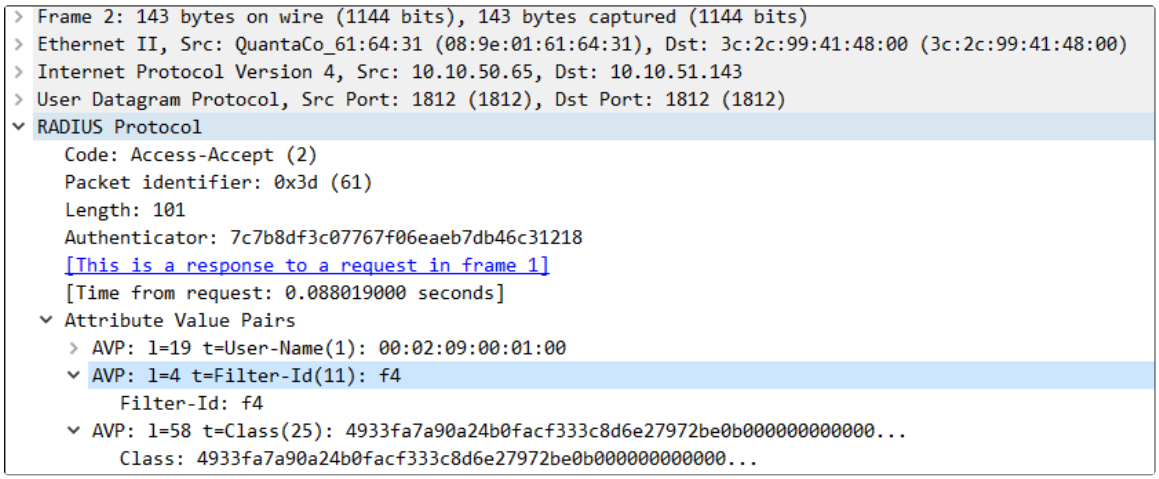
Dynamic ACL

The dynamic ACL is a dynamic packet filtering function that is implemented by the AAA server and the firewall filter module of the switch function. Instead of downloadable ACL getting the detailed ACL rules from the AAA server, the detailed rules of dynamic ACL should be preconfigured on the switch and the ACL should be applied just when the ACL name is received from AAA server. The name of the dynamic ACL is configured on the AAA server which uses the RADIUS standard attribute **Filter-Id**, an attribute defined by the RFC3576 standard and the attribute ID number is 11.

After the 802.1X authentication or MAB authentication has succeeded, the AAA server sends the ACL name to the switch in the Access-Accept message carried with Filter-Id field. The switch parses the received dynamic ACL field and implements packet filtering through the packet matching rules and processing operations. Each dynamic ACL is sent only with an Access-Accept message when any of MAB or 802.1X authentication has passed successfully on the AAA server for a specific client.

The switch delivers the ACL rule to match the packets and process the packets to implement packet filter rule. If the AAA server delivers a wrong ACL name, the switch prints a system log, and then drops the flow by using the default drop rule.

The following image shows the format of Filter-ID in the Access-Accept message which is sent from the AAA server to the switch:



On the switch, use the following commands to configure the NAC-based dynamic ACL rule.

set protocols dot1x filter <*filter-name*> **sequence** <*sequence-number*> **from** <*filter-condition*>

set protocols dot1x filter <*filter-name*> **sequence** <*number*> **then action** <**discard** | **forward**>

and is the logical operator between the matching fields with the same sequence number, that is, to be considered to match a firewall filter rule and included in a class, the packets must match all of the matching fields with the same sequence number. NOTE that there is a drop rule for each firewall filter rule by default.

On the switch, you can use the **run show dot1x interface** command to view the detailed information about the dynamic ACL applied to the interface.

For example,

admin@Xorplus# run show dot1x interface gigabit-ethernet ge-1/1/5

Interface ge-1/1/5:

==========

Client MAC : 08:9e:01:9e:cc:fe

Status : authorized

Dynamic VLAN ID : 200

Dynamic Filter Name : f2

The employment of the dynamic ACL and the configuration examples on the ClearPass/Cisco ISE and the switch are detailed in the document Configuring Dynamic and Downloadable ACL for ClearPass and Configuring Dynamic and Downloadable ACL on Cisco ISE in Typical Configuration of NAC.

NOTE:

- The filter name configured in the filter-id must be the same as the filter name of the dynamic ACL configured on the switch.
- PICOS supports configuring ACL rules based on firewall filter for ports on which dynamic/downloadable ACLs of NAC are already configured. If both types of ACL rules are configured, the matching rules are as follows:

  The priority of the firewall filter-based ACL rule is higher than that of the NAC dynamic/downloadable ACL. However, in the case when the message hits an ACL rule of discard action, the discard rule has the highest priority, that is to say, the message will be discarded, regardless of whether the rule is a firewall filter-based ACL rule or the dynamic/downloadable ACL of NAC.

Response to session-timeout Attribute

If the returned access-accept RADIUS message carries the attribute session-timeout after MAB/802.1X authentication, the authenticated session will expire after a period of session-timeout and start a new authentication process.

- If the access-accept RADIUS message carried the timeout-session attribute and the timeout value is not equal to 0 (such as 30s), the switch will send request packet to the AAA server or the client every 30s for re-authentication.
- If the access-accept RADIUS message carried the timeout-session attribute but the timeout value is equal to 0, the switch does not send any re-authentication request packet to the AAA server or the client. No action is taken, it has the same effect as if the session timeout attribute was not used or the returned access accept packet did not had the timeout attribute.
- If the access-accept RADIUS message does not include the timeout-session attribute, the switch will send the re-authentication request packet to the AAA server or the client every 60 mins (default value) for re-authentication. The default 60 minutes re-authentication applies in situations where the MAC address does not age out for 60 minutes.

Vendor Specific Attribute (VSA)

Vendor Specific Attribute (VSA) is a vendor defined attribute in the vendor's RADIUS dictionary. For the NAC function, PICOS defines four VSAs whereas the PICA8 vendor ID is 35098:

Pica8-AVPair, the attribute ID number is 1;

Pica8-IP-Downloadable-ACL-Rule, the attribute ID number is 2;

Pica8-IP-Downloadable-ACL-Name, the attribute ID number is 3;

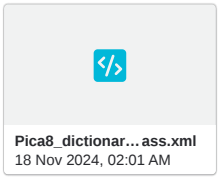
Pica8-Redirect-URL, the attribute ID number is 4.

To use these VSAs, the users have to import the PICA8 RADIUS dictionary to AAA server. We describe how to import PICA8 RADIUS dictionary to ClearPass, Cisco ISE and FreeRadius below.

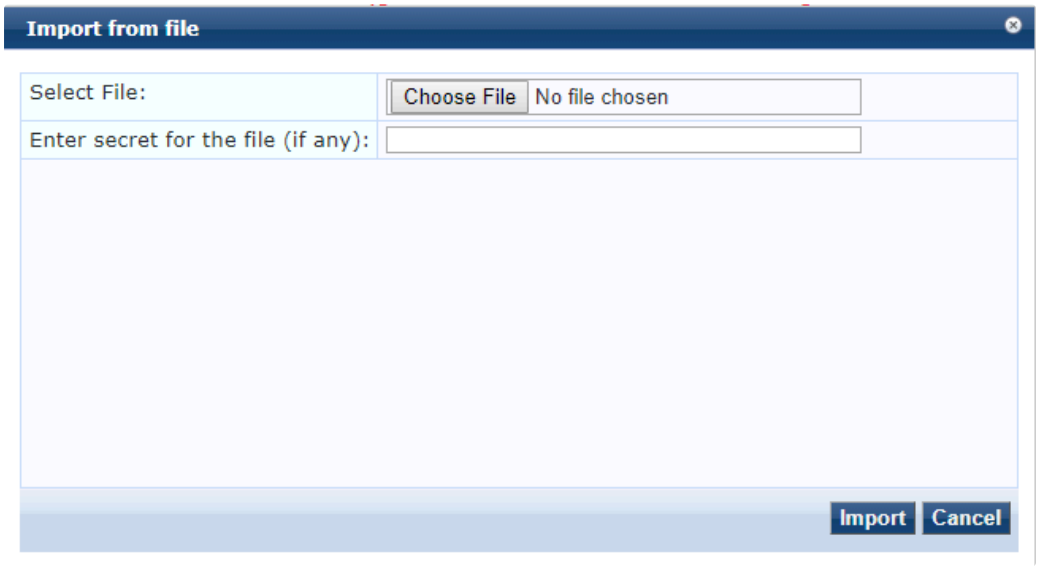
How to Import PICA8 RADIUS Dictionary to ClearPass

To import the PICA8 RADIUS dictionary file to ClearPass, perform the following tasks in CPPM on ClearPass.

1. Click on **AdministrationàDictionariesà**
2. Click on **Import** (top right corner).
3. Choose the PICA8 RADIUS dictionary file and click **Import**.
4. You can use the PICA8 RADIUS dictionary file attached below if you don't have it.



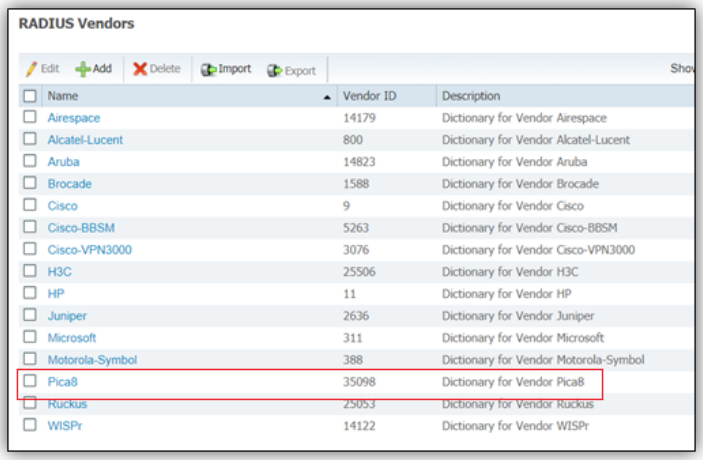
5. Refer to the image below for reference.

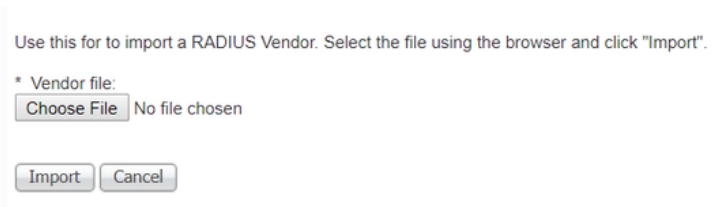


How to Import PICA8 RADIUS Dictionary for Cisco ISE

We need to import the Pica8 radius dictionary file to ISE for Pica8 switches to work properly with ISE. Follow the steps below to import the dictionary file.

1. Click on **Policy Elements -> Dictionaries -> System -> Radius -> RADIUS Vendors**.
2. Click on Import and choose the Pica8 dictionary file, now click import to load the dictionary file.
3. You should be able to see Pica8 dictionary file in the list of vendor dictionaries after successful import.

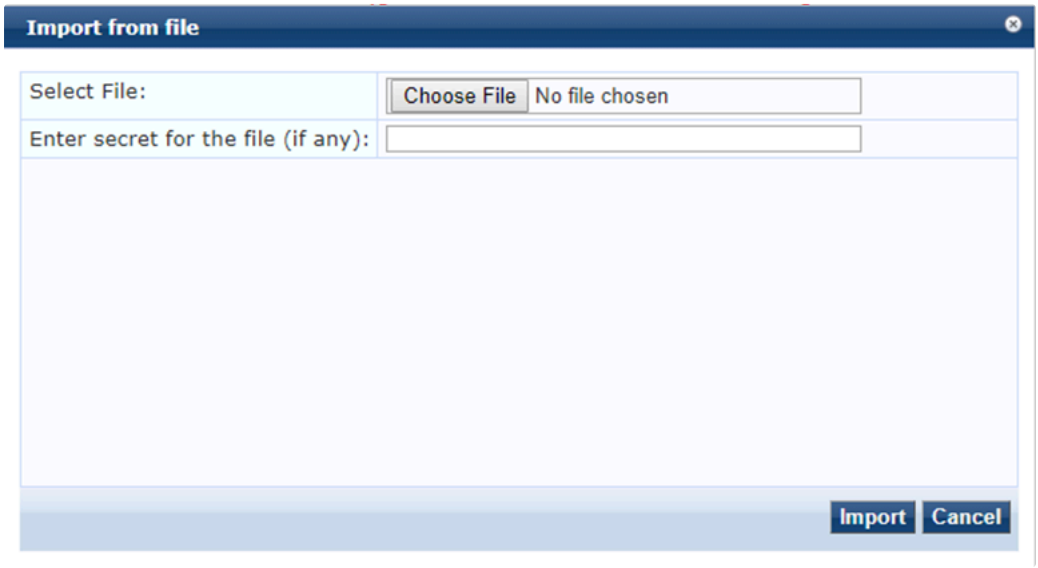




4. You can also create your dictionary file here by clicking Add and adding attributes as mentioned in dictionary file.
5. Please note adding a dictionary file manually you need to enter the attributes as they are in the dictionary files. The two most important items are the VENDOR name and ID and Pica8-AVPair attribute. The VENDOR name must be set to Pica8 and the ID should be 35098.
6. The dictionary file for Cisco ISE is attached below:

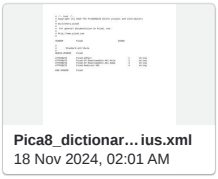
Pica8_dictionary_ISE.xml
18 Nov 2024, 02:01 AM

7. Refer to the image below for reference.



How to Import PICA8 RADIUS Dictionary to FreeRadius server

To import the Pica8 Radius dictionary to FreeRadius server, copy the file attached below to location ***/usr/share/freeradius/***.



Pica8_dictionar… ius.xml
18 Nov 2024, 02:01 AM

Configuring NTP and the Time Zone Parameter

> **NOTE:**
> NTP does support IPv6.

Configuring the NTP Server IP Address

The L2/L3 switch synchronizes with the NTP server only when the configuration commands are committed using the **commit** command. User can change the NTP server's IP address, as shown below.

```
admin@XorPlus# set system ntp server-ip 192.168.10.100
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring the NTP Source Interface

NTP source interface is required if inband management interface is used to connect with the NTP server. Note that if the NTP source interface is not configured, the system will print an error log.

```
admin@XorPlus# set system ntp source-interface vlan-300
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring the Time Zone

Configure the time zone as follows (The time zone configured below is Pacific/Kosrae).

```
admin@XorPlus# set system timezone Pacific/Kosrae
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring the System Clock

```
admin@XorPlus> set date 2012.01.01-23:59
Sun Jan 1 23:59:00 UTC 2012
admin@XorPlus>
```

The clock will be set in the hardware.

Configuring PTP

- Principle
  - Introduction to PTP
  - Basic Concepts
  - Delay Request-Response Mechanism
- Product Support
- PTP Configuration
  - Procedure
- Configuration Example

Principle

> The PicOS supports PTP function since 2.9.2.

Introduction to PTP

On a modern communication network, most telecommunications services require that the frequency offset or time difference between devices is within an acceptable range. To meet this requirement, network clock synchronization must be implemented.

Network clock synchronization includes phase synchronization and frequency synchronization.

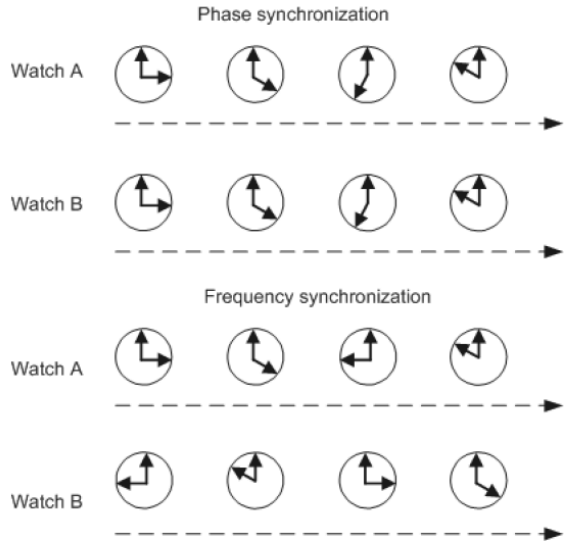
Phase synchronization

Phase synchronization, also called time synchronization, refers to the consistency of both frequencies and phases between signals. That is to say, the phase difference between signals is always 0.

Frequency synchronization

Frequency synchronization refers to constant phase difference between signals. It ensures that signals are sent or received at the same rate at a moment so that all devices on the communication network operate at the same rate.

Figure 1 Difference between phase synchronization and frequency synchronization



PTP (Precision Time Protocol) is a time synchronization protocol, which is not only used for high-precision time synchronization between devices, but can also be used to synchronize the frequency between devices. Compared to the existing time synchronization mechanism, PTP has the following advantages:

- Compared to NTP (Network Time Protocol), PTP can meet the more accurate time synchronization requirements, NTP generally can only achieve sub-second time synchronization accuracy, and PTP can reach sub-microsecond.
- Compared to GPS (Global Positioning System), PTP has lower construction and maintenance costs, and because it can get rid of the dependence on GPS, it has special meaning in national security.

Basic Concepts

PTP domain

A PTP domain is a logical grouping of clocks that synchronize to each other using the protocol IEEE 1588v2, but that are not necessarily synchronized to clocks in another domain. Each PTP domain is an independent PTP clock synchronization system and has only one clock source.

Clock node

Clock nodes are nodes in a PTP domain. PTP defines the following types of clock nodes:

- Ordinary clock (OC) device: provides only one physical port to participate in time synchronization in a PTP domain. An OC device uses this port to synchronize time with an upstream device or send time to a downstream device.

- Boundary clock (BC) device: provides two or more physical ports to participate in time synchronization in a PTP domain. One port synchronizes time with an upstream device, and the others send the time to downstream devices. A clock node is also a BC device if it functions as the clock source and sends time to downstream devices through multiple PTP ports.
- Transparent clock (TC) device: forwards PTP messages between its PTP ports and measures the link delay of the messages. Different from an OC device and a BC device, a TC device does not synchronize time with other devices through ports.
    - E2ETC (End-to-End Transparent Clock): forwards packets of non-P2P (non-Peer-to-Peer) types directly on the network and participates in the calculation of the entire link Time.

      E2ETC calculate the residence time of the device, which is the time it takes the event message from ingress port to egress port, then add the calculated residence time to the correctionfield of the event message.

    - P2PTC (Peer-to-Peer Transparent Clock): forwards only Sync messages, Follow_Up messages and Announce messages, and terminates other PTP packets, and participates in the calculation the delay of each link on the entire link.

PTP port

A PTP port is a port running PTP. PTP ports are classified into the following types based on roles:

- Master port: The port is the source of time on the path served by the port, located on a BC or OC device.
- Slave port: The port synchronizes to the device on the path with the port that is in the MASTER state, located on a BC or OC device.
- Passive port: The port is not the master on the path nor does it synchronize to a master. It is an idle port on a BC device and does not receive or send synchronization clock signals.

Master-slave hierarchy

Nodes in a PTP domain establish the master-slave hierarchy for clock synchronization. Master nodes send synchronization clock signals, while slave nodes receive synchronization clock signals. A device may receive synchronization clock signals from an upstream node and then send the synchronization clock signals to a downstream device.
If two clock nodes synchronize time with each other:

- The node that sends synchronization clock signals is the master node, and the node that receives synchronization clock signals is the slave node.
- The clock on the master node is the master clock, and the clock on the slave node is the slave clock.
- The port that sends synchronization clock signals is the master port, and the port that receives synchronization clock signals is the slave port.

Grandmaster clock

All clock nodes in a PTP domain are organized into the master-slave hierarchy. The grandmaster clock (GMC) is at the top of the hierarchy and is the reference clock in the PTP domain. Clock nodes exchange PTP messages to synchronize the time of the GMC to the entire PTP domain. Therefore, the GMC is also called the clock source. The GMC can be statically configured or dynamically elected through the best master clock (BMC) algorithm.

PTP message

Nodes exchange PTP messages to establish the master-slave hierarchy and implement time and frequency synchronization. PTP messages are classified into event messages and general messages depending on timestamps:

- Event message: is tagged with a timestamp when reaching or leaving a port. PTP devices calculate the link delay based on the timestamps carried in event messages. Event messages include Sync, Delay_Req, Pdelay_Req, and Pdelay_Resp messages.
- General message: is used to establish master-slave hierarchy, and to request and send time information. General messages are not tagged with timestamps. General messages include Announce, Follow_Up, Delay_Resp, Pdelay_Resp_Follow_Up, Management, and Signaling messages.

> **NOTE：**
> Currently, devices support only E2ETC function, and uses Sync, Delay_Req and Delay_Resp PTP messages.

Delay Request-Response Mechanism

Figure 2 shows the process of calculating the average link delay and time offset between the master and slave devices using the E2E mechanism.

Figure 2 Delay request-response mechanism

1. The master sends a Sync message to the slave and notes the time t1 at which it was sent.
2. The slave receives the Sync message and notes the time of reception t2.
3. The master conveys to the slave the timestamp t1 by:
   a) Embedding the timestamp t1 in the Sync message. This requires some sort of hardware processing for highest accuracy and precision.
   b) Embedding the timestamp t1 in a Follow_Up message.
4. The slave sends a Delay_Req message to the master and notes the time t3 at which it was sent.
5. The master receives the Delay_Req message and notes the time of reception t4.

The master conveys to the slave the timestamp t4 by embedding it in a Delay_Resp message.
By exchanging messages with the master device, the slave device obtains t1, t2, t3, and t4, and calculates the average link delay and time offset between the master and slave devices. Then the slave device can adjust the local time according to the calculated time offset to synchronize with the master device. The formulas for calculating the link delay and time offset are as follows:

Average link delay = [(t4- t1) - (t3- t2)]/2
Offset = [(t2- t1) + (t3- t4)]/2

Product Support

The table below shows the model and the corresponding switch ASIC that support the PTP function, others do not support.

Switch ASIC	Model
Trident3	AS7726-32X

PTP Configuration

Configure the device interface as the E2ETC node type, enable the PTP function on the interface, and implement the device to forward the PTP packets directly.

Procedure

Step 1. Configure the device interface as the E2ETC node type, enable the PTP function on the interface.

set interface gigabit-ethernet <*port*> **ptp mode** {e2etransparent | none}

By default, PTP is disabled on an interface.

NOTE :

- The PTP function can only be configured on the physical interface.
- On the TC device, PTP must be enabled on all the interfaces that receive and send PTP messages. Otherwise, the PTP function will work inproperly.

Configuration Example

Procedure

Step 1. Configure the port te-1/1/25 that receiving PTP messages and the port te-1/1/26 that sends PTP packets as E2ETC node.

admin@Xorplus#set interface gigabit-ethernet te-1/1/25 ptp mode e2etransparent

admin@Xorplus#set interface gigabit-ethernet te-1/1/26 ptp mode e2etransparent

Step 2. Verify the configuration.

After the configuration is complete, run the **run show interface detail** command to view the configuration of PTP.

```
admin@Xorplus# run show interface gigabit-ethernet te-1/1/25 detail
Physical interface: te-1/1/25, Enabled, error-discard False, Physical link is Down
Interface index: 25, Mac Learning Enabled
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Full
Source filtering: Disabled, Flow control: Disabled, Auto-negotiation: Enabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit ingress:0, egress:0
Precision Time Protocol mode:e2etransparent
Current address: 48:6e:73:01:00:61, Hardware address: 48:6e:73:01:00:61
Traffic statistics:
5 sec input rate 0 bits/sec, 0 packets/sec
5 sec output rate 0 bits/sec, 0 packets/sec
  -More-
```

Configuring the linux-config-unreliable

PicOS is a Linux distribution with Pica8 tools for Routing, Switching, and OpenFlow. As such, PicOS can be configured directly from the Linux shell.

But sometimes, operators would like to be sure the CLI configuration completely reflects the state of the system. It can be useful if the same parameter can be configured in the CLI, or in Linux at the same time. A good example of such parameters would be the IP address of the system or its default gateway.

In the PicOS CLI configuration, all of those parameters have been gathered under the system hierarchy. It is then the choice of the operator to choose either the CLI or Linux shell to configure the system parameters.

A new knob has been added for control, in case the CLI configuration should override the Linux configuration.

By default, the CLI configuration does NOT override the Linux system configuration.

> When the linux-config-unreliable knob is modified, please commit it first, then set other system settings.
> Do not commit the linux-config-unreliable and system delta at the same time.

You can choose bash control or xorp control. As shown below:

Xorp Control

```
admin@XorPlus# set system linux-config-unreliable true
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# show system
    linux-config-unreliable: true
    }
    log-level: "trace"
```

Bash Control

```
admin@XorPlus# set system linux-config-unreliable false
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# show system
    linux-config-unreliable: false
    log-level: "trace"
```

If user chooses bash control, the system settings should be set in bash, not from xorp. Otherwise, the system command should be set in xorp.

```
admin@XorPlus# show system
    linux-config-unreliable: false
    log-level: "trace"
admin@XorPlus# set system hostname pica8
admin@XorPlus# commit
The system is managed by linux
Commit failed.
admin@XorPlus#
```

> The following system commands should always be set in PicOS, even when system is under bash control:
>
> system aaa tacacs-plus
>
> system log-level
>
> > When changing the system control straight from xorp control to bash control, the xorp configurations related to system will be removed from the configuration tree automatically. When changing from Bash control to xorp control, the configuration related to the system will be read and added into the xorp configuration tree automatically.
>
> system log-facility

Configuring IPFIX

Configuring IPFIX Parameters

By default, IPFIX is disabled. You can enable IPFIX and configure its parameters, as shown below. Make sure the switch can connect to the IPFIX collector server correctly.

```
admin@XorPlus# set protocols ipfix collector 192.168.2.10 udp-port 9999
admin@XorPlus# set protocols ipfix interfaces ingress ge-1/1/1
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring sFlow

NOTEs:

- User needs to enable sFlow on global and on the port so that it can sample flow and counters. If sFlow is only enabled on global, it will only see the port count.
- The following sampling field of sFlow nexthop IP in sFlow version5 Extended Router Data is supported.

```
/* Extended Router Data */
/* opaque = flow_data; enterprise = 0; format = 1002 */
struct extended_router {
   next_hop nexthop;            /* IP address of next hop router */
   unsigned int src_mask_len;   /* Source address prefix mask
                                   (expressed as number of bits) */
   unsigned int dst_mask_len;   /* Destination address prefix mask
                                   (expressed as number of bits) */
}
```

- For packets forwarded via ECMP routes, sFlow selects nexthop of one of the ECMP routes as the nexthop information of the packet in the sampling information, which may not necessarily be the nexthop of the route used for actual packet forwarding.

Globally Enabling sFlow

By default, sFlow is disabled. User can enable sFlow and configure the parameters, verify that the switch can connect to the sFlow collector server, and configure the sFlow **agent-id** and **source-address** at the same time that sFlow is enabled.

```
admin@XorPlus# set protocols sflow disable false
admin@XorPlus# set protocols sflow agent-id 10.10.50.248
admin@XorPlus# set protocols sflow source-address 10.10.50.248
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring sFlow Parameters

User can configure global parameters for sFlow, including agent-id, collector IP, polling-interval, sampling-rate, and source-address.

```
admin@XorPlus# set protocols sflow agent-id 10.10.50.248
admin@XorPlus# set protocols sflow collector 10.10.50.221 udp-port 6343
admin@XorPlus# set protocols sflow polling-interval 30
admin@XorPlus# set protocols sflow sampling-rate ingress 2000
admin@XorPlus# set protocols sflow sampling-rate egress 2000
admin@XorPlus# set protocols sflow header-len 128
admin@XorPlus# set protocols sflow source-address 10.10.50.248
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# run show sflow
sFlow : Enabled
Agent ID : 10.10.50.248
Source Address : 10.10.50.248
Sample rate ingress: 1:2000
Sample rate egress : 1:2000
Polling interval : 30 seconds
Header Length : 128
admin@XorPlus#
admin@XorPlus# run show sflow collector
Collector address UDP-port No of Samples
---------------- -------- -------------
10.10.50.221 6343 5336
```

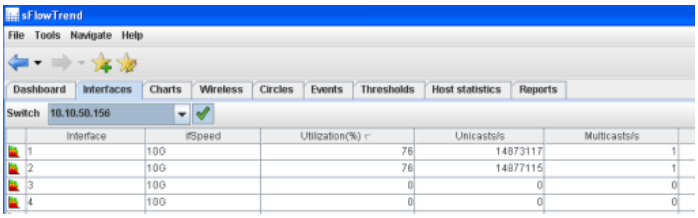
```
admin@XorPlus#
```

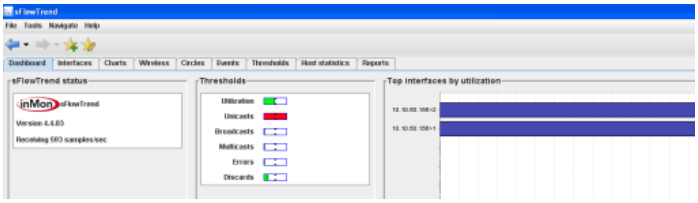
Configuring sFlow on a Specific Interface

User can configure sFlow parameters on a specific interface but needs to enable sflow protocols on global first.

```
admin@XorPlus# set protocols sflow interface ge-1/1/1 ?
Possible completions:
  <[Enter]>                    Execute this command
  disable                      Disable sflow on all interfaces by default
  header-len                   The Length of sampled packet in bytes, 64 by default
  polling-interval             How often the sflow agent polls the interface in seconds, 30 by default
  sampling-rate                The rate at which packets must be sampled, 2000 by default
admin@XorPlus# set protocols sflow interface ge-1/1/1 disable false
admin@XorPlus# set protocols sflow interface ge-1/1/1 header-len 128
admin@XorPlus# set protocols sflow interface ge-1/1/1 polling-interval 10
admin@XorPlus# set protocols sflow interface ge-1/1/1 sampling-rate ingress 1000
admin@XorPlus# commit
```

In the current version, sFlow samples only the ingress traffic of each interface. User can monitor the traffic with sFlow Trend.





Configuring the Syslog Log Level

Configuring the Syslog Level

Our system has five syslog levels. Listed in order of most fatal to least fatal, the levels are: Fatal, Error, Warning, Info, and Trace. By default, the system is set to the Warning level. You can, of course, change the log level by using the command **set system log-level**.

In the example below, the system logs messages from Info, Warning, Error, and Fatal levels since the system syslog level is set to Info.

```
admin@XorPlus# set system log-level info
admin@XorPlus# commit
Commit OK.
Save done.

admin@XorPlus#

// You can display the log messages on the console screen by entering the following command:

admin@XorPlus# exit
admin@XorPlus> syslog monitor on

// If the switch's syslog level is Trace, the trace options of the modules should be turned on, as illustrated belo

admin@XorPlus# set protocols ospf traceoptions packet all detail
admin@XorPlus# set system log-level trace
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# exit
admin@XorPlus> syslog monitor on
```

Configuring the Syslog Logging Facility

In accordance with the syslog standard, the logging facility can be configured as [0, 7].

```
admin@XorPlus# set system log-facility 0
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
Oct 17 15:22:42 XorPlus local0.warn : admin logined the switch
Oct 17 15:22:50 XorPlus local0.warn pica_sh: Tacacs send acct body send failed: wrote -1 of 127: Connection refused
Oct 17 15:22:42 XorPlus local2.warn : admin logined the switch
admin@XorPlus# set system log-facility 2
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring the Syslog Disk and Syslog Server

> **NOTE:**
> Syslog protocol runs in management VRF by default. If you use Ethernet management interface Eth0/1 to connect with the syslog server, you do not need to do the following operations.
>
> However, if the L3 VLAN interface is used to connect with the syslog server, the syslog protocol cannot run normally by default, as all the L3 VLAN interface is in the default VRF by default. You need to modify the configurations to make the L3 VLAN interface management interface and syslog protocol run in the same VRF, so as to run the syslog protocol normally. You can choose either one of the following two ways:
>
> Way 1. Use the command **set system management-services vrf default** to move syslog protocol to run in the default VRF. This way is recommended. Note that using this command also moves the NTP/TACACS+/RADIUS management services to the default VRF.
>
> Way 2. Use the command **set l3-interface vlan-interface** <*interface-name*> **vrf mgmt-vrf** to move the L3 VLAN interface connected to the syslog Collector to management VRF.

Configuring the Syslog Server

After you configure the syslog server IP address, the log files will be sent to the syslog server.

```
admin@XorPlus# set system syslog server-ip 192.168.1.1 ?
Possible completions:
  <[Enter]>                    Execute this command
  port                         Remote syslog server port
  protocol                     Remote syslog server protocol
  source-interface               Configure an existing network interface, e.g. vlan20, eth0, loopback or routed ir
admin@XorPlus# set system syslog server-ip 192.168.1.1 protocol udp
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

> It is recommended to configure **UDP** protocol as the port protocol.

Configuring Syslog for Local Storage

You can configure syslog messages to be stored in RAM or in a local SD card.

```
XorPlus# set system syslog local-file disk
XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
XorPlus#
XorPlus# set system syslog local-file ram
XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
XorPlus#
```

Displaying System Information

User can display a system's information, including fan, power supply unit, and serial number information.

Displaying the System Fan

```
admin@XorPlus>show system fan
Fan Status:
Fan 1 speed = 12529 RPM, PWM = 79
Fan 2 speed = 12413 RPM, PWM = 79
Fan 3 speed = 12300 RPM, PWM = 79
```

Displaying the System Power Supply Unit

```
admin@XorPlus> show system rpsu
RPSU 1: Powered on
    TEMPERATURE_1 : 35.62 C / 96.12 F

```

IPv6 Management Support

SNMP over IPv6

User can walk the SNMP model via IPv6 address.

SSH over IPv6

User can log in to the switch via IPv6 address. (Static IPv6 address for a management port can be configured.)

```
admin@XorPlus# set system management-ethernet eth0 ip-address ?
Possible completions:
<[Enter]> Execute this command
IPv4 IPv4 address or negotiated via DHCP, e.g. 192.168.1.2/24 or dhcp
IPv6 IPv6 address or negotiated via DHCP, e.g. fec0::10/64 or dhcp
admin@XorPlus# set system management-ethernet eth0 ip-gateway ?
Possible completions:
<[Enter]> Execute this command
IPv4 Configure the IPv4 gateway
IPv6 Configure the IPv6 gateway
```

Syslog over IPv6

User can send syslog via IPv6 address to remote server.

```
admin@XorPlus# set system syslog server-ip ?
Possible completions:
<IPv4> Remove syslog server
<IPv6> Remove syslog server for IPv6
```

NTP Client IPv6

User can synchronize the time via IPv6 address.

```
admin@XorPlus# set system ntp-server-ip ?
Possible completions:
<IPv4> Sync time with NTP server <IP>
<IPv6> Sync time with NTP server <IPv6>
```

DNS Client IPv6

User can configure an IPv6 dns server IP address.

```
admin@XorPlus# set system dns-server-ip ?
Possible completions:
<IPv4> DNS server IP address <IP>
<IPv6> DNS server IPv6 address <IP>
```

DHCPv6 Client

PicOS supports dhcpv6 function.

Radius over IPv6

User can configure an IPv6 address for the radius server.

```
admin@XorPlus# set system aaa radius authorization server-ip ?
Possible completions:
<IPv4> Radius authorization IPv4 server address
<IPv6> Radius authorization IPv6 server address
```

Configuring NETCONF

NETCONF is a network configuration and management protocol based on XML.

NETCONF protocol uses XML for configuration data and protocol message encoding, using RPC and Client/Server mechanism to update, install or delete the relevant part of the device configuration or all the management information.

- Currently, we support <get>, <get-config>, <get-schema> and <edit-config>.
- Authenticated RADIUS/TACACS+ users can access to PicOS switch via NETCONF.

Enable NETCONF on switch:

```
admin@XorPlus# set protocols netconf
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Delete NETCONF configuration on switch:

```
admin@XorPlus# delete protocols netconf
Deleting:
    netconf {
    }
OK
admin@XorPlus# commit
Commit OK.
Save done.
```

YANG is a data modeling language used to model configuration and state data manipulated by NETCONF.
You can find the YANG module file of different modules on your switch under the directory "/pica/etc/common/data-models".

```
admin@XorPlus$pwd
/pica/etc/common/data-models
admin@XorPlus$ls -lt *.yang
-rw-rw-r-- 1 root xorp  2288 Jul  9 16:14 arp.yang
-rw-rw-r-- 1 root xorp  4075 Jul  9 16:14 bfd.yang
-rw-rw-r-- 1 root xorp  6950 Jul  9 16:14 cos-with-pfc.yang
-rw-rw-r-- 1 root xorp  6062 Jul  9 16:14 cos-without-pfc.yang
-rw-rw-r-- 1 root xorp  3031 Jul  9 16:14 dhcp.yang
-rw-rw-r-- 1 root xorp  5173 Jul  9 16:14 dot1x.yang
-rw-rw-r-- 1 root xorp 14261 Jul  9 16:14 firewall-no-icmp-type-code.yang

-rw-rw-r-- 1 root xorp 13185 Nov  4 10:44 static-routes.yang
-rw-rw-r-- 1 root xorp 50887 Jul  9 16:14 system.yang
-rw-rw-r-- 1 root xorp  4126 Jul  9 16:14 udld.yang
-rw-rw-r-- 1 root xorp   871 Jul  9 16:14 version.yang
-rw-rw-r-- 1 root xorp 10137 Nov  4 10:44 vlan-interface.yang
-rw-rw-r-- 1 root xorp  8000 Jul  9 16:14 vlans.yang
-rw-rw-r-- 1 root xorp 11145 Nov  4 10:44 vrrp.yang
-rw-rw-r-- 1 root xorp  8679 Nov  4 10:44 vxlans.yang
```

```
-rw-rw-r-- 1 root xorp  4515 Jul  9 16:14 xovs.yang
```

Example of VLAN configuration via NETCONF use <edit-config>:

Step 1: Create an XML file according the vlan.yang for RPC request to create VLAN136:

```
<vlans xmlns="http://pica8.com/xorplus/vlans">
    <vlan-id>
      <id>136</id>
      <description/>
      <vlan-name>default</vlan-name>
      <l3-interface>vlan136</l3-interface>
    </vlan-id>
  </vlans>
```

Step 2: Display the configuration on switch after the client sending an RPC request.

```
The configuration has been changed by user root
DELTAS:
    vlans {
        vlan-id 136 {
            description: ""
            vlan-name: "default"
            l3-interface: "vlan136"
        }
    }
admin@XorPlus# show | display set
    set protocols netconf
    set vlans vlan-id 136 l3-interface "vlan136"
```

> Now, we only support get the system's version information and vxlan information via NETCONF <get> function.

Example of get the system's version information via NETCONF use <get>:

Display the RPC reply after the client sending an RPC request.

```
   <version xmlns="http://pica8.com/xorpplus/version">
     <mac_address>48:0f:cf:af:70:3b</mac_address>
     <hardware_mode>HP5712</hardware_mode>
     <system_version>2.8.0/aeec598</system_version>
     <system_released_date>10/13/2016</system_released_date>
     <L2_L3_version>2.8.0/aeec598</L2_L3_version>
     <L2_L3_released_date>10/13/2016</L2_L3_released_date>
   </version>
```

NETCONF client

About NETCONF client, you can use ncclient which is python lib now.

> If you use ncclient, you must modify the rpc.py : add two lines codes to work with pica8 switch.
>
> Edit the `rpc.py` file to contain the followings before the statement 'self._session.send(req)':
>
> req = req.replace('nc:','')
>
> req = req.replace(':nc','')

Get .yang or .yin File

The administrator can use get-schema operation to retrieve the **.yang** or **.yin** data file information on the PICA8 switch. For details about get-schema operation, see RFC6022 YANG Module for NETCONF Monitoring.

In the following example, the user builds the **testgetschema.py** script on ncclient. The script uses the get-schema operation to get the information from the **vlans.yang** file on the PICA8 switch.

```
[ncclient] $ vi  testgetschema.py
from ncclient import manager
import sys

host=sys.argv[1]
mgr = manager.connect(host=host, port=830, username='admin', password='pica8', hostkey_verify=False)
```

```
elem = mgr.get_schema(identifier='vlans')
with open("%s.xml" % host, 'w') as f:
    f.write(str(elem))
mgr.close_session()
```

Run the **testgetschema.py** script on ncclient. By issuing the get-schema command and receiving the reply from the PICA8 switch, we can get the **vlans.yang** module file information displayed as follows:

```
module vlans {
    namespace "http://pica8.com/xorplus/vlans";
    prefix vlans;
    // import some basic types
    import ietf-yang-types {
        prefix yang;
    }
    organization "PICA8, Inc";
    description
        "This module is data model for vlans configuration";
    revision 2015-12-25 {
        description "Initial revision.";
    }
    container vlans {
        description
            "Vlan configuration.";
        list vlan-id {
            description
                "VLAN tag identifier, range 1-4094, e.g. 2,3,5-100.";
            key "id";
            leaf id {
                type string;
            }
            leaf description {
                description
                    "Vlan description.";
                type string;
                default "";
            }
            leaf vlan-name {
                description
                    "VLAN name, up to 32 alphanumeric characters in length.";
                type string;
                default "default";
            }
            leaf l3-interface {
                description
                    "Associate a Layer 3 interface with an existing VLAN.";
                type string;
                default "";
            }
            leaf open-flow-enable {
                description
                    "Vlan will be used by open flow, maximum of 200 vlans enabled.";
                type boolean;
                default 'false';
            }
        }
........
  }
}
```

SNMP Configuration

- Configuring SNMPv2
- Configuring SNMPv3
- Configuring SNMP ACL
- Pica8 Private MIB
- Pica8 Public MIB
- SNMP Monitoring and Integration with Zabbix

Configuring SNMPv2

> **NOTE:**
> Once created, the loopback interface will always remain UP. Unlike any VLAN interface which can go down accidentally, the loopback interfaces are more stable and hence a much better choice for the SNMP configuration.
> If the Pica8 switch is used as an SNMP Agent device and communicates with the SNMP NMS through the inband port, it is highly recommended to use the IP address of the route reachable loopback interface on the Pica8 switch as the communication address for Snmpwalk, which will ensure that communication is not interrupted and provide stablibility to the SNMP process.

Configuring SNMPv2 Parameters

By default, SNMP is disabled. You can enable SNMP and configure its parameters (e.g. community, contact, location).

You can configure the source interface on the device from which traps are sent. The system specifies the IP address of this interface as the source IP address of traps. In this way, the trap source can be identified on the NMS. To ensure device security, it is recommended that you set the source interface to the loopback interface.

```
admin@Xorplus# set l3-interface loopback lo address 10.10.1.201 prefix-length 32
admin@XorPlus# set protocols snmp community Pica8-data-center
admin@XorPlus# set protocols snmp community Pica8-data-center authorization read-only
admin@XorPlus# set protocols snmp contact support@pica8.com
admin@XorPlus# set protocols snmp location Beijing
admin@XorPlus# set protocols snmp trap-group targets 10.10.1.1 security-name Pica8-data-center
admin@XorPlus# set protocols snmp trap-group version v2
admin@Xorplus# set protocols snmp trap-group source-interface loopback
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

> **In version 2.8.1,security-name has to be configured for trap-group targets whichever the version is .**

Configuring an SNMP ACL

By default, all hosts can *snmpwalk* the information of the switch. Configure an SNMP ACL to control which hosts within the subnetwork can snmpwalk the switch.

```
admin@XorPlus# set system snmp-acl network 1.1.1.0/24
admin@XorPlus# set system snmp-acl network 2.2.2.0/24
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring SNMPset

User can use "snmpset" (OID1.3.6.1.4.1.35098.2.0.0) to load a configuration and can use "snmpset" (OID 1.3.6.1.4.1.35098.2.1.0) to delete or load a configuration. However, only set and delete commands can be included in the command batch (which is OID 1.3.6.1.4.1.35098.2.1.0). Other commands are invalid and ignored. Note that clearing a dependent configuration is not allowed.

```
admin@XorPlus# set protocols snmp community private authorization read-write
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

Using snmpset to load a filter configuration:

```
root@dev:~# snmpset -v 2c -c private IP .1.3.6.1.4.1.35098.2.0.0 s "tftp:1.1.5.1:/pica8/acl.conf"
iso.3.6.1.4.1.35098.2.0.0 = STRING: "tftp:1.1.5.1:/pica8/acl.conf"
```

Using snmpset to delete a filter configuration:

```
root@dev:~# snmpset -v 2c -c private IP .1.3.6.1.4.1.35098.2.1.0 s "tftp:1.1.5.1:/pica8/delete-acl.conf"
iso.3.6.1.4.1.35098.2.0.0 = STRING: "tftp:1.1.5.1:/pica8/delete-acl.conf"
```

Enable or Disable LLDP SNMP Trap

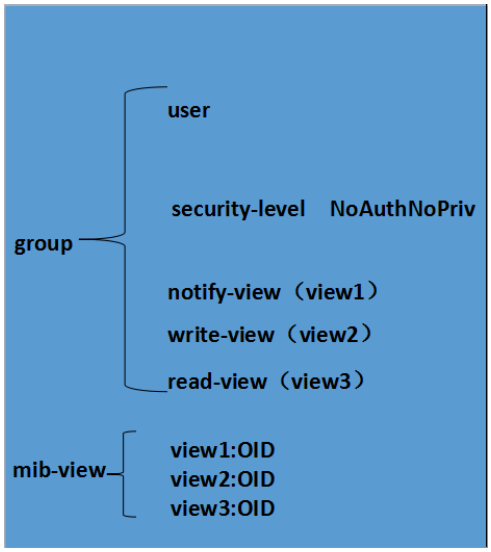
The LLDP SNMP trap is enabled by default. You can use the following command to disable LLDP SNMP trap, then there will be no more LLDP trap message sends to snmp.

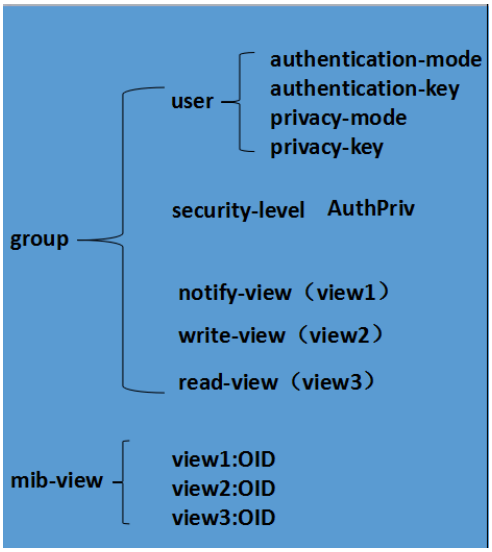
```
admin@Xorplus# set protocols lldp snmp-trap false
admin@Xorplus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

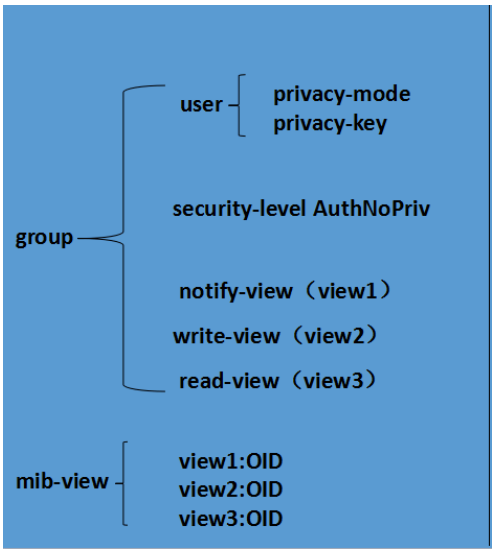
Configuring SNMPv3

Here is the configuration relation diagram in SNMPv3.A user can be added to a group or not as you need.Once a user joined a group,one or more kinds of views (notfiy-view, write-view, read-view) must be configured.Besides, configurations on user change with the security-level of the group as below 3 diagrams. Note notify-view,write-view and read-view are optional but you have to choose at least one view.In the below diagram,view1,view2,view3 can be the same or different.

> **NOTE:**
> Once created, the loopback interface will always remain UP. Unlike any VLAN interface which can go down accidentally, the loopback interfaces are more stable and hence a much better choice for the SNMP configuration.
> If the Pica8 switch is used as an SNMP Agent device and communicates with the SNMP NMS through the inband port, it is highly recommended to use the IP address of the route reachable loopback interface on the Pica8 switch as the communication address for Snmpwalk, which will ensure that communication is not interrupted and provide stablibility to the SNMP process.







Configuring Basic Information

Contact and location information can be configured as below which is the same as SNMPv2.

```
admin@XorPlus# set protocols snmp contact support@pica8.com
admin@XorPlus# set protocols snmp location beijing
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring trap-group

By default, trap messages are sent in the form of SNMPv2. But you can change it to SNMPv3 as below and designate NMS to which trap messages are sent. Note that in SNMPv3, security-name is user while in SNMPv2, security-name is community.

You can configure the source interface on the device from which traps are sent. The system specifies the IP address of this interface as the source IP address of traps. In this way, the trap source can be identified on the NMS. To ensure device security, it is recommended that you set the source interface to the loopback interface.

```
admin@Xorplus# set l3-interface loopback lo address 10.226.14.201 prefix-length 32
admin@XorPlus# set protocols snmp trap-group version v3
admin@XorPlus# set protocols snmp trap-group targets 10.10.51.42 security-name user1
admin@Xorplus# set protocols snmp trap-group source-interface loopback
admin@XorPlus# commit
Commit OK.
Save done.
```

Setting Up a User

By default, SNMPv3 is enabled. And you should set up a usm-user first before you configure other functions of SNMPv3. Besides, adding a user to a group is optional. When a user is added to a group, the needed views should be configured. If you create a user without adding to any groups, you can configure as below. However, under the below circumstance, all the OIDs can be visited by its NMS which can read but can't write and be notified.

```
admin@XorPlus# set protocols snmp v3 usm-user user1
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring Mib-view

If you want to improve security, the user needs to be added to a group. Because in this way, you can configure a read-view, write-view or notify-view(you can choose only one kind or more as you need) which defines the authority of a NMS. Before configuring a read-view(write-view or notify-view), please set up a mib-view which is used as a view of the group. Here are the configurations. As for a mib-view, you can include or exclude some subtrees and can also configure mask for them.

```
admin@XorPlus# set protocols snmp v3 usm-user user2 group group1
admin@XorPlus# set protocols snmp v3 mib-view view1 subtree 1.3.6.1.2.1 type included
admin@XorPlus# set protocols snmp v3 mib-view view1 subtree 1.3.6.1.2.1.6.13 type excluded
admin@XorPlus# set protocols snmp v3 mib-view view1 subtree 1.3.6.1.2.1 mask fc
admin@XorPlus# set protocols snmp v3 mib-view view1 subtree 1.3.6.1.2.1.6.13 mask ff
admin@XorPlus# set protocols snmp v3 group group1 read-view view1
admin@XorPlus# set protocols snmp v3 group group1 write-view view1
admin@XorPlus# set protocols snmp v3 group group1 notify-view view1
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring Security-level

You can improve security better by configuring security-level for the group. And the default setting of security-level is NoAuthNoPriv. You can change it to AuthNoPriv or AuthPriv. But please remember to configure authentication-mode, authentication-key, privacy-mode, privacy-key for the user. Configuration are as below.

```
admin@XorPlus# set protocols snmp v3 group group1 security-level AuthPriv
admin@XorPlus# set protocols snmp v3 usm-user user1 authentication-mode md5

NMS Visits Switch by user

NMS reads OID tree 1.3.6.1.2.1.6.13 as below. user1 is the user's name. AuthPriv is the security-level of group. 10.10.51.155 is the IP of the switch.

```
pica8@pica8:~$snmpwalk -u user1 -l AuthPriv -A sha -a u1111key -X des -x u1111key 10.10.51.155 1.3.6.1.2.1.6.13
```

Enable or Disable LLDP SNMP Trap

The LLDP SNMP trap is enabled by default. You can use the following command to disable LLDP SNMP trap, then there will be no more LLDP trap message sends to snmp.

```
admin@Xorplus# set protocols lldp snmp-trap false
admin@Xorplus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

Configuring SNMP ACL

- Concepts
- Matching Procedure
- Examples
  - Example 1
  - Example 2
  - Example 3

By default, no SNMP ACL list is configured on the switch and allows all network management station (NMS) to access the device through SNMP protocol. Users can configure access control white list for SNMP protocol on the device to restrict NMS access to the device, so as to improve the device security.

Concepts

SNMP ACL has two types of access control white list: As-per User List and Global List.

- As-per User List

The SNMP ACL that specifies the security name can be configured with multiple networks, is called the as-per user list. For example,

```
admin@XorPlus# set system snmp-acl security-name user1 network 10.10.50.0/24
```

Where "security-name" is the **community name** for SNMPv1 and SNMPv2, and the **usm-user** name in command **set protocols snmp v3 usm-user** *<user-name>* for SNMPv3.

- Global List

SNMP ACLs that do not specify a security name but only networks are called the global list. For example,

```
admin@XorPlus# set system snmp-acl network 10.10.50.0/24
admin@XorPlus# set system snmp-acl network 10.10.51.0/24
```

The global list is applied to NMS that are not configured with an as-per user list.

Matching Procedure

As-per user list and global list can be configured together. The matching procedure for SNMP ACL is as follows:

1. For the NMS that accesses the device (assuming its security name is ***s1***), if a valid as-per user list is configured on the device (i.e., an SNMP ACL with security name ***s1*** and network is configured), as-per user list matching is performed.

- If the SNMP query matches the as-per user list, allowing NMS to access to devices through SNMP protocol.
- If no as-per user list entry is matched, the NMS who sent the SNMP query is denied access to this device.

NOTE:

If an SNMP ACL with security name s1 is configured, but no network list is configured under it, the as-per user list is empty and invalid, then global list matching will be performed.

2. If no as-per user list is configured for this NMS (i.e., the SNMP ACL with security name ***s1*** is not configured), then global list matching is performed.

- If the SNMP query matches a global list, allowing NMS to access devices through SNMP protocol.
- If no global list entry is matched, the NMS who sent the message is denied access to this device.
- If global list is not configured then the NMS is allowed to access the device through SNMP protocol.

Examples

Three examples are given to illustrate the SNMP ACL procedure.

Example 1

The following configurations were set on the switch:

```
admin@XorPlus# set system snmp-acl network 10.10.50.0/24
admin@XorPlus# set system snmp-acl security-name user1 network 10.10.51.0/24
admin@XorPlus# set system snmp-acl security-name user1 network 10.10.52.0/24
```

- In case of ***user1***, SNMP queries from 10.10.10.51.0/24 and 10.10.52.0/24 are allowed to go to SNMP agent. And others will be denied.
- For other users, only SNMP queries from 10.10.50.0/24 (SNMP ACL global list configuration) are accepted.

Example 2

The following configurations were set on the switch:

```
admin@XorPlus# set system snmp-acl security-name user1 network 10.10.11.0/24
```

```
admin@XorPlus# set system snmp-acl security-name user1 network 10.10.12.0/24
```

- In case of ***user1***, SNMP queries from 10.10.10.11.0/24 and 10.10.12.0/24 are allowed to go to SNMP agent. And others will be denied.
- For other users, SNMP queries will be accepted by SNMP agent, as SNMP ACL global list configuration is NULL.

Example 3

The following configurations were set on the switch:

```
! SNMPv3 user pica8test123
    admin@XorPlus# set protocols snmp v3 mib-view readall subtree 1 mask ff
    admin@XorPlus# set protocols snmp v3 group Pica8 security-level AuthPriv
    admin@XorPlus# set protocols snmp v3 group Pica8 read-view readall
    admin@XorPlus# set protocols snmp v3 usm-user pica8test123 group Pica8
    admin@XorPlus# set protocols snmp v3 usm-user pica8test123 authentication-mode md5
    admin@XorPlus# set protocols snmp v3 usm-user pica8test123 authentication-key P3Ca8536bl4
    admin@XorPlus# set protocols snmp v3 usm-user pica8test123 privacy-mode des
    admin@XorPlus# set protocols snmp v3 usm-user pica8test123 privacy-key P3Ca8536bl8
    admin@XorPlus# set system snmp-acl security-name pica8test123 network 192.168.42.0/24

! SNMPv3 user pica8test321
    admin@XorPlus# set protocols snmp v3 mib-view readall subtree 1 mask ff
    admin@XorPlus# set protocols snmp v3 group Pica8 security-level AuthPriv
    admin@XorPlus# set protocols snmp v3 group Pica8 read-view readall
    admin@XorPlus# set protocols snmp v3 usm-user pica8test321 group Pica8
    admin@XorPlus# set protocols snmp v3 usm-user pica8test321 authentication-mode md5
    admin@XorPlus# set protocols snmp v3 usm-user pica8test321 authentication-key P3Ca8536bl4
    admin@XorPlus# set protocols snmp v3 usm-user pica8test321 privacy-mode des
    admin@XorPlus# set protocols snmp v3 usm-user pica8test321 privacy-key P3Ca8536bl8
    admin@XorPlus# set system snmp-acl security-name pica8test321 network 192.168.43.0/24
```

- Get switch model using SNMPv3 from an NMS IP located in the 172.168.42.0/24 network using the *pica8test123* user credentials. The expected result is: Switch model for switch at IP *192.168.42.171* is provided.

```
admin@NMS# snmpwalk -v3 -u pica8test123 -l AuthPriv -a md5 -A P3Ca8536bl4 -x des -X P3Ca8536bl8 192.168.42.171 1.3
iso.3.6.1.4.1.35098.1.13.0 = STRING: "N3248P-ON"
```

- Get switch model using SNMP v3 from an NMS IP located in the 172.168.42.0/24 network using the *pica8test321* user credentials. Switch model for switch at IP *192.168.42.171* is not provided. The requesting SNMP server IP is not in 192.168.43.0/24 network, hence it is not allowed to get the switch model.

```
admin@NMS# snmpwalk -v3 -u pica8test321 -l AuthPriv -a md5 -A P3Ca8536bl4 -x des -X P3Ca8536bl8 192.168.42.171 1.3
Timeout: No Response from 192.168.42.171
```

- After deleting SNMP ACL for pica8test321, it is able to get the hardware model:

```
admin@NMS# snmpwalk -v3 -u pica8test321 -l AuthPriv -a md5 -A P3Ca8536bl4 -x des -X P3Ca8536bl8 192.168.42.171 1.3
iso.3.6.1.4.1.35098.1.13.0 = STRING: "N3248P-ON"
```

Pica8 Private MIB

Pica8 added some private and trap MIBs listed below:

1：**SNMP Trap list:**

(1) **lldpStatistics**：1.0.8802.1.1.2.1.2

(2) **Ospf**：1.3.6.1.2.1.14

(3) **link up**: OID: 1.3.6.1.6.3.1.1.5.4

link down:OID:1.3.6.1.6.3.1.1.5.3

(support physical port's link up/down and lag port up/down)

(4) **Rpsu trap** :1.3.6.1.4.1.35098.21.1

(rpsu plugged in/out , rpsustatechange-power on/off, rpsuFanFailed)
oidRpsuFanFailed 1.3.6.1.4.1.35098.21.1.4
oidRpsuFanRecovery 1.3.6.1.4.1.35098.21.1.7
oidRpsuStateChange 1.3.6.1.4.1.35098.21.1.1
oidRpsuPlugIn 1.3.6.1.4.1.35098.21.1.2

Pica8 Public MIB

Download Pica8 supported publib MIBs here:

Supported Public MIBs.zip

The publib MIB SNMP-USER-BASED-SM-MIB is supported from PICOS 3.6.0, for details about this MIB, see http://net-snmp.sourceforge.net/docs/mibs/SNMP-USER-BASED-SM-MIB.txt.

SNMP Monitoring and Integration with Zabbix

Zabbix is an enterprise open-source monitoring solution for networking and applications. It is designed to monitor and track the status of various network services, servers, switches and other network hardware infrastructure.

SNMP can be used to monitor network devices in Zabbix. The Zabbix server uses SNMP OIDs for data collection, calculates triggers, and sends notifications to users on alerts.

We provide the following documents to guide the users to deploy PICOS SNMP with Zabbix.

1. PICOS Monitoring Solution Using Zabbix:

PICOS Monitoring Solution Using Zabbix.docx

2. **Zabbix Templates**:

PoE Configuration Guide

- Configuring PoE
- PoE over LLDP Power Negotiation
- UPoE
- Configuring Perpetual PoE

Configuring PoE

Introduction:

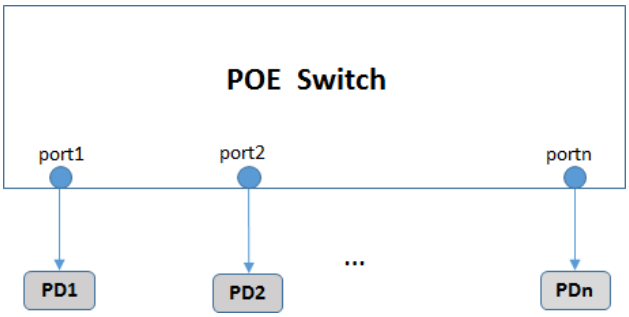
- Power over Ethernet(PoE) describes any of several standardized or ad-hoc systems which pass electric power along with data on twisted pair Ethernet cabling. This allows a single cable to provide both data connection and electric power to devices such as wireless access points and IP cameras.
- Power sourcing equipment (PSE) is a device such as a network Switch that provides (or sources) power on the Ethernet cable. The maximum allowed continuous output power per cable in IEEE 802.3af is 15.40 W. A later specification, IEEE 802.3at, offers 25.50 W.
- A powered device (PD) is a device powered by a PSE and thus consumes energy. Examples include wireless access points, IP Phones, and IP Cameras.

> ⚠ Only device models marked with P, PX, PXE, NPE, PE or EP support PoE. For FS switches, device models marked with P support PoE, device models marked with U support UPoE.

Topology:

Here is a typical topology for PoE. The PDs are power devices connected to a PoE switch.

Figure. Power devices(PD) connect with PoE switch



Configurations:

Enabling PoE on all ports is mandatory for other commands.

```
admin@XorPlus# set poe interface all enable true
admin@XorPlus# set poe interface all threshold-mode 2
admin@XorPlus# set poe interface all max-power 32
admin@XorPlus# set poe power management-mode 3
admin@XorPlus# set poe interface all mode signal
admin@XorPlus# set poe power mode redundant
admin@XorPlus# commit
```

For more details, please refer to PoE Configuration Commands.

PoE over LLDP Power Negotiation

- Introduction
  - Power via MDI TLV
  - PoE over LLDP Power Negotiation Mechanism
- Configuring PoE over LLDP Power Negotiation
  - Configuration Notes
  - Procedure
  - Configuration Example

Introduction

Power over Ethernet (PoE) enables electrical power to be carried over Ethernet cables, thus simplifying the deployment of networking equipment by eliminating the need for a power cord. Enabling it requires users to familiarize themselves with various PoE commands.

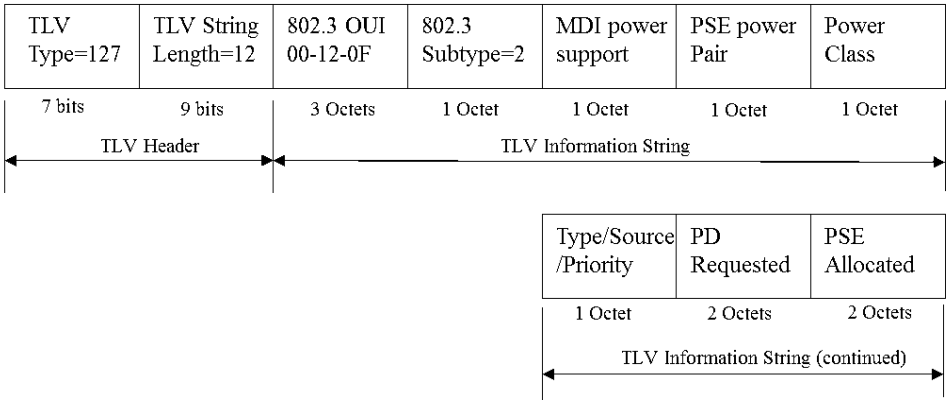
On this page, you will learn about one such PoE command, PoE over Link Layer Discovery Protocol (LLDP) power negotiation. This function allows a network switch, including an open white box switch, to assign the power priority value using LLDP to negotiate a power value, as opposed to using the power priority and value configured on the switch interface. The power negotiation process is described in detail, as is the switch configuration process.

Power via MDI TLV

IEEE 802.3 defines **Power via MDI TLV** to allow network management to advertise and discover power capability between LLDP-MED Endpoint and Network Connectivity Devices by sending LLDP negotiation packets.

The Power via MDI TLV is composed of 2-byte packet header and 12-byte TLV information field, as shown in Figure 1.

Figure 1. Power via MDI TLV packet format



The fields of Power via MDI TLV are described as follows:

- MDI power support

Field	Functions	Description
0	Port type	1: PSE-side port 0: PD-side port
1	Whether the PSE supports MDI power supply.	1: indicates that the PSE supports MDI power supply. 0: indicates that the PSE **does not** support MDI power supply.
2	MDI power supply status of the PSE.	1: enabled 0: disabled
3	Whether the PSE can control the line pair.	1: indicates that the PSE can control the line pair. 0: indicates that the PSE cannot control the line pair.
4-7	Reserved.	-

- PSE power Pair: The PSE power pair field contains an integer value as defined by the pethPsePortPowerPairs object in IETF RFC 3621.
- Power Class: The power class field contains an integer value as defined by the pethPsePortPowerClassifications object in IETF RFC 3621.
- Type/Source/Priority

Field	Functions	Description
Priority	Power supply priority of an interface.	11: indicates the lowest priority. 10: indicates the secondary highest priority. 01: indicates the highest priority. NOTE: This field contains four bits. The two left-most bits are reserved for the system.
Source	Power supply source.	PD: • 11: indicates the PSE and local source. • 10: indicates the local. • 01: indicates the PSE. PSE: • 11: indicates to be reserved. • 10: indicates the backup power supply. • 01: indicates the primary power supply.
Type	Power supply type.	01: indicates the PD that supports IEEE 802.3at. 00: indicates the PSE that supports IEEE 802.3at. 11: reserved. 10: reserved.

- PD Requested

Field	Functions	Value/Meaning
PD requested	PD requested power value	• Power=0.1*(decimal value of bits) Watts. The value is an integer that ranges from 1 to 255. For example, if the value of the field is 255, the exchange power is 25.5 W. • When the PoE power is sufficient, the values of PD Requested Power value and PSE allocated Power value are the same.

- PSE allocated

Field	Functions	Value/Meaning
PSE allocated	PSE allocated power value	• Power=0.1*(decimal value of bits) Watts. The value is an integer that ranges from 1 to 255. For example, if the value of the field is 255, the exchange power is 25.5 W. • When the PoE power is sufficient, the values of PD Requested Power value and PSE allocated Power value are the same.

PoE over LLDP Power Negotiation Mechanism

If PoE over LLDP power negotiation function is enabled on PSE, the PSE and the PD will periodically send LLDP packets to each other to perform LLDP power negotiation once the PD device is detected by the PSE. PoE over LLDP power negotiation starts when PSE receives LLDP packets from PD.

PoE over LLDP power negotiation message mechanism is as follows:

1. PD sends an LLDP packet to the PSE carries Power via MDI TLV, which contains the power supply priority of an interface and the PD requested power value.

2. PSE replies with an LLDP packet to the PD device. After receiving the LLDP packet from the PD device, the PSE allocates the corresponding power to the PD device and encapsulates it into the PSE allocated power value field in the Power via MDI TLV according to the PD requested value and its own power capabilities.

Configuring PoE over LLDP Power Negotiation

Configuration Notes

- All PoE devices support PoE over LLDP power negotiation function, except for S5810-48TS-P, S3410L-24TF-P, S5860-24XB-U,3410C-16TMS-P, 3410C-16TF-P and S3410C-8TMS-P.
- Enable LLDP function and PoE function before using PoE over LLDP power negotiation.
- When an expansion module is connected to the IP phone, in order to provide the required power to the expansion module, user should perform the following two operations to re-negotiate the PoE power supply.

  1). Enable the PoE over LLDP power negotiation function on the interface by using **set poe interface** <**all** | *interface-name*> **lldp-negotiation** <**true** | **false**> command.

  2). Disable and re-enable PoE function of the interface by using **set poe interface {**<*port-id*> | **all} enable <true | false>** command.

Procedure

- Use the following command to disable or enable the PoE over LLDP power negotiation function.

set poe interface <**all** | *interface-name*> **lldp-negotiation** <**true** | **false**>

By default, the function is enabled. To make the configuration take effect, user need to disable and re-enable PoE function of the interface by using **set poe interface {**<*port-id*> | **all} enable <true | false>** command.

Configuration Example

Networking Requirements

The networking requirements are as follows:

- An IP phone is connected to the Ge-1/1/1 port of the switch and an expansion module is connected to the IP phone.
- Enable PoE on port Ge-1/1/1 of the switch.
- When using PoE to power the IP phone, it also provides power for the expansion module which is connected to the IP phone. In this case, you need to enable the PoE over LLDP power negotiation function on the interface to assign the power priority and power value to the IP phone through LLDP power negotiation.

Procedure

Step1 Enable LLDP function.

```
admin@Xorplus# set protocols lldp enable true
```

Step2 Enable PoE function on interface Ge-1/1/1.

```
admin@XorPlus# set poe interface ge-1/1/1 enable true
```

Step3 Enable the PoE over LLDP power negotiation function on interface Ge-1/1/1.

```
admin@Xorplus# set poe interface ge-1/1/1 lldp-negotiation true
```

> When an expansion module is connected to the IP phone, in order to provide the required power to the expansion module, user should disable and re-enable PoE function of the interface by using **set poe interface {***<port-id>* | **all} enable <true | false>** command after enabled the PoE over LLDP power negotiation function.

Step4 Commit the configuration.

```
admin@Xorplus# commit
```

UPoE

With the development of technology, the maximum power required by the PD access devices has increased, and the maximum power provided by the PoE standard 802.3at cannot meet the power requirements. PICA8 supports the Universal Power over Ethernet (UPoE) function to provide more power to the PD devices, including IP cameras, video servers, compact switches and IP phones, etc. For details of UPoE support on each PoE platform, see set poe interface max-power.

You can use **set poe interface** {<*port-id*> | **all**} **max-power** <*integer*> command to set the maximum output power delivered by the PSE device.

Configuring Perpetual PoE

- Introduction
- Configuration Notes
- Configuring Perpetual PoE
  - Example

Introduction

Perpetual PoE (Power over Ethernet) is a feature that ensures continuous power supply to connected devices, even when the switch is rebooting. This capability is critical for maintaining uninterrupted operation of PoE-dependent devices such as IP cameras, VoIP phones, and wireless access points, ensuring they remain functional and avoid downtime during switch maintenance activities.

Configuration Notes

When configuring perpetual PoE, consider the following points:

- Only S5860-24XB-U switch supports perpetual PoE.
- Perpetual PoE supports maintaining uninterrupted power during a system reboot in the following scenarios.

  a. Execute the command **request system reboot** in L2/L3 CLI operating mode.

```
admin@PICOS> request system reboot
```

  b. Execute the **reboot** command in the Linux shell.

```
admin@PICOS:~$ sudo reboot
```

  c. Reboot during the upgrade process.

  d. For **nos-rollback** operation, if the version being rolled back to does not have Perpetual PoE configured, Perpetual PoE will not maintain uninterrupted power during the reboot in the NOS rollback process.

- Before restarting the S5860-24XB-U device, you need to save the configuration by executing **copy running-config startup-config** in L2/L3 CLI operating mode.
- Perpetual PoE will not maintain uninterrupted power in the following situations:

  a. Power failure or power cycling.

  b. PoE controller firmware update.

Configuring Perpetual PoE

- Use the following command to disable or enable the perpetual PoE function.

  set poe perpetual-power enable <**true** | **false**>

  By default, perpetual PoE is disabled.

Example

- This example shows how you can configure perpetual PoE on the switch.

```
admin@PICOS# set poe perpetual-power enable true
admin@PICOS# commit
```

Configuring USB Disable

Considering the system security, and in order to prevent the virus spreading through the USB interface, use USB disable function to disable external USB interface of the switch. All the external USB interfaces of the switch will be unavailable after they have been disabled.

Supported Platforms

The USB disable function is supported on the following platforms:

• AG9032

• 4806

• AS4610

• AS5712_54X

• AS5812_54X

• AS6712_32X

• AS7312_54X

• AS7712_32X

• S4048

• Z9100

Configuring USB Disable Function

Procedure

• Use the following command to disable or enable the USB interfaces of the switch.

set system usb disable [**true | false**]

The default setting is **set system usb disable false**. The command takes effect immediately after committing.

Configuration Example

• Disable the USB interfaces.

```
admin@Xorplus# set system usb disable true
admin@Xorplus# commit
```

• Enable the USB interfaces.

```
admin@Xorplus# set system usb disable false
admin@Xorplus# commit
```

Verify the Configuration

• Use **blkid** command to view the information of the switch disk. The external USB disk will not be shown if the USB interfaces are disabled.

```
 admin@Xorplus$blkid
/dev/sda1: LABEL="PicOS" UUID="4e223e38-59ca-40ca-93c0-7fc56afdf31b" TYPE="ext3"
/dev/sda2: LABEL="PICOS-BAK" UUID="f7908e2e-5054-4d6c-8d06-c227067dba01" SEC TYPE="ext2" TYPE="ext3"
```

Configuring CPU Usage Alarm Threshold

- Introduction
- Configuring CPU Usage Alarm Threshold
- Configuration Example
  - Procedure
  - Verify the Configuration

Introduction

The CPU is a core component of the device. When the system fails or suffers network attacks, it will take up a lot of CPU resources. This degrades system performance and results in data processing delays which in turn can potentially lead to high packet loss. During data processing, if the device can generate an SNMP Trap alarm when high CPU usage occurs, you can effectively monitor CPU usage and optimize system performance to maintain efficient data forwarding and network topology stability.

- CPU usage overload threshold and duration: When the CPU usage reaches the overload threshold with a continuous time, the system sends an SNMP Trap alarm message.
- CPU usage low threshold and duration: When the CPU usage falls below the low threshold for a continuous period of time, the system sends an SNMP Trap alarm message.

New PICA8 Private MIB Information

OID	Object Name	Description
1.3.6.1.4.1.35098.1.14.1.0	oidCpuThresholdStatus	This object is in configuration information node. The value of this object identifies whether the function of monitoring the switch CPU usage is enabled or disabled. The value could be 0 or 1. **0**: disable. **1**: enable.
1.3.6.1.4.1.35098.1.14.2.0	oidCpuHighThresholdValue	This object is in configuration information node. The value of this object identifies the overload threshold for CPU usage monitoring. The value is an integer that ranges from 1 to 100, indicating 1% to 100%. The default value is 80.
1.3.6.1.4.1.35098.1.14.3.0	oidCpuLowThresholdValue	This object is in configuration information node. The value of this object identifies the low threshold for CPU usage monitoring. The value is an integer that ranges from 1 to 100, indicating 1% to 100%. The default value is 20.
1.3.6.1.4.1.35098.1.14.4.0	oidCpuThresholdPeriod	This object is in configuration information node. The value of this object identifies the time duration when the CPU usage continues to exceed the overload threshold or fall below the low threshold. The value is an integer, in seconds, that ranges from 5 to 4294967295. The default value is 300s.
1.3.6.1.4.1.35098.21.4.1	oidCpuHighThreshold	This object is used in the syslog and SNMP Trap message, indicating the CPU usage reaches the overload threshold for a continuous period of time, the system sends an SNMP Trap alarm message.
1.3.6.1.4.1.35098.21.4.2	oidCpuLowThreshold	This object is used in the syslog and SNMP Trap message, indicating the CPU usage falls below the low threshold a continuous period of time, the system sends an SNMP Trap alarm message.

Configuring CPU Usage Alarm Threshold

Step1 Enable the function of monitoring the switch CPU usage.

set protocols snmp trap-group event cpu-threshold enable <**true** | **false**>

Step2 Set the overload threshold and low threshold for CPU usage monitoring to send SNMP Trap messages.

set protocols snmp trap-group event cpu-threshold high <*high-value*>

set protocols snmp trap-group event cpu-threshold low <*low-value*>

Step3 Configure the time duration for which the CPU usage continues to exceed the overload threshold or fall below the low threshold.

set protocols snmp trap-group event cpu-threshold interval <*interval*>

The system samples CPU usage one time every 5 seconds, if the CPU usage is out of the threshold range for this interval time, a SNMP trap message will be sent. But once CPU usage falls back into the threshold range and the duration time is not up, the duration time then will be recalculated and the trap message won't be sent.

Configuration Example

Procedure

Step1 Configure the target host with IP address 10.10.50.16 for receiving SNMP traps.

```
admin@Xorplus#set protocols snmp community public
admin@Xorplus#set protocols snmp trap-group targets 10.10.50.16 security-name public
```

Step2 Enable the function of monitoring the switch CPU usage.

```
admin@Xorplus# set protocols snmp trap-group event cpu-threshold enable true
```

Step3 Set the overload threshold and low threshold for CPU usage monitoring to send SNMP Trap messages.

```
admin@Xorplus# set protocols snmp trap-group event cpu-threshold high 80
admin@Xorplus# set protocols snmp trap-group event cpu-threshold low 20
```

Step4 Configure the time duration for which the CPU usage continues to exceed the overload threshold or fall below the low threshold, and an SNMP Trap message will be sent.

```
admin@Xorplus# set protocols snmp trap-group event cpu-threshold interval 300
```

Step5 Enable SNMP traceoptions for checking the SNMP syslog.

```
admin@Xorplus# set protocols snmp traceoptions flag all disable false
```

Step6 Commit the configuration.

```
admin@Xorplus# commit
```

Verify the Configuration

- User can check the syslogs when the CPU usage continuously exceeds the overload threshold or falls below the low threshold.

  Syslog message when the CPU usage monitoring continuously exceeds the overload threshold:

  2018-05-01 09:27:44.86 Xorplus local0.info : [SNMP]Trap: send v2 trap, community name public, oid: 1.3.6.1.4.1.35098.21.4.1, to:10.10.50.16/162

  Syslog message when the CPU usage monitoring continuously stays below the low threshold:

  2001-04-01 06:50:44.86 Xorplus local0.info : [SNMP]Trap: send v2 trap, community name public, oid: 1.3.6.1.4.1.35098.21.4.2, to:10.10.50.16/162

Configuring MAC Usage Alarm Threshold

- Introduction
- Configuring MAC address table usage Alarm Threshold
- Configuration Example
  - Procedure
  - Verify the Configuration

Introduction

MAC address table usage is an important indicator used to evaluate device performance. A high MAC address table usage will cause service faults. During data processing, if the device can generate an SNMP Trap alarm when high MAC address table usage occurs, you can effectively monitor MAC address table usage and optimize system performance to ensure system stability.

- MAC address table usage limit threshold and duration: When the MAC address table usage exceeds the limit threshold for a continuous period of time, the system sends an SNMP Trap alarm message.

New PICA8 Private MIB Information

OID	Object Name	Description
1.3.6.1.4.1.35098.1.15.1.0	oidMacThresholdStatus	This object is in configuration information node. The value of this object identifies whether the function of monitoring the switch MAC address table usage is enabled. The value could be 0 or 1. **0**: disable. **1**: enable.
1.3.6.1.4.1.35098.1.15.2.0	oidMacThresholdValue	This object is in configuration information node. The value of this object identifies the limit threshold for MAC address table usage monitoring. The value is an integer that ranges from 1 to 100, indicating 1% to 100%. The default value is 50.
1.3.6.1.4.1.35098.1.15.3.0	oidMacThresholdPeriod	This object is in configuration information node. The value of this object identifies the time duration when the MAC address table usage continues to exceed the limit threshold. The value is an integer, in seconds, that ranges from 5 to 4294967295. The default value is 300s.
1.3.6.1.4.1.35098.1.15.4.0	oidMacMonitorValue	This object is in configuration information node. The value of this object identifies the MAC address table usage when the system sends the last SNMP Trap message.
1.3.6.1.4.1.35098.21.5.1	oidMacThreshold	This object is used in the syslog and SNMP Trap message, indicating the MAC address table usage exceeds the limit threshold over a continuous time period. The system then sends an SNMP Trap alarm message.

Configuring MAC address table usage Alarm Threshold

Step1 Enable the function of monitoring the switch MAC address table usage.

set protocols snmp trap-group event mac-threshold enable <**true** | **false**>

Step2 Set the limit threshold for MAC address table usage monitoring to send SNMP Trap messages.

set protocols snmp trap-group event mac-threshold limit <*limit-value*>

Step3 Configure the time duration when the MAC address table usage continues to exceed the limit threshold.

set protocols snmp trap-group event mac-threshold interval <*interval*>

The system samples MAC address table usage one time every 10 seconds, if the MAC address table usage exceed the limit threshold over this interval time, a SNMP trap message will be sent. But once MAC address table usage falls back below the threshold when the duration time is not up, the duration time then will be recalculated and the trap message won't be sent.

Configuration Example

Procedure

Step1 Configure the target host with IP address 10.10.50.16 for receiving SNMP traps.

```
admin@Xorplus#set protocols snmp community public
```

```
admin@Xorplus#set protocols snmp trap-group targets 10.10.50.16 security-name public
```

Step2 Enable the function of monitoring the switch MAC address table usage.

```
admin@Xorplus# set protocols snmp trap-group event mac-threshold enable true
```

Step3 Set the limit threshold for MAC address table usage monitoring to send SNMP Trap messages.

```
admin@Xorplus# set protocols snmp trap-group event mac-threshold limit 50
```

Step4 Configure the time duration when the MAC address table usage continues to exceed the limit threshold, and an SNMP Trap message will be sent.

```
admin@Xorplus# set protocols snmp trap-group event mac-threshold interval 300
```

Step5 Enable SNMP traceoptions for checking the SNMP syslogs.

```
admin@Xorplus# set protocols snmp traceoptions flag all disable false
```

Step6 Commit the configuration.

```
admin@Xorplus# commit
```

Verify the Configuration

- User can check the syslog when the MAC address table usage monitoring continuously exceeds the limit threshold.

  2001-01-01 06:27:44.86 Xorplus local0.info : [SNMP]Trap: send v2 trap, community name public, oid: 1.3.6.1.4.1.35098.21.5.1, to:10.10.50.16/162

Mirror Configuration

- Introduction of Mirroring
- Configuration Notes of Mirroring
- Configuring Mirror
- Example for Configuring Local Port Mirroring
- Example for Configuring ERSPAN
- Example for Configuring ACL-based ERSPAN

Introduction of Mirroring

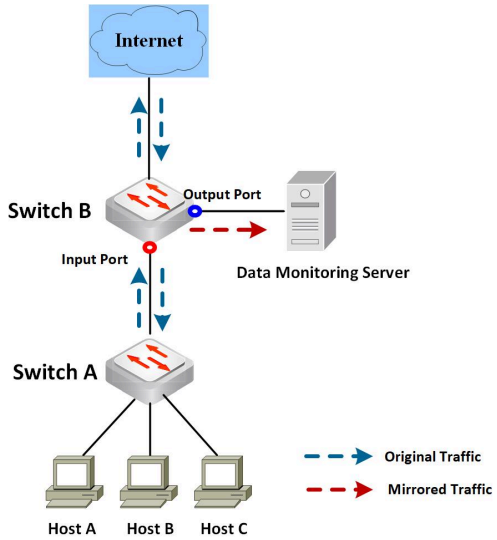
- Local Port Mirroring
- Remote Port Mirroring
  - ERSPAN
  - ACL-based ERSPAN

PICOS port mirroring supports two scenarios: local port mirroring and remote port mirroring.

Local Port Mirroring

In local port mirroring, the output port is directly connected to the Data Monitoring Server. As shown in **Figure 1**, local port mirroring is enabled on Switch B, the output port forwards the messages copied from the input port to the data monitoring server directly connected to it.

Figure1. Local Port Mirroring



NOTEs:

- The mirroring port can belong to any VLAN. This port can be either a trunk port or an access port but will not participate in Layer2 or Layer3 forwarding.
- The egress port or ingress port can be either an access port or a trunk port.
- When user sends untagged packets, the priority of mirroring is higher than the priority of adding tag.
- When user receives tagged packets, the priority of mirroring is higher than the priority of removing tag.
- The mirroring port can also analyze BPDU/LACP/LLDP packets.
- When user configures ACL for ingress/egress port, the priority of mirroring is higher than the priority of filter.
- The duplicated traffic of egress port may be different from the outgoing traffic as there are other forwarding operations before or after the mirroring operation. For example, if the received packet is tagged with PVID, the PVID tag needs to be stripped off before forwarding the packet, the duplicated traffic may be different from the outgoing traffic because it may have been duplicated to the mirroring port before the PVID was stripped off.

On the following platforms, the duplicate packets are the same as the outgoing packets, but it is not certain on other platforms.

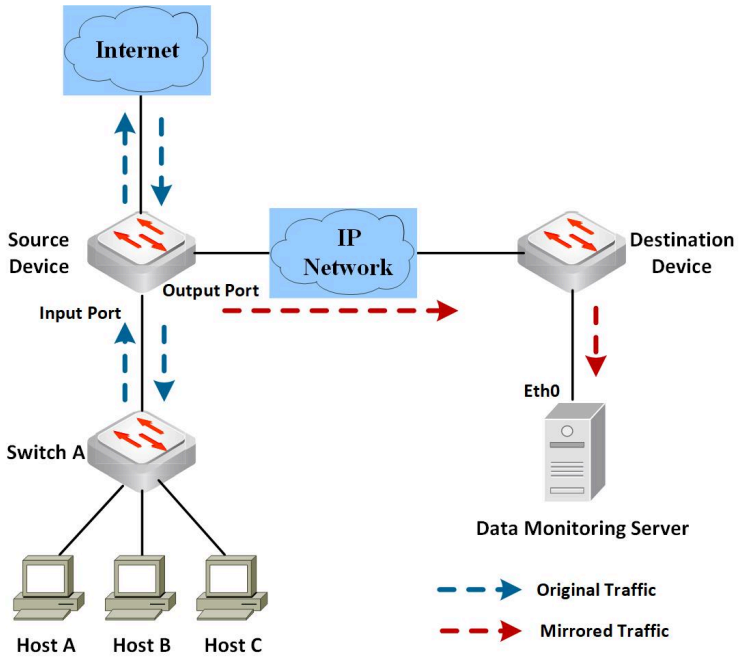
Switch ASIC	Model
Triumph2	PRONTO3296, PRONTO3295, PRONTO3290
Appllo2	ES4654
Helix4	AS4610 Series Switches

Remote Port Mirroring

ERSPAN

As shown in **Figure 2**, ERSPAN (Encapsulated Remote Switched Port Analyzer) is a remote port mirroring technology which is enabled on the mirror Source Device. In ERSPAN, the output port remotely connects to the Data Monitoring Server, and forwards the copied message from the input port to the Data Monitoring Server through a GRE tunnel over the IP network.

Figure 2. ERSPAN (Encapsulated Remote Switched Port Analyzer)



The output port encapsulates the original mirrored layer 2 packet with the GRE tunnel header, and then sends the entire GRE message in the data part of the IP message through the GRE tunnel. The encapsulated packets have the following format:

| MAC_HEADER | IP_HEADER | GRE_HEADER | L2_Mirrored_Packet |

The IP header encapsulated in the outer layer of the GRE message is manually configured by the following commands:

set interface ethernet-switching-options analyzer <*mirror-name*> **erspan output source-ip** <*source-ip*>

set interface ethernet-switching-options analyzer <*mirror-name*> **erspan output dest-ip** <*dest-ip*>

After configuration, use command **run show analyzer** [<*mirror-name*>] to display information about the mirroring information.

The switch finds the outgoing port of the mirror packet by looking for the destination IP network in its routing table. When configuring, the specified destination IP address should be configured the same as the IP address of the remote Data Monitoring Server to ensure the destination is reachable for the mirrored messages. Usually, the source IP address can be configured as the IP address of the Source Device.

As shown in **Figure 2**, the Source Device is not required to support the GRE function. ERSPAN is provided with GRE tunnel encapsulation capability. As a route forwarding device, Destination Device forwards GRE messages to the Data Monitoring Server.

The Data Monitoring Server does not need to support ERSPAN, but should support Linux GRE to decapsulate the receiving GRE messages.

NOTEs:

- A pair of source IP and destination IP addresses form a GRE tunnel.
- Multiple input ports mirroring through the same GRE tunnel is allowed only when the analyzer names are the same. However, the same GRE tunnel cannot be configured to different analyzer names, or it will commit fail and an error will be printed: "**the same erspan tunnel already exists**". For example,

```
admin@Xorplus# set interface ethernet-switching-options analyzer 333 erspan input egress te-1/1/2
admin@Xorplus# set interface ethernet-switching-options analyzer 333 erspan output source-ip 100.100.100.100
admin@Xorplus# commit
admin@Xorplus# set interface ethernet-switching-options analyzer 444 erspan input ingress te-1/1/1
admin@Xorplus# set interface ethernet-switching-options analyzer 444 erspan output source-ip 100.100.100.100
admin@Xorplus# set interface ethernet-switching-options analyzer 444 erspan output dest-ip 200.200.200.200
admin@Xorplus# commit
the same erspan tunnel already exist
Commit failed.
```

ACL-based ERSPAN

In ACL-based ERSPAN, service flows matching configured ACL rules is copied to the mirroring output port and then forwarded to the remote monitoring device through the GRE tunnel for analysis and monitoring. As shown in **Figure 2** in last section, on the Source Device, the input port copies the service flows matching the ACL rules to the output port, and then the output port forwards the copied service flows through the GRE tunnel to the remote monitoring device.

ACL-based ERSPAN is a remote port mirroring feature developed based on PICOS firewall filter feature, which supports all the firewall filter matching fields (*destination-address-ipv4, destination-mac-address, destination-port, ospf, etc.*) except the IPv6 filters (*destination-address-ipv6/ source-address-ipv6).*

Security ACL filter rules and ACL-based ERSPAN rules are put together in the order of the sequence number, which is also the match priority. The match criteria of ACL-based ERSPAN rules is the same as that of Security ACL rules, please refer to ACL configuration guide for details about Security ACL.

The ACL action commands of ACL-based ERSPAN are listed below, which are separated from the Security ACL action:

set firewall filter <*filter-name*> **sequence** <*number*> **then erspan source-ip** <*source-ip*>

set firewall filter <*filter-name*> **sequence** <*number*> **then erspan dest-ip** <*dest-ip*>

set firewall filter <*filter-name*> **sequence** <*number*> **then erspan vrf** <*vrf-name*>

set firewall filter <*filter-name*> **sequence** <*number*> **then erspan ttl** <*ttl-value*>

After configuration, use command **run show filter** [<*text*>] to display information about all filters or a specified filter.

Configuration Notes of Mirroring

- A device can be configured with up to four mirror analyzer names, including both local port mirroring and remote port mirroring.
- For local port mirroring, multiple input ports mirroring to the same output port is allowed only when the analyzer names are the same. However, multiple input ports mirroring to the same output port is not supported when analyzer names are different.
- For local port mirroring, the output port cannot participate in Layer 2 or Layer 3 forwarding.
- ERSPAN/ACL-based ERSPAN does not support IPv6.
- Due to hardware restrictions, currently it only supports to apply the ACL rules to the ingress direction of the mirroring input port.
- ERSPAN does not support BGP unnumbered routing and leaked route. The run show analyzer command, the mirror "state" is displayed as *Down* in these scenarios.
- ERSPAN does not support that the output port and input port are the same port.
- The ERSPAN output port cannot be a LAG port.

Configuring Mirror

- Configuring Local Port Mirroring
- Configuring ERSPAN
  - ERSPAN Configurations on the Source Device
- Configuring ACL-based ERSPAN

Configuring Local Port Mirroring

Step 1 Configure the input port for mirror.

set interface ethernet-switching-options analyzer <*mirror-name*> **input ingress** <*port-name*>

set interface ethernet-switching-options analyzer <*mirror-name*> **input egress** <*port-name*>

Step 2 Configure the output port for mirror.

set interface ethernet-switching-options analyzer <*mirror-name*> **output** <*port-name*>

Step 3 Commit the configurations.

commit

Step 4 Verify the configuration.

run show analyzer [<*mirror-name*>]

Configuring ERSPAN

In addition to the following ERSPAN configurations on the source device, you have to complete two extra configurations on the route device and remote data monitoring server. For details, please refer to Example for Configuring ERSPAN.

- The remote data monitoring server does not need to support ERSPAN, but should support Linux GRE to decapsulate the receiving GRE message.
- Configure routing protocols on all routing devices to ensure the mirroring source device and the data monitoring server route reachable.

ERSPAN Configurations on the Source Device

Step 1 Configure the input port for ERSPAN mirror.

set interface ethernet-switching-options analyzer <*mirror-name*> **erspan input ingress**<*port-name*>

set interface ethernet-switching-options analyzer <*mirror-name*> **erspan input egress**<*port-name*>

Step 2 Configure the source IP address and destination IP address for ERSPAN encapsulation.

set interface ethernet-switching-options analyzer <*mirror-name*> **erspan output source-ip** <*source-ip*>

set interface ethernet-switching-options analyzer <*mirror-name*> **erspan output dest-ip** <*dest-ip*>

Step 3 Enable IP routing for L3 forwarding.

set ip routing enable <**true|false**>

Step 4 Commit the configurations.

commit

Step 5 Verify the configuration.

run show analyzer [<*mirror-name*>]

Configuring ACL-based ERSPAN

Step 1 Configure ACL filter rules. You can refer to ACL configuration guide for details about how to configure ACL filter rules.

set firewall filter <*filter-name*> **sequence** <*number*> **from** *XX*

Step 2 Apply the ACL filter rules to the mirroring input port.

NOTE: Due to hardware restrictions, currently it only supports to apply the ACL rules to the ingress direction of the mirroring input port. That is, the command **set firewall filter** <*filter-name*> **output interface** <*interface-name*> does not support for ACL-based ERSPAN.

set firewall filter <*filter-name*> **input interface** <*interface-name*>

Step 3 Configure the source IP address and destination IP address for ACL-based ERSPAN GRE

NOTE: The configured source IPv4 address and destination IPv4 address are used for the IP header encapsulation in the outer layer of the GRE message. Users have to configure the routing protocol to ensure the devices at both ends of the GRE tunnel are route reachable.

set firewall filter <*filter-name*> **sequence** <*number*> **then erspan source-ip** <*source-ip*>

set firewall filter <*filter-name*> **sequence** <*number*> **then erspan dest-ip** <*dest-ip*>

Step 4 Enable IP routing for L3 forwarding.

set ip routing enable <**true|false**>

Step 5 Commit the configurations.

commit

Step 6 Verify the configuration.

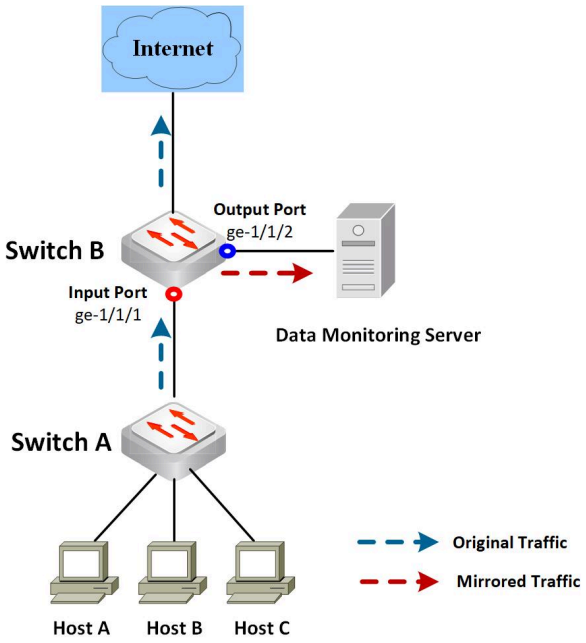
run show filter [*<filter-name>*]

Example for Configuring Local Port Mirroring

- Networking Requirements
- Procedure

Networking Requirements

Figure 1. Local Port Mirroring Configuration Example



As shown in **Figure 1**, Host A, Host B and Host C access the Internet through Switch B. The Data Monitoring Server needs to monitor the traffic from the three hosts accessing the internet.

Follow the following configuration procedure on Switch B to complete port mirroring configurations to achieve above requirement.

1. Configure interface ge-1/1/2 as the output port for mirroring, which is responsible for forwarding mirrored messages to the Data Monitoring Server.
2. Configure interface ge-1/1/1 as the input port for mirroring to make a copy of the traffic from Host A, Host B and Host C accessing the Internet to the mirroring output port.

Procedure

Step 1 Configure VLAN.

```
admin@SwitchB# set vlans vlan-id 110
admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 110
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 110
```

Step 2 Configure the input port for mirroring.

```
admin@SwitchB# set interface ethernet-switching-options analyzer 111 input ingress ge-1/1/1
admin@SwitchB# set interface ethernet-switching-options analyzer 111 input egress ge-1/1/1
```

Step 3 Configure the output port for mirroring.

```
admin@SwitchB# set interface ethernet-switching-options analyzer 111 output ge-1/1/2
```

Step 4 Commit the configurations.

```
admin@SwitchB# commit
```

Step 5 Verify the configuration.

```
admin@SwitchB# run show analyzer 111
```

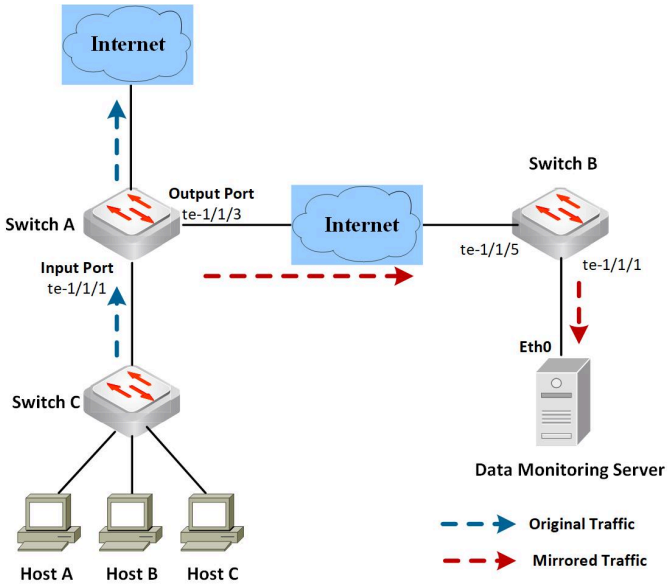
```
Analyzer name: 111
Output interface: <ge-1/1/2>
Ingress monitored interfaces: <ge-1/1/1>
Egress monitored interfaces: <ge-1/1/1>
```

Example for Configuring ERSPAN

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Data Monitoring Server
  - Host
- Verify Configuration

Networking Requirements

Figure 1. ERSPAN Configuration Example



As shown in **Figure 1**, Host A, Host B and Host C access the Internet through Switch A. The remote Data Monitoring Server connects to Switch A through Switch B. To monitor the traffic from the three hosts, the data needs to be mirrored to the output port and carried across the tunnel to the remote Data Monitoring Server.

Follow the configuration steps listed below to enable the remote port mirroring function:

1. Configure interface te-1/1/3 on Switch A as the output port for ERSPAN mirroring, which is responsible for forwarding mirrored messages to Switch B through GRE tunnel.
2. Configure interface te-1/1/1 on Switch A as the input port for ERSPAN mirroring to copy the traffic from Host A, Host B and Host C accessing the Internet to the output port.
3. On Switch B, create the VLAN and VLAN interface for forwarding mirrored messages to the Data Monitoring Server.
4. On Data Monitoring Server, configure Linux GRE to decapsulate the receiving GRE messages.

Procedure

Switch A

Step 1 Configure VLANs and VLAN interfaces.

```
admin@SwitchA# set vlans vlan-id 100
admin@SwitchA# set vlans vlan-id 230
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 230
admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchA# set vlans vlan-id 230 l3-interface vlan230
admin@SwitchA# set l3-interface vlan-interface vlan100 address 100.100.100.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan230 address 220.220.220.1 prefix-length 24
```

Step 2 Configure the input port for ERSPAN mirror.

```
admin@SwitchA# set interface ethernet-switching-options analyzer 112 erspan input ingress te-1/1/1
```

Step 3 Configure the source IP address and destination IP address for ERSPAN encapsulation.

```
admin@SwitchA# set interface ethernet-switching-options analyzer 112 erspan output source-ip 4.4.4.4
admin@SwitchA# set interface ethernet-switching-options analyzer 112 erspan output dest-ip 8.8.8.8
```

Step 4 Configure routing protocol and enable IP routing for L3 forwarding.

```
admin@SwitchA# set protocols ospf router-id 1.1.1.1
admin@SwitchA# set protocols ospf area 0
admin@SwitchA# set protocols ospf network 100.100.100.0/24 area 0
admin@SwitchA# set protocols ospf network 220.220.220.0/24 area 0
admin@SwitchA# set ip routing enable true
```

Step 5 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step 1 Configure VLANs and VLAN interfaces.

```
admin@SwitchB# set vlans vlan-id 100
admin@SwitchB# set vlans vlan-id 230
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 230
admin@SwitchB# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchB# set vlans vlan-id 230 l3-interface vlan230
admin@SwitchB# set l3-interface vlan-interface vlan100 address 8.8.8.1 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan230 address 220.220.220.2 prefix-length 24
```

Step 2 Configure routing protocol and enable IP routing for L3 forwarding.

```
admin@SwitchB# set protocols ospf router-id 3.3.3.3
admin@SwitchB# set protocols ospf area 0
admin@SwitchB# set protocols ospf network 220.220.220.0/24 area 0
admin@SwitchB# set protocols ospf network 8.8.8.0/24 area 0
admin@SwitchB# set ip routing enable true
```

Step 3 Commit the configurations.

```
admin@SwitchB# commit
```

Data Monitoring Server

On the Data Monitoring Server, configure Linux GRE to decapsulate the receiving GRE messages on Linux shell.

```
root@Monitoring_Server:/home/admin# ip addr add 8.8.8.8/24 dev eth0
root@Monitoring_Server:/home/admin# ip link add mm type erspan local 8.8.8.8 erspan_ver 0
root@Monitoring_Server:/home/admin# ip link set mm up
```

Host

No configuration is necessary on the hosts. Any packet the hosts send which flows through Switch A will automatically be copied across the ERSPAN tunnel to the Data Monitoring Server.

Verify Configuration

- On Switch A, run command **run show analyzer** to view the mirroring information.

```
admin@SwitchA# run show analyzer 112
Analyzer name: 112
Erspan Output:
       state: UP
       source-ip: 4.4.4.4
       dest-ip: 8.8.8.8
       output-port: te-1/1/3
       tagged vlan:
```

```
       vrf:
Ingress monitored interfaces: <te-1/1/1>
Egress monitored interfaces:
```

- The Data Monitoring Server can normally receive the mirrored message.
  - Check the received mirrored message.

```
root@ Monitoring_Server:/home/admin# tcpdump -i eth0 -net -vv
```

```
tcpdump: listening on eth0, link-type EN10MB (Ethernet), snapshot length 262144 bytes

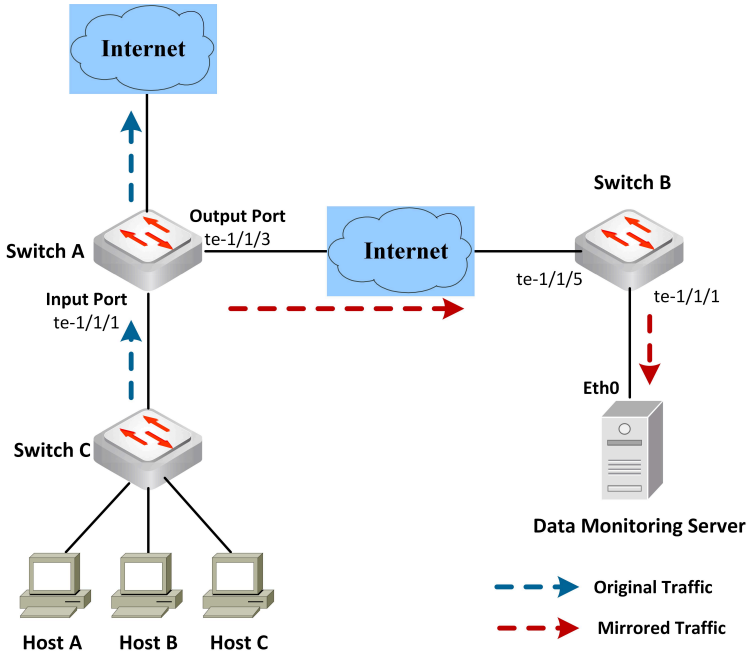
Example for Configuring ACL-based ERSPAN

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Data Monitoring Server
  - Host
- Verify Configuration

Networking Requirements

Figure 1. ACL-based ERSPAN Configuration Example



As shown in **Figure 1**, Host A, Host B and Host C access the Internet through Switch A. The remote Data Monitoring Server connects to Switch A through Switch B. To monitor the traffic from the three hosts, the data needs to be mirrored to the output port and carried across the tunnel to the remote Data Monitoring Server. The network administrator hopes that the Data Monitoring Server can analyze the packet flow matching both the TCP protocol and the source IPv4 address of 1.1.1.0/24 network segment, so as to locate the source of malicious attack.

Follow the configuration steps listed below to enable the ACL-based ERSPAN function:

1. On Switch A, configure ACL filter rules for ACL-based ERSPAN and apply the ACL rules to the mirroring input port te-1/1/1.
2. On Switch A, configure the source IP address and destination IP address for ACL-based ERSPAN GRE encapsulation.
3. On Switch B, create the VLAN and VLAN interface for forwarding mirrored messages to the Data Monitoring Server.
4. On Data Monitoring Server, configure Linux GRE to decapsulate the receiving GRE messages.

Procedure

Switch A

Step 1 Configure VLANs and VLAN interfaces.

```
admin@SwitchA# set vlans vlan-id 100
admin@SwitchA# set vlans vlan-id 230
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 230
admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchA# set vlans vlan-id 230 l3-interface vlan230
admin@SwitchA# set l3-interface vlan-interface vlan100 address 100.100.100.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan230 address 220.220.220.1 prefix-length 24
```

Step 2 Configure ACL filter rules. You can refer to ACL configuration guide for details about how to configure ACL filter rules.

```
admin@SwitchA# set firewall filter f1 sequence 1 from protocol tcp
admin@SwitchA# set firewall filter f1 sequence 1 from source-address-ipv4 1.1.1.0/24
```

Step 3 Apply the ACL filter rules to the mirroring input port.

NOTE: Due to hardware restrictions, currently it only supports to apply the ACL rules to the ingress direction of the mirroring input port. That is, the command **set firewall filter** <*filter-name*> **output interface** <*interface-name*> does not support for ACL-based ERSPAN.

```
admin@SwitchA# set firewall filter f1 input interface te-1/1/1
```

Step 3 Configure the source IP address and destination IP address for ACL-based ERSPAN encapsulation.

```
admin@SwitchA# set firewall filter f1 sequence 1 then erspan source-ip 4.4.4.4
admin@SwitchA# set firewall filter f1 sequence 1 then erspan dest-ip 8.8.8.8
```

Step 4 Configure routing protocol and enable IP routing for L3 forwarding.

```
admin@SwitchA# set protocols ospf router-id 1.1.1.1
admin@SwitchA# set protocols ospf area 0
admin@SwitchA# set protocols ospf network 100.100.100.0/24 area 0
admin@SwitchA# set protocols ospf network 220.220.220.0/24 area 0
admin@SwitchA# set ip routing enable true
```

Step 5 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step 1 Configure VLANs and VLAN interfaces.

```
admin@SwitchB# set vlans vlan-id 100
admin@SwitchB# set vlans vlan-id 230
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 230
admin@SwitchB# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchB# set vlans vlan-id 230 l3-interface vlan230
admin@SwitchB# set l3-interface vlan-interface vlan100 address 8.8.8.1 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan230 address 220.220.220.2 prefix-length 24
```

Step 2 Configure routing protocol and enable IP routing for L3 forwarding.

```
admin@SwitchB# set protocols ospf router-id 3.3.3.3
admin@SwitchB# set protocols ospf area 0
admin@SwitchB# set protocols ospf network 220.220.220.0/24 area 0
admin@SwitchB# set protocols ospf network 8.8.8.0/24 area 0
admin@SwitchB# set ip routing enable true
```

Step 3 Commit the configurations.

```
admin@SwitchB# commit
```

Data Monitoring Server

On the Data Monitoring Server, configure Linux GRE to decapsulate the receiving GRE messages on Linux shell.

```
root@Monitoring_Server:/home/admin# ip addr add 8.8.8.8/24 dev eth0
root@Monitoring_Server:/home/admin# ip link add mm type erspan local 8.8.8.8 erspan_ver 0
root@Monitoring_Server:/home/admin# ip link set mm up
```

Host

No configuration is necessary on the hosts. Any packet the hosts send which flows through Switch A will automatically be copied across the ERSPAN tunnel to the Data Monitoring Server.

Verify Configuration

- On Switch A, run command **run show filter** to view the configuration information about ACL-based ERSPAN.

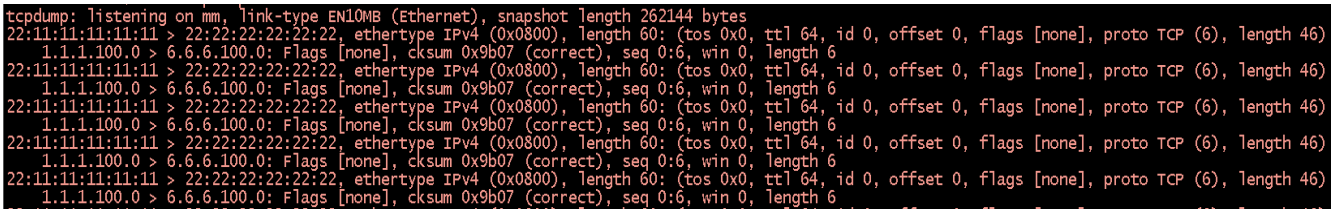
```
admin@SwitchA# run show filter f1
Filter: f1
    Description:
    Sequence: 1
        Description:
        match counter:  0 packets
        match-condition:
            protocol:                tcp
            source-address-ipv4:     1.1.1.0/24
        action: forward
        Erspan Output:
               state: UP
               source-ip: 4.4.4.4
               dest-ip: 8.8.8.8
               output-port: te-1/1/3
               tagged vlan:
               vrf:
               ttl: 255
        forwarding_class:
Input interface: te-1/1/1
```

- The Data Monitoring Server can normally receive the mirrored message.
  - Check the received mirrored message.

```
root@Monitoring_Server:/home/admin# tcpdump -i eth0 -net -vv
```

  - View the decapsulated mirrored message.

```
root@Monitoring_Server:/home/admin# tcpdump -i mm -net -vv
```

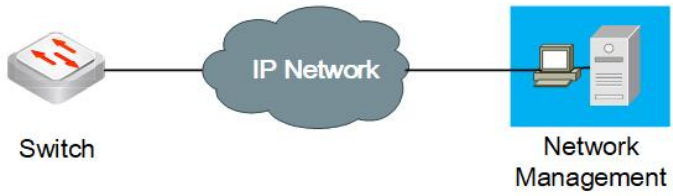


Configuring gNMI-gRPC Based Telemetry Technology

Overview

Telemetry is a remote data collection technology for monitoring device performance and faults. Telemetry technology uses the gRPC protocol to push data from the network device to a collector in the network management system. As shown in Figure 1, after a gRPC connection is established between the switch and the network management system, the network manager can subscribe to the data information of the specified service module on the switch.

Figure 1. gNMI-gRPC-based Telemetry Technology



PICOS currently only supports dial-in mode of Telemetry technology. In dial-in mode, the switch acts as a gRPC server and the collector acts as a gRPC client. The collector initiates a gRPC connection to the switch and subscribes to the data that needs to be collected.

PICOS Telemetry technology supports **Get** and **Subscribe** operations based on gNMI (gRPC Network Management Interface):

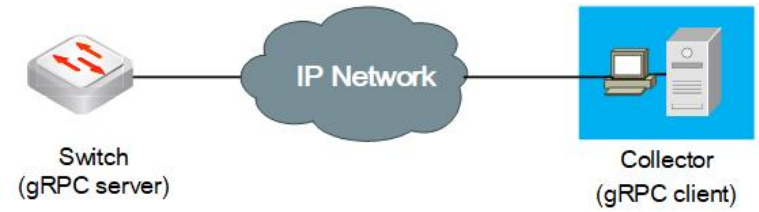
- **gNMI Get operation**: Get the device operating status and operating configuration.
- **gNMI Subscribe operation**: Subscribe to the data push service to the device, including event-triggered data and periodically sampled data.

gNMI uses gRPC (Google Remote Procedure Call) as its transport protocol.

Configuration Example for gRPC Dial-in Mode

Networking Requirements

Figure 2. gRPC Dial-in Mode Configuration Group Diagram



As shown in Figure 2, the Switch is connected to the Collector as a gRPC server. The Collector is the gRPC client. By configuring gRPC dial-in mode on the Switch, the Collector can subscribe to LLDP events on the Switch.

Configuring the gRPC Server

Before configuring the gRPC server, it is assumed that the IP addresses of both the gRPC server and the gRPC client are properly configured so that the two have valid routes to reach one another. Also make sure the gRPC environment is installed on the gRPC client.

Step 1 Enable gRPC function.

```
admin@XorPlus# set protocols grpc enable true
```

Step 2 (Optional) Configure the listening port number.

```
admin@XorPlus# set protocols grpc port 10500
```

Step 3 Commit the configuration.

```
admin@XorPlus# commit
```

Verify the Configuration

When an LLDP event occurs on the Switch, the gRPC client successfully receives the subscription information on the switch.

Remote Network Monitoring (RMON)

- Overview of RMON
- Configuring RMON
- Example for Configuring RMON

Overview of RMON

RMON is implemented based on the SNMP architecture and shares a set of Network Management Station (NMS) with SNMP to remotely manage devices.

The RMON standard (RFC2819) defines multiple RMON groups, and the device implements the four groups supported in public MIBs: statistics, history, alarms, and events, achieving the following four statistics and alarm functions for remote monitoring and management of devices in the network.

- **Ethernet statistics function (etherStatsTable in RMON MIB):** the basic statistics of each network being monitored. The system continuously gathers statistics for the traffic and the distribution of various types of packets like broadcast and multicast, the number of collisions, the number of CRC checksum error messages, the number of undersized (or oversized) data messages, and the number of received bytes and dropped packets.
- **History statistics function (etherHistoryTable in RMON MIB):** The system periodically samples, collects and stores the network statistics information. The statistics include bandwidth utilization, number of error packets and total packets, etc.
- **Event definition function (eventTable and logTable in RMON MIB):** The event group controls the events and prompts coming from the device, providing information about all events generated by RMON agent. When an event occurs, a log can be recorded or a trap can be sent to the network management station.
- **Alarm threshold setting function (alarmTable in RMON MIB):** The system monitors the specified alarm variable (alarm object corresponding to the SNMP OID). The RMON agent will record the monitored status as a log or send the trap to the network management station.

Configuring RMON

Downloading RMON MIB

Users can download RMON MIB from the page Pica8 Public MIB.

Configuring RMON

The RMON configuration contains two parts: RMON statistics and RMON alarm.

Configuring RMON Statistics

RMON statistics contains RMON ethernet statistics and history statistics:

- RMON Ethernet statistics monitors traffic with continuous statistics on the Ethernet interface. It counts the number of broadcast and multicast messages, the number of network conflicts, the number of CRC checksum error messages, the number of undersized (or oversized) data messages, the number of dropped messages, and the number of received packets in bytes.
- Configure RMON historical statistics function when you want to periodically collect data on a specified interface. It gathers statistics for the bandwidth utilization, the number of error packets, the total number of packets, etc.

Configuring RMON Ethernet Statistics

Step1 Configure RMON ethernet statistics on a specified interface.

set protocols snmp rmon statistics <*entry-index*> **interface** <*interface-name*>

Step2 Configure the owner's name of the RMON ethernet statistics table.

set protocols snmp rmon statistics <*entry-index*> **owner** <*string*>

Step3 Commit after completing all the above configurations.

commit

Step4 View RMON Ethernet statistics information.

run show rmon statistics [<*entry-index*>]

Configuring RMON History Statistics

Step1 Configure RMON history statistics on a specified interface.

set protocols snmp rmon history <*entry-index*> **interface** <*interface-name*>

Step2 Configure the sampling interval of RMON history statistics.

set protocols snmp rmon history <*entry-index*> **interval** <*interval*>

Step3 Configure the history statistics table capacity, that is, the maximum number of records that the history table can hold.

set protocols snmp rmon history <*entry-index*> **buckets** <*number*>

Step4 Configure the owner's name of the RMON history statistics table.

set protocols snmp rmon history <*entry-index*> **owner** <*string*>

Step5 Commit after completing all the above configurations.

commit

Step6 View RMON history statistics information.

run show rmon history [<*entry-index*>]

Configuring RMON Alarm

To configure RMON alarm function, users need to configure both RMON event definition function and RMON alarm threshold setting function. The RMON alarm threshold setting function configures the monitoring object and threshold. The RMON event definition function defines the action whether to record a log

or send a trap information to the NMS when a RMON alarm event triggered.

Configuring RMON Event

Step1 Configure the community for the RMON event.

set protocols snmp rmon event <*entry-index*> **community** <*community*>

Step2 Configure the RMON event action type.

set protocols snmp rmon event <*entry-index*> **type** <**none** | **log** | **trap** | **log-trap**>

Step3 Enable SNMP trap. If the event is triggered and the event action type is **trap** or **log- trap**, an SNMP trap will be sent to the management station. The value of **community** and **security-name** here should be the same as the **community** in step 1.

set protocols snmp community <*community*>

set protocols snmp trap-group targets <*ip_address*> **security-name** <*security-name*>

Step4 Configure the description for the RMON event.

set protocols snmp rmon event <*entry-index*> **description** <*event_description*>

Step5 Configure the owner's name of the RMON event.

set protocols snmp rmon event <*entry-index*> **owner** <*owner*>

Step6 Commit after completing all the above configurations.

commit

Step7 View RMON event and event log information.

run show rmon events [<*entry-index*>]

run show rmon eventlog [<*entry-index*>]

Configuring RMON Alarm

Step1 Configure the OID of the RMON alarm.

set protocols snmp rmon alarm <*entry-index*> **variable** <*oid-variable*>

Step2 Configure the sampling type of RMON alarm.

set protocols snmp rmon alarm <*entry-index*> **sample-type** <**absolute** | **delta**>

Step3 Configure the sampling interval of RMON alarm.

set protocols snmp rmon alarm <*entry-index*> **interval** <*interval*>

Step4 Configure the rising threshold of the RMON alarm, and the event to fire when the rising threshold is crossed.

set protocols snmp rmon alarm <*entry-index*> **rising-threshold** <*alarmRisingThreshold*>

set protocols snmp rmon alarm <*entry-index*> **rising-event-index** <*alarmRisingEventIndex*>

Step5 Configure the falling threshold of the RMON alarm, and the event to fire when the falling threshold is crossed.

set protocols snmp rmon alarm <*entry-index*> **falling-threshold** <*alarmFallingThreshold*>

set protocols snmp rmon alarm <*entry-index*> **falling-event-index** <*alarmFallingEventIndex*>

Step6 Configure the owner's name of the RMON alarm.

set protocols snmp rmon alarm <*entry-index*> **owner** <*owner*>

Step7 Commit after completing all the above configurations.

commit

Step8 View RMON alarms information.

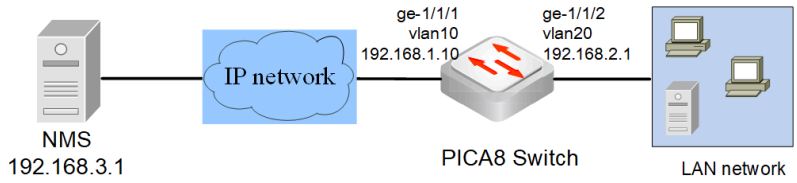
run show rmon alarms [<*entry-index*>]

Example for Configuring RMON

- Networking Requirements
  - Configuration Roadmap
- Procedure
- Verifying the Configuration

Networking Requirements

Figure 1. RMON Configuration Example



As shown in **Figure 1**, to monitor the LAN network connected to PICA8 Switch's interface ge-1/1/1, RMON is enabled to achieve the following requirement:

- Real-time and historical statistical information on traffic and the number of various types of packets.
- Record a log when the flow rate per minute (MIB variable 1.3.6.1.2.1.16.1.1.1.4.1) exceeds the set threshold.
- Monitor the broadcast and multicast traffic of this LAN subnet and report alarm messages to the NMS when exceeding the set threshold.

Configuration Roadmap

The RMON statistics function can be configured on PICA8 Switch to monitor real-time and history statistics of traffic and the number of various types of packets. Configuring RMON alarm function can record the log and actively report alarm information to NMS when the traffic exceeds the set threshold.

1. Configure the IP address of the switch interface and route reachability on the network.
2. Configure to allow Trap messages to be sent to the NMS.
3. Enable the RMON ethernet statistics and history statistics function.
4. Configure both RMON event definition function and alarm threshold setting function to achieve RMON alarm function.

Procedure

Step1 Configure the IP address of the switch interface.

```
admin@Switch# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@Switch# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@Switch# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@Switch# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@Switch# set vlans vlan-id 10 l3-interface vlan10
admin@Switch# set vlans vlan-id 20 l3-interface vlan20
admin@Switch# set l3-interface vlan-interface vlan10 address 192.168.1.10 prefix-length 24
admin@Switch# set l3-interface vlan-interface vlan20 address 192.168.2.1 prefix-length 24
```

Step2 Configure route reachability on the network.

```
admin@Switch# set protocols ospf router-id 1.1.1.1
admin@Switch# set protocols ospf area 0
admin@Switch# set protocols ospf network 192.168.1.0/24 area 0
admin@Switch# set protocols ospf network 192.168.2.0/24 area 0
admin@Switch# set ip routing enable true
```

Step3 Enable SNMP trap.

```
admin@Switch# set l3-interface loopback lo address 192.168.3.30 prefix-length 32
admin@Switch# set protocols snmp community Pica8-data-center
admin@Switch# set protocols snmp trap-group targets 192.168.3.1 security-name Pica8-data-center
admin@Switch# set protocols snmp trap-group source-interface loopback
```

Step4 Configure RMON ethernet statistics and history statistics.

```
admin@Switch# set protocols snmp rmon statistics 1 interface ge-1/1/2
admin@Switch# set protocols snmp rmon statistics 1 owner owner_pica8
```

```
admin@Switch# set protocols snmp rmon history 1 interface ge-1/1/2
admin@Switch# set protocols snmp rmon history 1 owner owner_pica8
```

Step5 Configure RMON event type to log and trap.

```
admin@Switch# set protocols snmp rmon event 1 type log-trap
admin@Switch# set protocols snmp rmon event 1 community Pica8-data-center
admin@Switch# set protocols snmp rmon event 1 description test
admin@Switch# set protocols snmp rmon event 1 owner public
```

Step6 Configure RMON alarm to monitor MIB variable 1.3.6.1.2.1.16.1.1.1.4.1, and the rising threshold to 600, falling threshold to 400.

```
admin@Switch# set protocols snmp rmon alarm 1 variable 1.3.6.1.2.1.16.1.1.1.4.1
admin@Switch# set protocols snmp rmon alarm 1 interval 20
admin@Switch# set protocols snmp rmon alarm 1 sample-type delta
admin@Switch# set protocols snmp rmon alarm 1 rising-threshold 600
admin@Switch# set protocols snmp rmon alarm 1 rising-event-index 1
admin@Switch# set protocols snmp rmon alarm 1 falling-threshold 400
admin@Switch# set protocols snmp rmon alarm 1 falling-event-index 1
admin@Switch# set protocols snmp rmon alarm 1 owner public
```

Step7 Commit after completing all the above configurations.

```
admin@Switch# commit
```

Verifying the Configuration

- The **run show rmon statistics** command can be used to view RMON Ethernet statistics information.

```
admin@Switch# run show rmon statistics
Entry 1 on ge-1/1/2 is active, and owned by owner_pica8,
    Monitors ifIndex.2 which has
    Received 354601 octets, 3643 packets,
    0 broadcast and 0 multicast packets,
    0 undersized and 0 oversized packets,
    0 fragments and 0 jabbers,
    0 CRC alignment errors and 0 collisions.
    dropped packet events (due to lack of resources):0.
    packets received of length (in octets):
        64: 0, 65-127: 3524, 128-255: 119,
        256-511: 0, 512-1023: 0, 1024-1518: 0
```

- The **run show rmon history** command can be used to view RMON history statistics information.

```
admin@Switch# run show rmon history
Entry 1 on ge-1/1/2 is active, and owned by owner_pica8,
    Monitors ifIndex.2 every 10 seconds, bucket is 50,
        Sample # 1 began measuring at 0:43:22
            Received 576000 octets, 9000 packets,
            0 broadcast and 9000 multicast packets,
            0 undersized and 0 oversized packets,
            0 fragments and 0 jabbers,
            0 CRC alignment errors and 0 collisions.
            network utilization is estimated at 0
        Sample # 2 began measuring at 0:43:32
            Received 0 octets, 0 packets,
            0 broadcast and 0 multicast packets,
            0 undersized and 0 oversized packets,
            0 fragments and 0 jabbers,
            0 CRC alignment errors and 0 collisions.
            network utilization is estimated at 0
        Sample # 3 began measuring at 0:43:42
            Received 0 octets, 0 packets,
            0 broadcast and 0 multicast packets,
            0 undersized and 0 oversized packets,
            0 fragments and 0 jabbers,
            0 CRC alignment errors and 0 collisions.
```

```
            network utilization is estimated at 0
```

- The **run show rmon events** command can be used to view RMON event information.

```
admin@Switch# run show rmon events
Entry 1 is active, and owned by public,
    Description is test,
    Event firing causes trap to community Pica8-data-center,
    Last event fired at 0:01:19,
    Current uptime 1:02:17.
```

- The **run show rmon eventlog** command can be used to view RMON event log information.

```
admin@Switch# run show rmon eventlog
Entry 1 owned by public is VALID.
    Generates eventLog 1.1 at 2:01:19.
    Description: The 1.3.6.1.2.1.16.1.1.1.4.1 defined in alarmEntry 1, equal or more than 600 with alarm value 3698
```

- The **run show rmon alarms** command can be used to view RMON alarms information.

```
admin@Switch# run show rmon alarms
Entry 1 is active, and owned by public
    Monitors 1.3.6.1.2.1.16.1.1.1.4.1 every 20 seconds
    Taking delta samples, last value was 369804
    Rising threshold is 600, assigned to event 1
    Falling threshold is 400, assigned to event 1
    On startup enable rising or falling alarm
```

RESTCONF Configuration

- Introduction of RESTCONF
- RESTCONF Operation Methods
- Configuring RESTCONF

Introduction of RESTCONF

- Overview
  - Figure 1. RESTCONF Components
- YANG Model
- Authentication
- HTTP Status Code
- RESTCONF Error Codes

NOTE:

When the `picos-web` service is enabled, it occupies ports 80 and 443 by default. Since `RESTCONF` also uses these default ports, it may fail to function properly, returning authentication errors. To use `RESTCONF` on switches with `picos-web` enabled, you must configure RESTCONF to use a custom port.

Overview

RESTCONF is a network configuration management protocol that uses HTTP methods, including OPTIONS, HEAD, GET, POST, PATCH, PUT and DELETE, to provide a set of Create, Read, Update, Delete (CRUD) operations on YANG-defined datastore to manage network devices.

RESTCONF is developed based on the integration of NETCONF and HTTP protocols, which can be implemented on a device that supports the NETCONF protocol.

RESTCONF provides a programming interface in line with the popular RESTful style, providing users with the ability to efficiently develop Web-based operation and maintenance tools.

RESTCONF Components

As shown in **Figure 1**, the RESTCONF protocol consists of two parts: RESTCONF Client and Server.

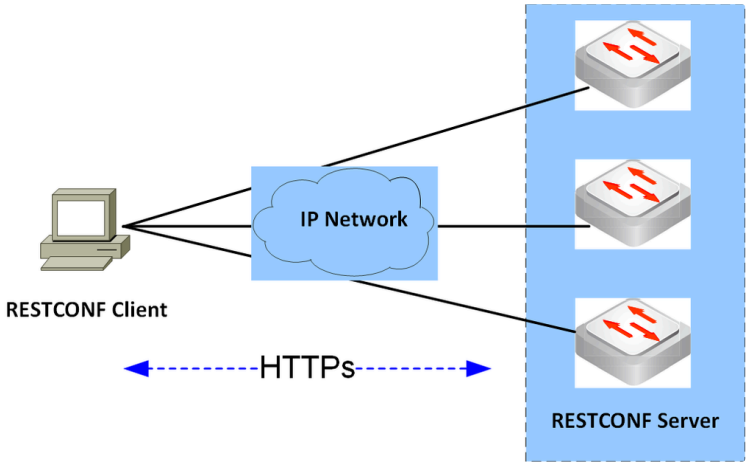
- RESTCONF Client

The client utilizes the RESTCONF protocol for system management of network devices. The client sends HTTP requests to the server to create, delete, modify or query one or more data, encoded in XML or JSON format.

- RESTCONF Server

The server device is used to maintain the information data of the managed devices. When receiving a HTTP request from the RESTCONF client, the server parses and processes the request message, and then returns a response to the client.

Figure 1. RESTCONF Components



The information that the client obtains from the running server includes configuration data and status data.

- The client can query the status data and the configuration data.
- The client can modify the configuration data and manipulate it to achieve the desired state of the server.
- The client cannot modify the status data, which mainly includes the running status and statistical information of the server.

Advantage

- RESTCONF provides RESTful style programming interface to support Web development.
- Adopting XML or JSON encoding.
- Standardized interface, compatible with devices from multiple manufacturers, can reduce development and maintenance costs.
- Good extensibility, different manufacturer devices can define their own protocol operation.

YANG Model

Same as NETCONF, RESTCONF also works based on YANG.

Most YANG files independent of the device type are placed in the following path:

/pica/etc/common/data-models.

```
root@PICOS:/pica/etc/common/data-models# ls -lt *.yang
-rw-r--r-- 1 root root 178165 May 19  2023 bgp.yang
-rw-r--r-- 1 root root   4487 May 12  2023 arp.yang
-rw-r--r-- 1 root root  56906 May  5  2023 ospfv2.yang
-rw-r--r-- 1 root root  22047 May  5  2023 ospfv3.yang
-rw-r--r-- 1 root root  16808 Apr 12  2023 bfd.yang
-rw-r--r-- 1 root root   7163 Apr 12  2023 cos-with-pfc.yang
-rw-r--r-- 1 root root   8350 Apr 12  2023 dhcp.yang
-rw-r--r-- 1 root root  23978 Apr 12  2023 firewall-no-icmp-type-code.yang
-rw-r--r-- 1 root root  24752 Apr 12  2023 firewall.yang
-rw-r--r-- 1 root root   2416 Apr 12  2023 igmp.yang
-rw-r--r-- 1 root root   8168 Apr 12  2023 igmpsnooping.yang
-rw-r--r-- 1 root root   4244 Apr 12  2023 lacp.yang
-rw-r--r-- 1 root root   5081 Apr 12  2023 mlag.yang
-rw-r--r-- 1 root root  26129 Apr 12  2023 mstp.yang
-rw-r--r-- 1 root root   5118 Apr 12  2023 ovsdb.yang
-rw-r--r-- 1 root root   7986 Apr 12  2023 pim.yang
-rw-r--r-- 1 root root  58523 Apr 12  2023 routing.yang
-rw-r--r-- 1 root root   5240 Apr 12  2023 sflow.yang
```

```
-rw-r--r-- 1 root root  10446 Apr 12  2023 snmp.yang
-rw-r--r-- 1 root root  13186 Apr 12  2023 static-routes.yang
-rw-r--r-- 1 root root  17509 Apr 12  2023 vlan-interface.yang
-rw-r--r-- 1 root root   8591 Apr 12  2023 vlans.yang
-rw-r--r-- 1 root root  11408 Apr 12  2023 vrrp.yang
-rw-r--r-- 1 root root   9920 Apr 12  2023 vxlans.yang
-rw-r--r-- 1 root root   5173 Aug 24  2022 dot1x.yang
-rw-r--r-- 1 root root   6062 Aug 12  2022 cos-without-pfc.yang
-rw-r--r-- 1 root root  16760 Aug 12  2022 ietf-inet-types.yang
-rw-r--r-- 1 root root  18034 Aug 12  2022 ietf-yang-types.yang
-rw-r--r-- 1 root root   5475 Aug 12  2022 ipfix.yang
-rw-r--r-- 1 root root   6944 Aug 12  2022 lldp.yang
-rw-r--r-- 1 root root   1411 Aug 12  2022 mfea.yang
-rw-r--r-- 1 root root   1629 Aug 12  2022 mpls.yang
-rw-r--r-- 1 root root   4825 Aug 12  2022 neighbour.yang
-rw-r--r-- 1 root root   8833 Aug 12  2022 policy.yang
-rw-r--r-- 1 root root   4592 Aug 12  2022 rip.yang
-rw-r--r-- 1 root root   3669 Aug 12  2022 ripng.yang
-rw-r--r-- 1 root root  50887 Aug 12  2022 system.yang
-rw-r--r-- 1 root root   4126 Aug 12  2022 udld.yang
-rw-r--r-- 1 root root    871 Aug 12  2022 version.yang
-rw-r--r-- 1 root root   4515 Aug 12  2022 xovs.yang
```

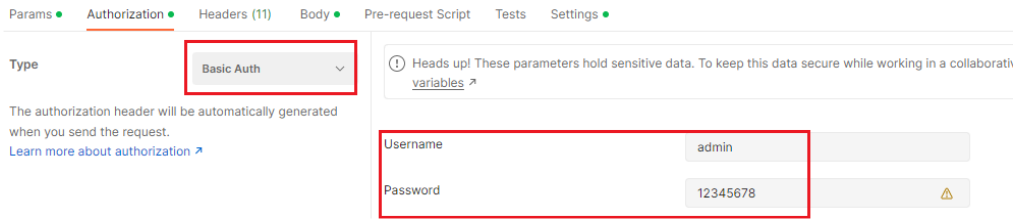
The yang files related to the device type are placed in the following path. This path contains a soft link to the yang file above, use an ellipsis instead.

```
root@PICOS:/pica/etc/as5712_54x/data-models# ls -lt *.yang
……
-rw-r--r-- 1 root root 58741 Apr 12  2023 interface.yang
-rw-r--r-- 1 root root  2211 Aug 12  2022 stm.yang
```

Authentication

RESTCONF supports setting authorization to “Basic Auth”, the username and password should be set to the same as the accounts used for authentication of the RESTCONF server.

In the HTTPs request message sent by the client, you need to fill in the authentication information correctly to ensure that the connection between the RESTCONF client and server can be established successfully.



HTTP Status Code

RESTCONF uses the Status-Line part of an HTTP response message to inform clients of their request’s result. HTTP defines these standard status codes that can be used to convey the results of a client’s request.

Table 1. HTTP status codes

Status Code	Description
200 OK	Indicates that the request has succeeded.

201 Created	Indicates that the request has succeeded and a new resource has been created as a result.
204 No Content	The server has fulfilled the request but does not need to return a response body. The server may return the updated meta information.
400 Bad Request	The request could not be understood by the server due to incorrect syntax. The client SHOULD NOT repeat the request without modifications.
401 Unauthorized	Indicates that the request requires user authentication information. The client MAY repeat the request with a suitable Authorization header field
403 Forbidden	Unauthorized request. The client does not have access rights to the content. Unlike 401, the client's identity is known to the server.
404 Not Found	The server cannot find the requested resource.
405 Method Not Allowed	The request HTTP method is known by the server but has been disabled and cannot be used for that resource.
408 Request Timeout	Indicates that the server did not receive a complete request from the client within the server's allotted timeout period.
409 Conflict	The request could not be completed due to a conflict with the current state of the resource.
410 Gone	The requested resource is no longer available at the server.
412 Precondition Failed	The client has indicated preconditions in its headers which the server does not meet.
413 Request Entity Too Large	Request entity is larger than limits defined by server.
414 Request-URI Too Long	The URI requested by the client is longer than the server can interpret.
415 Unsupported Media Type	The media-type in Content-type of the request is not supported by the server.
500 Internal Server Error	The server encountered an unexpected condition that prevented it from fulfilling the request.
501 Not Implemented	The HTTP method is not supported by the server and cannot be handled.

RESTCONF Error Codes

The tree of YANG model <errors> is defined as follows:

```
+---- errors
      +---- error*
         +---- error-type       enumeration
         +---- error-tag        string
         +---- error-app-tag?   string
         +---- error-path?      instance-identifier
         +---- error-message?   string
         +---- error-info?
```

When an error occurs, the server returns a response message carried with above error information.

- **error-type**

The value of error-type can be：

Value	Description
transport	Transport Layer
tpc	RPC Layer
protocol	Operation Layer
application	Application Layer

- **error-tag**

<error-tag>	Error description	Status code
in-use	The requested resource is already in use	409
invalid-value	The parameter value in the request is incorrect	400, 404 or 406
too-big	Request or reply messages are too large to process	413 or 400
missing-attribute	Missing attribute on element node	400
bad-attribute	Attribute error on element node	400
unknown-attribute	Unknown attribute on element node	400
bad-element	The element node value is incorrect	400
unknown-element	Unrecognized elements	400
unknown-namespace	Unrecognized namespaces	400
access-denied	Access denied	401 or 403
lock-denied	The configuration process is locked	409
resource-denied	Insufficient resources to complete the request	409
rollback-failed	Rollback failure	500
data-exists	The data already exists and POST creates a duplicate record	409
data-missing	Deleting a non-existent object returns this error	409
operation-not-supported	The operation is not supported. For example, POST and DELETE	405 or 501

	operations are not supported for current container nodes	
operation-failed	Operation execution failed	412 or 500
partial-operation	Some operations failed	500
malformed-message	The message format is incorrect	400

- **error-app-tag:** Indicates a specific error type.
- **error-path:** Represents the location where the error occurred.
- **error-message:** Indicates detailed error information.
- **error-info:** Indicates the description of error parameters.

For example,

- Example 1: Input an error path when using GET method causes error: **"error-type": "application"**.

The response result is:

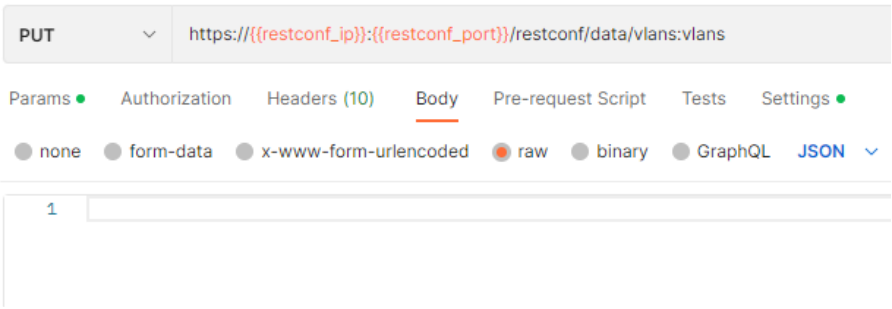
```
400 Bad Request
{
    "ietf-restconf:errors": {
        "error": {
            "error-type": "application",
            "error-tag": "unknown-element",
            "error-info": {
                "bad-element": "vlan"
            },
            "error-severity": "error",
            "error-message": "No such yang module prefix"
        }
    }
}
```

- Example 2: Input a non-exist path when using PATCH method causes error: **"error-type": "protocol"**.

The response result is:

```
400 Bad Request
{
    "ietf-restconf:errors": {
        "error": {
            "error-type": "protocol",
            "error-tag": "invalid-value",
            "error-severity": "error",
            "error-message": "API-resource type"
        }
    }
}
```

- Example 3: No data was provided when using PUT method causes error: **"error-type": "rpc"**.



The response result is:

```
400 Bad Request
{
    "ietf-restconf:errors": {
        "error": {
            "error-type": "rpc",
            "error-tag": "malformed-message",
            "error-severity": "error",
            "error-message": "The message-body MUST contain exactly one instance of the expected data resource"
        }
    }
}
```

RESTCONF Operation Methods

- OPTIONS
- HEAD
- GET
- POST
- PATCH
- PUT
- DELETE

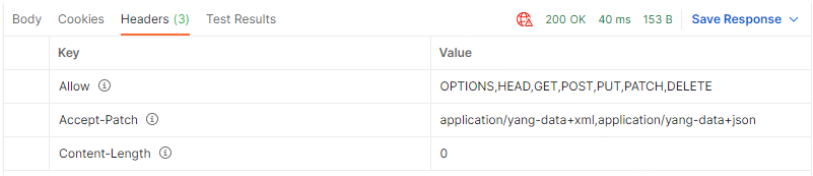
RESTCONF supports **OPTIONS, HEAD, GET, POST, PATCH, PUT** and **DELETE** methods which can be used to query and modify resources. If RESTCONF request sent from the client contains data to be operated on a specific method, the data will be placed in either XML or JSON format in the Body.

The following sections describe the usage of each method with specific examples, where HTTP client tools Postman and PyCharm are used.

OPTIONS

- Function description: The client sends the OPTIONS method to discover which methods the server supports for a particular resource (for example, GET, POST, DELETE).
- URL: https://device_ip:port/restconf/data
- Example: Request from RESTCONF client using Postman

The response result is:



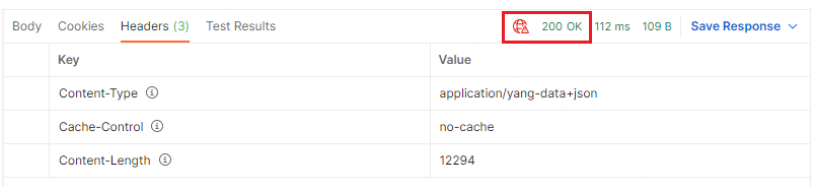
In the result,

- "**Allow**" shows the RESTCONF methods supported by the server. In this example, the RESTCONF methods supported by the server are OPTIONS, HEAD, GET, POST, PATCH, PUT and DELETE.
- "**Accept-Patch**" shows the data formats supported by the PATCH method. In this example, the data formats can be accepted are **application/yang-data+xml** and **application/yang-data+json**.

HEAD

- Function description: The HEAD method is sent by the client to query whether the configuration data and status data exist, only the Header fields that would be returned for the comparable GET method, without the response message-body. It is supported for all resources that support the GET method.
- URL: https://device_ip:port/restconf/data/modulename:node
- Example: Request from RESTCONF client using Postman

The response result is:

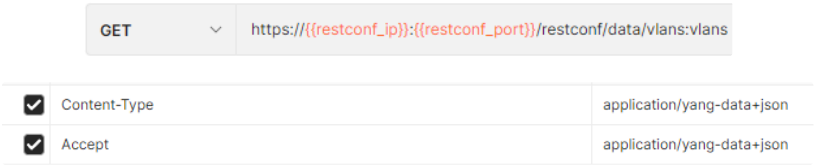


If the query data exists, the "**200 OK**" status code is returned, you can use GET method to get the data information.

GET

- Function description: The GET method is sent by the client to retrieve data and metadata for a resource.

- URL: https://device_ip:port/restconf/data/modulename:node
- Example 1: Request from RESTCONF client using Postman

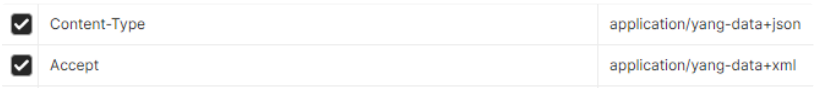


As shown in above figure,

- "**Content-Type**" field in the header defines the body format of request messages.
- "**Accept**" field defines the body format of response messages.

If set "Accept" field to "application/yang-data+json", the response result received is in JSON format:

If set "Accept" field to "application/yang-data+xml":



The response result received is in XML format:

- Example 2: Request from RESTCONF client using PyCharm

```
import requests
from requests.auth import HTTPBasicAuth
import json
import urllib3
urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)

AUTH = HTTPBasicAuth('admin', '12345678')
ACCEPT_TYPE  = 'application/yang-data+json'
CONTENT_TYPE = 'application/yang-data+json'
HEADERS = { 'Accept': ACCEPT_TYPE, 'Content-Type': CONTENT_TYPE }

def get_request(url):
    response = requests.get(url, auth=AUTH, headers=HEADERS, verify=False)
    print("URL:", url)
    print("ret code:", response.status_code)
    if response.status_code in [200]:
        print("Successful")
    else:
        print("Error in API Request")
    output = json.loads(response.text)
    print(output)
```

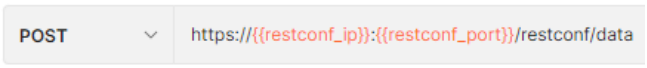
```
22
23 url = "https://10.10.51.186/restconf/data/vlans:vlans"
24
25 get_request(url)
```

The response result is:

```
1 URL: https://10.10.51.186/restconf/data/vlans:vlans
2 ret code: 200
3 Successful
4 {'vlans:vlans': {'vlan-id': [{'id': '1000', 'vlan-name': 'test1000'}]}}
```

POST

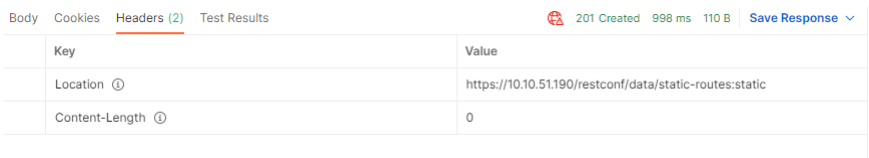
- Function description: The POST method is sent by the client to create top-level resource or sub-resource.
- URL: https://device_ip:port/restconf/data
- Example 1: Request from RESTCONF client using Postman



Data format defined in the header:

The expected settings are written to the body in JSON format:

Response is:



The result can be shown on the managed network device:

```
1 admin@PICOS# The configuration has been changed by user root
2 DELTAS:
3     protocols {
4         static {
5             route 8.8.8.0/24 {
6                 next-hop 10.10.10.10
7             }
8         }
9     }
10 admin@PICOS# show protocols static
11     route 8.8.8.0/24 {
```

```
        next-hop 10.10.10.10
    }
```

- Example 2: we can write the body in XML format in PyCharm:

```
import requests
from requests.auth import HTTPBasicAuth
import json
import urllib3
urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)

AUTH = HTTPBasicAuth('admin', '12345678')
ACCEPT_TYPE  = 'application/yang-data+json'
CONTENT_TYPE = 'application/yang-data+xml'
HEADERS = { 'Accept': ACCEPT_TYPE, 'Content-Type': CONTENT_TYPE }

def get_request(url):
    payload = '<static xmlns="http://pica8.com/xorplus/static-routes" xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0">' \
              '<route>' \
                '<name>8.8.8.0/24</name>' \
                '<next-hop>' \
                  '<ip-address>10.10.10.10</ip-address>' \
                '</next-hop>' \
              '</route>' \
              '</static>'
    response = requests.post(url, auth=AUTH, headers=HEADERS, verify=False,data=payload)
    print("URL: ", url)
    print(response.status_code)
    if response.status_code in [201]:
        print("Successful")
    else:
        print("Error in API Request")
    #output = json.loads(response.text)
    print(response.text)

url = "https://10.10.51.186/restconf/data"

get_request(url)
```

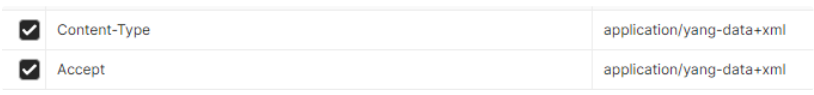
The response result is:

```
URL:  https://10.10.51.186/restconf/data
201
Successful
```

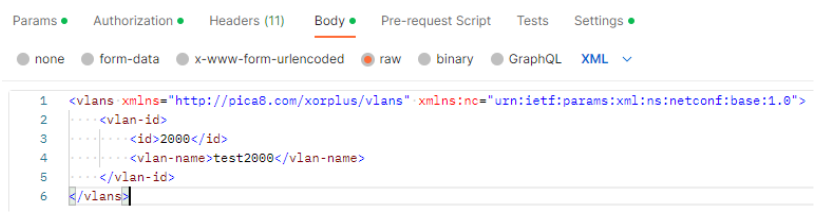
PATCH

- Function description: The PATCH method is sent by the client to modify the configuration data.
- URL: https://device_ip:port/restconf/data/modulename:node
- Example 1: Request from RESTCONF client using Postman

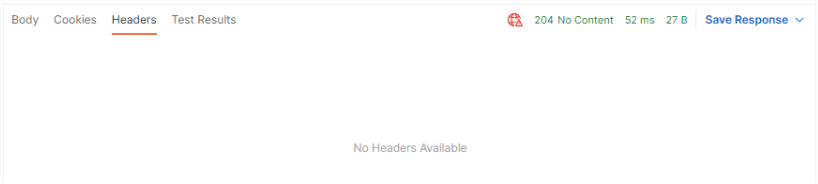
Data format defined in the header:



The expected settings are written to the body in XML format:



Response received is:



Then the configuration has been set to the device.

```
admin@PICOS# show vlans
    vlan-id 1000 {
        vlan-name: "test1000"
    }

admin@PICOS# The configuration has been changed by user root
DELTAS:
    vlans {
        vlan-id 2000 {
            vlan-name: "test2000"
        }
    }
admin@PICOS#
admin@PICOS# show vlans
    vlan-id 1000 {
        vlan-name: "test1000"
    }
    vlan-id 2000 {
        vlan-name: "test2000"
    }
```

- Example 2: we can write the body section in JSON format in PyCharm

```
import requests
from requests.auth import HTTPBasicAuth
import json
import urllib3
urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)

AUTH = HTTPBasicAuth('admin', '12345678')
ACCEPT_TYPE  = 'application/yang-data+json'
CONTENT_TYPE = 'application/yang-data+json'
HEADERS = { 'Accept': ACCEPT_TYPE, 'Content-Type': CONTENT_TYPE }

def get_request(url):
    payload = '{"vlans:vlans":{"vlan-id":[{"id":"2000","vlan-name":"test2000"}]}}'
    response = requests.patch(url, auth=AUTH, headers=HEADERS, verify=False, data=payload)
    print("URL:", url)
    print("ret code:", response.status_code)
    if response.status_code in [204]:
        print("Successful")
    else:
        print("Error in API Request")
    #output = json.loads(response.text)
    print(response.text)

url = "https://10.10.51.186/restconf/data/vlans:vlans"

get_request(url)
```

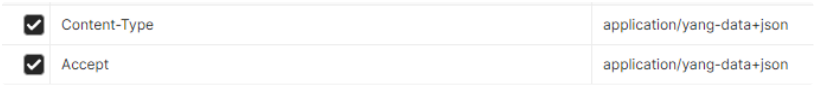
The response result is:

```
URL: https://10.10.51.186/restconf/data/vlans:vlans
ret code: 204
Successful
```

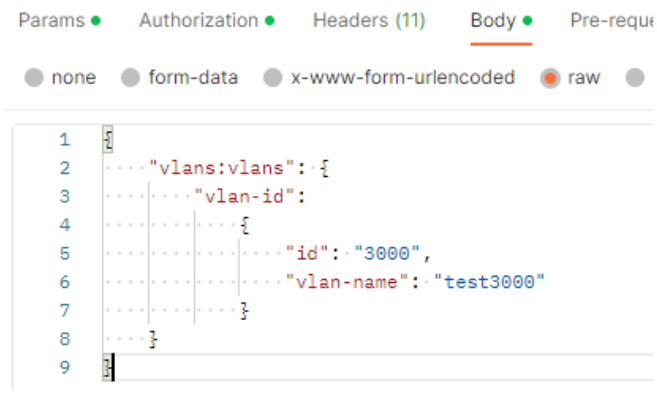
PUT

- Function description: The PUT method is sending the latest configuration to the device to replace the data on the device.
- URL: https://device_ip:port/restconf/data/modulename:node
- Example 1: Request from RESTCONF client using Postman

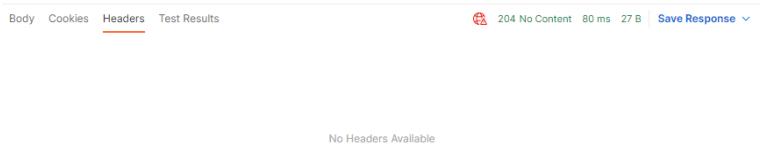
Data format defined in the header:



The expected settings are written to the body in JSON format:



Response is:



The expected configuration takes effect and the old configuration is deleted.

```
admin@PICOS# show vlans
    vlan-id 1000 {
        vlan-name: "test1000"
    }
    vlan-id 2000 {
        vlan-name: "test2000"
}
admin@PICOS# The configuration has been changed by user root
DELETIONS:
    vlans {
        vlan-id 1000
        vlan-id 2000
    }
DELTAS:
    vlans {
        vlan-id 3000 {
            vlan-name: "test3000"
        }
    }
admin@PICOS# show vlans
    vlan-id 3000 {
        vlan-name: "test3000"
    }
```

- Example 2: we can do it in PyCharm:

```
import requests
from requests.auth import HTTPBasicAuth
import json
import urllib3
urllib3.disable_warnings(urllib3.exceptions.InsecureRequestWarning)

AUTH = HTTPBasicAuth('admin', '12345678')
ACCEPT_TYPE  = 'application/yang-data+json'
```

```
CONTENT_TYPE = 'application/yang-data+json'
HEADERS = { 'Accept': ACCEPT_TYPE, 'Content-Type': CONTENT_TYPE }

def get_request(url):
    payload = '{"vlans:vlans":{"vlan-id":{"id":"3000","vlan-name":"test3000"}}}'
    response = requests.put(url, auth=AUTH, headers=HEADERS, verify=False, data=payload)
    print("URL:", url)
    print("ret code:", response.status_code)
    if response.status_code in [204]:
        print("Successful")
    else:
        print("Error in API Request")
    #output = json.loads(response.text)
    print(response.text)

url = "https://10.10.51.186/restconf/data/vlans:vlans"

get_request(url)
```

The response result is:

```
URL: https://10.10.51.186/restconf/data/vlans:vlans
ret code: 204
Successful
```

DELETE

- Function description: The DELETE method is used to delete the node or data specified by the URL.

There are several application scenarios are supported when using DELETE method:

Scenario 1: Delete all the configurations of a specified module

- URL: https://device_ip:port/restconf/data/modulename:node
- Example: Request from RESTCONF client using Postman

On the managed network device, we can see that the configurations under module "**static-route**" is removed:

```
admin@PICOS# show protocols static
    route 8.8.8.0/24 {
        next-hop 10.10.10.10
    }

admin@PICOS# The configuration has been changed by user root
DELETIONS:
    protocols {
        static {
        }
    }
admin@PICOS# show protocols static
ERROR: try to show a non existing configure tree node.
```

Scenario 2: Delete specified list member

- URL: https://device_ip:port/restconf/data/modulename:node/container
- Example: Request from RESTCONF client using Postman

On the managed network device, we can see that *vlan-id=1000* in the vlan-id list is removed:

```
admin@PICOS# show vlans
    vlan-id 1000 {
        vlan-name: "test1000"
    }
    vlan-id 2000 {
        vlan-name: "test2000"
    }

```

```
admin@PICOS# The configuration has been changed by user root
DELETIONS:
    vlans {
        vlan-id 1000
    }
admin@PICOS# show vlans
    vlan-id 2000 {
        vlan-name: "test2000"
    }
```

Scenario 3: Delete specified container

- URL: https://device_ip:port/restconf/data/modulename:node[/parant-container]/child-container
- Example: Request from RESTCONF client using Postman

On the managed network device, we can see that child container family in specified parent container interface is removed:

```
admin@PICOS# show interface gigabit-ethernet xe-1/1/6
    mtu: 2000
    family {
        ethernet-switching {
        }
    }
admin@PICOS# The configuration has been changed by user root
DELETIONS:
    interface {
        gigabit-ethernet "xe-1/1/6" {
            family {
            }
        }
    }
admin@PICOS# show interface gigabit-ethernet xe-1/1/6
    mtu: 2000
```

Scenario 4: Delete specified leaf

- URL: https://device_ip:port/restconf/data/modulename:node/container/leaf
- Example: Request from RESTCONF client using Postman

On the managed network device, we can see that leaf "**vlan-name**" is removed:

```
admin@PICOS# show vlans
    vlan-id 2000 {
        vlan-name: "test2000"
    }

admin@PICOS# The configuration has been changed by user root
DELETIONS:
    vlans {
        vlan-id 2000 {
            vlan-name: "test2000"
        }
    }
admin@PICOS# show vlans
    vlan-id 2000 {
    }
```

Scenario 5: Restores a leaf that has a default value to its default value

- URL: https://device_ip:port/restconf/data/modulename:node/container/leaf=configured_value
- Example: Request from RESTCONF client using Postman

On the managed network device, we can see that the MTU configuration is removed and restored to the default value 1514:

```
admin@PICOS# show interface gigabit-ethernet xe-1/1/6
```

```
    mtu: 2000

admin@PICOS# The configuration has been changed by user root
DELETIONS:
    interface {
        gigabit-ethernet "xe-1/1/6" {
            mtu: 2000
        }
    }
admin@PICOS# show interface gigabit-ethernet xe-1/1/6

```

Configuring RESTCONF

- Configuration on RESTCONF Server
- Configuration Example
  - Networking Requirements
    - Figure 1. Application Scenarios for RESTCONF
  - Procedure

NOTE:

When the `picos-web` service is enabled, it occupies ports 80 and 443 by default. Since `RESTCONF` also uses these default ports, it may fail to function properly, returning authentication errors. To use `RESTCONF` on switches with `picos-web` enabled, you must configure RESTCONF to use a custom port.

Configuration on RESTCONF Server

Step 1 Enable RESTCONF on the server side.

set protocols restconf

Step 2 (Optional) Configure RESTCONF service listening port on the server side.

set protocols restconf port *<port-number>*

By default, the RESTCONF service port number is 443.

> **NOTE**:
>
> The RESTCONF service listening port in the HTTP request URL sent by RESTCONF Client needs to be consistent with the port configured on the server side.

Step 3 Commit the configurations.

commit

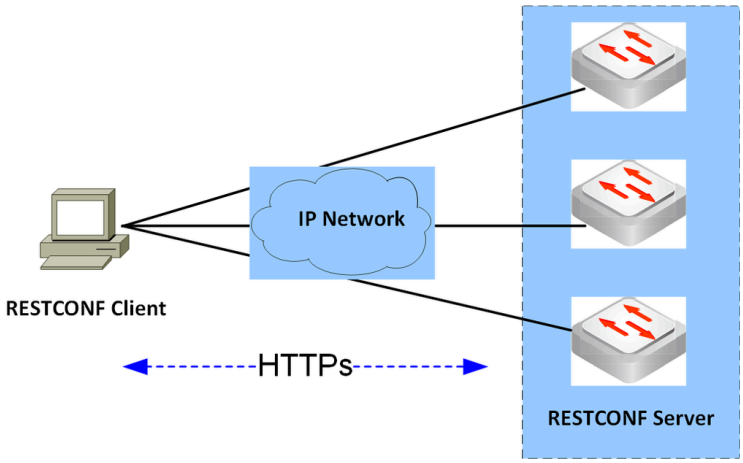
Configuration Example

Networking Requirements

When users want to manage network devices through a unified management device with high security and scalability, administrators can utilize RESTCONF protocol to remotely configure and manage network devices using HTTP methods, and monitor these devices in real-time.

As shown in **Figure 1**, RESTCONF Client and RESTCONF Server are connected to each other via an IP network. As an HTTPs client, RESTCONF Client sends HTTP requests to the RESTCONF Server, which is an HTTPs server, using the OPTIONS, HEAD, GET, POST, PATCH, PUT and DELETE methods to create, delete, modify or query one or more data, thus realizing the management of profiles through RESTCONF.

Figure 1. Application Scenarios for RESTCONF



Deploy and configure RESTCONF through the following approach:

1. Configure the RESTCONF Client and Server to achieve Layer 3 route reachability between them. This will not be detailed in the following configuration procedure.

2. Enable RESTCONF function and configure RESTCONF service listening port on the RESTCONF Server.

3. After completing the above configuration, the RESTCONF Client can send HTTP requests to the RESTCONF Server to remotely manage the network devices.

Procedure

Step 1 Enable RESTCONF on the server side.

```
admin@RESTCONF-Server# set protocols restconf
```

Step 2 (Optional) Configure RESTCONF service listening port on the server side.

```
admin@RESTCONF-Server# set protocols restconf port 1024
```

By default, the RESTCONF service listening port number is 443.

> **NOTE**:
>
> The RESTCONF service listening port in the HTTP request URL sent by RESTCONF Client needs to be consistent with the port configured on the server side.

Step 3 Commit the configurations.

```
admin@RESTCONF-Server# commit
```

EFM OAM Configuration

- Introduction of EFM OAM
- Configuring EFM OAM

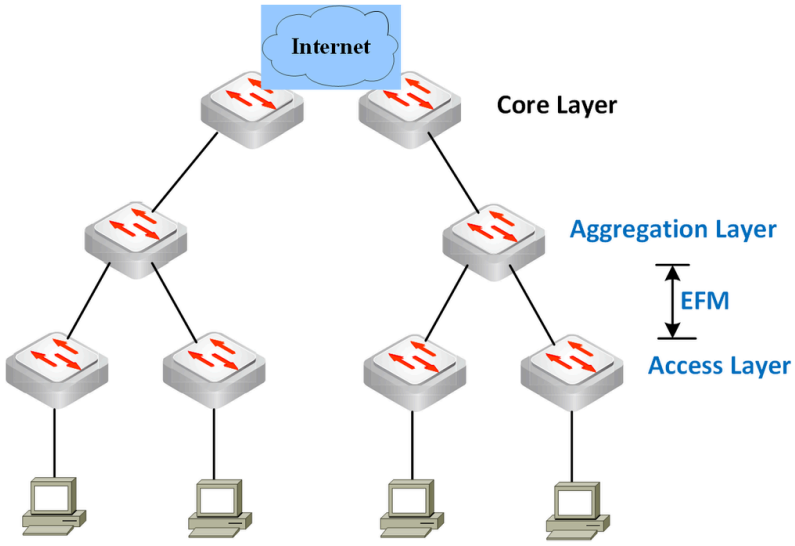
Introduction of EFM OAM

- Overview
- Types of EFM OAMPDU
- EFM OAM Mode
- EFM OAM Operation Mechanism
  - EFM OAM Discovery
  - Remote Loopback

Overview

Ethernet in the First Mile (EFM) is the Ethernet physical layer specification which is mainly used between the link of the access layer and the aggregation layer for Ethernet management and maintenance. EFM is the link-level OAM (Operation and Management). For the link between two directly connected devices, it provides link connectivity detection function, link failure monitoring function and remote loopback function.

Figure 1. Networking diagram for Ethernet OAM



Types of EFM OAMPDU

EFM works at the data link layer, and its protocol messages are called OAMPDUs (OAM Protocol Data Units). EFM detects and reports link status through periodic OAMPDUs between devices, enabling network administrators to manage the network effectively. **Table 1** shows the OAMPDUs types supported by PICOS.

Table 1. Types of EFM OAMPDU Supported by PICOS

OAMPDU Type	Description
Information OAMPDU	For EFM peer discovery, the OAM entity in the handshake phase periodically sends Information OAMPDUs at certain period to detect the connectivity of a link.

Loopback Control OAMPDU	It is used for remote loopback operation to control the OAM loopback state of the remote device, and to enable or disable the remote loopback function according to the remote loopback enabling or disabling information in the OAMPDU.

EFM OAM Mode

There are two EFM OAM modes: active mode and passive mode. EFM connections can only be initiated by active mode OAM entities, while passive mode OAM entities can only wait for connection requests from peer OAM entities. Different connection modes have different processing capabilities for OAMPDU which is shown in **Table 2**.

Table 2. Comparison of OAMPDU processing capability between active and passive modes

Processing capability of OAMPDU	Active Mode	Passive Mode
Initialization of Discovery process (initiating a connection request, i.e., sending an Information OAMPDU for the first handshake)	Support	Not Support
Responding to the Discovery initialization process (responding to connection requests)	Support	Support
Sending Information OAMPDU	Support	Support
Sending Loopback Control OAMPDU	Support	Not Support
Responding Loopback Control OAMPDU	Support (Requires active mode on the peer)	Support

EFM OAM Operation Mechanism

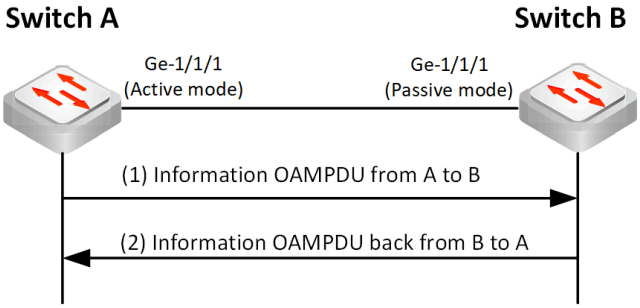
EFM OAM operation supported by PICOS includes Discovery and Remote Loopback.

EFM OAM Discovery

The implementation of EFM OAM function is based on EFM OAM connectivity. The process of establishing EFM OAM connectivity is also known as the Discovery phase, i.e., the process by which the local OAM entity discovers the remote OAM entity and establishes a stable connectivity with it.

When the EFM OAM function is enabled on an interface, and the EFM mode of the interface is active mode, then an EFM OAM connection is initiated from the interface to the remote end. During the process of establishing an EFM OAM connection, the connected OAM entities exchange the EFM OAM configuration information through the Information OAMPDUs to decide whether to establish an EFM OAM connection.

Figure 2. EFM OAM Discovery Diagram



As shown in **Figure 2**, interface Ge-1/1/1 on Switch A operates in EFM OAM active mode:

(1) Switch A sends an Information OAMPDU message to Switch B, which contains the EFM OAM configuration information of Switch A.

(2) After receiving the OAMPDU, Switch B compares the EFM OAM configuration of its own with Switch A, then replies to Switch A with an Information OAMPDU, which includes not only the EFM OAM configuration information for both Switch A and Switch B, but also the flag information indicating whether EFM OAM configurations of Switch B match Switch A.

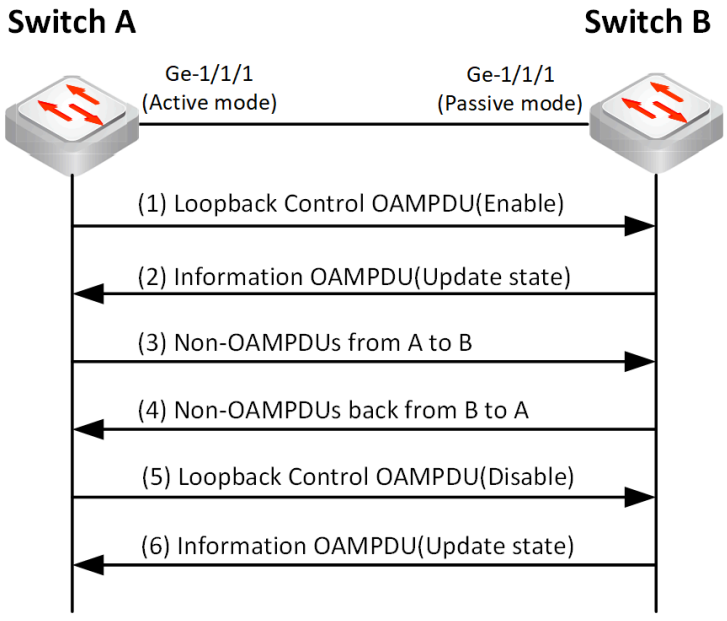
After receiving the response OAMPDU from Switch B, Switch A will then determine whether the EFM OAM configuration of Switch B matches its own configuration.

Through the above process, if the EFM OAM configurations of both sides match, the EFM OAM connection is established, after which the OAM entities at both ends will send Information OAMPDUs periodically to detect whether the connection is normal.

Remote Loopback

The remote loopback function means that when an OAM entity in active mode sends a message to the far end, the far end does not forward the message (except for OAMPDUs) based on its destination address after receiving it, but returns the message to the sender along the original path. It can be used to locate link faults and detect link quality: the network administrator can judge the link performance (including packet loss rate, delay, jitter, etc.) by observing the return of non-OAMPDU messages.

Figure 3. Schematic diagram of remote loopback



As shown in **Figure 3**, the EFM OAM connection between Switch A and Switch B is established, the interface Ge-1/1/1 of Switch A is working in EFM OAM active mode.

(1) When implementing the operations of start EFM OAM remote loopback tests on Switch A, Switch A sends a Loopback Control OAMPDU carried with remote loopback enabling information to Switch B, then waits for a reply.

(2) After receiving the OAMPDU, Switch B enters to the loopback state and replies to Switch A with an Information OAMPDU of the state change.

(3) & (4) In loopback state, Switch B returns all non-OAMPDU messages received along the original path to Switch A.

(5) When implementing the operations of stop EFM OAM remote loopback tests on Switch A, Switch A sends a Loopback Control OAMPDU carried with remote loopback disabling information to Switch B.

(6) When Switch B receives this OAMPDU, it exits the loopback state and replies to Switch A with an Information OAMPDU of the state change.

When remote loopback function is implemented, the interface no longer participates in any other Layer 2 or Layer 3 protocols. For example, Spanning Tree Protocol (STP) or Open Shortest Path First (OSPF). This is because when two connected ports are in a loopback session, no packets other than the OAM PDUs are sent to the CPU for software processing, services will be disrupted.

Configuring EFM OAM

- Configuration Notes and Constraints
- Configuring EFM OAM
- Example for Configuring EFM OAM
  - Networking Requirements
  - Procedure

Configuration Notes and Constraints

When configuring EFM OAM, pay attention to the following notes:

- An EFM connection cannot be established between two EFM OAM entities that are both in passive mode.
- Only the **active** mode end can run commands **ethernet-oam remote-loopback start interface** <*interface-name*> or **ethernet-oam remote-loopback stop interface** <*interface-name*> to start | stop EFM OAM remote loopback tests.
- Before starting the EFM OAM remote loopback tests, make sure:
  - The EFM OAM connection has been established successfully.
  - Users have to configure command **set protocols ethernet-oam interface** <*interface-name*> **remote-loopback supported** on the responding end to enable reactions to loopback control OAMPDUs from peers.
- Remote loopback cannot be configured on the same port as the loopback of the physical port.

Configuring EFM OAM

Step 1 Enable EFM OAM function on both end of the link.

set protocols ethernet-oam interface <*interface-name*> **enable** <**true | false**>

Step 2 Configure the EFM mode for this Ethernet port. By default, the EFM OAM interface works in **active** mode.

set protocols ethernet-oam interface <*interface-name*> **mode** <**active | passive**>

Step 3 Enable reactions to loopback control OAMPDUs from peers.

set protocols ethernet-oam interface <*interface-name*> **remote-loopback supported**

Step 4 (Optional) Configure EFM OAM timeout values.

set protocols ethernet-oam interface <*interface-name*> **remote-loopback timeout** <*loopback-timeout*>

set protocols ethernet-oam interface <*interface-name*> **timeout** <*oam-timeout*>

Step 5 Enable EFM OAM remote loopback tests on the specified port.

NOTEs:

- The commands **ethernet-oam remote-loopback start interface** and **ethernet-oam remote-loopback stop interface** are operational mode commands which should be executed under the prompt “admin@PICOS>”.
- Only the **active** mode end can run commands **ethernet-oam remote-loopback start interface** <*interface-name*> or **ethernet-oam remote-loopback stop interface** <*interface-name*> to start| stop EFM OAM remote loopback tests.
- Before starting the EFM OAM remote loopback tests, make sure:
  - The EFM OAM connection has been established successfully.

- Users have to configure command **set protocols ethernet-oam interface** *<interface-name>* **remote-loopback supported** on the responding end to enable reactions to loopback control OAMPDUs from peers.

- It is not allowed to modify EFM OAM mode when remote loopback function is implemented.

ethernet-oam remote-loopback start interface *<interface-name>*

Step 6 Stop EFM OAM remote loopback tests on the specified port.

ethernet-oam remote-loopback stop interface *<interface-name>*

Step 7 Commit the configuration.

commit

Step 8 View EFM OAM configuration information, session status and interface statistics.

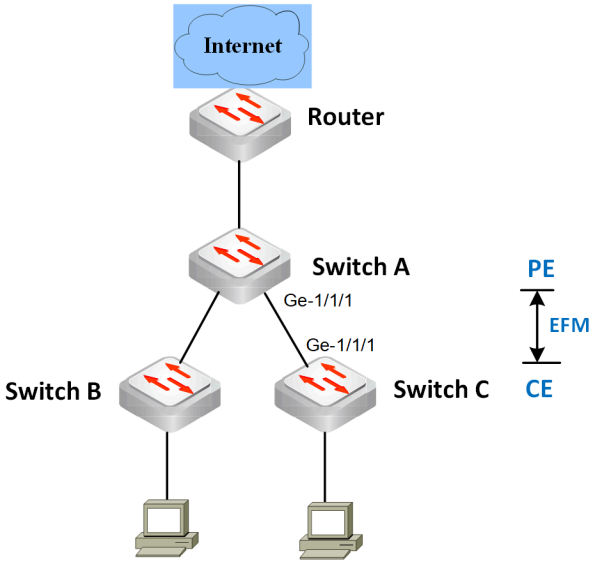
run show ethernet-oam [**interface** *<interface-name>*]

run show ethernet-oam statistics [**interface** *<interface-name>*]

Example for Configuring EFM OAM

Networking Requirements

Figure 1. EFM OAM Configuration Example



As shown in **Figure 1**, the link between Switch C to Switch A is a newly deployed network. The administrator hopes to achieve the following network management:

- Test network connectivity and quality before enabling the new network.
- Dynamically monitor the link quality after the link is properly enabled.

Follow the configuration roadmap below to configure EFM function:

1. Configure EFM basic functions on Switch A and Switch C devices to achieve automatic detection of link connectivity.
2. Configure EFM remote loopback on Switch A and Switch C to conduct link connectivity and performance testing.

Procedure

Step 1 Configure EFM basic function.

a) Enable EFM OAM function on interface ge-1/1/1 on Switch A.

```
admin@SwitchA# set protocols ethernet-oam interface ge-1/1/1 enable true
```

b) Configure the EFM OAM mode for this Ethernet port.

```
admin@SwitchA# set protocols ethernet-oam interface ge-1/1/1 mode active
admin@SwitchA# commit
```

c) Enable EFM OAM function on interface ge-1/1/1 on Switch C.

```
admin@SwitchC# set protocols ethernet-oam interface ge-1/1/1 enable true
```

d) Configure the mode of EFM OAM mode for this Ethernet port.

```
admin@SwitchC# set protocols ethernet-oam interface ge-1/1/1 mode passive
admin@SwitchC# commit
```

e) Verify the Configuration.

If the EFM configurations of Switch A and Switch C are correct, a connection will be established between them after successful negotiation in the Discovery phase. Run the command **run show ethernet-oam** on Switch A or Switch C, you can see that the EFM OAM protocol status of interface ge-1/1/1 is **SEND_ANY**.

```
admin@SwitchC# run show ethernet-oam
Interface ge-1/1/1
Local client
    Admin state:       enable
    OAM Mode:          passive
    OAM timeout:       30 seconds
    Loopback timeout:  3 seconds
    Loopback status:   no loopback
    PDU revision:      3
    OAM status:        SEND_ANY
    PDU:               ANY
Remote client
    MAC address:       18:5a:58:5c:8c:21
    OUI:               48:6e:73
    PDU revision:      3
    OAM Mode:          active
    Unidirection:      not supported
    Link monitor:      not supported
    Remote loopback:   not supported
    MIB retrieval:     not supported
    Mtu size:          1500
```

Step 2 Enable remote loopback.

a) Enable reactions to loopback control OAMPDUs from peers on Switch C.

```
admin@SwitchC# set protocols ethernet-oam interface ge-1/1/1 remote-loopback supported
admin@SwitchC# commit
```

b) Start EFM OAM remote loopback tests on interface ge-1/1/1 on Switch A.

> **NOTE**s:

- The commands **ethernet-oam remote-loopback start interface** and **ethernet-oam remote-loopback stop interface** are operational mode commands which should be executed under the prompt “admin@PICOS>”.
- Before starting the EFM OAM remote loopback tests:
  - The EFM OAM connection has been established successfully.
  - Users have to configure command **set protocols ethernet-oam interface** <*interface-name*> **remote-loopback supported** on the responding end to enable reactions to loopback control OAMPDUs from peers.

```
admin@SwitchA> ethernet-oam remote-loopback start interface ge-1/1/1
```

c) Verify the Configuration.

- After successfully configuring EFM remote loopback, run the command **run show ethernet-oam**, and you can see that the loopback status is **local loopback** on Switch C and **remote loopback** on Switch A.

```
admin@SwitchC# run show ethernet-oam
--------------------------------------------------
Interface ge-1/1/1
Local client
    Admin state:       enable
    OAM Mode:          passive
    OAM timeout:       30 seconds
    Loopback timeout:  3 seconds
    Loopback status:   local loopback
    PDU revision:      3
    OAM status:        SEND_ANY
    PDU:               ANY
Remote client
    MAC address:       18:5a:58:5c:8c:21
    OUI:               48:6e:73
    PDU revision:      3
    OAM Mode:          active
    Unidirection:      not supported
    Link monitor:      not supported
    Remote loopback:   not supported
    MIB retrieval:     not supported
    Mtu size:          1500
--------------------------------------------------

admin@SwitchA# run show ethernet-oam interface ge-1/1/1
--------------------------------------------------
Interface ge-1/1/1
Local client
    Admin state:       enable
    OAM Mode:          active
    OAM timeout:       30 seconds
    Loopback timeout:  3 seconds
    Loopback status:   remote loopback
    PDU revision:      3
    OAM status:        SEND_ANY
    PDU:               ANY
Remote client
    MAC address:       18:5a:58:03:35:81
    OUI:               48:6e:73
    PDU revision:      3
    OAM Mode:          passive
```

```
    Unidirection:      not supported
    Link monitor:      not supported
    Remote loopback:   supported
    MIB retrieval:     not supported
    Mtu size:          1500

```

- View the statistics information of EFM OAMPDU packets, we can see the number of received Loopback Control OAMPDU packet is 1 on Switch C.

```
admin@SwitchC# run show ethernet-oam statistics interface ge-1/1/1
Packets statistics for interface ge-1/1/1
Packet type                       OAM Tx Count     OAM Rx Count
---------------------------------------------------------------------
OAMInformation                   11365            11372
OAMLoopbackControl               0                1
OAMUnsupported                   0                0
```

Step 3 Stop EFM remote loopback.

```
admin@SwitchC> ethernet-oam remote-loopback stop interface ge-1/1/1
```

Step 4 Verify the Configuration.

- Run the command **run show ethernet-oam**, and you can see that the loopback status is **no loopback** on Switch C and Switch A.

```
admin@SwitchC# run show ethernet-oam
-------------------------------------------------
Interface ge-1/1/1
Local client
    Admin state:       enable
    OAM Mode:          passive
    OAM timeout:       30 seconds
    Loopback timeout:  3 seconds
    Loopback status:   no loopback
    PDU revision:      3
    OAM status:        SEND_ANY
    PDU:               ANY
Remote client
    MAC address:       18:5a:58:5c:8c:21
    OUI:               48:6e:73
    PDU revision:      3
    OAM Mode:          active
    Unidirection:      not supported
    Link monitor:      not supported
    Remote loopback:   not supported
    MIB retrieval:     not supported
    Mtu size:          1500
-------------------------------------------------
```

- View the statistics information of EFM OAMPDU packets, we can see the number of received Loopback Control OAMPDU packet is 2 on Switch C.

```

Configure Telnet to Access to the Remote Device

Before using the telnet command to connect to a Telnet server, the Telnet client and the Telnet server need to be route reachable, and the Telnet service must be enabled on the Telnet server side.

Run the following command to Telnet to the server via IPv4/IPv6 address or host name:

telnet {<*ip-address*>|<*host-name*>} [<*port-number*>] [**vrf** <*vrf-name*>]

- <*ip-address*>|<*host-name*>: Specifies the IPv4/IPv6 address or host name of a remote system.
- <*port-number*>: Optional. Specifies the TCP port number on which the remote device provides Telnet service. The default port number is 23 which do not need to specified.
- <*vrf-name*>: Optional. Specifies the name of the VRF for the telnet connection. When a VRF name is specified, find the next hop routing information from the specified VRF domain. When no VRF is specified, find the next hop routing information from the default VRF.

Example

- Establish a Telnet connection with a remote device in default VRF.

```
admin@PICOS>  telnet 10.10.51.205 vrf mgmt-vrf
Trying 10.10.51.205...
Connected to 10.10.51.205.
Escape character is '^]'.

User Access Verification

Username:
```

- Establish a Telnet connection with a remote device in management VRF.

```
admin@PICOS>  telnet 10.10.51.25 vrf mgmt-vrf
Trying 10.10.51.205...
Connected to 10.10.51.205.
Escape character is '^]'.

The physical interfaces supported by Pica8 switch are shown in Table 1:

Table 1. Physical Interface Supported by Pica8 Switch

Interface Type	Description
GE interface	The GE interface works at the data link layer, provides a maximum transmission rate of 1000 Mbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding.
5GE/2.5GE interface	The 5GE/2.5GE interface works at the data link layer, provides a maximum transmission rate of 10 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding.
10GE interface	The 10GE interface works at the data link layer, provides a maximum transmission rate of 10 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding.
25GE interface	The 25GE interface works at the data link layer, provides a maximum transmission rate of 25 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding.
40GE interface	The 40GE interface works at the data link layer, provides a maximum transmission rate of 40 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding. A 40GE optical interface can work as an independent interface or be split into four 10GE optical interfaces.
100GE interface	The 100GE interface works at the data link layer, provides a maximum transmission rate of 100 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding. A 100GE optical interface can work as an independent interface or be split into four 10GE optical interfaces or four 25GE optical interfaces.
200GE interface	The 200GE interface works at the data link layer, provides a maximum transmission rate of 200 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding. A 200GE optical interface can work as an independent interface or be split into four 25GE optical interfaces, two 50GE optical interfaces, four 50GE optical interfaces or two 100GE optical interfaces.
400GE interface	The 400GE interface works at the data link layer, provides a maximum transmission rate of 400 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding. A 400GE optical interface can work as an independent interface or be split into two or four interfaces: • Two 200GE, 100GE or 50GE interfaces. • Four 100GE, 50GE or 25GE interfaces.

800GE interface	The 800GE interface works at the data link layer, provides a maximum transmission rate of 800 Gbit/s, processes Layer 2 protocol packets, and implements Layer 2 forwarding. An 800GE optical interface can work as an independent interface or be split into two, four or eight interfaces: • Two 400GE, 200GE or 100GE interfaces. • Four 200GE or 1000GE interfaces. • Eight 100GE or 50GE interfaces.

Physical interfaces naming in PICOS are specified as follows:

type-1/1/port

The convention is as follows:

- *type* - The Pica8 device interfaces use the following types:
  - ge - 1G/5G/2.5G Ethernet interface
  - te - 10G/25G Ethernet interface
  - xe - 40G/100G/200G/400G/800G Ethernet interface
- *port* - The port number of Pica8 device. Note that: On the same device, the port number of different types of port starts from 1.

Split Interfaces

The 40G/100G/200G/400G/800G optical interfaces on Pica8 switch can be used as a single interface or split into two or four independent interfaces.

- The 40GE interface can be split into four 10 Gigabit Ethernet interfaces.
- The 100GE interface can be split into four 25 Gigabit Ethernet interfaces or split into four 10 Gigabit Ethernet interfaces. By default, the 100G interface will be split into 4 x 25GE interfaces.
- The 200GE interface can be split into four 25G Gigabit Ethernet interfaces，two 50G Gigabit Ethernet interfaces, four 50G Gigabit Ethernet interfaces or two 100G Gigabit Ethernet interfaces.
- The 400GE interface can be split into four 100 Gigabit Ethernet interfaces, two 200 Gigabit Ethernet interfaces, four 50GE optical interfaces, two 100GE optical interfaces, four 25G Gigabit Ethernet interfaces or two 50G Gigabit Ethernet interfaces.
- The 800GE interface can be split into eight 100GE interfaces, four 200GE interfaces or two 400GE interfaces, and then be reduced into eight 50GE interfaces, four 100GE interfaces, two 200GE interfaces or two 100GE interfaces.

If the port name of the 40G/100G/200G/400G/800G optical interfaces are xe-1/1/n before port breakout; however, after port breakout the port names of the four interfaces are xe-1/1/n.1, xe-1/1/n.2, xe-1/1 /n.3 and xe- 1/1/n.4. For details about port breakout and merge please refer to Configuring Port Breakout and Merge.

Physical Ethernet Port Configuration

You can enable (or disable) the Ethernet port, configure the Ethernet port's MTU, rate-limit, flow control and the duplex mode of optical port.

Shutting Down the Ethernet Port

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 disable true
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring the MTU

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 mtu 1200
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Enabling Port Flow Control

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 ether-options flow-control true
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring the Duplex Mode of Optical Port as Auto-negotiation Mode

Notes:

- Currently, duplex mode for optical port is only available for the 10 optical port when its port rate set to 1G.
- Duplex mode for optical port currently only supports to configure as auto, i.e. auto-negotiation mode.

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/1 speed 1000
admin@Xorplus# set interface gigabit-ethernet te-1/1/1 duplex auto
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Port Breakout and Merge

- Overview of Port Breakout
- 100GE and 40GE
- 400GE and 200GE
- 800GE

Overview of Port Breakout

NOTEs:

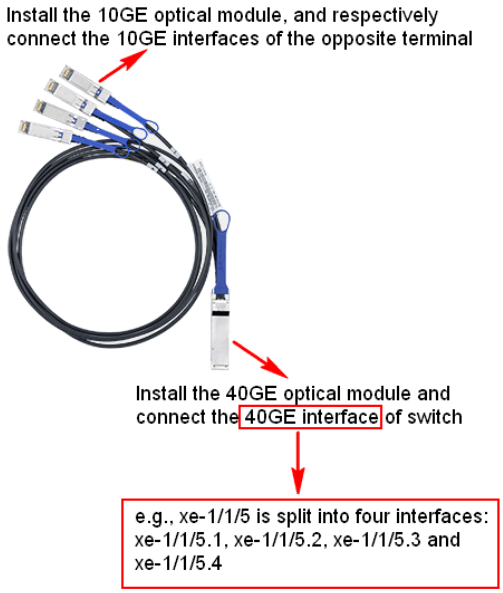
- The 800GE interfaces can be split into two, four, or eight ports. The 400GE and 200GE interfaces can be split into two or four ports, and the 40GE and 100GE interfaces can only be split into four ports.
- You **must** reboot system to make the setting take effect after performing port breakout or merge operation.
- The original interface is illegal after port breakout, and the split interfaces are illegal after port merge. You need to delete related configurations of illegal interfaces before running the command **commit.** Otherwise, error prompts will appear.

An optical interface with high bandwidth can be split into multiple independent low-bandwidth interfaces, which can improve the interface density, reduce the usage cost and increase the network flexibility.

The switch interface can be split into two, four or eight ports. After the interface is split, the configurations and features remain unchanged, while it is named in a different way. For example, the optical interface *xe-1/1/5* is split into four logical interfaces with names of *xe-1/1/5.1~xe-1/1/5.4.*

The split interface can be connected by a common cable or a breakout cable. If interfaces of both terminals are split in the same way, you can use the common cable, and the spilt interfaces are logically connected one to one; if only the interface of one terminal is split, you need use the breakout cable to connect two terminals, as shown in the figure below.

Figure 1. The breakout cable



100GE and 40GE

Overview

NOTEs:

- Due to ASIC limitation, there are some 100GE interfaces on certain platforms do not support port splitting. For details, see Limitation of Port Breakout.

Certain 100GE and 40GE optical interfaces can be used as a single interface or split into four independent interfaces. The 40GE interface can be split into four independent and logical 10 Gigabit Ethernet interfaces. The 100GE interface can be split into four independent and logical 25 Gigabit Ethernet interfaces or four 10 Gigabit Ethernet interfaces.

You can use **set interface gigabit-ethernet** <*port-name*> **breakout true** command to enable port splitting, use **set interface gigabit-ethernet** <*port-name*> **breakout false** command to merge four interfaces into one interface.

Configuring Port Breakout and Port Merge

To configure port breakout for the 40GE or 100GE interfaces of the switch, the procedures are described as below.

Step 1 Split the interface as required.

set interface gigabit-ethernet <*port-name*> **breakout true**

NOTEs:

- When you want to cancel the interface split, use **set interface gigabit-ethernet** <*port-name*> **breakout false** command to restore four interfaces to one interface.
- The interface name is modified after port breakout or merge, that is the original interface does not exist, and you **must** manually delete the configurations associated with the original interfaces before restarting system, to make sure that the configuration file can be loaded normally when system boots up.
- The 100GE interface can be split into four 25G or four 10G Ethernet interfaces. By default, the 100GE interface is split into four 25G Ethernet interfaces. If you want to further split 25G Ethernet interfaces into 10G Ethernet interfaces, configure the speed to 10G through CLI after port breakout. For detailed information of configuring interface speed, see Interface Rate Configuration. **Note**: The speed of the split four interfaces is required to be consistent.

Step 2 Commit the configuration.

commit

Step 3 Enter the Linux shell mode, and restart PICOS to make the setting take effect.

sudo systemctl restart picos

Step 4 Verify the configuration.

For example, split the 40GE interface xe-1/1/25 into four 10GE interfaces and run **run show interface brief** command to view the interface information after system startup.

```
admin@PICOS# set interface gigabit-ethernet xe-1/1/25 breakout true
admin@PICOS# commit
Commit OK.
Save done.
Interface breakout setting has been changed, please reboot the system for changes to take effect!
Make sure to delete all the configurations associated with the unavailable interfaces, otherwise loading
startup configuration will fail.
```

```
admin@PICOS# exit
admin@PICOS> start shell sh
admin@PICOS:~$ sudo systemctl restart picos
admin@PICOS> configure
admin@PICOS# run show interface brief
Interface   Management  Status  Flow Control  Duplex  Speed    Description

......
xe-1/1/25.1 Enabled     Down    Disabled      Full    Auto
xe-1/1/25.2 Enabled     Down    Disabled      Full    Auto
xe-1/1/25.3 Enabled     Up      Disabled      Full    40Gb/s

......
```

400GE and 200GE

Overview

NOTE:

When configuring the split interfaces speed of a certain interface, for N8550-24CD8D, the speed should be consistent; for N9550-64D, N9550-32D and AS9716-32D, the speed can be different.

The 400GE and 200GE optical interface can be used as a single interface or split into two or four independent and logical interfaces. The detailed information is shown as below.

Table 1. Detailed Information of Split Type

Hardware Platform	Panel Interface Type	Optical Module	Split Type
N9550-64D N9550-32D AS9716-32D	400G	400G	4*100G
			2*200G
N8550-24CD8D	400G	400G	4*100G
			2*200G
		200G	4*50G
			2*100G
		100G	4*25G
			2*50G
	200G	200G	4*50G
			2*100G
		100G	4*25G
			2*50G

The speed of certain split interfaces can be further reduced through running command set interface gigabit-ethernet speed. The detailed information is shown below.

Table 2. Detailed Information of the Speed Reduction

Hardware Platform	Panel Interface Type	Optical Module	Split Type	Reduced Speed
N8550-24CD8D	400G	QSPF-DD-SR8-400G	4*100G	4*50G, 4*25G
			2*200G	2*50G, 2*100G

Limitation for N8550-24CD8D

For N8550-24CD8D, it supports thirty-two panel interfaces, which belong to four pipes, that is every eight panel ports (six 200G and two 400G ports) belong to one pipe. For only 18 ports are allowed to be split in one pipe, you need to split interfaces within this limitation. The corresponding relationship **of panel ports and pipes** is shown as below.

Table 2. Corresponding relationships of panel ports and pipes

pipe0	pipe1	pipe2	pipe3
1, 2, 3, 4, 5, 7, 26, 28	6, 8, 13, 15, 17, 19, 30, 32	9, 11, 18, 20, 21, 23, 27, 29	10, 12, 14, 16, 22, 24, 25, 31

Configuring Port Breakout and Port Merge

To configure port breakout for the 400GE interfaces of the switch, take the following steps:.

Step 1 Enable the port breakout function.

set interface gigabit-ethernet <*port-name*> **breakout true**

Step 2 Split the interface as required. The breakout type is different based on switch models.

For N9550-64D, N9550-32D and AS9716-32D, only 400G interface is supported, and you can specify the breakout type as 4 x 100G or 2 x 200G.

set interface gigabit-ethernet <*port-name*> **breakout-type** {**4*100G** | **2*200G**}

For N8550-24CD8D, 400G and 200G interfaces are supported, and you can specify the breakout type as 4 x 100G, 2 x 200G, 4 x 50G, 2 x 100G or 4 x 25G.

set interface gigabit-ethernet <*port-name*> **breakout-type** {**4*100G** | **2*200G** | **4*50G** | **2*100G** | **4*25G**}

NOTEs:

- For 400G interfaces of N8550-24CD8D, when you specify the breakout type as 2*200G or 4*100G:
  - The interface will be split into two 200GE interfaces or four 100GE interfaces with 400G optical module inserted.
  - the interface will be split into two 100GE interfaces or four 50GE interfaces with 200G optical module inserted.
  - The interface will be split into two 50GE interfaces or four 25GE interfaces with 100G optical module inserted.
- For 200G interfaces of N8550-24CD8D:
  - When you specify the breakout type as 2*100G or 4*50G, the interface will be split into two 100GE interfaces or four 50GE interfaces with 200G optical module inserted.
  - When you specify the breakout type as 4*25G, the interface will be split into four 25GE interfaces with 100G optical module inserted.
  - When you specify the breakout type as 2*100G, the interface will be split into two 50GE interfaces with 100G optical module inserted.
- To cancel the interface split, use **set interface gigabit-ethernet** <*port-name*> **breakout false** command to restore the split interfaces into one interface.
- If you enable the breakout function of interface without configuring the breakout-type, the 400GE interface will be split into four 100G Ethernet interfaces and the 200GE interface will be split into four 50G Ethernet interfaces by default.
- The interface name is modified after port breakout or merge, that is the original interface does not exist, and you need to manually delete the configurations associated with the original interfaces before restarting system, to make sure that the configuration file can be loaded normally when system boots up.

Step 3 Commit the configuration.

commit

Step 4 Restart PicOS to make the setting take effect. **Note**: the split interfaces cannot be viewed before restarting PicOS.

sudo systemctl restart picos

Step 5 View the interface information after system startup. You can view the information of split interfaces.

run show interface brief

Configuration Example of Port Breakout

Overview

For N8550-24CD8D, split the 400GE interface into two 200GE interfaces, further reduce the speed of one split interface to 100GE, and view the interface information after system startup.

Procedure

Step 1 Enable the port breakout function.

```
admin@PICOS# set interface gigabit-ethernet xe-1/1/48 breakout true
```

Step 2 Specify the breakout type as 2 x 200G.

```
admin@PICOS# set interface gigabit-ethernet xe-1/1/48 breakout-type 2*200G
```

Step 3 Commit the configuration.

```
admin@PICOS# commit
```

Step 4 Restart PicOS to make the setting take effect.

```
admin@PICOS# exit
admin@PICOS> start shell sh
admin@PICOS:~$ sudo systemctl restart picos
```

Step 5 Reduce the speed of split interface xe-1/1/48.1 to 100GE.

```
admin@PICOS> configure
admin@PICOS# set interface gigabit-ethernet xe-1/1/48.1 speed 100000
admin@PICOS# commit
```

Verify the configuration

Use the **run show interface brief** command to view the interface xe-1/1/48 information after system startup.

```
admin@PICOS# run show interface brief
Interface       Management Status   Flow Control   Duplex   Speed    Description

--------------  ----------  ------  ------------  ------  -------  ------------------------------

…….           …….      …….     …….        …….    …….

xe-1/1/48.1      Enabled     Up    Disabled      Full    100Gb/s

xe-1/1/48.2      Enabled     Up    Disabled      Full    200Gb/s

xe-1/1/49       Enabled     Down    Disabled      Full    Auto
```

```

```

800GE

Overview

The 800GE optical interface can be used as a single interface or split into multiple independent and logical interfaces. The speed of split interfaces can be further reduced through running command **set interface gigabit-ethernet speed**. The detailed information is shown below.

Table 1. Detailed Information of Split Type and Speed Reduction

Hardware Platform	Panel Interface Type	Optical Module	Split Type	Reduced Speed
N9600-64OD	800G	800G	8*100G	8*50G
			4*200G	4*100G
			2*400G	2*200G, 2*100G

Configuration Notes and Constraints

When configuring the port breakout and port merge, pay attention to the following notes:

- Currently, only the platform of N9600-64OD supports 800GE optical interfaces.
- After you split an interface into 8 x 100G, another port in the same group cannot be split or can only be split into 2 x 400G due to chip limitations. For example, xe-1/1/1 and xe-1/1/2 are in a group, if you split the interface xe-1/1/1 into 8 x 100G, the interface xe-1/1/2 cannot be split or can only be split into 2 x 400G.
- Certain 800G optical modules do not support certain split types and speed reduction for their own limitations. For detailed information, contact the FS support staff.
- If you enable the breakout function of interface without configuring the breakout-type, the 800GE interface will be split into four 200G Ethernet interfaces by default.
- The interface name is modified after port breakout or merge, and the original interface does not exist. To make sure that the configuration file can be loaded normally when system boots up, you need to manually delete the configurations associated with the original interfaces before restarting system.
- To cancel the interface split, use the command **set interface gigabit-ethernet** <*port-name*> **breakout false** to restore the split interfaces into one interface.

Configuring Port Breakout and Port Merge

To configure the port breakout for the 800GE interfaces, take the following steps:

Step 1 Enable the port breakout function.

set interface gigabit-ethernet <*port-name*> **breakout true**

Step 2 Split the interface as needed. You can specify the breakout type as 8 x 100G, 4 x 200G or 2 x 400G.

set interface gigabit-ethernet <*port-name*> **breakout-type** {**2*400G** | **4*200G | 8*100G**}

Step 3 Commit the configuration.

commit

Step 4 Restart PICOS to make the setting take effect. **NOTE**: the split interfaces cannot be viewed before restarting PICOS.

sudo systemctl restart picos

Step 5 View the interface information after system startup. You can view the information of split interfaces.

run show interface brief

Configuration Example of Port Breakout

Overview

For N9600-64OD, split the 800GE interface into two 400GE interfaces, and further reduce the speed of one split interface to 200GE. You can view the interface information after system startup.

Procedure

Step 1 Enable the port breakout function.

```
admin@PICOS# set interface gigabit-ethernet xe-1/1/48 breakout true
```

Step 2 Specify the breakout type as 2 x 400G.

```
admin@PICOS# set interface gigabit-ethernet xe-1/1/48 breakout-type 2*400G
```

Step 3 Commit the configuration.

```
admin@PICOS# commit
```

Step 4 Restart PICOS to make the setting take effect.

```
admin@PICOS# exit
admin@PICOS> start shell sh
admin@PICOS:~$ sudo systemctl restart picos
```

Step 5 Reduce the speed of split interface xe-1/1/48.1 to 200GE.

```
admin@PICOS> configure
admin@PICOS# set interface gigabit-ethernet xe-1/1/48.1 speed 200000
admin@PICOS# commit
```

Verifying the configuration

Use the command **run show interface brief** to view the interface xe-1/1/48 information after system startup.

```
admin@PICOS# run show interface brief
Interface       Management Status   Flow Control   Duplex   Speed    Description

```

Interface Rate Configuraion

- Introduction of Interface Rate
- Configuring the Force Rate of an Interface
- Configuring the Auto-Negotiation Mode

Introduction of Interface Rate

Interface rate can be configured in the two modes: force rate (non-auto-negotiation mode) and auto-negotiation mode.

> **NOTE:**
>
> - Interfaces at both ends of a link SHOULD work in the same auto-negotiation mode. Otherwise, the interfaces may not be able to communicate with each other.
> - The 2.5G/5G RJ45 ports don't support to set the force speed by using **set interface gigabit-ethernet**<*interface-name*> **speed** <*speed*> command. Users can configure auto-negotiation mode to auto-negotiate the interface rate for these ports, together with the optional **set interface gigabit-ethernet** <*interface-name*> **auto-speeds** <*auto-speed*> command to manually specify the auto-negotiation rate range.

Force Rate (Non-auto-negotiation Mode)

If you want to use a specific interface rate for communication rather than auto-negotiate the interface rate, you can configure the force rate of the interface.

You can configure the force rate of an interface by using the **set interface gigabit-ethernet**<*interface-name*> **speed** <*speed*> command.

> **NOTE:**
>
> When configuring the force rate of an interface, make sure that the interface rates configured on the two ends of the link are the same.

Instructions for the switch interface rate configuration:

1. 1G RJ45 port: The interface rate can be configured to 100M, 10M or auto. By default, the interfaces work in auto-negotiation mode.
2. 1G optical port: The interface rate can be configured to 1000M or auto. By default, the interfaces work in auto-negotiation mode.
3. 10G RJ45 port: The interface rate can be configured to 100M or auto. By default, the interfaces work in auto-negotiation mode.
4. 10G optical port:

- When a 10G optical module is inserted, the interface rate can be configured to 10G or 1G. When no force rate is configured, the interface recognizes the interface rate of itself as 10G.
- When a 1G optical module is inserted, the interface rate can be configured to 1G. When no force rate is configured, the interface recognizes the interface rate of itself as 1G.

5. 40G optical port: The interface rate can be configured to 40G. When no force rate is configured, the interface recognizes the interface rate of itself as 40G. If the interface configured interface split, the split interface rate can be configured to 10G or 1G.
6. 100G optical port:

- When a 100G optical module is inserted, the interface rate can be configured to 100G or 40G. When no force rate is configured, the interface recognizes the interface rate of itself as 100G. If the interface configured interface split, the split interface rate can be configured to 25G or 10G.
- When a 40G optical module is inserted, the interface rate can be configured to 40G. When no force rate is configured, the interface recognizes the interface rate of itself as 40G. If the interface configured interface split, the split interface rate can be configured to 10G.

7. 200G optical port:

- When a 200G optical module is inserted, the interface rate can be configured to 200G,100G or 50G. When no force rate is configured, the interface recognizes the interface rate of itself as 200G. If the interface configured interface split, the split interface rate can be configured to 100G or 50G.
- When a 100G optical module is inserted, the interface rate can be configured to 100G,50G or 25G. When no force rate is configured, the interface recognizes the interface rate of itself as 100G. If the interface configured interface split, the split interface rate can be configured to 50G or 25G.

8. 400G optical port:

- When a 400G optical module is inserted, the interface rate can be configured to 400G, 200G or 100G. When no force rate is configured, the interface recognizes the interface rate of itself as 200G. If the interface configured interface split, the split interface rate can be configured to 200G or 100G.
- When a 200G optical module is inserted, the interface rate can be configured to 200G,100G or 50G. When no force rate is configured, the interface recognizes the interface rate of itself as 200G. If the interface configured interface split, the split interface rate can be configured to 100G or 50G.
- When a 100G optical module is inserted, the interface rate can be configured to 100G, 50G or 25G. When no force rate is configured, the interface recognizes the interface rate of itself as 100G. If the interface configured interface split, the split interface rate can be configured to 50G or 25G.

9. 800G optical port: Only 800G optical module can be inserted, and the interface rate can be configured to 800G, 400G, 200G or 100G. When no force rate is configured, the interface recognizes the interface rate of itself as 800G.

- If the interface configured interface split, the split interface rate can be configured to 400G, 200G or 100G.
- The speed of split interfaces can be further reduced by running the command **set interface gigabit-ethernet speed**. The reduced speed of split interfaces: 400G supports 200G and 100G; 200G supports 100G; 100G supports 50G.

Auto-negotiation Mode

When the ports of the switch in the network support multiple transmission rate, the user can configure auto-negotiation mode to auto-negotiate the interface rate. The devices at both ends of the link exchange interactive messages with the device capability, thus automatically negotiate the optimal interface rate of the interfaces at both ends of the link.

Use the **set interface gigabit-ethernet**<*interface-name*> **speed auto** command to enable the auto-negotiation mode of the interface.

Only the 10G, 5G/2.5G and 1G RJ45 ports support auto-negotiation mode. By default, these interfaces work in auto-negotiation mode. In auto-negotiation mode the ports negotiate any rate supported by the two devices. To enable non-auto-negotiation mode, you can configure the force rate of the interface by using **set interface gigabit-ethernet**<*interface-name*> **speed** <*speed*> command.

If the negotiated interface rate is not the required value, you can use the **set interface gigabit-ethernet** <*interface-name*> **auto-speeds** command to manually specify the auto-negotiation rate to make the interface negotiate the rate within the specified range. The auto-negotiation rates configured on the interfaces must have an intersection at both ends of the link.

Use **set interface gigabit-ethernet** <*interface-name*> **auto-speeds** multiple times to set multiple negotiation rates.

Example 1:

The following commands configure multiple auto-negotiation rates on interface ge-1/1/1 to specify the range of auto-negotiation rate to 1000M, 100M and 10M.

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 auto-speeds 1000
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 auto-speeds 100
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 auto-speeds 10
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 speed auto
```

Example 2:

The following commands configure one auto-negotiation rate on interface ge-1/1/1 to specify the range of auto-negotiation rate to 1000M.

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 auto-speeds 1000
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 speed auto
```

NOTE:

- Only the 10G, 5G/2.5G and 1G RJ45 ports support auto-negotiation mode and auto-negotiation rate.
- Run the **set interface gigabit-ethernet**<*interface-name*>**speed auto** command to configure the Ethernet interface to work in auto-negotiation mode before using the **set interface gigabit-ethernet**<*interface-name*>**auto-speeds** command to manually specify the auto-negotiation rate.
- In auto-negotiation mode, the device automatically negotiates the duplex mode of the interface while negotiating the interface rate.

Configuring the Force Rate of an Interface

This section describes how to configure the force rate of an interface.

Procedure

- Configure the force rate of an interface.

  set interface gigabit-ethernet<*interface-name*> **speed** <*speed*>

Configuration Example

- Configure the force rate of the Te-1/1/5 port to 100 M.

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/5 speed 100
admin@Xorplus# commit
```

Verify the Configuration

- Use **run show interface gigabit-ethernet** command to view the current interface status information of te-1/1/5 interface. Check the **Speed** and **Auto-negotiation** field in the command output. **Auto-negotiation** field is **Disabled** when in non-auto-negotiation mode.

```
admin@XorPlus# run show interface gigabit-ethernet te-1/1/5
Physical interface: te-1/1/5, Enabled, error-discard False, Physical link is Up
Interface index: 5, SFP type: unknown, Mac Learning Enabled
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1514, Speed: 1Gb/s, Duplex: Full
Source filtering: Disabled, Flow control: Disabled
Auto-negotiation: Disabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress:unlimited, egress:unlimited
Link fault signaling  ignore local fault:false, ignore remote fault:false
force up mode:false
Precision Time Protocol mode:none
Current address: 48:6e:73:01:00:bb, Hardware address: 48:6e:73:01:00:bb
Traffic statistics:
  5 sec input rate 0 bits/sec, 0 packets/sec
  5 sec output rate 544 bits/sec, 0 packets/sec
  Input Packets.....................0
  Output Packets....................9149
  Input Octets......................0
  Output Octets.....................1125327
```

Configuring the Auto-Negotiation Mode

This section describes how to configure the auto-negotiation mode.

- Procedure
- Configuration Example
- Verify the Configuration

Procedure

Step1 Enable auto-negotiation mode.

set interface gigabit-ethernet<*interface-name*> **speed auto**

> **NOTE:**
>
> Only the 10G, 5G/2.5G and 1G RJ45 ports support auto-negotiation mode and to set auto-negotiation rate.

Step2 Configure the auto-negotiation rate of Ethernet interfaces in auto-negotiation mode.

set interface gigabit-ethernet <*interface-name*> **auto-speeds** <*auto-speed*>

Configuration Example

Step1 Enable auto-negotiation mode.

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 speed auto
```

> **NOTE:**
>
> Only the 10G, 5G/2.5G and 1G RJ45 ports support auto-negotiation mode and to set auto-negotiation rate.

Step2 Configure the auto-negotiation rate of ge-1/1/1.

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 auto-speeds 100
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 auto-speeds 10
```

Verify the Configuration

- Use **run show interface gigabit-ethernet ge-1/1/1** command to view the current interface status information of ge-1/1/1 interface. Check the **Speed** and **Auto-negotiation** field in the command output.

```
admin@XorPlus# run show interface gigabit-ethernet ge-1/1/1
Physical interface: ge-1/1/1, Enabled, error-discard False, Physical link is Up
Interface index: 5, SFP type: unknown, Mac Learning Enabled
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1514, Speed: 1Gb/s, Duplex: Full
Source filtering: Disabled, Flow control: Disabled
Auto-negotiation: Enabled, Advertised speed modes: 10M,100M
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress:unlimited, egress:unlimited
Link fault signaling  ignore local fault:false, ignore remote fault:false
force up mode:false
Precision Time Protocol mode:none
Current address: 48:6e:73:01:00:bb, Hardware address: 48:6e:73:01:00:bb
Traffic statistics:
  5 sec input rate 0 bits/sec, 0 packets/sec
  5 sec output rate 544 bits/sec, 0 packets/sec
  Input Packets.....................0
  Output Packets....................9149
  Input Octets......................0
  Output Octets.....................1125327
```

Port Security Configuration

Port security function limits the number of MAC addresses that can access the switch port, preventing illegal users from communicating with the network through the switch interface, thus enhancing the security of network resources.

The dynamic MAC address learned by the secure interface is converted into secure MAC address, and the maximum number of secure MAC addresses is allowed to be configured. When the number of learned MAC addresses exceeds the MAC limit, a violation action is triggered to protect the system, which can be configured by the user to shut down the port or discard packets with new source MAC addresses.

NOTE:
When configuring port security, follow the guidelines and restrictions described below:

- By enabling the port security function, the dynamic MAC address table entries learned previously on the secure interface will be deleted automatically and the static MAC address table entry configured previously will be prompted to manually delete.
- Port security and static MAC configurations on the same interface are mutually exclusive.
- Port security does not support to configure on a LAG interface.
- Make sure MAC learning is enabled before enabling port security on the same interface. (By default, MAC learning is enabled.)
- Executing the command "**run clear MAC address table all**" will clear only the dynamic secure MAC addresses, but not clear static secure MAC and sticky secure MAC.
- When the secure port goes Down and Up, the system clears only dynamic secure MAC, but not clear static secure MAC and sticky secure MAC.
- A secure interface can learn only one secure MAC address by default. Set the maximum number of secure MAC addresses according to the actual networking requirement.
- For dynamic security MACs, you can move them to any other port; however, for sticky security MACs, learning on any other port is not supported unless statically configured.
- The new learned MAC addresses will temporarily occupy the system MAC address table resources when it reaches the MAC limit. In this case, if the interface still learns a large number of MAC addresses, it may cause the device to temporarily fail to learn the new MAC address.

Enabling Port Security

When port security is enabled, the dynamic MAC address table entries learned previously on the secure interface will be deleted automatically and the static MAC address table entry configured previously will be prompted to manually delete.

After port security is enabled, the dynamic MAC addresses learned on the secure interface will be changed to a dynamic secure MAC address.

When port security is disabled, all the secure MAC addresses on the interface will be deleted, and the port will need to re-learn the MAC address on the port.

The following example enables port security on interface ge-1/1/1.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security
admin@XorPlus# commit
Commit OK.
Save done.
```

Three Types of Secure MAC

There are three types of secure MAC address on a secure port: Dynamic Secure MAC, Static Secure MAC and Sticky Secure MAC.

1. Dynamic Secure MAC

Dynamic secure MAC is the MAC address dynamically learned on the secure port.

When the secure port goes Down and Up, or device reboots/restarts, the dynamic secure MAC addresses are lost and needs to be re-learned.

Dynamic secure MAC addresses will be aged out by the following MAC aging time CLI command.

```
admin@XorPlus# set interface ethernet-switching-options mac-table-aging-time 100
admin@XorPlus# commit
Commit OK.
Save done.
```

2. Static Secure MAC

Static secure MAC addresses are configured by the user with the following CLI command.

The configuration will not be lost when the switch is rebooted/restarted, or port goes down and up.

Static secure MAC addresses do not age.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security mac-address 00:00:23:23:23:23 vlan 1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security mac-address 00:00:23:23:23:24 vlan 1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security mac-address 00:00:23:23:23:25 vlan 1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security mac-address 00:00:23:23:23:26 vlan 1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security mac-address 00:00:23:23:23:27 vlan 1
admin@XorPlus# commit
```

```
Commit OK.
Save done.
admin@XorPlus#
admin@XorPlus# run show port-security address
Secure Mac Address Table
-----------------------------------------------------
Vlan MAC Address Type Interface
---- ----------------- ------- ----------
1 00:00:23:23:23:23 static ge-1/1/1
1 00:00:23:23:23:24 static ge-1/1/1
1 00:00:23:23:23:25 static ge-1/1/1
1 00:00:23:23:23:26 static ge-1/1/1
1 00:00:23:23:23:27 static ge-1/1/1
-----------------------------------------------------
MAC age time :300s
```

3. Sticky Secure MAC

When sticky function is enabled on the secure port, the system changes the dynamic secure MAC to sticky secure MAC.

Port security with sticky MAC addresses retains dynamically learned MAC addresses when the port goes down and restores the MAC addresses when the link is up.

Sticky secure MAC addresses also do not age.

NOTE:

- After a device reboots/restarts, sticky secure MAC addresses are lost and need to be re-learned.
- Disabling the sticky function converts the sticky secure MAC addresses on the current interface to dynamic secure MAC addresses.

For example, enable sticky function on secure port ge-1/1/1.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security sticky true
admin@XorPlus# commit
Merging the configuration.
Commit OK.
Save done.
admin@XorPlus#
```

In **run show port-security address**, the MAC type of the sticky secure MAC is displayed as sticky; however, in **run show MAC address table**, the MAC type of the sticky secure MAC is displayed as static.

For example,

```
admin@XorPlus# run show port-security address
Secure Mac Address Table
-----------------------------------------------------
Vlan MAC Address Type Interface
---- ----------------- ------- ----------
1 00:00:11:11:11:11 sticky ge-1/1/1
1 00:00:23:23:23:25 static ge-1/1/1
-----------------------------------------------------
MAC age time :300s

admin@Xorplus# run show mac-address table
Total entries in switching table:   2
Static entries in switching table:  2
Dynamic entries in switching table: 0

VLAN   MAC address    Type      Age    Interfaces      User
----      -----------------    ---------    ----    ----------------   ----------
1        00:00:11:11:11:11 static      300    ge-1/1/1       xorp
1        00:00:23:23:23:25 static      300    ge-1/1/1       xorp
```

Configuring the Maximum Number of Secure MACs

The MAC limit number is used to limit the number of secure MACs on the interface, including the number of dynamic secure MAC and manually configured secure static MAC. If sticky is enabled, MAC limit includes sticky secure MAC and secure static MAC.

A secure interface can learn only one secure MAC address by default. Set the maximum number of secure MAC addresses according to the actual networking requirement.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security mac-limit 5
admin@XorPlus# commit
Commit OK.
Save done.
```

```
admin@XorPlus# run show port-security address
Secure Mac Address Table
-----------------------------------------------------
Vlan MAC Address Type Interface
---- ----------------- ------- ----------
1 00:00:11:11:11:11 dynamic ge-1/1/1
1 00:00:11:11:11:12 dynamic ge-1/1/1
1 00:00:11:11:11:13 dynamic ge-1/1/1
1 00:00:11:11:11:14 dynamic ge-1/1/1
1 00:00:11:11:11:15 dynamic ge-1/1/1
-----------------------------------------------------
MAC age time :300s
```

Configuring Port Security Violation Mode on a Port

Violation mode can be configured for the system to take a protective action when the number of learned MAC addresses exceeds the MAC limit on the secure port, as one of the following four:

- **protect**: Discards packets with new source MAC addresses when the number of learned MAC addresses exceeds the limit. This is the default value.
- **restrict**: Discards packets with new source MAC addresses and generates a warning syslog message when the number of learned MAC addresses exceeds the limit.
- **shutdown**: Shuts the interface down, sets the interface status toerror-discard and generates a warning syslog message when the number of learned MAC addresses exceeds the limit. User can recover the port with the **run clear port-security port-error** command.
- **shutdown-temp**: Shuts the interface down temporarily, sets the interface status to error-discard and generates a warning syslog message when the number of learned MAC addresses exceeds the limit. After 20 seconds (default), the interface comes up. The **set interface ethernet-switching-options port-error-discard timeout** command configures the port recovery interval when the port security violation mode is configured to **shutdown-temp**.

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/33 port-security violation ?
Possible completions:
  protect                      Drop packets with unknown source addresses
  restrict                     Drop packets with unknown source addresses and log violation
  shutdown                    Disable interface
  shutdown-temp               Disable interface temporarily (20 seconds by default)

admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security violation restrict
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring Port Security Auto-recovery Time

When the port security violation mode is configured to shutdown-temp, user can configure the recovery interval with the command below.

```
admin@XorPlus# set interface ethernet-switching-options port-error-discard timeout 30
admin@XorPlus# commit
Commit OK.
Save done.
```

Recovering the Port in Error-discard

When the port security violation mode is configured to **shutdown**, the port will be set to error-discard state after detecting a violation. User can recover the port with the following command.

```
admin@Xorplus# run show interface gigabit-ethernet ge-1/1/23
Physical interface: ge-1/1/23, Enabled, error-discard True(Port Security), Physical link is Down
Interface index: 23, Mac Learning Enabled
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1518, Speed: Auto, Duplex: Full
Source filtering: Disabled, Flow control: Disabled
Auto-negotiation: Enabled, Advertised speed modes: 10M,100M,1G
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress:unlimited, egress:unlimited
Interface burst limit ingress:unlimited, egress:unlimited
Precision Time Protocol mode:none
Current address: 20:04:0f:01:63:4a, Hardware address: 20:04:0f:01:63:4a
Traffic statistics:
  5 sec input rate 0 bits/sec, 0 packets/sec
  5 sec output rate 0 bits/sec, 0 packets/sec
```

```
  Input Packets.........................42
  Output Packets........................31
  Input Octets..........................4781
  Output Octets.........................4545

admin@XorPlus# run clear port-security port-error interface gigabit-ethernet ge-1/1/33
Clear done.
```

Configuring Port Security Block Mode

Port security can be configured to take one of five block actions:

- **all**: Discards all the packets in egress direction of the port.
- **broadcast**: Discards only the broadcast packets in egress direction of the port.
- **multicast**: Discards only the multicast packets in egress direction of the port.
- **uni-multi-cast**: Discards both the unknown unicast packets and multicast packets in egress direction of the port.
- **unicast**: Discards only the unknown unicast packets in egress direction of the port.

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/33 port-security block ?
Possible completions:
  all                           Block broadcast and unknown addresses
  broadcast                     Block broadcast address
  multicast                     Block unknown multicast addresses
  uni-multi-cast                Block unknown uni/multi cast addresses
  unicast                       Block unknown unicast addresses

admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 port-security block broadcast
admin@XorPlus# commit
Commit OK.
Save done.
```

Displaying Port Security Settings

To display port security settings, enter this command:

```
admin@Xorplus# run show port-security brief
Secure Port    MaxMacLimit    CurrentAddr    ViolationCount    Action
-------------------------------------------------------------------------------------------------------------------
ge-1/1/22      2              0              0                 restrict
ge-1/1/23      1              0              0                 shutdown-temp
ge-1/1/34      1              0              0                 protect

admin@XorPlus# run show port-security address
Secure Mac Address Table
-----------------------------------------------------
Vlan MAC Address Type Interface
---- ----------------- ------- ----------
1 00:00:11:11:11:11 dynamic ge-1/1/1
1 00:00:23:23:23:26 static ge-1/1/1
1 00:00:23:23:23:27 static ge-1/1/1
-----------------------------------------------------
MAC age time :100s

admin@Xorplus# run show port-security interface
Interface ge-1/1/22
---------------------------------------
Port Security               : enabled
Violation action            : restrict
Block type                  : N/A
Sticky                      : true
Maximum MAC limit           : 2
Total MAC addresses         : 0
Configured MAC addresses    : 0
Sticky MAC addresses        : 0
Security violation count    : 0

Interface ge-1/1/23
---------------------------------------
Port Security               : enabled
```

```
Violation action            : shutdown-temp
Block type                  : N/A
Sticky                      : true
Maximum MAC limit           : 1
Total MAC addresses         : 0
Configured MAC addresses    : 0
Sticky MAC addresses        : 0
Security violation count    : 0
```

Disabling Port Security

To disable port security, enter this command:

```
admin@XorPlus# delete interface gigabit-ethernet ge-1/1/1 port-security
Deleting:
port-security {
mac-limit: 5
violation: "restrict"
mac-address 00:00:23:23:23:23 {
vlan 1 {
}
}
mac-address 00:00:23:23:23:24 {
vlan 1 {
}
}
mac-address 00:00:23:23:23:25 {
vlan 1 {
}
}
mac-address 00:00:23:23:23:26 {
vlan 1 {
}
}
mac-address 00:00:23:23:23:27 {
vlan 1 {
}
}
sticky: true
block: "broadcast"
}
OK
admin@XorPlus# commit
Commit OK.
Save done.
```

CDR Function Configuration

Clock and Data Recovery (CDR) is a process that is dependent upon a clock signal synchronous with the data flow. When a data flow arrives at the receiver, it is sent without additional clocking information, the receiver generates a clock from an approximate frequency reference, and then phase-aligns the clock to the transitions in the data flow with a phase-locked loop (PLL). Data distortion, noise, and jitter on the incoming data can be reduced if the CDR technology is used for data recovery from the transmission channel.

> **NOTEs:**
>
> - CDR function can only be configured on the 800G, 400G, 200G, 100G or 40G optical module interface and the split interfaces broke out from them.
> - The CDR configurations of split interfaces which broke out from the 800G, 400G, 200G, 100G or 40G optical module interface should be the same.

Procedure

- Use the following command to disable or enable the CDR function.

  set interface gigabit-ethernet <*interface-name*> **cdr** [**true | false**]

  The default setting is **true**. The command takes effect immediately after committing.

Configuration Example

- Enable the CDR function on interface te-1/1/49.

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/49 cdr true
admin@Xorplus# commit
```

- Disable the CDR function on interface te-1/1/49.

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/49 cdr false
admin@Xorplus# commit
```

Time Domain Reflectometry (TDR)

- Introduction
- Configuration Notes
- Configuring TDR Function
  - Procedure
  - Configuration Example

Introduction

Time Domain Reflectometry (TDR) technology is used to detect faults in metallic cables that are connected to the Ethernet electrical interface of a switch. When a pulse signal is transmitted through a cable, part of the energy is reflected back if it encounters a cable end or a fault point. The TDR algorithm measures the time that a pulse travelling through the cable, reaching the fault point, and returning, and then converts the measured time into a distance.

Assume the distance between the interface and the fault point is **Distance**, the time interval from the pulse signal being sent to when it is received is **T**, and the transmission rate of the pulse signal in the cable is **V**. Then the formula for calculating the distance from the fault point to the switch interface is as follows:

Distance = (V x T) / 2

The TDR test command detects the cable connected to the Ethernet electrical interface and display the detection result:

- When the cable is not faulty, the Pair length displayed refers to the total length of the cable.
- When the cable is faulty, the Pair length displayed is the length from the interface to the fault point in the cable.

Configuration Notes

When employing TDR test on a switch interface, pay attention to the following points:

- TDR test is only used on the Ethernet electrical interface but not suitable for the Optical interface.
- As there is a certain error (refers to the Pair length column in the test results) in the TDR test, so the results are for reference only.
- The recommended cable length for TDR test is less than 100m.
- The interface on which the TDR test is running flaps for a short period of time, this may cause service interruption for a short time.
- Make sure that the interface is enabled when running TDR test.
- The time consumed for TDR test is different on different platforms, from 2 to 8 seconds.
- The combo interface of the switch does not support the TDR function.

Configuring TDR Function

Procedure

- Run the following command to start the TDR cable test and check the test result from the displayed information.

  run show interface diagnostics tdr *<interface-name>*

  After the command is issued, the test result will be displayed. The time consumed for TDR test is different on different platforms, from 2 to 8 seconds.

Configuration Example

- Run the following command to start the TDR cable test. The following example shows the cable length (Pair length) is approximately 31 meters long with a possible error of +/- 10 meters.. All four pairs are working fine (Pair status).

```
admin@Xorplus# run show interface diagnostics tdr ge-1/1/1
Interface  Local pair Pair length(meter) Remote pair Pair status
---------- ---------- ------------------ ----------- -----------
ge-1/1/1   Pair A     31   +/- 10        Pair A      OK
           Pair B     31   +/- 10        Pair B      OK
           Pair C     31   +/- 10        Pair C      OK
           Pair D     30   +/- 10        Pair D      OK
```

Table 1. Description of the run show interface diagnostics tdr output

Item	Description
Interface	Indicates the interface name of the switch.
Local pair	Local four pairs.

Item	Description
Pair length(meter)	Displays the length and error of the cable pair in meters. • When the pair is not faulty, the Pair length in the displayed message refers to the total length of the pair. • When the pair is faulty, the Pair length in the displayed message is the length from the interface to the fault point in the cable.
Remote pair	Remote four pairs.
Pair status	The pair status could be "**OK**", "**OPEN**", "**SHORT**", "**OPENSHORT**", "**CROSSTALK**" or "**N/A**". • **OK**: indicates the link is up, the cable are working fine. • **OPEN**: indicates an open circuit, meaning a broken wire or maybe cable unplugged. • **SHORT**: indicates there is a short circuit on the cable. • **N/A**: indicates the port does not support TDR test.

Configuring Port Mapping On S4148 Series Switch

This document is only available for S4148 series switch.

- Procedure
- Configuration Example
- Verify the configuration

The six interfaces of QSFP+ and QSFP28 on the switch, with port numbers from 25 to 30, form an interface group. You can configure the port mapping mode of this interface group as required, the value could be **6 x 40G** or **4 x 100G**.

- **6 x 40G**: This is the default port mapping mode. In this mode, all the six interfaces work at 40G mode. The interface names are xe-1/1/1, xe-1/1/2, xe-1/1/3, xe-1/1/4, xe-1/1/5 and xe-1/1/6.
- **4 x 100G**: In this port mapping mode, the four QSFP28 interfaces numbering 25, 26, 29 and 30 work at 100G mode and the other two QSFP+ interfaces numbering 27 and 28 are unavailable. In this mode, the interface names of the four QSFP28 interfaces are xe-1/1/1, xe-1/1/2, xe-1/1/3 and xe-1/1/4.

Procedure

- From the Linux shell prompt, run the following command.

```
admin@XorPlus:~$ sudo picos_boot port-layout
Configure the front panel QSFP interfaces port map options:
    [1]  6x40G_QSFP    * default
    [2]  4x100G_QSFP
Enter your choice(1,2):
```

Type the option number at the "**Enter your choice(1,2):**" prompt and press Enter to select the port mapping mode.

NOTE:

- Run this command in Linux shell.
- To run this command, you need root privileges.
- The default setting is 6x40G_QSFP.
- After changing the port mapping mode, you need to restart PICOS to make the setting take effect.
- Manually remove the user configuration files **/pica/config/pica_startup.boot** and **/pica/config/pica.conf** after changing port mapping mode and before restarting PICOS. Be cautious that all the user configurations will be lost after these operations. We suggest you backup the configuration file before proceeding with these operations.
- Hardware limitation – if power cycle the switch, wait for 10 - 30 seconds before power on.

Configuration Example

The example below shows the steps for configuring the port mapping mode as 4 x 100G.

Step1 From the Linux shell prompt, run **picos_boot port-layout** command to configure the port mapping mode to 4x100G.

```
admin@XorPlus:~$ sudo picos_boot port-layout
Configure the front panel QSFP interfaces port map options:
    [1]  6x40G_QSFP    * default
    [2]  4x100G_QSFP
Enter your choice(1,2):
```

Step2 Type "**2**" and press Enter to set the port mapping mode to 4x100G_QSFP. By default, the port mapping mode is set to 6x40G_QSFP.

Step3 Manually remove the user configuration files.

After changing the port mapping mode and before restarting PICOS, you need to manually remove the user configuration files **/pica/config/pica_startup.boot** and **/pica/config/pica.conf**.

```
admin@XorPlus:~$ sudo rm /pica/config/pica_startup.boot
admin@XorPlus:~$ sudo rm /pica/config/pica.conf
```

Step4 After changing the port mapping mode, you need to restart PICOS to make the setting take effect.

```
admin@XorPlus:~$ exit
admin@XorPlus> request system reboot
```

Verify the configuration

- After the system boots, run **run show interface brief** command to view the interface information.

In 4x100G_QSFP mode, we can see that the four QSFP28 interfaces numbering 25, 26, 29 and 30 are working at 100G, and the other two QSFP+ interfaces numbering 27 and 28 are unavailable. The interface names of the four QSFP28 interfaces are xe-1/1/1, xe-1/1/2, xe-1/1/3 and xe-1/1/4.

```
admin@XorPlus# run show interface brief
Interface     Management  Status  Flow Control  Duplex  Speed    Description
----------    ----------  ------  ------------  ------  -------  ------------------------------
xe-1/1/1(25)   Enabled     Up      Disabled      Full    Auto
xe-1/1/2(26)   Enabled     Down    Disabled      Full    Auto
xe-1/1/3(29)   Enabled     Down    Disabled      Full    Auto
xe-1/1/4(30)   Enabled     Down    Disabled      Full    Auto
```

10G-Base-KR Interface Configuration

NOTEs:

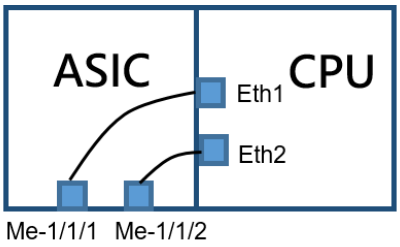
- Only AS7726-32X and AS7326-56X support to disable the 10G-Base-KR ports. By default, they are disabled on AS7726-32X and AS7326-56X.
- On other platforms, by default, the two 10G-Base-KR ports are two 10G-KR management ports linked to CPU.
- If you change the mapping mode of a 10G Base KR port, the port name will also change. Therefore, before changing the mapping mode of the 10G Base KR port, you need to manually delete or modify the configuration of the unavailable interfaces (such as me-1/1/1, me-1/1/2, te-1/1/1, or te-1/1/2) to ensure that the configuration file can be loaded properly upon system restart.
- There is a limitation when enabled the 10G-Base-KR ports as either front panel ports or management ports, namely:
  - On AS7726-32X and N8550-32C, port xe-1/1/32 is not allowed to be split into four Gigabit Ethernet ports.
  - On AS7326-56X and N8550-48B8C, port xe-1/1/8 is not allowed to be split into four Gigabit Ethernet ports.
- The interface rate of the two Me ports can only support auto-negotiation mode.

Introduction

AS7726-32X, AS7326-56X, N8550-48B8C and N8550-32C have two 10G-Base-KR ports (10G-KR) on the front panel to support additional high-speed link between CPU and ASIC (switch chip). PICOS supports to configure the two 10G-Base-KR ports as two 10G SFP+ front panel data ports or they can be configured to provide additional high speed links between the switch CPU and ASIC.

When configured as front panel data ports, they can be used as normal SFP+ port. As a data port, the interface name becomes *Te-1/1/m*. As shown in **Figure 1**, when configured as two 10G-KR ports, the ports are linked to two management ports eth1 and eth2 on the CPU with 10G bandwidth, and the port name becomes *Me-1/1/n* (Management Ethernet port) under PICOS CLI. This alllows the management traffic and data traffic through the *Me-1/1/n* ports can be processed by eth1 and eth2 ports on the CPU.

Figure 1. 10G-KR ports link between CPU and ASIC



Supported Platforms

Currently only AS7726-32X, AS7326-56X, N8550-48B8C and N8550-32C switches have the 10G-Base-KR ports which can be configured as two 10G SFP+ data ports on the front panel or as two 10G-KR management ports linked to CPU. By default, 10G-Base-KR ports are disabled.

Configuration

This section describes how to configure the two 10G-Base-KR ports as front panel ports or management ports linked to CPU.

Configuring as the Management Port

- From the Linux shell prompt, run **sudo picos_boot management-port-mapping** command to configure the 10G-Base-KR ports as two 10G-KR management ports linked to CPU. The option ***[3] No me Port(s)*** indicates that the 10G-Base-KR ports are disabled. Only AS7726-32X and AS7326-56X support to disable the 10G-Base-KR ports.

```
admin@PICOS:~$ sudo picos_boot management-port-mapping
    [1]  To Host CPU
    [2]  To Front Panel
    [3]  No me Port(s)      * default
Enter your choice(1,2,3):1

 To Host CPU is selected.
Please restart the PICOS service
```

- Restart PICOS to make the configuration take effect.

```
admin@Xorplus:~$ exit
admin@Xorplus> request system reboot
```

- We can use **run show interface brief** to check the interface configuration information.

Take AS7726-32X as an example, we can see that the port name of the last two 10G-Base-KR ports are me-1/1/1 and me-1/1/2. They are two 10G-KR management ports linked to CPU.

```
admin@Xorplus# run show interface brief
Interface   Management  Status  Flow Control  Duplex  Speed    Description
----------  ----------  ------  ------------  ------  -------  ------------------------------
xe-1/1/1    Enabled     Down    Disabled      Full    Auto
xe-1/1/2    Enabled     Down    Disabled      Full    Auto
xe-1/1/3    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/4    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/5    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/6    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/7    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/8    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/9    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/10   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/11   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/12   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/13   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/14   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/15   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/16   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/17   Enabled     Down    Disabled      Full    Auto
xe-1/1/18   Enabled     Down    Disabled      Full    Auto
xe-1/1/19   Enabled     Down    Disabled      Full    Auto
xe-1/1/20   Enabled     Down    Disabled      Full    Auto
xe-1/1/21   Enabled     Down    Disabled      Full    Auto
xe-1/1/22   Enabled     Down    Disabled      Full    Auto
xe-1/1/23   Enabled     Down    Disabled      Full    Auto
xe-1/1/24   Enabled     Down    Disabled      Full    Auto
xe-1/1/25   Enabled     Down    Disabled      Full    Auto
xe-1/1/26   Enabled     Down    Disabled      Full    Auto
xe-1/1/27   Enabled     Down    Disabled      Full    Auto
xe-1/1/28   Enabled     Down    Disabled      Full    Auto
xe-1/1/29   Enabled     Down    Disabled      Full    Auto
xe-1/1/30   Enabled     Down    Disabled      Full    Auto
xe-1/1/31   Enabled     Down    Disabled      Full    Auto
xe-1/1/32   Enabled     Down    Disabled      Full    Auto
me-1/1/1(33)  Enabled     Up      Disabled      Full    Auto
me-1/1/2(34) Enabled     Up      Disabled      Full    Auto
```

Under Linux shell, you can see the two ports eth1 and eth2 in addition to the management port eth0 as the **ifconfig -a** command shows below. Under PICOS CLI, the Me ports are bound to the two management ports eth1 and eth2 on CPU. Applications of Linux including PICOS can access (read/write) eth1 and eth2. For example, port configurations such as trunk VLANs can be applied to Me ports.

```
root@Xorplus:/home/admin# ifconfig -a
dummy0    Link encap:Ethernet  HWaddr 72:c9:69:6f:35:2d
          BROADCAST NOARP  MTU:1500  Metric:1

          TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
```

Configuring as Front Panel Ports

- From the Linux shell prompt, run **sudo picos_boot management-port-mapping** command to configure the 10G-Base-KR ports as 10G SFP+ data ports on the front panel.

```
admin@PICOS:~$ sudo picos_boot management-port-mapping
    [1]  To Host CPU        * default
    [2]  To Front Panel
    [3]  No me Port(s)
Enter your choice(1,2,3):2

To Front Panel is selected.
Please restart the PICOS service
```

- Restart PICOS to make the configuration take effect.

```
admin@Xorplus:~$ exit
admin@Xorplus> request system reboot
```

- We can use **run show interface brief** to check the interface configuration information.

Take AS7726-32X as an example, we can see the last two 10G-Base-KR ports are configured as two 10G SFP+ ports and the port names are te-1/1/1 and te-1/1/2. When configured as the front panel ports, the 10G-Base-KR ports can be used as normal 10G SFP+ ports.

```
admin@Xorplus# run show interface brief
Interface   Management  Status  Flow Control  Duplex  Speed    Description
----------  ----------  ------  ------------  ------  -------  ------------------------------
xe-1/1/1    Enabled     Down    Disabled      Full    Auto
xe-1/1/2    Enabled     Down    Disabled      Full    Auto
xe-1/1/3    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/4    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/5    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/6    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/7    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/8    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/9    Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/10   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/11   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/12   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/13   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/14   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/15   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/16   Enabled     Up      Disabled      Full    40Gb/s
xe-1/1/17   Enabled     Down    Disabled      Full    Auto
xe-1/1/18   Enabled     Down    Disabled      Full    Auto
xe-1/1/19   Enabled     Down    Disabled      Full    Auto
xe-1/1/20   Enabled     Down    Disabled      Full    Auto
xe-1/1/21   Enabled     Down    Disabled      Full    Auto
xe-1/1/22   Enabled     Down    Disabled      Full    Auto
xe-1/1/23   Enabled     Down    Disabled      Full    Auto
xe-1/1/24   Enabled     Down    Disabled      Full    Auto
xe-1/1/25   Enabled     Down    Disabled      Full    Auto
xe-1/1/26   Enabled     Down    Disabled      Full    Auto
xe-1/1/27   Enabled     Down    Disabled      Full    Auto
xe-1/1/28   Enabled     Down    Disabled      Full    Auto
xe-1/1/29   Enabled     Down    Disabled      Full    Auto
xe-1/1/30   Enabled     Down    Disabled      Full    Auto
xe-1/1/31   Enabled     Down    Disabled      Full    Auto
xe-1/1/32   Enabled     Down    Disabled      Full    Auto
te-1/1/1(33)    Enabled     Up      Disabled      Full    10Gb/s
te-1/1/2(34)    Enabled     Up      Disabled      Full    10Gb/s
```

Forwarding Error Correction (FEC)

Introduction

Forwarding Error Correction (FEC) is a technique used for controlling errors in data transmission over unreliable or noisy communication channels. The sender sends the data together with a certain redundant error correction code. When the data is received at the receiver's end, it is checked according to the error correction code. If an error is found, the receiver recognizes it and corrects the error without data retransmission.

The FEC function can be applied to 100G, 40G and 25G ports of the switch and works only when all the three following conditions are matched:

- FEC function is enabled on both ends of the link.
- Optical modules are plugged in.
- Interface rate is auto or at the default value, i.g. 100G optical port works at 100Gb/s.

PICOS offers FEC algorithm RS-FEC (CL91) on 100G port and FEC BASE-R (CL74) on 40G port.

For 25G port, PICOS offers two different FEC algorithms on different switch platforms:

Trident 3, Maverick2, Helix5 and Tomahawk 2 platform switches support RS-FEC (CL108) mode, Tomahawk+/Tomahawk platform switches support BASE-R (CL74) mode.

> **NOTE：**
>
> - AS5812_54T and AS5812_54X don't support FEC.
> - The port can link up only when the FEC configurations and the FEC algorithm mode on both ends of the link are the same.
> - For 200G, 400G and 800G ports, the FEC function is enabled by default, and cannot be disabled.

Configuring FEC Function

Procedure

- Use the following command to enable or disable the FEC function on the 100G, 40G or 25G port of the switch.

  set interface gigabit-ethernet <*interface-name*> **fec** <**true | false**>

By default, FEC function is disabled on the 100G, 40G and 25G port of the switch.

Configuration Example

- Disable FEC function on the switch port xe-1/1/1.

```
admin@Xorplus# set interface gigabit-ethernet xe-1/1/1 fec false
admin@Xorplus# commit
```

- Enable FEC function on the switch port xe-1/1/2.

```
admin@Xorplus# set interface gigabit-ethernet xe-1/1/2 fec true
admin@Xorplus# commit
```

Verify the Configuration

- Use **run show interface gigabit-ethernet** *<interface-name>* command to view the interface status information of xe-1/1/2. Check the "**FEC Enable:** " field in the command output to find the FEC configuration.

```
admin@XorPlus# run show interface gigabit-ethernet xe-1/1/2
Physical interface: xe-1/1/2, Enabled, error-discard False, Physical link is Down
Interface index: 2, QSFP28 type: DAC, Mac Learning Enabled

```

Configuring the Loopback Interface

The loopback interface is always Up to ensure network reliability.

The loopback interface has the following features:

- The loopback interface is always Up and has the loopback feature.
- The loopback interface can be configured with the mask of all 1s.

Based on the preceding features, the loopback interface has the following applications.

- The IP address of a loopback interface is specified as the source address of packets to improve network reliability.
- When no Router ID is configured for dynamic routing protocols, the maximum IP address of the loopback interface is configured as the router ID automatically.

The following commands can be used to configure a loopback interface：

set l3-interface loopback {**lo |** <*vrf-name*>} **address** <*ipv4-address*> **prefix-length 32**

set l3-interface loopback {**lo |** <*vrf-name*>} **address** <*ipv6-address*> **prefix-length 128**

The following command creates a IPv4 loopback interface in the default VRF.

```
admin@Xorplus# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
admin@Xorplus# commit
```

The following commands can be used to disable a loopback interface.

```
admin@Xorplus# set l3-interface loopback lo2 disable true
admin@Xorplus# commit
```

The following commands can be used to bind the loopback interface to a VRF. Users can configure multiple loopback interfaces per VRF.

```
admin@Xorplus# set l3-interface loopback lo2 vrf vrf2
admin@Xorplus# commit
```

Layer 3 VLAN Interface Configuration

Configuring a Layer 3 VLAN Interface

The Layer 3 interface is a VLAN interface. Use the following configuration sequence:

1. Create a VLAN using the **set vlans vlan-id** command.
2. Associate an L3 interface with the VLAN using the **set vlans vlan-id l3-interface** command.
3. Configure the IP address and prefix length for the virtual interface using the **set l3-interface vlan-interface address prefix-length** command.

- When all the interfaces in a VLAN are link-down, the VLAN interface will be link-down. The VLAN interface will be link-up only when at least one of the member interfaces is link-up.
- Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 192.168.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 192.168.2.1 prefix-length 24
admin@XorPlus# commit
Commit OK.

admin@XorPlus#
```

Configuring the MTU

- When the MTU value is less than 1280 bytes, it will affect the normal functioning of IPv6. Therefore, set the MTU value of the VLAN interface to be greater than or equal to 1280 bytes for IPv6 to function normally.
- When modifying the MTU from a value less than 1280 bytes to a value greater than or equal to 1280 bytes, you need to restart the switch to resume the normal functioning of IPv6.

```
admin@Xorplus# set l3-interface vlan-interface vlan-2 mtu 2000
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring the Rate Limiting

L3 VLAN interface rate limit is applied to packets delivered out from the CPU, controlling shock of large flow on CPU, releasing the burden on CPU.

```
admin@Xorplus# set l3-interface vlan-interface vlan200 rate-limit 1024
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring 31-bit Prefixes IPv4 Address

PicOS supports configuring 31-bit prefixes on IPv4 point-to-point links. The point-to-point link has only two endpoints and broadcast support is not required. Two addresses in the subnet with 31-bit address prefix (the address with host ID all 0 and the address with host ID all 1) are allocated to the point-to-point hosts. For more details, refer to RFC 3021.

The following example commands configure the 31-bit prefixes IPv4 addresses 192.168.100.4 and 192.168.100.5 respectively on two switches for the point-to-point connected L3 interfaces.

```
#On Switch 1
admin@Switch1# set l3-interface vlan-interface vlan10 address 192.168.100.4 prefix-length 31
admin@Switch1# commit

#On Switch 2
admin@Switch2# set l3-interface vlan-interface vlan10 address 192.168.100.5 prefix-length 31
admin@Switch2# commit
```

Configuring Routed Interface

- Introduction of Routed Interface
- Configuration Notes of Routed Interface
- Configuring Routed Interface and Sub-interface
- Example for Configuring Routed Interface

Introduction of Routed Interface

- Routed Interface
- Reserved VLAN
- Sub-interface

Layer 3 interfaces, including VLAN interface, loopback interface, routed interface and sub- interface, share the same hardware resources. When configuring IP address, it is required that the IP address of different layer 3 interfaces in the same VRF cannot be in the same subnet. However, overlapped layer 3 interface addresses in different VRFs is supported.

> **NOTE:**
> To avoid conflict with the preserved interface names, the routed interface name and sub-interface name must start with the string "**rif-**". Otherwise, commit will fail with the error message "*The name of interface must start with "rif-"*.

Routed Interface

All Ethernet ports are layer 2 interfaces by default. When you need to use an Ethernet port for layer 3 communication, you can enable the Ethernet port as a routed interface. The routed interface is a layer 3 interface which can be assigned an IP address and can be configured with a routing protocol for connecting to other layer 3 routing devices.

A routed interface can be enabled on a physical port or a LAG interface. You can use the following commands to configure the routed interface:

set vlans reserved-vlan *<reserved-vlan>*

set interface gigabit-ethernet *<interface-name>* **routed-interface enable** <**true | false**>

set interface gigabit-ethernet *<interface-name>* **routed-interface name** *<string>*

set interface aggregate-ethernet *<lag-name>* **routed-interface enable <true | false>**

set interface aggregate-ethernet *<lag-name>* **routed-interface name** *<string>*

When enabling an Ethernet port/LAG interface as a layer 3 routed interface, a name for the routed interface should be configured by using the command **set interface gigabit-ethernet** *<interface-name>* **routed-interface name** *<string>*. This name will be referred to as the “interface name” in other CLI commands.

Reserved VLANs need to be configured on the device before configuring the routed interface.

Routed interface is mutually exclusive with the following layer 2 features, you have to delete all of the following configurations on the interface before enabling it as a routed interface, otherwise the routed interface commands will fail to commit.

set interface gigabit-ethernet *<interface-name>* **backup-port** *XX*
set interface aggregate-ethernet *<lag-name>* **backup-port** *XX*
set interface gigabit-ethernet *<interface-name>* **crossflow** *XX*
set interface aggregate-ethernet *<lag-name>* **crossflow** *XX*
set interface gigabit-ethernet *<interface-name>* **family** *XX*
set interface aggregate-ethernet *<lag-name>* **family** *XX*
set interface gigabit-ethernet *<interface-name>* **loopback true**
set interface gigabit-ethernet *<interface-name>* **port-security** *XX*
set interface aggregate-ethernet *<lag-name>* **port-security** *XX*
set interface gigabit-ethernet *<interface-name>* **static-ethernet-switching mac-address** *XX*
set interface aggregate-ethernet *<lag-name>* **static-ethernet-switching mac-address** *XX*
set interface gigabit-ethernet *<interface-name>* **voice-vlan** *XX*
set interface aggregate-ethernet *<lag-name>* **voice-vlan** *XX*
set protocols dhcp snooping trust-port *<trust-port>*
set protocols igmp-snooping vlan-id *<vlan-id>* **mrouter interface** *<interface-name>*
set protocols igmp-snooping vlan-id *<vlan-id>* **static group** *<group-address>* **interface** *<interface-name>*
set protocols dot1x interface *<interface-name>*
set interface gigabit-ethernet *<interface-name>* **breakout true**

Besides the layer 2 features listed above, routed interface does not support Spanning Tree Protocol (STP) and MAC learning. However, the Layer 2 feature of LLDP is supported on an Ethernet port enabled as routed interface.

As a layer 3 interface, routed interface supports layer 3 routing protocols, such as BGP/OSPF/static route/IGMP/PIM/BFD, and features such as VRRP/VRF/ARP/ IPv6 Neighbor Discovery/VXLAN/DHCP relay.

After a routed interface is enabled, you have to configure the following node to bring the routed interface up. Only after this, the corresponding sub-interfaces can be used normally.

set l3-interface routed-interface *<interface-name>*

Layer 3 sub-interfaces can be configured on the routed interface, so as to extend more layer 3 functions on the same physical port or LAG interface and conduct more flexible network topology design. Here, we call the routed interface the parent interface.

Reserved VLAN

The physical port/LAG interface that enabled routed interface is still consuming a special VLAN, although it is not allowed to explicitly configure VLANs for the routed interface by using the following commands:

set interface gigabit-ethernet *<interface-name>* **family ethernet-switching vlan members** *<vlan-id>*

set interface gigabit-ethernet *<interface-name>* **family ethernet-switching native-vlan-id** *<vlan-id>*

set interface aggregate-ethernet *<lag-name>* **family ethernet-switching vlan members** *<vlan-id>*

set interface aggregate-ethernet *<lag-name>* **family ethernet-switching native-vlan-id** *<vlan-id>*

Reserved VLANs need to be configured on the device with the command **set vlans reserved-vlan** *<reserved-vlan>* before configuring routed interface. Whenever a routed interface is configured, the system will automatically assign a VLAN internally to the routed interface from the reserved VLANs in order of smallest to largest.

The system supports up to 128 reserved VLANs.

VLAN 1 cannot be used as a reserved VLAN.

A reserved VLANs are VLANs dedicated to the routed interfaces (sub-interfaces are not included) and cannot be used for other interfaces, or other VLAN functions, such as PVLAN.

Reserved VLAN is mutually exclusive with the following settings, before configuring, please delete all these commands that uses the reserved VLAN, otherwise the reserved VLAN command will fail to commit.

set protocols dhcp snooping vlan *<vlan-id>*
set protocols igmp-snooping vlan-id *<vlan-id>*
set protocols dot1x block-vlan-id *<vlan-id>*
set protocols dot1x server-fail-vlan-id *<vlan-id>*
set vlans vlan-id *<vlan-id>* **private-vlan** *XX*

Note that: If you want to modify the value of the reserved VLANs, all the routed interface configurations need to be removed first.

You can use the commands **run show vlans** and **run show vlans routed-vlan** to check the VLAN information of all routed interfaces. For example,

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/2 routed-interface name rif-te2
admin@Xorplus# set interface gigabit-ethernet te-1/1/2 routed-interface enable true
admin@Xorplus# set interface gigabit-ethernet te-1/1/4 routed-interface name rif-te4
admin@Xorplus# set interface gigabit-ethernet te-1/1/4 routed-interface enable true
admin@Xorplus# set vlans reserved-vlan 80-85
admin@Xorplus# commit

admin@Xorplus# run show vlans

admin@Xorplus# run show vlans routed-vlan
VlanID  Vlan Name           Tag         Interfaces     Routed-interfaces
------  ------------------  --------    ------------   --------------------
80                          untagged    te-1/1/2        rif-te2
81                          untagged    te-1/1/4        rif-te4
```

NOTE:

- When using the command **set interface gigabit-ethernet** *<interface-name>* **disable true** to disable the physical port, it will also bring down the associated routed interface.
- The member port of a LAG port cannot be enabled as a routed interface, correspondingly, the physical port enabled as a routed interface cannot be configured as a LAG member port.
- To perform layer 3 forwarding, don't forget to configure the command **set ip routing enable true** to enable IP routing.

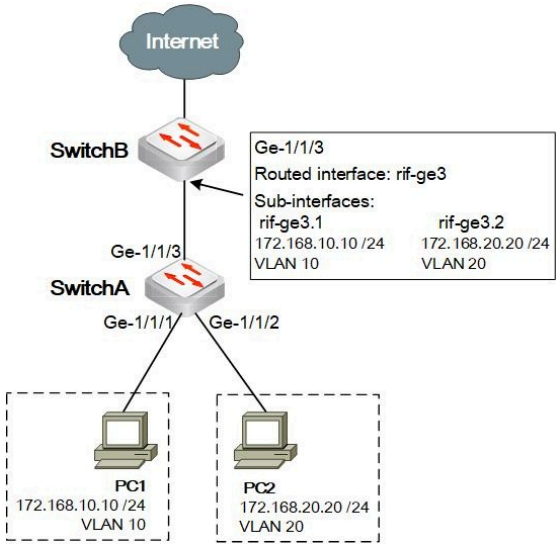
Sub-interface

A layer 3 sub-interface is a virtual interface configured under a physical port or LAG interface, which has been enabled as a routed interface. The routed interface is called the parent interface. Sub-interface is a layer 3 interface, and you can configure IP address for it. This enables routing and communication between multiple VLANs configured under a single physical interface by dividing it into multiple sub-interfaces.

The sub-interface name is a string of up to 15 alphanumeric characters (including three special characters . – and @). The suggested naming convention for the sub-interfaces should be like this: parent name (for example, rif-ge2) followed by a period and then by a number that is unique to that sub-interface, for example, rif-ge2.1, rif-ge2.2 and so on.

As shown in the figure below, when a layer 3 device Switch B connects to a layer 2 network device Switch A through a routed interface. The ports of the Switch A are divided into different VLANs, in order for the layer 3 routed interface on Switch B to correctly identify different VLAN messages, it is necessary to create multiple sub-interfaces on the routed interface to correspond to the VLANs of downstream devices respectively. This ensures that users in different VLANs can communicate normally. We provide a detailed configuration process about this example in section Example for Configuring Routed Interface.

Figure 1. Routed Interface and Sub-interface Application



When creating a sub-interface, VLAN ID needs to be specified at the same time. Different sub-interfaces of the same parent interface cannot be configured to the same VLAN.

Different layer 3 interfaces belong to different subnets, and the sub-interfaces of different parent interfaces can be configured with the same VLAN. But even if they are in the same VLAN, the two sub-interfaces are in different flood domains.

When configuring the routed interface, you have to run the following command to bring up the parent routed interface. Only after this, the corresponding sub-interfaces can be used normally.

set l3-interface routed-interface <*interface-name*>

If the parent interface is down, then all of its sub-interfaces will also be down. When using the command **set interface gigabit-ethernet** <*interface-name*> **disable true** to disable the physical port, it will also bring down the associated routed interface and its sub-interfaces.

When sub-interfaces are used for inter-VLAN routing, the data flow will occupy the bandwidth of the entire physical interface. This can lead to communication bottlenecks when the network is busy. To balance the traffic load on the physical interface, it is recommended that the sub-interfaces be configured on multiple physical interfaces.

Pay attention to the following precautions before configuring the sub-interfaces:

- Enable the Ethernet port as a routed interface before configuring the sub-interfaces.
- Define the VLAN ID by using the command **set vlans vlan-id** <*vlan-id*> before configuring the sub-interface and adding to VLAN.
- The IP address for each sub-interface should be in a different subnet from all the other sub-interfaces under that parent interface. That is, the IP subnets of all the sub-interfaces should be unique under the same parent interface.
- It is not supported to configure MTU on the sub-interfaces. The sub-interfaces use the MTU value configured on the parent interface.
- On greyhound2 switches (including Dell N22xx series switches and N3208PX-ON), the sub-interface does not support user defined VRF and can only be used in the default VRF.
- The sub-interface of LAG port does not support user defined VRF and can only be used in the default VRF.

Configuration Notes of Routed Interface

Pay attention to the following precautions before configuring the routed interfaces:

- To avoid conflict with the preserved interface names, the routed interface name and sub-interface name must start with the string "**rif-**". Otherwise, commit will fail with the error message "*The name of interface must start with "rif-"*.
- Routed interface and sub-interface are supported in VXLAN underlay configuration, but not in VXLAN overlay configuration. In VXLAN underlay configuration, if the outgoing interface of a VXLAN tunnel is a sub-interface, then the VLAN of this sub-interface is not allowed to be assigned to other interfaces.
- If a VLAN has already been configured in other layer 3 functions, such as been assigned to a sub-interface, then it cannot be used for layer 2 functions, for example, it cannot be assigned to other interfaces, or be used in other layer 2 functions, such as PVLAN.

Configuring Routed Interface and Sub-interface

- Configuring Routed Interface
- Configuring Sub-interface
- (Optional) Other Settings for Routed Interface and Sub-interface
- Checking the Configuration

Configuring Routed Interface

Step 1 Configure reserved VLAN for the use of routed interface.

set vlans reserved-vlan <*reserved-vlan*>

Step 2 Enable Ethernet port as a layer 3 routed interface.

set interface gigabit-ethernet <*interface-name*> **routed-interface enable <true | false>**

set interface gigabit-ethernet <*interface-name*> **routed-interface name** <*string*>

Step 3 Run the following command to bring up the parent routed interface. Only after this, the corresponding sub-interfaces can be used normally.

set l3-interface routed-interface <*interface-name*>

Step 4 Enable IP routing to perform layer 3 forwarding.

set ip routing enable true

Step 5 Commit the configuration.

commit

Configuring Sub-interface

Step 1 Configure the VLAN.

set vlans vlan-id <*vlan-id*>

Step 2 Create sub-interface and configure its IP address.

set interface gigabit-ethernet <*interface-name*> **routed-interface sub-interface** <*sub-interface-name*> **vlan-id** <*vlan-id*>

set l3-interface routed-interface <*interface-name*> address <*ip-address*> prefix-length <*prefix-number*>

Step 3 Commit the configuration.

commit

(Optional) Other Settings for Routed Interface and Sub-interface

Step 1 Configure the CPU egress rate limit for the routed interfaces and sub-interfaces.

set l3-interface routed-interface <*interface-name*> **rate-limit** <*rate-limit*>

Step 2 Configure the MTU for the routed interfaces. It is not supported to configure MTU on the sub-interfaces. The sub-interfaces use the MTU value configured on the parent interface.

set l3-interface routed-interface <*interface-name*> **mtu** <*mtu-value*>

Step 3 Bind the routed interface and sub-interface to the VRF.

set l3-interface routed-interface <*interface-name*> **vrf** <*vrf-name*>

Step 4 Commit the configuration.

commit

Checking the Configuration

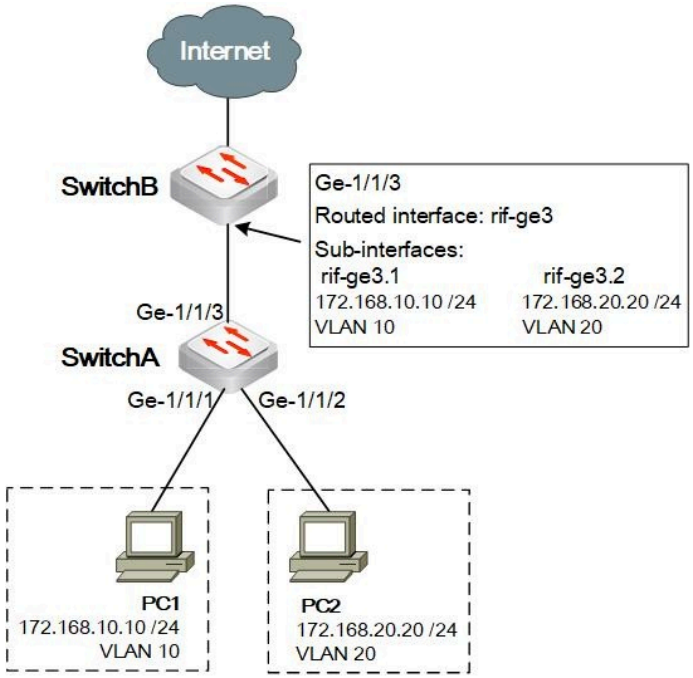
- Run the command **run show vlans routed-vlan** to check the VLAN information of the routed interfaces and sub-interfaces.
- Run the command **run show interface routed-interface brief** to check the brief interface information of the routed interfaces and sub-interfaces.
- Run the command **run show l3-interface routed-interface** <*interface-name*> to check the detailed layer 3 interface information of a specific routed interface or sub-interface.

Example for Configuring Routed Interface

- Networking Requirements
- Procedure
  - Switch A
  - Switch B

Networking Requirements

Figure 1. Routed Interface and Sub-interface Configuration Example



As shown in Figure 1, PC1 and PC2 are local computers which belong to VLAN 10 and VLAN 20 respectively, and they are in different network segments 172.168.10.10/24 and 172.168.20.20/24 respectively. They connect to the layer 3 device Switch B through the layer 2 device Switch A. There is only one free physical port ge-1/1/3 on Switch B. In this scenario, it is required that Switch B can connect to two different network segments through only one physical port.

This can be accomplished by enabling interface ge-1/1/3 as a routed interface, under it configuring two different sub-interfaces to connect to PC1 and PC2 respectively.

Complete the following configurations on the Switch B:

- Enable interface ge-1/1/3 as a routed interface and name its layer 3 interface as rif-ge3.
- Create two layer 3 sub-interfaces, rif-ge3.1 and rif-ge3.2, assign IP addresses 172.168.10.10/24 and 172.168.20.20/24, to serve as gateway addresses for VLAN 10 and VLAN 20 users, respectively.

Procedure

Switch A

As a layer 2 switch, Switch A needs to configure VLANs and add the access ports to the corresponding VLANs.

```
admin@XorPlus# set vlans vlan-id 10
admin@XorPlus# set vlans vlan-id 20
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 10
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 20
admin@XorPlus# commit
```

Switch B

Step 1 Configure two VLANs.

```
admin@XorPlus# set vlans vlan-id 10
```

```
admin@XorPlus# set vlans vlan-id 20
```

Step 2 Configure reserved VLAN for the use of routed interface.

```
admin@XorPlus# set vlans reserved-vlan 80-90
```

Step 3 Enable Ethernet port ge-1/1/3 as a layer 3 routed interface.

> **NOTE:**
> To avoid conflict with the preserved interface names, the routed interface name and sub-interface name must start with the string "**rif-**". Otherwise, commit will fail with the error message "*The name of interface must start with "rif-"*.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 routed-interface enable true
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 routed-interface name rif-ge3
```

Step 4 Run the following command to bring up the parent routed interface. Only after this, the corresponding sub-interfaces can be used normally.

```
admin@XorPlus# set l3-interface routed-interface rif-ge3
```

Step 5 Create the sub-interfaces and specify the IP addresses.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 routed-interface sub-interface rif-ge3.1 vlan-id 10
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 routed-interface sub-interface rif-ge3.2 vlan-id 20
admin@XorPlus# set l3-interface routed-interface rif-ge3.1 address 172.168.10.10 prefix-length 24
admin@XorPlus# set l3-interface routed-interface rif-ge3.2 address 172.168.20.20 prefix-length 24
```

Step 6 Enable IP routing to perform layer 3 forwarding.

```
admin@XorPlus# set ip routing enable true
```

Step 7 Commit the configuration.

```
admin@XorPlus# commit
```

Step 8 Verify the configuration.

- After the above configurations are completed, ping PC1 from PC2 to test the connectivity.
- Run the command **run show vlans routed-vlan** to check the VLAN information of the routed interfaces and sub-interfaces.

```
admin@SwitchB# run show vlans routed-vlan
VlanID  Vlan Name           Tag        Interfaces     Routed-interfaces
------  ------------------  --------   ------------   --------------------
10      default             tagged      ge-1/1/3       rif-ge3.1
20      default             tagged      ge-1/1/3       rif-ge3.2
80                          untagged      ge-1/1/3       rif-ge3
```

- Run the command **run show interface routed-interface brief** to check the brief information of the routed interfaces and sub-interfaces.

```
admin@Xorplus# run show interface routed-interface brief
Interface       RoutedIfName     SubRoutedIfName  VLANID  Management  Status  Flow Control   Duplex  Speed    Descr
--------------  ---------------  ---------------   ------ ----------  ------  ------------   ------  -------  -----
ge-1/1/3        rif-ge3                           80      Enabled     Up      Disabled       Full     Auto
                                 rif-ge3.1         10
                                 rif-ge3.2         20
```

- Run the command **run show l3-interface routed-interface** <*interface-name*> to check the detailed layer 3 information of a specific routed interface or sub-interface.

```
admin@Xorplus# run show l3-interface routed-interface rif-ge3
rif-ge3         Hwaddr 18:5A:58:1F:63:A1, Vlan:80, MTU: 1500, State:UP
            Inet addr: 120:1:1::49/64
                       fe80::1a5a:5820:131f:63a1/64
            Traffic statistics:

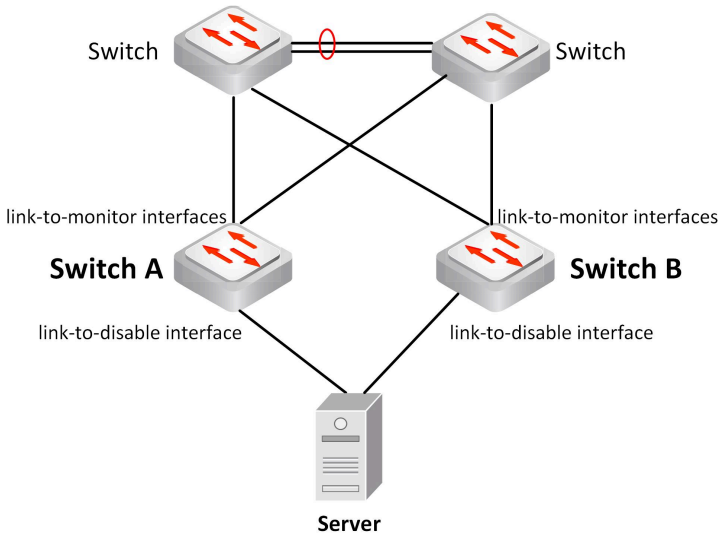
Uplink Failure Detection

- Description
- Configuring Uplink Failure Detection
- Uplink Failure Detection Configuration Example
  - Networking Requirements
  - Procedure
    - Switch A
    - Switch B

Description

Uplink Failure Detection (UFD) provides a mechanism to disable all the associated downlink interfaces when all the uplink interfaces go down, which is very useful in the case of network redundancy for the downlink server going with network adapter teaming.

Figure 1. Uplink Failure Detection



All the network interface cards (NICs) in a network adapter teaming works under stand-by mode with the same IP address. Namely, when the primary link goes down, the server automatically changes to the secondary link. If uplink failure detection is enabled, the switch monitors the uplink interfaces (link-to-monitor interfaces). When all the uplink interfaces go down, the switch will disable all the associated downlink interfaces (link-to-disable interface). When the server detects disabled downlink interfaces on the switch side, it switches over to the secondary link, which helps to quickly detect link failures and reduce network packet loss.

Configuring Uplink Failure Detection

NOTEs:

- Only the physical interfaces or LAG interfaces can be configured as UFD uplink interfaces or downlink interfaces, logical interfaces are not supported.
- In the same UFD group, the same interface cannot be configured as both the UFD uplink interface and the downlink interface.
- The same interface can be configured as the UFD downlink interface only in one UFD group. That is, it is not allowed to configure the same interface as the UFD downlink interface in different UFD groups.

Step 1 Configure the uplink interface to an uplink failure detection group. Repeat this step to add more uplink interfaces to the uplink failure detection group.

set interface ufd <*ufd-group-name*> **link-to-monitor** <*interface-name*>

Step 2 Configure the downlink interface to an uplink failure detection group. Repeat this step to add more downlink interfaces to the uplink failure detection group.

set interface ufd <*ufd-group-name*> **link-to-disable** <*interface-name*>

Step 3 Commit the configurations.

commit

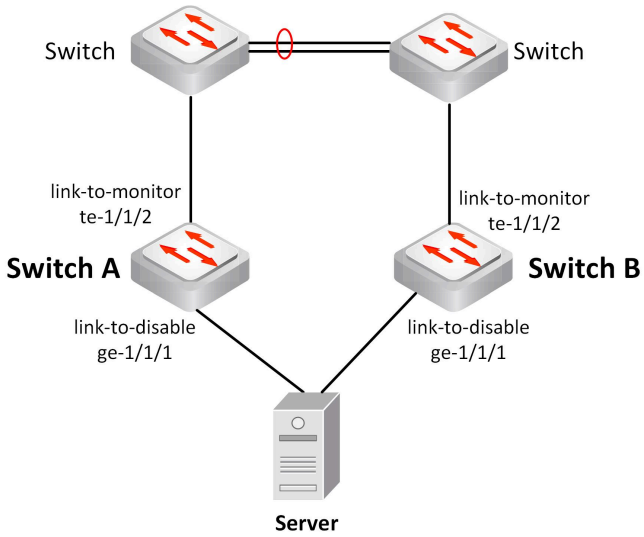
Step 4 View the uplink failure detection configuration information and status.

run show interface ufd

Uplink Failure Detection Configuration Example

Networking Requirements

Figure 2. Uplink Failure Detection Configuration Example



As shown in **Figure 2**, on the Server, all the network interface cards (NICs) in a network adapter teaming works under stand-by mode with the same IP address. Namely, when the primary link goes down, the server automatically changes to the secondary link.

To quickly detect link failures and reduce network packet loss, uplink failure detection can be enabled on Switch A and Switch B separately to monitor the uplink interfaces (link-to-monitor interfaces) on each side. When all the uplink interfaces on one switch side go down, Switch A/Switch B will disable all the associated downlink interfaces (link-to-disable interface). When the server detects disabled downlink interfaces on one switch side, it switches over to the secondary link. For simplicity, there is only one uplink interface and one downlink interface in each UFD group in this configuration example.

This example does not describe how to configure the dual-homed server or the aggregation switches. Please refer to the documentation for each of these devices for more information.

Procedure

Switch A

Step 1 Configure the uplink interface to an uplink failure detection group.

```
admin@SwitchA# set interface ufd ufd1 link-to-monitor te-1/1/2
```

Step 2 Configure the downlink interface to an uplink failure detection group.

```
admin@SwitchA# set interface ufd ufd1 link-to-disable ge-1/1/1
```

Step 3 Commit the configurations.

```
admin@SwitchA# commit
```

Step 4 View the uplink failure detection configuration information and status. Hence the uplink interface and the downlink interface are up, so in the result the status of *Failure Action* is **Inactive**.

```
admin@SwitchA# run show interface ufd
UFD: ufd1
------------------------------------------------------
Uplink        : te-1/1/2
Downlink      : ge-1/1/1
Failure Action: Inactive
```

Switch B

Step 1 Configure the uplink interface to an uplink failure detection group.

```
admin@SwitchB# set interface ufd ufd1 link-to-monitor te-1/1/2
```

Step 2 Configure the downlink interface to an uplink failure detection group.

```
admin@SwitchB# set interface ufd ufd1 link-to-disable ge-1/1/1
```

Step 3 Commit the configurations.

```
admin@SwitchB# commit
```

Step 4 View the uplink failure detection configuration information and status. Hence the uplink interface and the downlink interface are up, so in the result the status of *Failure Action* is **Inactive**.

```
admin@SwitchB# run show interface ufd
UFD: ufd1
------------------------------------------------------
Uplink        : te-1/1/2
Downlink      : ge-1/1/1
Failure Action: Inactive
```

Layer 2 Switching Configuration

This chapter describes the configuration steps of Layer 2 switching, including MAC address learning, LLDP, LACP, 802.1Q VLAN, flow control, mirroring, storm control, and the Spanning Tree Protocol (STP/RSTP/MSTP).

Static MAC entries and Dynamic MAC Address Learning

You can configure a static MAC entry in the FDB and manage dynamic MAC address learning (for example, configuring aging time or deleting the dynamic MAC address entry).

Configuring a Static MAC Entry and Managing the FDB

```
admin@PICOS# set interface gigabit-ethernet ge-1/1/1 static-ethernet-switching mac-address 22:22:22:22:22:22 vlan 1
admin@PICOS# set interface ethernet-switching-options mac-table-aging-time 60
admin@PICOS# commit
Commit OK.
Save done.
admin@PICOS# run show ethernet-switching table
Total entries in switching table: 0
Static entries in switching table: 0
Dynamic entries in switching table: 0

VLAN MAC address Type Age Interfaces User
---- ----------------- --------- ---- ---------------- ----------
admin@PICOS# run clear ethernet-switching table ge-1/1/1
admin@PICOS# run show ethernet-switching table
Total entries in switching table: 0
Static entries in switching table: 0
Dynamic entries in switching table: 0
VLAN MAC address Type Age Interfaces User
---- ----------------- --------- ---- ---------------- ----------

admin@PICOS#
```

Cut-Through Switching Method

By default, the switch forwards the packets in a cut-through switching method. That is, the switch begins forwarding a packet before the entire frame is received, normally as soon as the destination address is processed. This process reduces latency. Error handling is performed by the destination devices. User can configure the switch to the "store-and-forward" method with the commands below.

> P-3290, P-3295, P-3297 and 4610 series switches don't support cut-through mode.

Configuring your Switch to the Store-and-Forward Method

```
admin@XorPlus# set interface cut_through_mode false
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

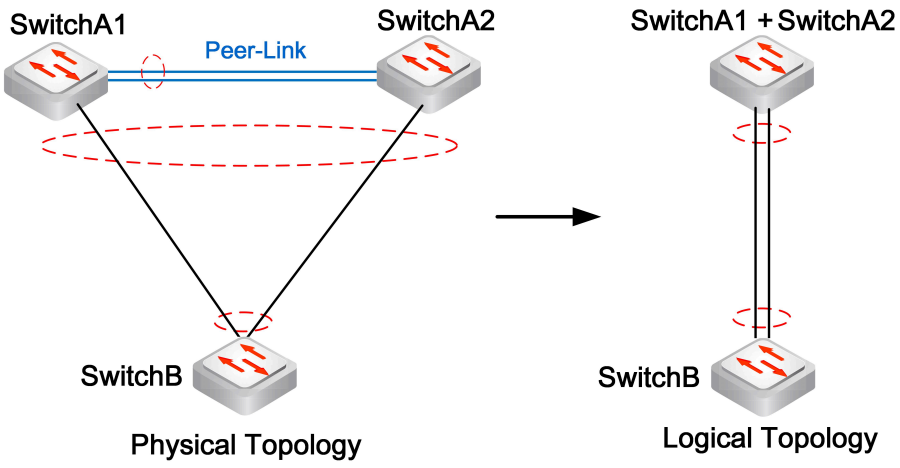
Definition

MLAG (Multi-chassis Link Aggregation Group) as the name suggests, deploys LAG (Link Aggregation Group) technology to different member ports on a pair of devices which appear to be on a single device to the downstream third device in Layer 2. The figure below shows the physical topology and the logical topology of the MLAG network in Layer 2. The two MLAG peer devices, SwitchA1 and SwitchA2, maintain communication by exchanging MLAG control plane messages and MAC address learning of the LAG interface to ensure MAC synchronization using L2 multicast packets. The downstream device could be any endpoint equipment (L2 switch or server) that supports LACP Link Aggregation technology. It won't get a feel that there are two devices linked with it at the other end of the link when dual-homing to the network through the MLAG peer devices.

Figure 1. Physical Topology and Logical Topology of the MLAG Networking



MLAG is mainly applied in scenarios where a downstream switch or host has to or needs to dual-access to the network. In **Figure 1**, before deploying MLAG, suppose SwitchB single-accesses to the network through SwitchA1 when spanning tree is enabled. If SwitchA1 device fails or the link fails, SwitchB fails to communicate with the network. By using MLAG, the downstream switch or host can dual-access to the network through SwitchA1 and SwitchA2 which enables link-level and device-level redundancy and protection.

This provides redundancy by giving the downstream switch or host two uplink paths as well as full bandwidth utilization since the MLAG domain appears to be a single switch to Spanning Tree Protocol (STP). So, there are no blocked ports as the MLAG domain appears to STP as a single switch.

As MLAG has the following advantages, it can be used to build a highly resilient and highly reliable Layer 2 network.

- Increased Bandwidth

MLAG aggregates multiple Ethernet ports across two switches, this increases the uplink bandwidth. The maximum bandwidth of the link aggregation interface can reach the sum of the bandwidths of individual MLAG member ports.

- Higher Reliability

Dual-working mechanism to ensure high reliability. When a link or device fails, traffic can be switched to the other available member links or device to improve the reliability of the MLAG domain.

- Load Balancing

  In an MLAG domain, you can achieve load balancing on each active aggregation interface link.

Basic Concepts

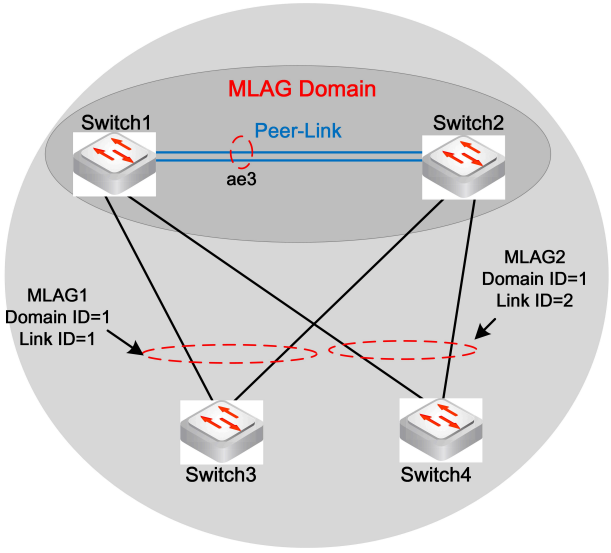
- **MLAG domain and domain ID**

MLAG domain defines the topology range of the MLAG calculations and control. An MLAG domain includes a pair of MLAG peer switches, the MLAG peer-link and the MLAG member ports. The MLAG domain ID is a unique identifier for an MLAG domain, which should be configured identically on each MLAG peer device in the same MLAG domain.

Currently, only one MLAG domain is allowed to be configured on one MLAG device. A pair of MLAG peer devices can be connected to different third-party devices to form different MLAGs. An MLAG domain can hold multiple MLAGs.

Figure 2 shows an MLAG domain with multiple MLAGs, where Switch1, Switch2 and the MLAG member ports connected to Switch3 form an MLAG1; Switch1, Switch2 and the MLAG member ports connected to Switch4 form another MLAG2.

Figure 2. Multiple MLAGs Network



Use the **run show mlag domain** command to view the MLAG domain information:

```
admin@Xorplus# run show mlag domain summary

Domain ID: 1    Domain MAC: 48:6E:73:FF:00:01    Node ID: 0
-------------------------------------------------------------------------------------------
Peer Link  Peer IP          Peer Vlan  Neighbor Status    Config Matched       MAC Synced  # of Links
---------  ---------------  ---------  ---------------    --------------      ----------  ----------
ae23       1.1.1.2          4088        ESTABLISHED         Yes                Yes          2
```

NOTE:

- MLAG domain ID is required to be unique within the Layer 2 network.
- The maximum number of MLAG interfaces/ports supported by the system is subject to the maximum number of LAGs supported by the switch. The maximum number of LAGs supported by each model is described in the command reference **set interface aggregate-ethernet** <*lag_name*>, the link is Collection of Feature Specification of Different Platforms.

- **MLAG domain MAC**

Each MLAG domain has a unique domain ID which should be different between different MLAG domains. Once configured, both MLAG peer devices use the MLAG domain ID to automatically produce a unique MLAG domain MAC address which is defined as **48:6E:73:FF:00:**<***MLAG domain ID in hexadecimal***>. For example, if the MLAG domain ID is 12, then the corresponding MLAG domain MAC address would be 48:6E:73:FF:00:0C.

MLAG domain MAC address is identical on both MLAG peer devices, it is used by LACP as part of system ID and by STP as part of bridge ID to communicate with other L2 devices. Use the command **run show mlag domain** {<*domain-id*>| **summary**} to show the MLAG domain information which includes the MLAG domain MAC.

- **MLAG peer**

MLAG peer devices are a pair of switches that enables the MLAG function, which are defined as MLAG **Node 0** or **Node 1**. Users have to use the CLI command **set protocols mlag domain** <*domain-id*> **node** <**0 | 1**> to specify the Node ID for the MLAG peer devices. If one of the MLAG peer devices is configured as Node 0, the other one should be configured as Node 1. The two nodes are all active, providing a reliable dual-access to the network for the MLAG access device.

The two nodes function equally and are not distinguished as master or slave. In most application scenarios, the two nodes have no difference, except for the following two cases:

1. The single-homed port uses the original port ID on Node 0 peer device, however, an offset **1024** is added to the **Port Index** as a new port ID on Node 1.
2. The MLAG member ports use the original port ID on Node 0 peer device, however, an offset **512** is added to the **Link ID** as a new port ID on Node 1.

We can see the port ID information in the display of LACP/STP related show command and BPDU packets.

- **MLAG peer link**

MLAG peer link is the direct link between MLAG peer devices, used for transmitting part of the data traffic, MLAG state and MLAG control plane messages. Use the **set protocols mlag domain** <*domain-id*> **peer-ip** <*peer-ipv4-address*> **peer-link** <*peer-interface-name*> command to configure the remote peer-link port IP and the local peer-link interface. The interfaces directly connected to the two ends of the peer-link are peer-link ports.

A specified VLAN MUST be assigned to the peer-link interface, MLAG peer VLAN, which is dedicated to transmitting MLAG control plane messages and not transmitting data messages. Peer VLAN is always set to forwarding in order to allow MLAG information negotiation between MLAG peers. The following CLI commands is used to configure MLAG peer VLAN, the recommended value is 4088.

set protocols mlag domain <*domain-id*> **peer-ip** <*peer-ipv4-address*> **peer-vlan** <*vlan-id*>

If peer-link is down for any reason, MLAG control plane messages cannot be exchanged properly, causing the MLAG system to operate abnormally. Especially when peer-link is down, but both the MLAG member ports are up, the split-brain failure scenario occurs. The system cannot be automatically recovered in this scenario.

Therefore, to ensure the reliability of peer-link, note the following points when configuring and deploying peer link:

1. Only one peer link connecting the two peer devices is allowed in an MLAG domain.
2. When configuring the peer link, only one LAG port can be used as peer link.
3. Use a LAG port with at least two **directly connected** physical ports to guarantees reliable communication between the peer devices on the peer link. Use of any intermediate transmission device between the two peer devices on the peer link is not allowed. All of the directly connected physical ports should be added into one LAG port to form the peer-link. We don't support more than one L2 connection between MLAG peer switches.
4. 10G or 40G speed ports should be used for peer link to enough bandwidth is provided when the network is deployed.
5. Any manual action to shut down the peer link is strictly forbidden.
6. Any MLAG VLAN and non-MLAG VLAN traffic MUST be allowed on MLAG peer-link.
7. When numerous rapid PVST+ instances are configured, exceeding the default BPDU queue processing rate in CPU will result in BPDU packets loss or network loops. To resolve this problem, you can use the following CoPP command to increase the maximum bandwidth of BPDU queue. The default value is 80pps.

   set class-of-service scheduler bpdu-scheduler max-bandwidth-pps <*value*>

8. When numerous MLAG instances are configured, exceeding the default MLAG queue processing rate in CPU will result in MLAG control packets loss. To resolve this problem, you can use the following CoPP command to increase the maximum bandwidth for MLAG and MLAG MAC SYNC queues. The default value is 80pps.

   set class-of-service scheduler mlag-scheduler max-bandwidth-pps <*value*>

   set class-of-service scheduler mlag-mac-sync-scheduler max-bandwidth-pps <*value*>

NOTE:

- When spanning tree protocol is enabled, the peer link port is always in forwarding state and won't participate in the spanning tree calculation after peer link is established.
- It is strongly recommended to use LACP protocol when configuring the peer link port.

- **MLAG member port**

MLAG member port is the LAG port on the MLAG peer devices that interconnects to the downstream device.

Usually, we configure MLAG member ports on the MLAG peer devices with the same LAG ID to form an MLAG. However, this is not required.

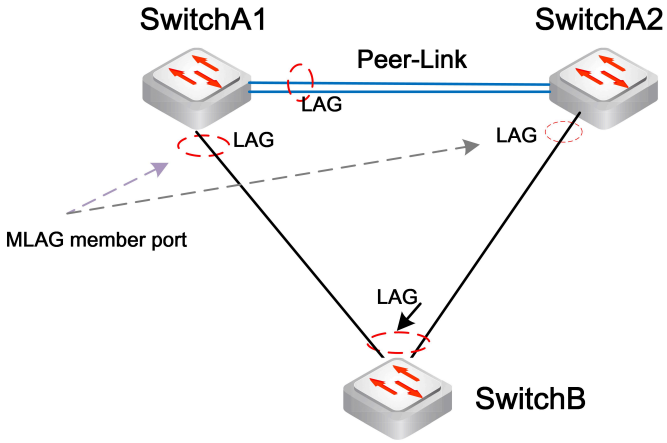
We have to bind the MLAG member port to the MLAG link ID. The paired MLAG member ports of the same MLAG must be bound to the same MLAG link ID. Different MLAGs are identified by different link IDs. For example we have two MLAGs in an MLAG Domain then link ID 1 could be used to identify one MLAG while link ID 2 could be used to identify the other MLAG in the MLAG Domain.

After all the MLAG configurations are finished, MLAG peer devices send MLAG control plane messages to each other to determine an MLAG pair. Upon receiving the MLAG Control message from the peer device, the local device determines whether the link ID carried in the MLAG Control message is the same as that of the local. If the link IDs configured on the two devices are the same, the two devices make an MLAG pair successfully.

User can use command **run show mlag link** to show the information about each MLAG and the MLAG member ports status.

```
admin@XorPlus# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
1      ae1         IDLE          UP             UNKNOWN       No               No
2      ae2         IDLE          UP             UNKNOWN       No               No
```

Figure 3. MLAG Member Port



When accessing the MLAG domain, the access devices are required to support LAG protocol. As shown in Figure 3, SwitchB is required to configure a LAG interface to interconnect to the MLAG member ports.

NOTE:

It is strongly recommended to use LACP protocol when configuring the LAG interface.

MLAG State Machine

The MLAG state machine describes the state of the MLAG peer link and the MLAG member ports on the local device and the remote peer device. The MLAG state machine facilitate link fault detection and recovery. The system defines MLAG neighbor state and MLAG interface state to establish peer link and different MLAGs configured in this MLAG Domain.

MLAG uses the TCP protocol for reliably transmitting the MLAG control messages between the two peer devices to exchange the MLAG state change. The system changes the state based on the local MLAG state and the received peer MLAG Control message. You can view the MLAG interface state, and MLAG neighbor state by using related show commands.

MLAG Neighbor State

MLAG neighbor state shows the global status of MLAG peer device and peer-link, including the following values:

- **IDLE**: The initial state of the global neighbor state machine when MLAG peer-link is configured.
- **CONNECTING**: The peer-link ports are up. The peer-link connection is started. Both MLAG peers try to setup a TCP connection to each other.
- **ESTABLISHED**: This state indicates that peer-link connection between the MLAG peer devices is established, the peer session and neighbor relationship is setup.

You can use the **run show mlag domain** {*<domain-id>*|**summary**} command to view the MLAG peer-link configuration information and the neighbor state. For example,

```
admin@Xorplus# run show mlag domain summary
Domain ID: 1    Domain MAC: 48:6E:73:FF:00:01    Node ID: 0
-------------------------------------------------------------------------------------------
Peer Link  Peer IP          Peer Vlan  Neighbor Status    Config Matched       MAC Synced  # of Links
---------  ---------------  ---------  ---------------    --------------      ----------  ----------
ae23       1.1.1.2          4088        ESTABLISHED         Yes                Yes          2
```

MLAG Interface State

MLAG interface state defines the status of peer link and MLAG member port, including the following values:

- **INIT**: The initial state of MLAG, MLAG is disabled and no information is exchanged in this state.
- **IDLE**: In this state, peer-link is configured, MLAG peer device initiates a TCP connection with the peer and changes its state. However, the peer-link session has not been established, MLAG link state switches from INIT to IDLE.
- **DOWN**: In this state, peer-link session is established, that is, the MLAG neighbor state is ESTABLISHED, but the MLAG member port is not configured on the MLAG peer device. If the local MLAG member port is down, then the MLAG interface state is DOWN.
- **STANDBY**: In this state, peer-link session is established, that is, the MLAG neighbor state is ESTABLISHED, but the MLAG member port is not configured on the MLAG peer device. If the local MLAG member port is up, then the MLAG interface state is STANDBY.
- **AS_DOWN**: In this state, peer-link session is established, that is, the MLAG neighbor state is ESTABLISHED. MLAG member ports are configured on both MLAG devices. If the MLAG member ports on both sides are down, the MLAG interface state is AS_DOWN.
- **AS_PEER:** In this state, peer-link session is established, that is, the MLAG neighbor state is ESTABLISHED. MLAG member ports are configured on both MLAG devices. If the local MLAG member port is down but peer MLAG member port is up, then the MLAG interface state is AS_PEER.
- **AS_LOCAL:** In this state, peer-link session is established, that is, the MLAG neighbor state is ESTABLISHED. MLAG member ports are configured on both MLAG devices. If the local MLAG member port is up but peer MLAG member port is down, then the MLAG interface state is AS_LOCAL.
- **FULL:** Peer session is established and MLAG member ports on both peer devices are up.

In brief, it can be summarized as the following table:

MLAG Interface State	Peer link session is established	Peer MLAG member port is configured	Local MLAG member port is up	Peer MLAG member port is up
INIT	-	-	-	-
IDLE	-	-	-	-
DOWN	√	-	-	-

MLAG Interface State	Peer link session is established	Peer MLAG member port is configured	Local MLAG member port is up	Peer MLAG member port is up
INIT	-	-	-	-
IDLE	-	-	-	-
STANDBY	√	-	√	-
AS_DOWN	√	√	-	-
AS_PEER	√	√	-	√
AS_LOCAL	√	√	√	-
FULL	√	√	√	√

You can use the **run show mlag link** {*<link-id>***| summary**} command to view the state of the MLAG interface. For example,

```
admin@XorPlus# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
1      ae1         IDLE          UP             UNKNOWN       No               No
2      ae2         IDLE          UP             UNKNOWN       No               No
```

In the output, **Link Status** shows the MLAG interface state, **Local Status** shows the status of local MLAG member port.

MLAG Control Plane Messages

The MLAG provides MLAG control plane messages, which is used to transmit the following information between the MLAG peer devices:

- MLAG state information.
- Synchronization information (including STP information synchronization and multicast control information synchronization).
- Configuration consistency check.

The MLAG control plane messages can be divided into two categories: L2 and TCP packets.

- For L2 packet, the destination MAC is 01:80:C2:00:00:0F and EtherType is 0x6666.
- For TCP packets, the destination port is 0xE290.

The format of MLAG control plane messages common header is:

Field	Descriptions
Version	This field specifies the MLAG version. Currently, the version is 0x1.
Type	This field specifies the type of MLAG control plane messages. • 0x1 indicates MLAG Control message. • 0x2 indicates MAC Sync message. • 0x3 indicates STP Sync message. • 0x5 indicates Multicast Control Sync message. • 0x6 indicates Configuration Consistency message.

MLAG control message includes the following four types and MAC Synchronization message:

- **MLAG Control message**

The MLAG Control message is used to maintain the MLAG status.

MLAG device sends an MLAG Control message under the following conditions:

1. MLAG neighbor state changes to ESTABLISHED.
2. Any MLAG interface state changes.

MLAG Control messages are encapsulated and transmitted via TCP protocol.

- **STP Sync**

The STP Sync message is used to sync up STP dynamic information, such as the calculated root priority and link cost from the received BPDUs to the peer switch. The STP Sync message is encapsulated and transmitted via TCP protocol.

- **Multicast Control Sync**

The Multicast Control Sync message is used to sync up IGMP/PIM dynamic information from the received IGMP/PIM message to the peer switch. The Multicast Control Sync message is encapsulated and transmitted via TCP protocol.

IGMP sees the MLAG LAG link as a unique logical link, so IGMP packets are synced between the MLAG peer devices through peer-link by Multicast Control Sync message:

IGMP packet received by either of the MLAG peer switches from MLAG port is synced to the other peer switch through peer link as if it is received by local MLAG port.

- **Configuration Consistency**

The Configuration Consistency message is used to check the MLAG related configuration consistency between MLAG peers. The Configuration Consistency message is encapsulated and transmitted via TCP protocol.

MLAG device sends a Configuration Consistency message under the following conditions:

1. A new MLAG related configuration is committed.

2. MLAG neighbor state changes to ESTABLISHED.

MAC Synchronization

In order to ensure that the traffic of the same user can be forwarded normally at both ends of the MLAG peer device, the MAC address table on both peer devices needs to be consistent with each other. This is accomplished by MAC synchronization mechanism which sends MAC synchronization message that is transferred by L2 multicast packets with destination address 01: 80: c2: 00: 00: 0f. MD5 checksum is added to the message to ensure that the MAC address table is correctly synchronized.

Meanwhile, in order to control bandwidth consumption of the MLAG peer link caused by flooding of unknown unicast traffic, the MLAG peer switches should synchronize MAC address table with each other.

Only when both of the following two conditions are satisfied, the MAC Sync message will be sent:

- MLAG neighbor state changes to ESTABLISHED.
- There is a change in the MAC table.

There are three types of MAC addresses defined in MLAG: Static, Dynamic, and Peer-Sync, where Peer-Sync represents the dynamic MAC address synchronized from the MLAG peer device, and its priority is lower than that of static MAC. If one of the MLAG peer switch fails, the Peer-Sync MAC address on the other switch will be deleted from the MAC address table.

Static and learned MAC addresses from any port except the peer link port are synced to MLAG peer switch through peer link. The MLAG peer's system MAC address which is learned on peer link is internally configured as static MAC address. New learned MAC addresses are immediately synced to the peer switch.

- How to update the MAC table with synced MAC addresses:
  - The MAC addresses learned on the single-homed port are synced to peer link port of the peer switch on the peer link.
  - The mac addresses learned on the MLAG member port are synced to the respective MLAG member port of the peer device through the MLAG peer link.
  - System MAC will be synchronized to the peer switch MLAG peer-link port as a **static** MAC address.
  - The MAC addresses learned on the peer link port are not synced.
- How to define the type of the MAC addresses:
  - If a MAC address is not statically configured but only learned on local MLAG switch, it is marked as "Dynamic" on local switch and "Peer-Sync" on peer switch.
  - If a MAC address is not statically configured but learned on both MLAG peer switches, it is marked as "Dynamic" on Node 0 switch and "Peer-Sync" on Node 1 switch.
  - Static MAC address has a higher priority so that it is not overridden by "Dynamic" and "Peer-Sync" MAC, but can override the "Dynamic" and "Peer-Sync" MAC types .
  - Static MAC addresses are not synced automatically, they should be synced manually.
  - If a static MAC address bound to a single-homed port is configured on one MLAG device, the static MAC address entry should be manually configured to bind to the peer-link interface on peer switch.
  - If a static MAC address bound to an MLAG member port is configured on one MLAG device, the static MAC address entry should be configured to bind to the MLAG member port on peer switch.
- How the MAC addresses age out:

  If the MAC addresses (Dynamic or Peer-Sync) age out or are cleared by CLI command on one of the MLAG peer devices, it is synced to the peer switch and removed from the peer switch as well.

You can use the **run show mac-address table** command to view the information about MAC address table, such as MAC address statistics, VLAN ID, MAC address, MAC address type and outbound interface.

For example,

Figure 4. A MAC Sync Example

When showing the MAC table on Switch A and Switch B, we can see that the dynamic MAC entry learned from the MLAG member port will be synchronized to the corresponding MLAG member port on the peer device, and dynamic MAC learned from the single-homed port will be synchronized to the peer-link port on the peer device.

```
admin@SwitchA# run show mac-address table
Total entries in switching table:   3
Static entries in switching table:  0
Dynamic entries in switching table: 3

VLAN      MAC address           Type         Age      Interfaces         User
----      -----------------     ---------    ----     ----------------   ------
1         08:9e:01:61:64:13     Dynamic      300      ge-1/1/2           xorp
1         cc:37:ab:4f:ad:01     Peer-Sync    300      ae1                xorp
4088      8c:ea:1b:88:5b:81     Static       300      ae3                xorp

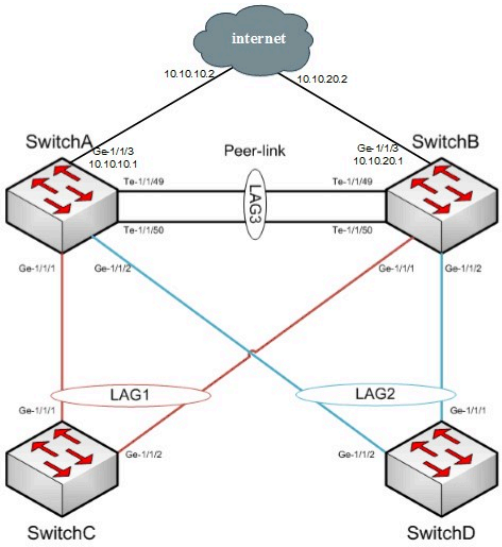
admin@SwitchB# run show mac-address table
Total entries in switching table:   3
Static entries in switching table:  0
Dynamic entries in switching table: 3

VLAN      MAC address           Type         Age      Interfaces         User
----      -----------------     ---------    ----     ----------------   ------
1         08:9e:01:61:64:13     Peer-Sync    300      ae3                xorp
1         cc:37:ab:4f:ad:01     Dynamic      300      ae1                xorp
4088      8c:ea:1b:88:5b:82     Static       300      ae3                xorp
```

When VXLAN is deployed in an MLAG domain, MAC sync between MLAG peer devices is different.

As shown in the following figure, the switches on the access side, SwitchC and SwitchD, are dual-homed to an MLAG domain. At the same time, a VXLAN tunnel is established between MLAG peer device SwitchA and SwitchB, so that Layer 2 devices on the access side can communicate over Layer 3 networks.

Figure 5. MLAG Topology with VXLAN



In this application, the MAC synchronization process is,

- The MAC addresses learned on the local network side port (Ge-1/1/3) are synced to the respective network side port (Ge-1/1/3) of the peer device through the MLAG peer link, as the system regards the network side ports on SwitchA and SwitchB as the same port.
- The MAC addresses learned on the local access side port, the MLAG member port in the figure, are synced to the respective access side port of the MLAG peer device through the MLAG peer link.
- MAC addresses learned on the single-homed port will not be synced to the peer-link port of the remote MLAG Node except in the following two cases.
  - When MLAG interface state is AS_LOCAL, the MAC addresses learned on the local access side port, the MLAG member port in the figure, are synced to the peer-link port of the MLAG peer device.
  - If the network port on one VTEP device goes down, the corresponding network on the peer VTEP is regarded as a single port and the MAC addresses learned this single port will be synchronized to the peer-link port of the MLAG peer device.

When showing the MAC address table, the value in **Interfaces** column is ***vxlan*** for MAC addresses synced from the peer VTEP device. For example,

```
admin@Xorplus# run show mac-address table
Total entries in switching table:   3909
Static entries in switching table:  6
Dynamic entries in switching table: 3903
VLAN      MAC address          Type         Age     Interfaces         User
----      -----------------    ---------    ----    ----------------   ----------
1         20:04:0f:0f:49:d1    Dynamic      300     ae2                xorp
N/A       00:00:0a:11:11:11    Peer-Sync    300     vxlan              xorp
N/A       00:00:0a:11:11:12    Peer-Sync    300     vxlan              xorp
```

You can also use command **run show vxlan address-table** to show VXLAN MAC table. For example,

```
admin@Xorplus# run show vxlan address-table
VNID           MAC address          Type       Interface      VTEP
-------------------------------------------------------------------------------------
10000          00:00:0a:11:11:11    Sync                      145.145.145.145
10000          00:00:0a:11:11:12    Sync                      145.145.145.145
10000          20:04:0f:0f:49:d1    Sync         ae2
```

The first two lines in the display result show the MAC addresses synced from the VXLAN network side port of the peer VTEP device, and the third line shows the MAC address synced from the access side port of the peer VTEP device.

Configuration Consistency Check

To ensure that the MLAG peer devices appear as one device to the downstream device, and to make the MLAG function operate normally and smoothly, the configuration on each MLAG peer device needs to be consistent.

PICOS automatically checks the configuration consistency of the MLAG peer devices by exchanging Configuration Consistency messages.

MLAG device sends a Configuration Consistency message under the following conditions:

- MLAG neighbor is established.
- An MLAG related new configuration is committed.

Configuration consistency check is divided into two types: **Global configuration** and **Per MLAG configuration**.

Global configuration refers to the global configuration of the MLAG module, STP module, DHCP snooping module and the IGMP snooping module. The configuration inconsistency affects the overall establishment and operation of the MLAG domain, the peer-link establishment, and the entire network topology. **Per MLAG configuration** is mainly for the configuration of a single MLAG. Inconsistent configuration only affects the establishment and operation of a single MLAG, but does not affect other MLAGs.

Depending on the impact of the configuration inconsistency on the system and the different MLAG processing methods, the consistency parameters are divided into six categories: **type 1**, **type 2**, **type 3**, **type 4**, **type 5** and **type 6**.

Type 1 Configuration Consistency Parameters

Table 1 shows all the type 1 parameters. When these parameters are inconsistent on MLAG peer, it might result in a traffic loop or losing MAC SYNC events of MLAG. A warning log will be generated to alert the users. Meanwhile,

- If the type 1 parameter is Global, MLAG will turn down all the MLAG member ports on the secondary spine (node ID= 1), regardless whether the corresponding MLAG member ports of the primary spine (node ID= 0) are up or down when these parameters are inconsistent on the MLAG peer.
- If the type 1 parameter is per MLAG type, MLAG will turn down only the MLAG port of the secondary spine, regardless whether the corresponding MLAG port of the primary spine is up or down when these parameters are inconsistent on the MLAG peer.

Table 1. Type 1 Configuration Consistency Check List

Configuration Parameter to Check	Type	Result When Inconsistent
Port settings (native vlan, trunk vlan count, trunk vlans)	Per MLAG	FAIL
PVST settings(root guard, vlan count, vlans, port priority, path cost)	Per MLAG	FAIL
MSTP settings(external path cost, internal path cost, port priority, mst count, msti, mst port priority, mst path cost, configuration name, revision level, vlan count, vlans)	Per MLAG	FAIL
RSTP/PVST/MSTP enable or disable	Global	FAIL
RSTP/PVST/MSTP mode	Global	FAIL

Type 2 Configuration Consistency Parameters

Table 2 shows all the type 2 parameters. When these parameters are inconsistent, it does NOT cause a loop or MAC SYNC issue. However, some traffic may be impacted. A warning log will be generated to alert the users when these parameters are inconsistent on the MLAG peer.

Note that VXLAN settings belongs to both type 2 and type 6, when these parameters are inconsistent, the check result is "FAIL".

Table 2. Type 2 Configuration Consistency Check List

Configuration to Check	Type	Result When Inconsistent
MLAG link ID	Global	ALERT
MLAG link count	Global	ALERT
MLAG peer VLAN	Global	ALERT
MTU	Global	ALERT
LACP priority	Global	ALERT
LACP key	Global	ALERT
MAC learning	Global	ALERT
Port LAG mode (LACP/Static)	Global	ALERT
Port mode (Access/Trunk)	Global	ALERT
RSTP settings (BPDU filter, BPDU Guard, Edge, Root Guard, TCN Guard, Bridge priority, Max age, Hello time, Forward delay, Link type, Port priority, Path cost)	Global/Per MLAG	ALERT
PVST settings (VLAN count, VLANs, Bridge priority, Hello time, Forward delay, Max age, BPDU guard, Manual forwarding, Link type)	Global/Per MLAG	ALERT
MSTP settings (BPDU filter, BPDU Guard, Edge, Root Guard, TCN Guard, Bridge priority, Max age, Hello time, Forward delay, Link type, Path cost, Max hops, VLANs, Manual forwarding)	Global/Per MLAG	ALERT
VXLAN settings (UDP port, MAC learning, VXLAN enable, vni count, vni to vlan mapping, vni to vtep count, vni to vteps, vni count, vnis, vni to vlan count, vni to vlans)	Global/Per MLAG	FAIL
IGMP snooping vlan count, IGMP snooping vlans	Global	ALERT

Type 3 Configuration Consistency Parameters

Table 3 shows all the type 3 parameters. When these parameters are inconsistent, a loop may be formed. In some cases, turning down the MLAG port is not enough to prevent the loop. Hence, if a type 3 parameter is inconsistent, all VLANs (except MLAG peer VLAN) on the peer link will be blocked to prevent the loop. Also, a warning log will be generated to alert the users. The log will repeat every 60s until the configuration is modified to be consistent.

Table 3. Type 3 Configuration Consistency Check List

Configuration to Check	Type	Result When Inconsistent
MLAG domain ID	Global	FAIL
RSTP/PVST/MSTP enable or disable	Global	FAIL
RSTP/PVST/MSTP mode	Global	FAIL

Type 4 Configuration Consistency Parameters

Table 4 shows all the type 4 parameters. When these parameters are inconsistent, MAC addresses will not be synchronized between MLAG peer devices.

Table 4. Type 4 Configuration Consistency Check List

Configuration to Check	Type	Result When Inconsistent
MLAG domain ID	Global	FAIL

Type 5 Configuration Consistency Parameters

Table 5 shows all the type 5 parameters. When these parameters are inconsistent, only MSTP parameters in instance 0 can be synchronized between MLAG peer devices.

Table 5. Type 5 Configuration Consistency Check List

Configuration to Check	Type	Result When Inconsistent
MSTP settings(configuration name, revision level, vlan count, vlans)	Global	FAIL

Type 6 Configuration Consistency Parameters

Table 6 shows all the type 6 parameters. It will stop DHCP table sync between the MLAG peer when any of the following DHCP snooping configurations inconsistency are detected: dhcp snooping vlan count, dhcp snooping vlans.

Table 6. Type 6 Configuration Consistency Check List

Configuration to Check	Type	Result When Inconsistent
DHCP snooping (vlan count, vlans)	Global	FAIL
VXLAN settings (UDP port, MAC learning, VXLAN enable, vni count, vni to vlan mapping, vni to vtep count, vni to vteps, vni count, vnis, vni to vlan count, vni to vlans)	Global/Per MLAG	FAIL

NOTEs:

- Some parameters belong to two types, for example, parameter "RSTP/PVST/MSTP enable or disable" belongs to both type 1 and type 3. When this configuration is inconsistent, MLAG will take actions necessary for both type 1 and type 3 inconsistencies.
- VXLAN settings belongs to both type 2 and type 6,
  - When VXLAN is deployed simultaneously with DHCP snooping, it will stop DHCP table sync between the MLAG peer when any of the VXLAN settings in **Table 6** are inconsistent on the MLAG peer devices.
  - When VXLAN deployment is independent of DHCP snooping, a warning log will be generated to alert the users when VXLAN settings parameters are inconsistent on the MLAG peer devices.
- If “domain ID” inconsistency is detected, all VLANs (except MLAG peer VLAN) on the peer link will be blocked to prevent the network loop. And also, MAC synchronization will not be performed between the MLAG peers until the configuration is modified to be consistent. A warning log will be generated to alert the users.
- When any of the following MSTP configurations inconsistency is detected: configuration name, revision level, mst count, msti, vlan count, MSTP only uses parameters of instance zero from peer to prevent loop. A warning log will also be generated to alert the users.

To ensure that the configuration parameters are consistent, we recommend that you run the MLAG consistency check command to display the configurations and the consistency check results for each MLAG peer device once you set a new MLAG related configuration.

You can use the **run show mlag consistency-parameter** {**link** <*link-id*>| **summary**} command to view the consistency check results. For example:

```
admin@Xorplus# run show mlag consistency-parameter summary
Overall : PASS with ALERT
--------------
Global  : PASS with ALERT
Link 1  : PASS with ALERT

MLAG Configurations:

Instance Count           1               1               PASS
Instance Vlan 3
-- Port Priority         128             128             PASS
-- Path Cost             0               0               PASS

VXLAN Configurations:
------------------------------------------------------------------
Property                 Local Value     Peer Value      Result
-----------------------  --------------  --------------  ------
Link   1 VXLAN           N/A             N/A             FAIL
```

Result in the show commands shows the consistency check results, the value could be **PASS**, **FAIL** or **ALERT**:

- If **Result** is PASS, the configurations of the MLAG peer-link devices are consistent.
- If **Result** is FAIL or ALERT, the configurations of the MLAG peer-link devices are inconsistent.

In the consistency check results,

- if there exists one "FAIL" result, the "Overall" result would be "FAIL".
- Else, if there exists one "ALERT" result, the "Overall" result would be "ALERT".
- Else, the "Overall" result would be "PASS".

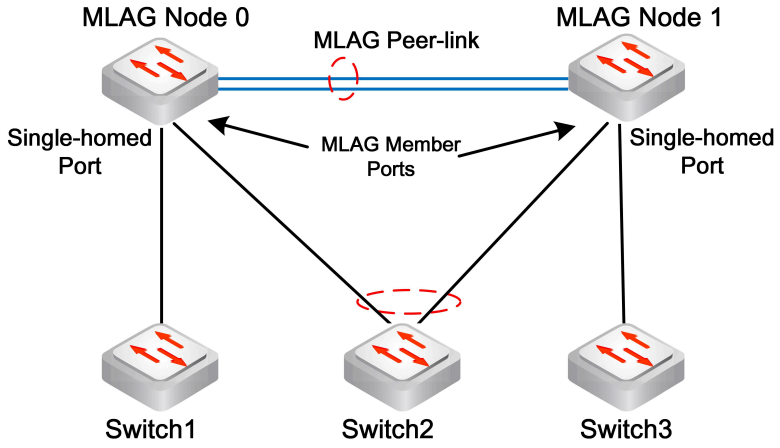
NOTE:

- Inconsistent configurations may cause MLAG to run abnormally.
- After the configuration is changed from inconsistent to consistent, you need to restart the MLAG peer devices to ensure that MLAG functions normally.

Single-homed Port

Single-homed port is a port on the MLAG peer device which provides access device single-access to the network through either MLAG Node 0 or Node 1 device. The single-homed port on the MLAG peer devices can connect to both hosts or servers and it can also be connected to other access switch devices. As shown in **Figure 6**, Switch 1 and Switch 3 are single-homed devices, the ports on the MLAG peer devices connected to Switch 1 and Switch 3 are called single-homed ports. Traffic between Switch1 and Switch3 always crosses the MLAG peer-link as Switch1 and Switch3 are active on different switches. With single-homed ports, servers and other standalone switches are able to single-home into the network.

Figure 6. MLAG network



The MAC address entries learned on the single-homed port will be synchronized to the MLAG peer-link port on the MLAG peer device, and the address type is **Peer-Sync** in the MAC address table. However, the MAC synchronization on the single-homed port will be done only when the MLAG neighbor state is ESTABLISHED. This MAC synchronization ensures that the devices connected to the single-homed port can communicate normally.

Physical ports and LAG ports could be a single-homed port, an MLAG member port matching the following conditions could be a single-homed port, but the peer-link port could not be a single-homed port.

An MLAG member port is a single-homed port when one LAG port of the dual-homed access device is down, then the other LAG port becomes a single-homed port. We can also say that when MLAG interface state is **ASY_LOCAL**, then MLAG member port on local MLAG device is a single-homed port. MAC address entry learned on this port will be synchronized to MLAG peer-link port on the MLAG peer device.

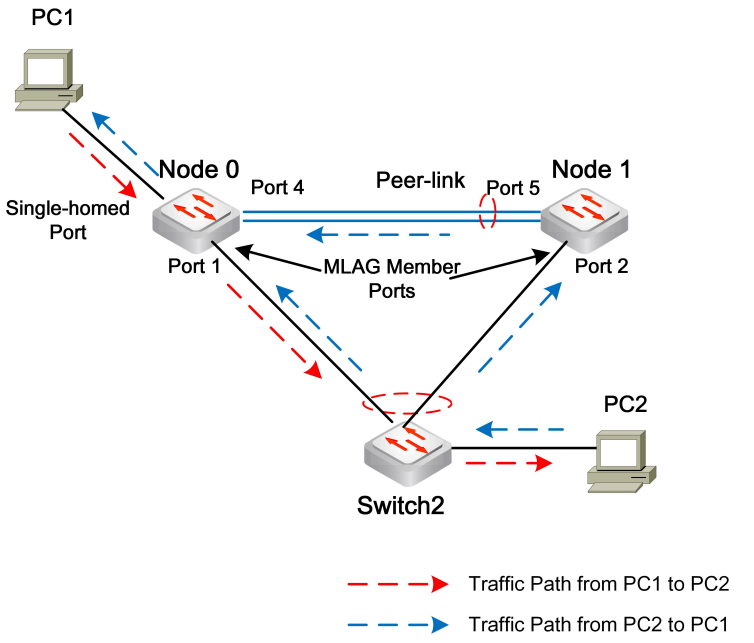
NOTE:

To make the single-homed port work normally, the peer-link ports should be added into the VLAN of the single-homed port.

Application Scenarios

As shown in **Figure 7**, PC 2 connects to the MLAG downlink switch (Switch 2), and communicates with PC 1 through the MLAG peer devices.

Figure 7. Network 1 of PC 1 and PC 2 Communication in MLAG Topology



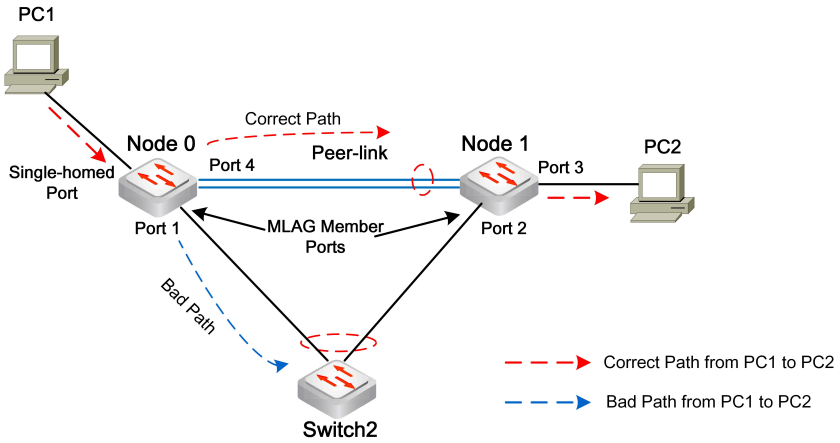
Normally, the traffic from PC 1 to PC 2 will go out through Port 1 to Switch 2. Any packet received from peer-link on MLAG Node 1 device will be blocked on all MLAG member ports.

Traffic sent from PC 2 to PC1 will be hashed to one of the MLAG peer devices. If the traffic is hashed to the MLAG Node 1, the traffic is therefore forwarded by the Node 1 device across the peer-link to MLAG Node 0. This is because the MAC address learned on the single-homed port will be synchronized to the peer-link port Port 5 on MLAG Node 1 device.

When the topology changes, as shown in **Figure 8**, PC 2 changes location and accesses the network through the MLAG Node 1 on Port 3. The MAC address of PC 2 will be learned on Port 3 of MLAG Node 1 device. At this time, since Port 3 is a single-homed port, the MAC address entry learned on Port 3 will be synchronized to the peer-link port Port 4 on MLAG Node 0 device. The traffic sent from PC 1 to PC 2 will go out of Port 4 instead of Port 1 on MLAG Node 0 device and sent to the Node 1 device via peer-link.

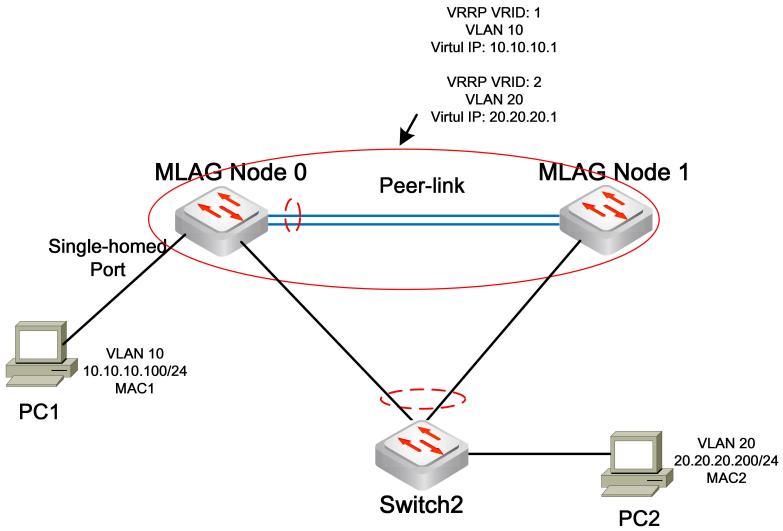
Similarly, as Port 3 is a single-homed port, MAC addresses of single-homed hosts connected to the MLAG Node 1 device will automatically be learned by MLAG Node 0 device. The traffic flow path from PC 2 to PC 1 is similar. This ensures that the devices connected to the single-homed port can communicate normally.

Figure 8. Network 2 of PC 1 and PC 2 Communication in MLAG Topology



When considering the case of IP routing communication, as shown in **Figure 9**, PC1 and PC2 belong to different subnets. In this scenario, you can apply VRRP in the MLAG topology to make PC1 and PC2 communicate with each other through IP routing. Configure two VRRP groups on the two VRRP group devices which belong to different L3 VLAN interfaces. Configure a different virtual IP address for each VRRP group, virtual IP address 10.10.10.1 is used as the gateway for PC1 access network, and virtual IP address 20.20.20.1 is used as the gateway for PC2 access network.

Figure 9. Network 3 of PC 1 and PC 2 Communication in MLAG with VRRP Topology



If VXLAN is deployed in an MLAG domain, MAC addresses learned on the single-homed port will not be synced to the peer-link port of the remote MLAG Node except in the following two cases.

- When MLAG interface state is AS_LOCAL, the MAC addresses learned on the local access side port, the MLAG member port in the figure, are synced to the peer-link port of the MLAG peer device.
- If the network port on one VTEP device goes down, the corresponding network on the peer VTEP is regarded as a single port and the MAC addresses learned this single port will be synchronized to the peer-link port of the MLAG peer device.

Flood Control

To prevent the downstream switches from receiving multiple copies from both ends of MLAG peer, a block mask is used to prevent forwarding all the traffics received on the MLAG peer link toward the MLAG member port, this is called Flood Control mechanism.

As shown in **Figure 10**, peer-link is usually not used to forward data traffic, the unicast traffic from the access device or the network side to the MLAG peer device will be forwarded locally. When receiving the traffic from the peer-link, the MLAG member ports start flood control and form a forwarding block mask. That is, traffic received from the peer-link port will not be forwarded out the MLAG port; this prevents loops in the MLAG network.

The forwarding block mask for a given MLAG will be cleared off if the MLAG member port goes down on the MLAG peer.

Figure 10. MLAG Flood Control

1. Unknown unicast, multicast or broadcast received from the MLAG member ports will be flooded to any other ports in MLAG VLAN including the peer-link port.
2. Any packets (Unicast, multicast or broadcast) received from peer-link will be forbidden to transfer through the MLAG member port.

You can run the **run show mlag link** {<link-id>**| summary**} command to view the status of flood control. For example:

```
admin@XorPlus# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer-Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
1      ae1         IDLE          UP             UNKNOWN       No               No
2      ae2         IDLE          UP             UNKNOWN       No               No
```

In the show result, **Link Status** indicates MLAG interface state. Generally, **Flood** is **No**, indicates that all the traffic received on the MLAG peer-link port will be blocked to all MLAG member ports on MLAG peer device except the DHCP Offer/Ack packets.

However, in one case, when peer MLAG member port is down, the MLAG interface state changes to AS_LOCAL, then **Flood** changes to **Yes**, indicating that traffic received on the MLAG peer-link can be transferred through the MLAG member port.

> **NOTE:**
>
> All the packets received from peer-link shall be blocked to all MLAG member ports except the DHCP Offer/Ack packets.

MLAG Peer-Gateway

As shown in the figure below, Switch 1 and Switch 2 are a pair of MLAG devices. The host can dual-access to the network through the MLAG peer devices. VRRP is not deployed in this topology.

Let's assume that the default gateway address on the host is the address of Switch 2. In this case, any message from the host directly sent to Switch 2 can be routed correctly. However, there may exist one case that message from the host is hashed to Switch 1, Switch 1 finds that the destination MAC address of the message is Switch 2, then the message will be forwarded to Switch 2 through the peer link. When the message received from the peer link is about to be forwarded on the MLAG member port on Switch 2, it will be dropped due to MLAG flood control mechanism.

To solve this problem, you can enable Peer-Gateway functionality on both sides of the MLAG devices. Each MLAG local device will then replicate the system MAC address of the peer MLAG device, allowing the local device to function as a gateway to forward packets destinated for the MLAG peer device.

In the scenario above, when Switch 1 receives a message in which the destination MAC is the system MAC address of the peer MLAG device Switch 2, which is also the gateway MAC of the host, Peer-Gateway feature allows the local MLAG device Switch 1 to function as the gateway for forwarding message. This avoids forwarding message through the peer link, avoiding packet drops on Switch 2 due to MLAG flood control mechanism.

You can use the command **set protocols mlag domain** <*domain-id*> **peer-gateway enable** <**true** | **false**> to enable or disable MLAG Peer-Gateway functionality.

For example,

- Enable MLAG Peer-Gateway functionality.

```
admin@Xorplus# set protocols mlag domain 1 peer-gateway enable true
admin@Xorplus# commit
```

- Disable MLAG Peer-Gateway functionality.

```
admin@Xorplus# set protocols mlag domain 1 peer-gateway enable false
admin@Xorplus# commit
```

When MLAG Peer-Gateway is enabled on the MLAG peer devices, where DHCP Relay is also enabled, you have to configure an IP address of the DHCP relay agent through the command **set protocols dhcp relay interface** <*vlan-interface-name*> **relay-agent-address** <*agent-ipv4-address*>. In this command, **interface** <*vlan-interface-name*> is the VLAN interface with DHCP relay enabled; **relay-agent-address** <*agent-ipv4-address*> needs to be configured as an IP in the same network segment as the VLAN interface but a different value. Note that the DHCP relay agent address should be identical on both MLAG peer devices.

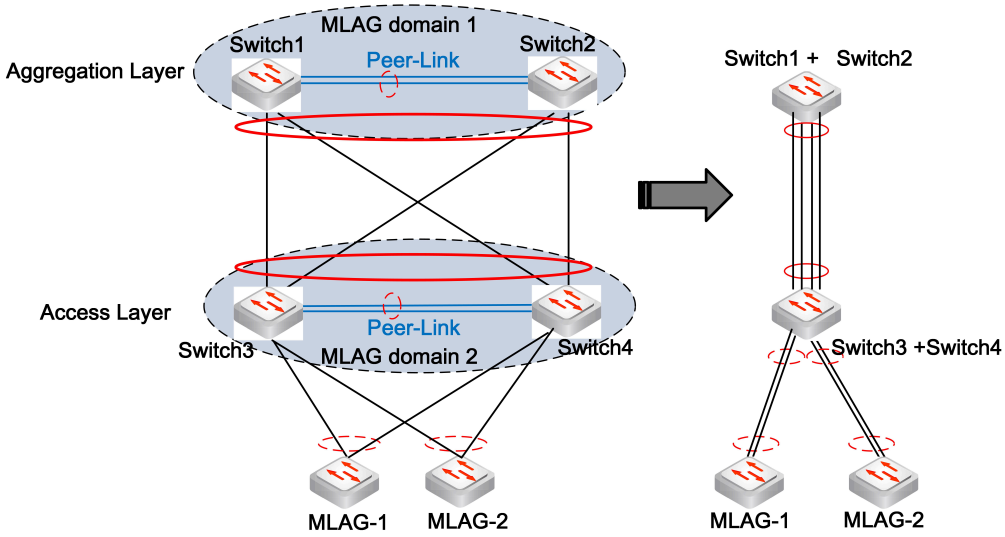
Multi-layer MLAG Application Networking

A two-layer MLAG network is shown in **Figure 11**. Access devices dual-homed to the network through the lower MLAG peer devices at the access layer, and the upper MLAG peer devices are used as the active-active gateway at the aggregation layer. In the two-layer MLAG topology, MLAG member ports of the MLAG peer device in the same MLAG domain MUST belong to the same MLAG, that is, they should be configured with the same link ID.

NOTE:

It is mandatory that different pairs of MLAG peer devices should use different domain IDs. In the topology below, domain ID of Aggregation Layer MLAG peer switches and domain ID of Access Layer MLAG peer switches should be different.

Figure 11. Multi-layer MLAG Application Networking Diagram



Compared with one layer MLAG, multi-layer MLAG has the following advantages:

- Expanded layer 2 range.
- Provides a highly flexible architecture. In the multi-layer MLAG, both access devices and access layer switches devices are dual-homed to the network, which increases network reliability.

Provides greater network bandwidth from the access layer to the aggregation layer.

Interoperability with Other Features

LACP

LAG (Link Aggregation Group) is a way of binding multiple physical links into a combined logical link. MLAG domain MAC address will be used for LACP negotiation when performing link aggregation with the downlink access device.

We recommend that you enable LACP on the interfaces of each link aggregation group when configuring peer-link port and the LAG ports connected to the downlink access devices. This allows you to more easily detect compatibility between devices, link failures, and provides dynamic reaction to configuration changes and link failures.

Rapid PVST+

MLAG itself has an anti-loop feature for MLAG member ports, but for non-MLAG ports, the possibility of a loop still exists in the network. There could be a number of networking scenarios that could lead to loops in the network, so to avoid unexpected loops forming in the network, it is strongly recommended to enable Rapid PVST+ protocol on all devices in the MLAG domain.

The two MLAG peer switches are seen as a single device to the PVST+ instance. Rapid PVST+ configuration should be identical on both MLAG peer devices. For example, rapid PVST+ enable or disable, rapid PVST+ mode and rapid PVST+ parameters (such as bridge priority, hello time, forward delay) should be identical on both MLAG peer devices.. See Table 1 in section 1.1.6 Configuration Consistency Check to find the MLAG configuration consistency check list.

After the rapid PVST+ protocol is enabled, MLAG peer devices will automatically send STP Sync messages, which are used to sync up rapid PVST+ dynamic information from the received BPDUs to the peer switch. Once the peer-link is successfully established, the two peers are virtualized into one device to perform port role calculation and fast convergence calculation by using the rapid PVST+ protocol. The peer link port is always in forwarding state and does not participate in the spanning tree calculation.

NOTE: To avoid network loop, it is strongly recommended all the VLANs on the peer-link port to enable with rapid PVST+, including MLAG peer VLAN.

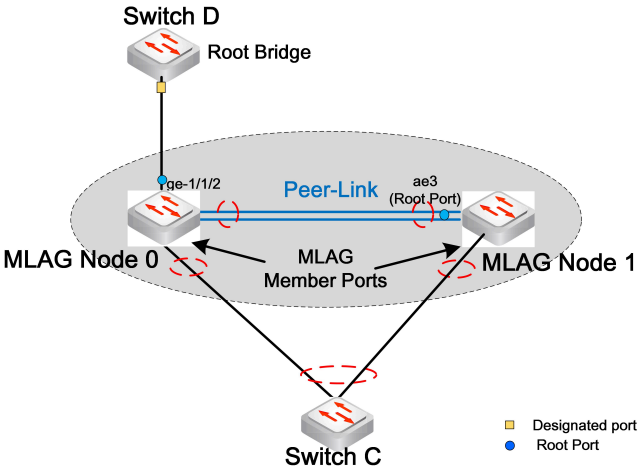
An offset has been added to the port index which is encapsulated in the BPDUs, see the following table:

	MLAG Port Index	Non-MLAG Port Index
MLAG Node 0	512 + MLAG Link ID	Local Port Index
MLAG Node 1	512 + MLAG Link ID	1024 + Local Port Index

Supported Root Bridge Topologies

Root bridge could be any bridge in the L2 domain, connected through the following three types of link:

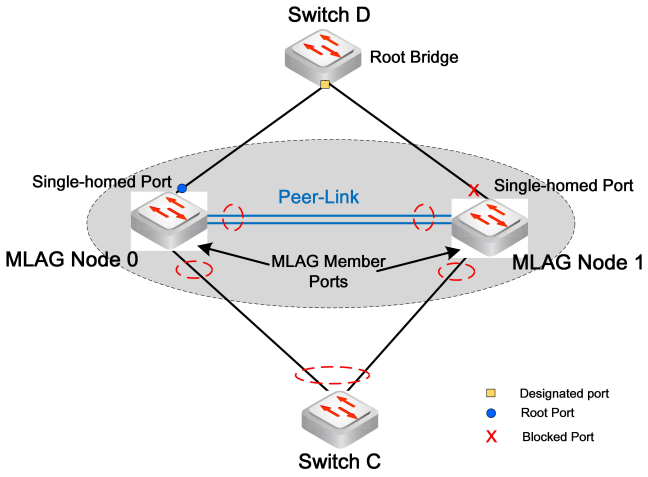
1. Non-MLAG link, i.e. single-homed connection to either one or both of the peer nodes.



In the figure above, Switch D is single-homed to MLAG Node 0 device, suppose Switch D is the root bridge, then ge-1/1/2 port is the root port of MLAG Node 0, and the peer-link port ae3 is the implicit root port of MLAG node 1 device.

In the figure above, Switch D is single-homed to both MLAG Node 0 and Node 1 devices. Suppose Switch D is the root bridge, in the upper side of the topology, one of the single-homed ports will be blocked after spanning tree calculation as there is a loop in the topology.

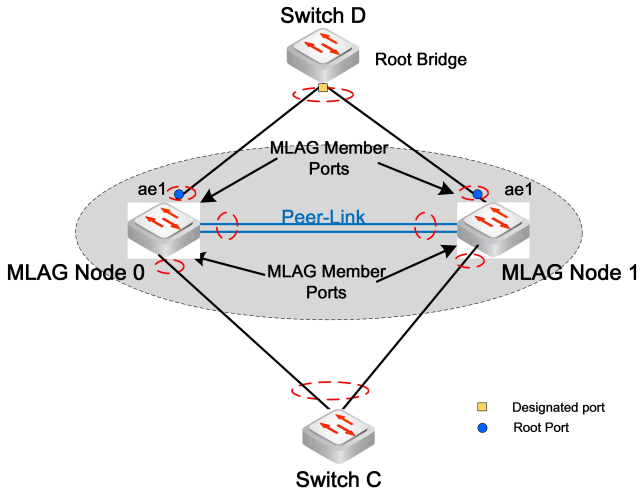
2. MLAG link



In the figure above, Switch D is dual-homed to MLAG peer devices, suppose Switch D is the root bridge, LAG port ae1 is the root port of MLAG Node 0. After STP synchronization between MLAG peer devices, LAG port ae1 becomes the root port of MLAG node 1 device.

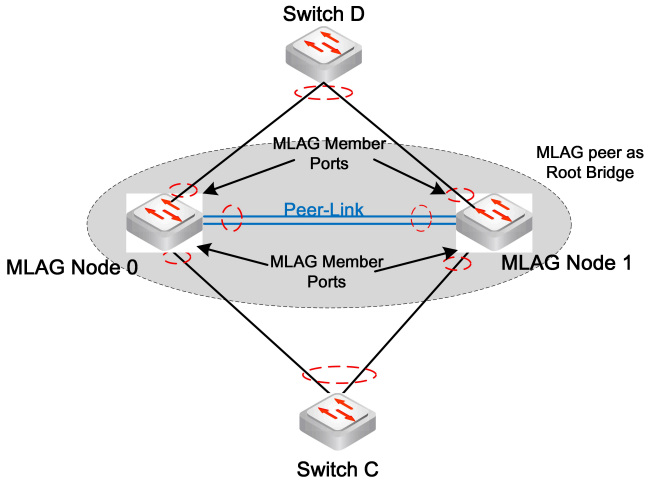
If one of the MLAG member port goes down, the role of paired MLAG member port remains unchanged in the MLAG domain.

For example,



In the figure above, if the MLAG member port ae1 on MLAG Node 0 goes down, the role of the paired MLAG member port in the MLAG domain is still the root port.

3. MLAG nodes as the root bridge



In the figure above, Switch C and Switch D are dual-homed to MLAG peer devices, MLAG peer devices functions as a root bridge. One of the MLAG peer devices transmits configuration BPDUs.

Configuration recommendation:

- For a small scale network, it is recommended to disable spanning tree protocol to reduce the network convergence delay caused by spanning tree calculation.
- If the network topology changes, MAC address table will be cleared.

DHCP Snooping & DHCP Relay

Devices in the MLAG topology support enabling DHCP snooping or DHCP relay function on the MLAG peer devices to implement address allocation for the DHCP clients.

When configuring DHCP snooping and DHCP relay in MLAG topology, pay attention to the following points:

- DHCP snooping configurations, such as Option 82 policy, VLANs enabled or disabled DHCP snooping, should be configured identically on both MLAG peer devices, the inconsistent configuration can cause undesirable behavior in the traffic flow.
- If the VLANs enabled or disabled DHCP snooping are not identical on MLAG peer devices or the MLAG global configuration are not identical on MLAG peer devices, the DHCP binding table entries will be cleared.
- When configuring DHCP snooping, the ports directly or indirectly connect the DHCP server should be configured as trust port on the network device between the DHCP Client and the Server, including the MLAG peer devices.
- DHCP relay configurations should be configured identically on both MLAG peer devices.

DHCP snooping and DHCP relay in MLAG topology present the following characteristics:

1. DHCP snooping binding table and DHCP relay table of the MLAG member ports will be synchronized to the associated member ports on MLAG peer device. DHCP Sync message is defined to undertake the synchronization tasks.
2. If the MLAG configuration consistency check passes, the MLAG system syncs the DHCP snooping binding table and DHCP relay table; If the MLAG configuration consistency check fails, the MLAG system does not sync the DHCP snooping binding table and DHCP relay table.
3. DHCP snooping binding table and DHCP relay table of the single-homed ports will not be synchronized to the MLAG peer device.
4. When receiving the DHCP message from MLAG peer link, the MLAG device won't do Layer 3 forwarding for this message, but can do Layer 2 forwarding.
5. MLAG flood control module processes DHCP packets just like other packets: When the MLAG member port is in the FULL state, DHCP packets received from the peer link port cannot be forwarded out from the MLAG member port; However, when the MLAG interface state changes to AS_LOCAL, the prohibition is lifted.
6. MLAG device forwards one copy of the DHCP Discover/Request/Release/Decline packet received from the MLAG member ports to the MLAG peer device through the peer link.
7. The format of DHCP Option 82 sub-options remote ID and circuit ID is fixed in MLAG topology,

- MLAG domain MAC address is used to fill in remote ID field.

- MLAG Link ID and Port Index are used for circuit ID field with an offset, see the following table for details:

	MLAG Port	Non-MLAG Port
MLAG Node 0	512 + MLAG Link ID	Local Port Index
MLAG Node 1	512 + MLAG Link ID	1024 + Local Port Index

IGMP Snooping

IGMP snooping can be deployed in an MLAG topology to shield hosts on a local network from receiving traffic for a multicast group they have not explicitly joined. The multicast traffic is forwarded according to the L2 multicast forwarding table which is generated by IGMP snooping. If there is no matching entry in the L2 multicast forwarding table, the multicast traffic is forwarded to the mrouter ports except the one the multicast traffic is received on.

IGMP sees the MLAG LAG link as a single logical link, so IGMP packets are synced between the MLAG peer devices through peer-link by Multicast Control Sync message:

IGMP packet that is received on either MLAG peer switch from their MLAG port is synced to the other peer device through peer link as if it is received by local MLAG port.

Configuration notes:

- IGMP snooping configuration should be identical on both MLAG peer devices.
- Generally, it is not necessary to configure mrouter port on the peer link.

VXLAN

Implementing VXLAN technology on the MLAG peer devices provides overlay network on top of existing layer 2 and layer 3 technologies to support elastic compute architectures, thus makes it easier for network engineers to scale out a cloud computing environment while logically isolating cloud apps and tenants.

The two MLAG peer switches are seen as a single device in the VXLAN network. VXLAN configurations should be identical on each VTEP device. This includes the VNI value, VLAN included in the same VNI and all the configurations on the VXLAN network side ports and access side ports.

To avoid duplicate packets being sent from MLAG and VXLAN networks, traffic from the peer link will not be forwarded on the VXLAN network side ports or access sides ports, unless in the case that the uplink or downlink of the peer VTEP device fails.

When VXLAN is deployed in MLAG domain, pay attention to the following notes:

- When deploying VXLAN, peer link should not be the outcoming interface of VXLAN tunnel for routing VXLAN traffic, otherwise packet loss may occur.
- Untagged packets do not support VNI mapping to the PVID of a port by using command **set vxlans vni** *<text>* **vlan** *<vlan-id>*.
- In MLAG with VXLAN network, configuring static MAC address entries on VXLAN tunnel interfaces is not supported, so the command **set vxlans vni***<text>* **flood vtep** *<ipv4-addr>* **mac-address** *<macaddr> is useless.*
- Traffic from the single-homed port cannot be sent from the peer spine's network side port of VXLAN because of the limitation that the traffic from the peer link will not be forwarded through the VXLAN network side ports.
- Only one VLAN can be configured for one VNI when you use the command **set vxlans vni** *<text>* **vlan** *<vlan-id>* to configure the VLAN permitted to pass through the VXLAN tunnel.
- If the local VXLAN access port status is Down, packets from the VXLAN network side will be discarded on the local MLAG peer-link port if they become packets without a VLAN tag after VXLAN decapsulation.
- The single-homed port is not supported as VXLAN access port, only dual-homed MLAG member port can be configured as VXLAN access port.
- Only MLAG Node 0 device can forward the BUM packets through the VXLAN tunnel.

ARP Inspection

ARP Inspection can be deployed on the MLAG peers to defend against man-in-the-middle attack scenarios, preventing ARP table entry being maliciously modified by a forged ARP message sent by an attacker.

Configuration notes:

- ARP inspection configuration should be identical on both MLAG peer devices.
- We recommend the you don't enable ARP inspection in the peer-link VLAN which is dedicated to transmitting MLAG control plane messages.

However, if ARP inspection is enabled in peer link VLAN, an ARP access list must be configured by the following commands for ARP inspection to make MLAG work normally:

set protocols arp inspection access-list *<acl-name>* **ip** *<ipv4-addr>* **mac-address** *<mac-addr>*

set protocols arp inspection vlan *<peer-vlan-id>* **access-list** *<acl-name>*

where IP, MAC address and VLAN should be configured as the corresponding values of peer link port on the MLAG peer device.

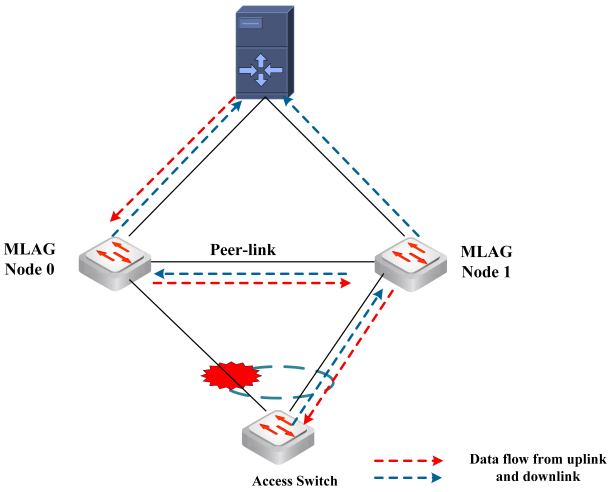
Traffic Forwarding in Typical Fault Scenarios

Downstream Link from Access Switch Down

This scenario includes the case in which an MLAG member port goes down or downstream link develops a fault. In this case, all traffic will be transmitted to and from the active MLAG member port of the peer device as illustrated in **Figure 12**.

From Figure 11, when the member port on Node 0 goes down, MLAG interface state on MLAG Node 1 changes to AS_LOCAL. MLAG member port on Node 1 becomes an MLAG single-homed port. Frames received from the peer link are then forwarded to the MLAG single-homed port.

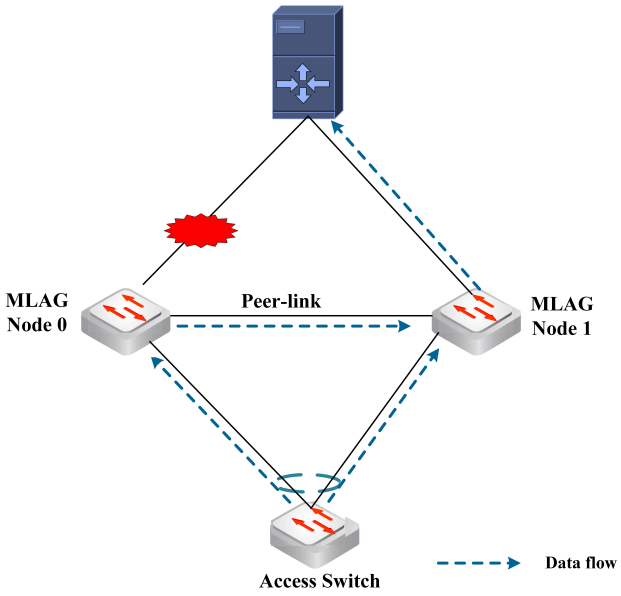
Figure 12. Typical Fault Scenario of Downstream Link Down



Upstream Link to Layer-3 Device Down

In this case, traffic load-sharing to MLAG Node 0 is sent to the MLAG Node 1 device via MLAG peer-link, and then forwarded to the upstream device.

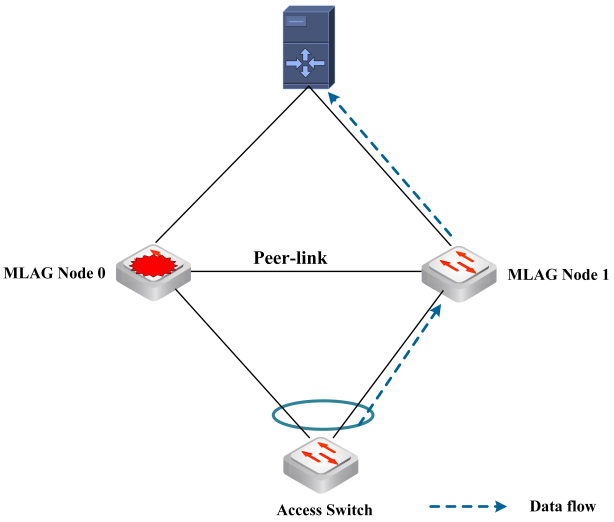
Figure 13. Typical Fault Scenario of Upstream Link Down



MLAG Node Fault

If one of the MLAG Node reboots, shuts down or develops some unforeseen fault, traffic will be transmitted through the other active MLAG Node.

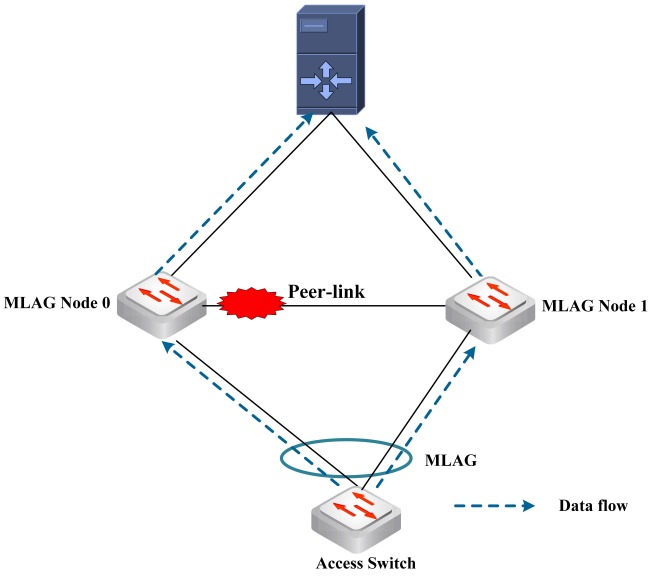
Figure 14. Typical Fault Scene of MLAG Node 0 Fault



MLAG Peer-link Down

Any manual action to shut down the peer-link is strictly forbidden. However, if the peer-link goes down for some reason, MLAG control plane messages cannot be exchanged, causing the MLAG system to operate abnormally. Especially when the peer-link is down, but both the MLAG member ports are up will create the split-brain failure scenario. The system cannot be automatically recovered in this scenario.

Figure 15. Typical Fault Scenario of Peer-link Down



Therefore, we have to ensure the reliability of the peer-link, follow the points described in section 1.1.2 Basic Concepts when configuring and deploying the peer-link.

When the peer-link is down, the MLAG peer relationship cannot be established. You can run the **run show mlag domain** command to check the peer-link status, the **Neighbor Status** is not ESTABLISHED when peer-link is in process of establishment or is down.

For example,

```
admin@Xorplus# run show mlag domain summary
Domain ID: 1    Domain MAC: 48:6E:73:FF:00:01    Node ID: 1
-------------------------------------------------------------------------------------------
Peer Link  Peer IP          Peer Vlan  Neighbor Status    Config Matched       MAC Synced  # of Links
---------  ---------------  ---------  ---------------    --------------      ----------  ----------
ae65       1.1.1.1          4088        ESTABLISHED         Yes                Yes          64
```

Backward Compatibility

Compared with existing CLI interface, from 3.6.0, the new CLI is not backward compatibility as follows:

- “set interface mlag” is changed to “set protocols mlag”.
- “disable”/“hello-interval”/”priority”/“reload-delay”/”source”/”system-id” are obsoleted.
- “set interface aggregate-ethernet xx aggregated-ether-options mlag domain-id” is changed to “set protocols mlag domain xx interface xx link”.
- No MLAG link level “peer-ip” and “peer-link” anymore. Instead only global level configuration for all MLAG links within the same domain are provided.
- “set interface mlag peer x.x.x.x peer-link xx” is changed to “set protocols mlag peer-ip x.x.x.x peer-link xx”.

- By default, all existing MLAG configuration is moved under MLAG domain 1.

Compared with existing MLAG behavior, from 3.6.0, the major differences are as follows:

- No MLAG master/slave election. Instead the MLAG primary/secondary role is determined by the MLAG node configuration.
- No interval-based Hello message. Instead the MLAG Control message is triggered on-demand.
- The MLAG message encapsulation is changed from UDP to TCP.
- The MLAG message format is changed to TLV style.
- Configuration Consistency check is introduced and there is no more configuration sync from master to slave.
- MLAG state machine is changed more user friendly.
- MLAG domain MAC is always used in LACP and STP instead of master's MAC.
- When VXLAN is enabled, the peer link port is always set to access port.

Configuration Notes and Constraints

When configuring MLAG, pay attention to the following notes:

- When peer-link is down, but both the MLAG member ports are up, the split-brain failure scenario occurs. The MLAG system will operate abnormally and cannot be automatically recovered in this scenario. To ensure the reliability of peer-link, note the following points when configuring and deploying the peer-link:
  - When configuring the peer link, only the LAG port is supported. In other words, the peer link must always be a LAG port.
  - A minimum of two directly connected physical ports should be used for peer link LAG port. The peer link connecting the two MLAG peer devices should be directly connected meaning that no intermediate transmission devices should be used on the peer link. All of the directly connected physical ports should be added into one LAG port to form the peer-link. We don't support more than one L2 connection between MLAG peer switches meaning that only one peer link is supported between the two peer devices.
  - 10G or 40G speed ports should be used on peer link. It is highly recommended to provide enough bandwidth for the peer link when the network is deployed.
  - Any manual action to shutdown the peer link is strictly forbidden.
  - Any MLAG VLAN and non-MLAG VLAN MUST be allowed on MLAG peer-link.
  - When numerous rapid PVST+ instances are configured, exceeding the default BPDU queue processing rate in CPU will result in BPDU packet loss or network loops. To resolve this problem, you can use CoPP command **set class-of-service scheduler bpdu-scheduler max-bandwidth-pps** <*value*> to increase the maximum bandwidth of BPDU queue. By default, the value is 80pps.
  - When numerous MLAG instances are configured, exceeding the default MLAG queue processing rate in CPU will result in MLAG packet loss. To resolve this problem, you can use the following CoPP command to increase the maximum bandwidth for MLAG and MLAG MAC SYNC queues. By default, the value is 80pps.

    set class-of-service scheduler mlag-scheduler max-bandwidth-pps <*value*>

    set class-of-service scheduler mlag-mac-sync-scheduler max-bandwidth-pps <value>
- Please proceed with caution when removing the peer-link interface from a VLAN, it may cause problems in spanning tree calculation if proper attention is not paid to its potential ramifications.
- MLAG supports to deploy with IGMP snooping.
- MLAG supports to deploy with DHCP snooping.
- MLAG supports to deploy with DHCP relay.
- MLAG supports to deploy with rapid PVST+ or MSTP.
- MLAG supports to deploy with VXLAN.
- If an L3 device is dual-home attached to the MLAG domain as a leaf node, ECMP should be configured on the uplink ports of the leaf node instead of LAG.
- When deploying VRRP in MLAG topology, pay attention to following points:
  - A pair of MLAG ports should be added into one VRRP instance. Multiple pairs within the same VLAN can be added into one VRRP instance as well. However, MLAG ports with different VLANs should be added into different VRRP instances.
  - Active-active VRRP should be used in order to support load-balancing between the two links connected to the Access Layer device.
- After the configuration is changed from inconsistent to consistent, you need to restart the MLAG peer devices to ensure that MLAG functions normally.

Configuring MLAG

MLAG configuration process is in the following steps:

1. Configure the VLAN and the VLAN interface.
2. Configure LAG interface and add ports to the LAG.
3. Ping peer IP to verify L3 connection is ok on peer link.
4. Configure the MLAG domain, MLAG node and peer link.
5. Show MLAG domain and configuration consistency to verify MLAG session status is ok.
6. Configure link ID on the MLAG member port.
7. Show MLAG link to verify MLAG port is ok.

Procedure

Step1 Configure the VLAN and the VLAN interface.

a) Configure a VLAN ID.

set vlans vlan-id <*vlan-id*>

b) Configur the L3 VLAN interface.

set vlans vlan-id <*vlan-id*> **l3-interface** <*interface-name*>

c) Configure the L3 interface IP address for peer link port on local MLAG peer device.

set l3-interface vlan-interface <*interface-name*> **address** <ip-*address*> **prefix-length** <*number*>

Step2 Configure LAG interface and add ports to the LAG.

set interface aggregate-ethernet <*lag-interface-name*>

set interface gigabit-ethernet <*port-name*> **ether-options 802.3ad** <*lag-interface-name*>

Step3 Ping peer IP to verify L3 connection is ok on peer link.

Step4 Configure an MLAG domain ID.

set protocols mlag domain <*domain-id*>

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify the node number for each MLAG peer device. One of the MLAG peer devices should be Node 0 and the other is Node 1.

set protocols mlag domain <*domain-id*> **node** <**0 | 1**>

Step6 Configure the peer IP address and peer link port.

set protocols mlag domain <*domain-id*> **peer-ip** <*peer-ipv4-address*> **peer-link** <*peer-interface-name*>

NOTE: Peer-link port should be configured as a LAG port.

Step7 Show the MLAG domain and configuration consistency to verify MLAG session status is ok.

run show mlag domain {<*domain-id*>| **summary**}

run show mlag consistency-parameter { **link** <link-id>| **summary**}

Step8 Configure link ID on the MLAG member port.

set protocols mlag domain <*domain-id*> **interface** <*lag-interface*> **link** <*link-id*>

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

set protocols mlag domain <*domain-id*> **peer-ip** <*peer-ipv4-address*> **peer-vlan** <*vlan-id*>

Step10 Show the MLAG link to verify MLAG port is ok.

run show mlag link {<*link-id*>| **summary**}

Configuration Example of MLAG

- Example for Configuring a Basic MLAG
- Example for Configuring MLAG with Active-Active-VRRP
- Example for Configuring MLAG with DHCP Relay
- Example for Configuring MLAG with DHCP Snooping
- Example for Configuring MLAG with IGMP Snooping
- Example for Configuring MLAG with Rapid PVST+

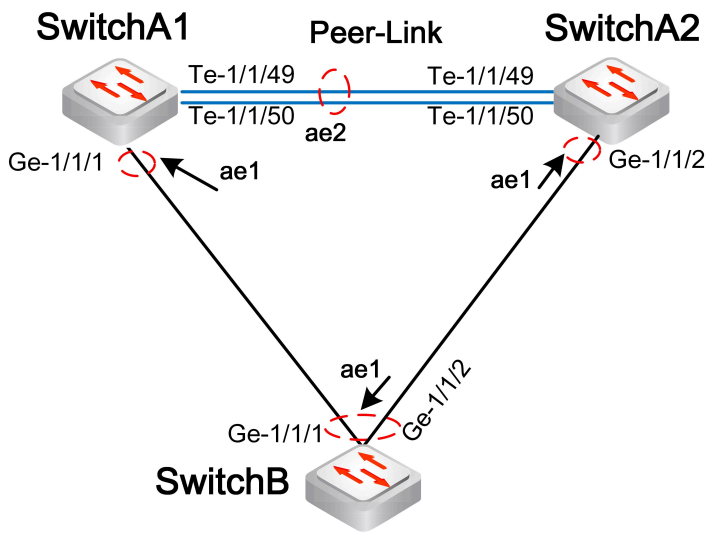
Example for Configuring a Basic MLAG

- Networking Requirements
- Procedure
  - SwitchA1
  - SwitchA2
  - SwitchB
- Verify the Configuration

Networking Requirements

Figure 1 Basic MLAG Topology



In **Figure 1**, SwitchB dual accesses the network through SwitchA1 and SwitchA2 using LACP LAG.

At first, SwitchB accesses the network through SwitchA1. If SwitchA1 or the link between SwitchB and SwitchA1 fails, SwitchB cannot communicate with the network. To avoid service interruptions, we can configure MLAG on SwitchA1 and SwitchA2. When communication between SwitchB and SwitchA1 fails, traffic from the SwitchB will be switched to SwitchA2 seamlessly. When SwitchA1 or the link between SwitchB and SwitchA1 recovers, traffic from the SwitchB will be switched back to SwitchA1.

The peer link between SwitchA1 and SwitchA2 is configured to carry MLAG related control traffic and is very critical to the operation of MLAG function.

Procedure

SwitchA1

Step1 Configure the VLANs.

```
admin@SwitchA1# set vlans vlan-id 15
admin@SwitchA1# set vlans vlan-id 16
admin@SwitchA1# set vlans vlan-id 4088 l3-interface vlan4088
admin@SwitchA1# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@SwitchA1# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15
admin@SwitchA1# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16
admin@SwitchA1# set interface aggregate-ethernet ae2 family ethernet-switching native-vlan-id 4088
admin@SwitchA1# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk
admin@SwitchA1# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15
admin@SwitchA1# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16
```

Step2 Configure MLAG interfaces with LACP mode.

```
admin@SwitchA1# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
```

Step3 Add member interfaces to a LAG.

```
admin@SwitchA1# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@SwitchA1# set interface gigabit-ethernet te-1/1/49 ether-options 802.3ad ae2
admin@SwitchA1# set interface gigabit-ethernet te-1/1/50 ether-options 802.3ad ae2
```

Step4 Configure an MLAG domain ID.

admin@SwitchA1# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify SwitchA1 as MLAG Node 0.

admin@SwitchA1# set protocols mlag domain 10 node 0

Step6 Configure the peer IP address and peer link port.

admin@SwitchA1# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-link ae2

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@SwitchA1# set l3-interface vlan-interface vlan4088 address 10.10.0.1 prefix-length 24

Step8 Configure link ID for the MLAG member port.

admin@SwitchA1# set protocols mlag domain 10 interface ae1 link 2

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

admin@SwitchA1# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-vlan 4088

Step10 Commit the configuration.

admin@SwitchA1# commit

SwitchA2

The configuration on SwitchA2 is the same as SwitchA1.

Step1 Configure the VLANs.

admin@SwitchA2# set vlans vlan-id 15

admin@SwitchA2# set vlans vlan-id 16

admin@SwitchA2# set vlans vlan-id 4088 l3-interface vlan4088

admin@SwitchA2# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@SwitchA2# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15

admin@SwitchA2# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16

admin@SwitchA2# set interface aggregate-ethernet ae2 family ethernet-switching native-vlan-id 4088

admin@SwitchA2# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk

admin@SwitchA2# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15

admin@SwitchA2# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16

Step2 Configure MLAG interfaces with LACP mode.

admin@SwitchA2# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

Step3 Add member interfaces to a LAG.

admin@SwitchA2# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@SwitchA2# set interface gigabit-ethernet te-1/1/49 ether-options 802.3ad ae2

admin@SwitchA2# set interface gigabit-ethernet te-1/1/50 ether-options 802.3ad ae2

Step4 Configure an MLAG domain ID.

admin@SwitchA2# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify SwitchA2 as MLAG Node 1.

admin@SwitchA2# set protocols mlag domain 10 node 1

Step6 Configure the peer IP address and peer link port.

admin@SwitchA2# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-link ae2

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@SwitchA2# set l3-interface vlan-interface vlan4088 address 10.10.0.2 prefix-length 24

Step8 Configure link ID for the MLAG member port.

admin@SwitchA2# set protocols mlag domain 10 interface ae1 link 2

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

admin@SwitchA2# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-vlan 4088

Step10 Commit the configuration.

admin@SwitchA2# commit

SwitchB

Step1 Enable aggregation interface with LACP mode.

admin@SwitchB# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

Step2 Add member interfaces to a LAG.

admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1

Step3 Configure VLAN.

admin@SwitchB# set vlans vlan-id 15

admin@SwitchB# set vlans vlan-id 16

admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15

admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16

Step4 Commit the configuration.

admin@SwitchB# commit

Verify the Configuration

- You can use the **run show mlag domain** command to display the global MLAG domain information.

```
admin@SwitchA1# run show mlag domain summary
Domain ID: 10    Domain MAC: 48:6E:73:FF:00:0a    Node ID: 0
-------------------------------------------------------------------------
Peer Link  Peer IP          Peer Vlan  Neighbor Status  Config Matched   MAC Synced   # of Links
---------  ---------------  ---------  ---------------  --------------   ----------   ----------
ae2        10.10.10.2       4088       ESTABLISHED       Yes              Yes           1
```

- You can use the **run show mlag link** command to display MLAG link information.

```
admin@SwitchA1# run show mlag link summary
# of Links: 1
Link   Local LAG   Link Status   Local Status   Peer Status    Config Matched   Flood
----   ---------   -----------   ------------   -----------     --------------   -----
2      ae1          IDLE            UP           UNKNOWN        No              No
```

- You can use the **run show mlag consistency-parameter** command to display the result of MLAG configuration consistency check, including the global and per MLAG configuration.

```
admin@SwitchA1# run show mlag consistency-parameter link 2

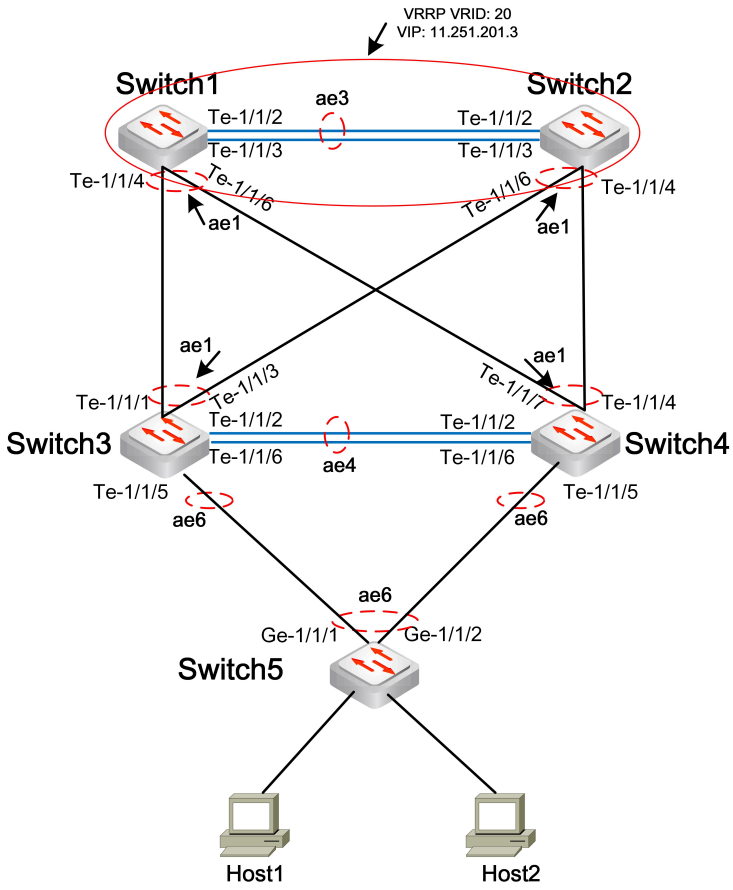
Example for Configuring MLAG with Active-Active-VRRP

- Networking Requirements
  - Basic Deployment
  - Networking Address Planning
- Procedure
  - Switch1
  - Switch2
  - Switch3
  - Switch4
  - Switch5
- Verify the Configuration

Networking Requirements

Figure 1. User Configuration Topology of MLAG with VRRP



When an MLAG is configured to provide L3 routing functions to downstream clients, the MLAG peers should provide the same gateway address to the downstream clients. VRRP groups combine the MLAG peer devices into a virtual router and use the IP address of the VRRP virtual router to communicate with the access devices as the default gateway address. When one device in the VRRP group fails, VRRP mechanism can elect a new gateway to transmit service traffic thus ensuring the reliable operation of the layer-3 network.

Basic Deployment

- In **Figure 1**, a two-layer MLAG is deployed in the topology, where Switch1 and Switch2 form an MLAG peer at aggregation layer, Switch3 and Switch4 form an MLAG peer at access layer. Switch1and Switch2 are in MLAG domain 1; Switch3 and Switch4 are in MLAG domain 2. It is mandatory that different pairs of MLAG peer devices should use different domain IDs.
- In the two-layer MLAG topology, MLAG member ports on the MLAG peer in the same domain MUST belong to the same MLAG, that is, the member ports should be configured with the same link ID. Use link ID 1 on Switch1 and Switch2 to bind all the MLAG member ports, link ID 2 is used on Switch3 and Switch4.
- Active-Active VRRP is deployed on Switch1 and Switch2 as Gateway for Host devices of VLAN 20.
- Access Switch5 dual-accesses to the network through Switch3 and Switch4 by LAG interface.

Networking Address Planning

The networking IP address planning is shown in the following table.

Switch	Physical Interface	Aggregate Interface	VLAN Interface and IP Address
Switch1	Te-1/1/2	ae3	VLAN interface 4092: 192.168.45.2
	Te-1/1/3		
	Te-1/1/4	ae1	VLAN interface 20: 11.251.201.1
	Te-1/1/6		VRRP virtual IP: 11.251.201.3
Switch2	Te-1/1/2	ae3	VLAN interface 4092: 192.168.45.1
	Te-1/1/3		
	Te-1/1/4	ae1	VLAN interface 20: 11.251.201.2
	Te-1/1/6		VRRP virtual IP: 11.251.201.3
Switch3	Te-1/1/2	ae4	VLAN interface 4093: 192.168.46.2
	Te-1/1/6		
	Te-1/1/1	ae1	-
	Te-1/1/3		
	Te-1/1/5	ae6	-
Switch4	Te-1/1/2	ae4	VLAN interface 4093: 192.168.46.1
	Te-1/1/6		
	Te-1/1/4	ae1	-
	Te-1/1/7		
	Te-1/1/5	ae6	-
Switch5	Ge-1/1/1	ae6	-
	Ge-1/1/2		

Procedure

Switch1

Step1 Configure the aggregation interface with LACP mode.

```
admin@Switch1# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
```

Step2 Configure the VLANs.

```
admin@Switch1# set vlans vlan-id 10-19
admin@Switch1# set vlans vlan-id 20 l3-interface 20
admin@Switch1# set vlans vlan-id 4088 l3-interface 4088
admin@Switch1# set interface aggregate-ethernet ae1 family ethernet-switching native-vlan-id 10
admin@Switch1# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 10-19
admin@Switch1# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 20
admin@Switch1# set interface aggregate-ethernet ae3 family ethernet-switching native-vlan-id 4088
admin@Switch1# set interface aggregate-ethernet ae3 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 10-19
admin@Switch1# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 20
```

Step3 Configure the L3 interface IP address.

```
admin@Switch1# set l3-interface vlan-interface 4088 address 192.168.45.2 prefix-length 24
admin@Switch1# set l3-interface vlan-interface 20 address 11.251.201.1 prefix-length 24
```

Step4 Add interfaces to the LAG port.

```
admin@Switch1# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae3
admin@Switch1# set interface gigabit-ethernet te-1/1/3 ether-options 802.3ad ae3
admin@Switch1# set interface gigabit-ethernet te-1/1/4 ether-options 802.3ad ae1
admin@Switch1# set interface gigabit-ethernet te-1/1/6 ether-options 802.3ad ae1
```

Step5 Configure MLAG domain ID.

```
admin@Switch1# set protocols mlag domain 1
```

Step6 Specify Switch1 as Node 0 of MLAG domain 1.

```
admin@Switch1# set protocols mlag domain 1 node 0
```

Step7 Configure link ID on the MLAG member port.

```
admin@Switch1# set protocols mlag domain 1 interface ae1 link 1
```

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step8 Configure the peer IP address and the peer-link for the MLAG peer.

```
admin@Switch1# set protocols mlag domain 1 peer-ip 192.168.45.1 peer-link ae3
```

Step9 Configure MLAG peer VLAN.

```
admin@Switch1# set protocols mlag domain 1 peer-ip 192.168.45.1 peer-vlan 4088
```

Step10 Enable Active-Active-VRRP function.

```
admin@Switch1# set protocols vrrp interface 20 vrid 20 ip 11.251.201.3
admin@Switch1# set protocols vrrp interface 20 vrid 20 load-balance disable false
```

Step11 Commit the configuration.

```
admin@Switch1# commit
```

Switch2

Step1 Configure the aggregation interface with LACP mode.

```
admin@Switch2# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
```

Step2 Configure the VLANs.

```
admin@Switch2# set vlans vlan-id 10-19
admin@Switch2# set vlans vlan-id 20 l3-interface 20
admin@Switch2# set vlans vlan-id 4088 l3-interface 4088
admin@Switch2# set interface aggregate-ethernet ae1 family ethernet-switching native-vlan-id 10
admin@Switch2# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@Switch2# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 10-19
admin@Switch2# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 20
admin@Switch2# set interface aggregate-ethernet ae3 family ethernet-switching native-vlan-id 4088
admin@Switch2# set interface aggregate-ethernet ae3 family ethernet-switching port-mode trunk
admin@Switch2# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 10-19
admin@Switch2# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 20
```

Step3 Configure the L3 interface IP address.

```
admin@Switch2# set l3-interface vlan-interface 4088 address 192.168.45.1 prefix-length 24
admin@Switch2# set l3-interface vlan-interface 20 address 11.251.201.1 prefix-length 24
```

Step4 Add interfaces to the LAG port.

```
admin@Switch2# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae3
admin@Switch2# set interface gigabit-ethernet te-1/1/3 ether-options 802.3ad ae3
admin@Switch2# set interface gigabit-ethernet te-1/1/4 ether-options 802.3ad ae1
admin@Switch2# set interface gigabit-ethernet te-1/1/6 ether-options 802.3ad ae1
```

Step5 Configure MLAG domain ID.

```
admin@Switch2# set protocols mlag domain 1
```

Step6 Specify Switch2 as Node 1 of MLAG domain 1.

```
admin@Switch2# set protocols mlag domain 1 node 1
```

Step7 Configure link ID on the MLAG member port.

```
admin@Switch2# set protocols mlag domain 1 interface ae1 link 1
```

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step8 Configure the peer IP address and the peer-link for the MLAG peer.

```
admin@Switch2# set protocols mlag domain 1 peer-ip 192.168.45.2 peer-link ae3
```

Step9 Configure MLAG peer VLAN.

```
admin@Switch2# set protocols mlag domain 1 peer-ip 192.168.45.2 peer-vlan 4088
```

Step10 Enable Active-Active-VRRP function.

```
admin@Switch2# set protocols vrrp interface 20 vrid 20 ip 11.251.201.3
admin@Switch2# set protocols vrrp interface 20 vrid 20 load-balance disable false
```

Step11 Commit the configuration.

```
admin@Switch2# commit
```

Switch3

Step1 Configure the aggregation interfaces with LACP mode.

```
admin@Switch3# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
admin@Switch3# set interface aggregate-ethernet ae6 aggregated-ether-options lacp enable true
```

Step2 Configure the VLANs.

```
admin@Switch3# set vlans vlan-id 10-20
admin@Switch3# set vlans vlan-id 4088 l3-interface 4088
admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching native-vlan-id 10
admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 10-20
admin@Switch3# set interface aggregate-ethernet ae4 family ethernet-switching native-vlan-id 4088
admin@Switch3# set interface aggregate-ethernet ae4 family ethernet-switching port-mode trunk
admin@Switch3# set interface aggregate-ethernet ae4 family ethernet-switching vlan members 10-20
admin@Switch3# set interface aggregate-ethernet ae6 family ethernet-switching native-vlan-id 10
admin@Switch3# set interface aggregate-ethernet ae6 family ethernet-switching port-mode trunk
admin@Switch3# set interface aggregate-ethernet ae6 family ethernet-switching vlan members 10-20
```

Step3 Configure the L3 interface IP address.

```
admin@Switch3# set l3-interface vlan-interface 4088 address 192.168.46.2 prefix-length 24
```

Step4 Configure MLAG domain ID.

```
admin@Switch3# set protocols mlag domain 2
```

Step5 Specify Switch3 as Node 0 of MLAG domain 2.

```
admin@Switch3# set protocols mlag domain 2 node 0
```

Step6 Configure link ID on the MLAG member port.

```
admin@Switch3# set protocols mlag domain 2 interface ae1 link 2
```

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step7 Add member interfaces to the LAG ports.

```
admin@Switch3# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae4
admin@Switch3# set interface gigabit-ethernet te-1/1/6 ether-options 802.3ad ae4
admin@Switch3# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae1
admin@Switch3# set interface gigabit-ethernet te-1/1/3 ether-options 802.3ad ae1
admin@Switch3# set interface gigabit-ethernet te-1/1/5 ether-options 802.3ad ae6
```

Step8 Configure the peer IP address and the peer-link for the MLAG peer.

```
admin@Switch3# set protocols mlag domain 2 peer-ip 192.168.46.1 peer-link ae4
```

Step9 Configure MLAG peer VLAN.

```
admin@Switch3# set protocols mlag domain 2 peer-ip 192.168.46.1 peer-vlan 4088
```

Step10 Commit the configuration.

```
admin@Switch3# commit
```

Switch4

Step1 Configure the aggregation interfaces with LACP mode.

```
admin@Switch4# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
admin@Switch4# set interface aggregate-ethernet ae6 aggregated-ether-options lacp enable true
```

Step2 Configure the VLANs.

```
admin@Switch4# set vlans vlan-id 10-20
admin@Switch4# set vlans vlan-id 4088 l3-interface 4088
admin@Switch4# set interface aggregate-ethernet ae1 family ethernet-switching native-vlan-id 10
admin@Switch4# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@Switch4# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 10-20
admin@Switch4# set interface aggregate-ethernet ae4 family ethernet-switching native-vlan-id 4088
admin@Switch4# set interface aggregate-ethernet ae4 family ethernet-switching port-mode trunk
admin@Switch4# set interface aggregate-ethernet ae4 family ethernet-switching vlan members 10-20
admin@Switch4# set interface aggregate-ethernet ae6 family ethernet-switching native-vlan-id 10
admin@Switch4# set interface aggregate-ethernet ae6 family ethernet-switching port-mode trunk
admin@Switch4# set interface aggregate-ethernet ae6 family ethernet-switching vlan members 10-20
```

Step3 Configure the L3 interface IP address.

```
admin@Switch4# set l3-interface vlan-interface 4088 address 192.168.46.1 prefix-length 24
```

Step4 Configure MLAG domain ID.

```
admin@Switch4# set protocols mlag domain 2
```

Step5 Specify Switch4 as Node 1 of MLAG domain 2.

```
admin@Switch4# set protocols mlag domain 2 node 1
```

Step6 Configure link ID on the MLAG member port.

```
admin@Switch4# set protocols mlag domain 2 interface ae1 link 2
```

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step7 Add member interfaces to the LAG ports.

```
admin@Switch4# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae4
admin@Switch4# set interface gigabit-ethernet te-1/1/6 ether-options 802.3ad ae4
admin@Switch4# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae1
admin@Switch4# set interface gigabit-ethernet te-1/1/3 ether-options 802.3ad ae1
admin@Switch4# set interface gigabit-ethernet te-1/1/5 ether-options 802.3ad ae6
```

Step8 Configure the peer IP address and the peer-link for the MLAG peer.

```
admin@Switch4# set protocols mlag domain 2 peer-ip 192.168.46.2 peer-link ae4
```

Step9 Configure MLAG peer VLAN.

```
admin@Switch4# set protocols mlag domain 2 peer-ip 192.168.46.2 peer-vlan 4088
```

Step10 Commit the configuration.

```
admin@Switch4# commit
```

Switch5

Step1 Enable the aggregation interface with LACP mode.

```
admin@Switch5# set interface aggregate-ethernet ae6 aggregated-ether-options lacp enable true
```

Step2 Add the interfaces to the LAG ports.

```
admin@Switch5# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae6
admin@Switch5# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae6
```

Step3 Configure the VLANs.

```
admin@Switch5# set vlans vlan-id 10-20
admin@Switch5# set interface aggregate-ethernet ae6 family ethernet-switching native-vlan-id 10
admin@Switch5# set interface aggregate-ethernet ae6 family ethernet-switching port-mode trunk
admin@Switch5# set interface aggregate-ethernet ae6 family ethernet-switching vlan members 10-20
```

Verify the Configuration

- You can use the **run show mlag domain** command to display the global MLAG domain information.

```
admin@Switch1# run show mlag domain summary
Domain ID: 1 Domain MAC: 48:6E:73:FF:00:01 Node ID: 0
------------------------------------------------------------------------

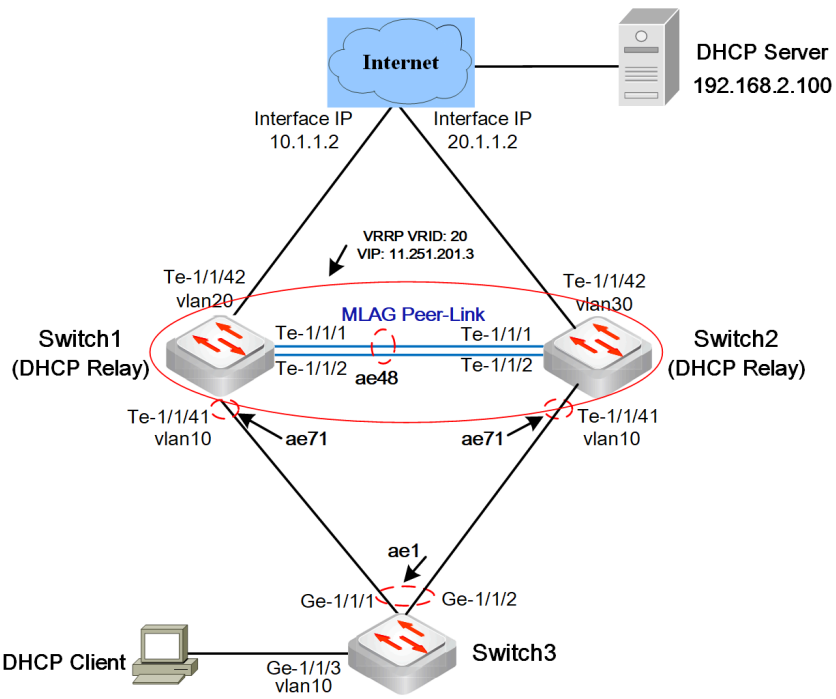
Networking Requirements

Figure 1. Example for Configuring MLAG with DHCP Relay



As shown in **Figure 1**, Switch 1 and Switch 2 are a pair of MLAG peers. DHCP client connects to Switch 3 which is dual-homed to the MLAG network. The DHCP client in network segment 10.20.20.0/24 wants to dynamically obtain IP address from the DHCP server which is in a different subnet. In this case, we need to configure DHCP relay on MLAG peers to forward DHCP packets between client and server.

When an MLAG is deployed to provide L3 routing functions to downstream clients, the MLAG peers should provide the same gateway address to the downstream clients. VRRP groups combine the MLAG peer devices into a virtual router and use the IP address of the VRRP virtual router to communicate with the access devices as the default gateway address.

Follow the configuration roadmap below to complete the example for configuring MLAG with DHCP relay:

1. Configure Switch 1 and Switch 2 as an MLAG pair.
2. Configure Active-Active VRRP on Switch1 and Switch2 as a virtual Gateway for DHCP client.
3. Enable DHCP relay on Switch 1 and Switch 2.
   - DHCP relay configuration should be identical on both MLAG peer devices.
   - Configure DHCP relay agent IP address to use VRRP virtual IP.
4. Configure a route to DHCP server on Switch 1 and Switch 2. The static route is used as an example.
5. As a Layer 2 device, access Switch3 dual-accesses to the network through Switch1 and Switch2 by a LAG interface.
6. Configure the DHCP client with a gateway address that is the IP address of the VRRP virtual router.

Procedure

Switch1

MLAG Configuration

Step1 Configure the VLANs.

```
admin@Switch1# set vlans vlan-id 10
admin@Switch1# set vlans vlan-id 4088 l3-interface vlan4088
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching native-vlan-id 4088
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching vlan members 10
admin@Switch1# set interface aggregate-ethernet ae71 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae71 family ethernet-switching vlan members 10
```

Step2 Configure aggregation interfaces with LACP mode.

```
admin@Switch1# set interface aggregate-ethernet ae71 aggregated-ether-options lacp enable true
admin@Switch1# set interface aggregate-ethernet ae48 aggregated-ether-options lacp enable true
```

Step3 Add member interfaces to the LAG.

```
admin@Switch1# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae48
admin@Switch1# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae48
admin@Switch1# set interface gigabit-ethernet te-1/1/41 ether-options 802.3ad ae71
```

Step4 Configure an MLAG domain ID.

```
admin@Switch1# set protocols mlag domain 10
```

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify Switch1 as MLAG Node 0.

```
admin@Switch1# set protocols mlag domain 10 node 0
```

Step6 Configure the L3 interface IP address for peer link port on local MLAG peer device.

```
admin@Switch1# set l3-interface vlan-interface vlan4088 address 10.10.0.1 prefix-length 24
```

Step7 Configure link ID for the MLAG member port.

```
admin@Switch1# set protocols mlag domain 10 interface ae71 link 1
```

NOTE: The paired MLAG member ports separately configured on two MLAG peer must be bound to the same MLAG link ID.

Step8 Configure MLAG peer link and peer VLAN.

```
admin@Switch1# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-link ae48
admin@Switch1# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-vlan 4088
```

NOTE: Peer-link port should be configured as a LAG port.

VRRP Configuration

Step 1 Configure the L3 interface IP address.

```
admin@Switch1# set l3-interface vlan-interface vlan10 address 11.251.201.1 prefix-length 24
```

Step 2 Enable Active-Active-VRRP function.

```
admin@Switch1# set protocols vrrp interface vlan10 vrid 100 ip 11.251.201.3
admin@Switch1# set protocols vrrp interface vlan10 vrid 100 load-balance disable false
```

DHCP Relay Configuration

Step 1 Enable IP routing function when using DHCP relay.

```
admin@Switch1# set ip routing enable true
```

Step 2 Enable the DHCP relay function on L3 VLAN interface vlan10.

```
admin@Switch1# set protocols dhcp relay interface vlan10 disable false
```

Step 3 Configure the IP address of DHCP server 192.168.2.100.

```
admin@Switch1# set protocols dhcp relay interface vlan10 dhcp-server-address 192.168.2.100
```

Step 4 Configure DHCP relay agent IP address to use VRRP virtual IP.

```
admin@Switch1# set protocols dhcp relay interface vlan10 relay-agent-address 11.251.201.3
```

Other Configuration

Step1 Configure VLAN and VLAN interface.

```
admin@Switch1# set vlans vlan-id 20
admin@Switch1# set vlans vlan-id 20 l3-interface vlan20
admin@Switch1# set interface gigabit-ethernet te-1/1/42 family ethernet-switching native-vlan-id 20
admin@Switch1# set l3-interface vlan-interface vlan20 address 10.1.1.1 prefix-length 24
```

Step 2 Configure route to DHCP server. The following command configures static route as an example.

```
admin@Switch1# set protocols static route 192.168.2.0/24 next-hop 10.1.1.2
```

Step 3 Commit the configuration.

```
admin@Switch1# commit
```

Switch2

MLAG Configuration

Step 1 Configure the VLANs.

```
admin@Switch2# set vlans vlan-id 10
admin@Switch2# set vlans vlan-id 4088 l3-interface vlan4088
admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching native-vlan-id 4088
admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching port-mode trunk
admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching vlan members 10
admin@Switch2# set interface aggregate-ethernet ae71 family ethernet-switching port-mode trunk
admin@Switch2# set interface aggregate-ethernet ae71 family ethernet-switching vlan members 10
```

Step 2 Configure aggregation interfaces with LACP mode.

```
admin@Switch2# set interface aggregate-ethernet ae71 aggregated-ether-options lacp enable true
admin@Switch2# set interface aggregate-ethernet ae48 aggregated-ether-options lacp enable true
```

Step 3 Add member interfaces to the LAG.

```
admin@Switch2# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae48
admin@Switch2# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae48
admin@Switch2# set interface gigabit-ethernet te-1/1/41 ether-options 802.3ad ae71
```

Step 4 Configure an MLAG domain ID.

```
admin@Switch2# set protocols mlag domain 10
```

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step 5 Specify Switch2 as MLAG Node 1.

```
admin@Switch2# set protocols mlag domain 10 node 1
```

Step 6 Configure the L3 interface IP address for peer link port on local MLAG peer device.

```
admin@Switch2# set l3-interface vlan-interface vlan4088 address 10.10.0.2 prefix-length 24
```

Step 7 Configure link ID for the MLAG member port.

```
admin@Switch2# set protocols mlag domain 10 interface ae71 link 1
```

NOTE: The paired MLAG member ports separately configured on two MLAG peer must be bound to the same MLAG link ID.

Step 8 Configure MLAG peer link and peer VLAN.

```
admin@Switch2# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-link ae48
admin@Switch2# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-vlan 4088
```

NOTE: Peer-link port should be configured as a LAG port.

VRRP Configuration

Step 1 Configure the L3 interface IP address.

```
admin@Switch2# set l3-interface vlan-interface vlan10 address 11.251.201.2 prefix-length 24
```

Step 2 Enable Active-Active-VRRP function.

```
admin@Switch2# set protocols vrrp interface vlan10 vrid 100 ip 11.251.201.3
admin@Switch2# set protocols vrrp interface vlan10 vrid 100 load-balance disable false
```

DHCP Relay Configuration

Step 1 Enable IP routing function when using DHCP relay.

```
admin@Switch2# set ip routing enable true
```

Step 2 Enable the DHCP relay function on L3 VLAN interface vlan10.

```
admin@Switch2# set protocols dhcp relay interface vlan10 disable false
```

Step 3 Configure the IP address of DHCP server 192.168.2.100.

```
admin@Switch2# set protocols dhcp relay interface vlan10 dhcp-server-address 192.168.2.100
```

Step 4 Configure DHCP relay agent IP address to use VRRP virtual IP.

```
admin@Switch2# set protocols dhcp relay interface vlan10 relay-agent-address 11.251.201.3
```

Other Configuration

Step1 Configure VLAN and VLAN interface.

```
admin@Switch2# set vlans vlan-id 30
admin@Switch2# set vlans vlan-id 30 l3-interface vlan30
admin@Switch2# set interface gigabit-ethernet te-1/1/42 family ethernet-switching native-vlan-id 30
admin@Switch2# set l3-interface vlan-interface vlan30 address 20.1.1.1 prefix-length 24
```

Step2 Configure a route to DHCP server. The following command uses the static route as an example.

```
admin@Switch2# set protocols static route 192.168.2.0/24 next-hop 20.1.1.2
```

Step3 Commit the configuration.

```
admin@Switch2# commit
```

Switch3

Step1 Enable aggregation interface with LACP mode.

```
admin@Switch3# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
```

Step2 Add member interfaces to a LAG.

```
admin@Switch3# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@Switch3# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1
```

Step3 Configure VLAN.

```
admin@Switch3# set vlans vlan-id 10
admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching native-vlan-id 10
```

Step4 Commit the configuration.

```
admin@Switch3# commit
```

Verify the Configuration

- You can use the **run show mlag domain** command to display the global MLAG domain information.

```
admin@Switch1# run show mlag domain summary
Domain ID: 10    Domain MAC: 62:9E:73:FF:00:01    Node ID: 0

```

- You can use **run show vrrp** command to view the configuration information of VRRP group. The result of show command on Switch1 is as follows.

```
admin@Switch1# run show vrrp
Interface: vlan10
VRID: 100
Version: 2
Load-balance: enable
State: Master
Master IP: 11.251.201.1
Virtual MAC: 00:00:5e:00:01:01
Preempt: disable
Adver Interval: 1
Priority: 250
Virtual IP: 11.251.201.3
Auth-type: none
Auth-key:
```

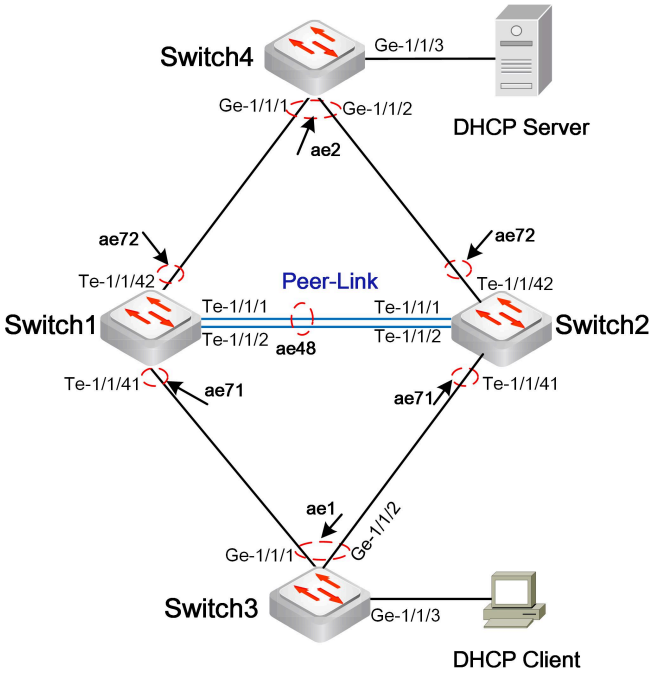
- DHCP client can obtain the IP address normally.

Example for Configuring MLAG with DHCP Snooping

- Networking Requirements
- Procedure
  - Switch1
  - Switch2
  - Switch3
  - Switch4
  - Verify the Configuration

Networking Requirements

Figure 1 User Configuration Topology of MLAG with DHCP Snooping



As shown in **Figure 1**, Switch 1 and Switch 2 are Layer 2 switches and form a pair of MLAG peer devices. The DHCP client is connected to Switch3 which is dual-homed to the MLAG network. The DHCP server is connected to Switch4 which is dual-homed to the MLAG network. In the MLAG topology, to provide better services to DHCP client, the network administrator can configure DHCP snooping on Switch1, Switch2, Switch3 and Switch4, to defend against DHCP attacks.

When configuring the network, you need to pay attention to the following points:

- Switch3 is dual-homed to MLAG peer devices Switch 1 and Switch 2, the link ID is 1. Switch 4 is dual-homed to Switch 1 and Switch 2, the link ID is 2.
- DHCP snooping configuration should be identical on both MLAG peer devices.
- The peer link port should be configured as trust port on demand.
- On Switch1, Switch2, Switch3 and Switch4, configure the interfaces in the direction of the DHCP server as DHCP snooping trusted interfaces.

Procedure

Switch1

Step1 Configure the VLANs.

```
admin@Switch1# set vlans vlan-id 10
admin@Switch1# set vlans vlan-id 4088 l3-interface vlan4088
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching native-vlan-id 4088
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching vlan members 10
admin@Switch1# set interface aggregate-ethernet ae71 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae71 family ethernet-switching vlan members 10
admin@Switch1# set interface aggregate-ethernet ae72 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae72 family ethernet-switching vlan  members 10
```

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch1# set interface aggregate-ethernet ae71 aggregated-ether-options lacp enable true

admin@Switch1# set interface aggregate-ethernet ae72 aggregated-ether-options lacp enable true

Step3 Add member interfaces to a LAG.

admin@Switch1# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae48

admin@Switch1# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae48

admin@Switch1# set interface gigabit-ethernet te-1/1/41 ether-options 802.3ad ae71

admin@Switch1# set interface gigabit-ethernet te-1/1/42 ether-options 802.3ad ae72

Step4 Configure an MLAG domain ID.

admin@Switch1# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify Switch1 as MLAG Node 0.

admin@Switch1# set protocols mlag domain 10 node 0

Step6 Configure the peer IP address and peer link port.

admin@Switch1# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-link ae48

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@Switch1# set l3-interface vlan-interface vlan4088 address 10.10.0.1 prefix-length 24

Step8 Configure link ID for the MLAG member port.

admin@Switch1# set protocols mlag domain 10 interface ae71 link 1

admin@Switch1# set protocols mlag domain 10 interface ae72 link 2

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

admin@Switch1# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-vlan 4088

Step10 Enable DHCP snooping function.

admin@Switch1# set protocols dhcp snooping vlan 10 disable false

Step11 Configure the interface connected to the DHCP server and peer-link port as DHCP snooping trusted interfaces.

admin@Switch1# set protocols dhcp snooping trust-port ae48

admin@Switch1# set protocols dhcp snooping trust-port ae72

Step12 Commit the configuration.

admin@Switch1# commit

Switch2

Step1 Configure the VLANs.

admin@Switch2# set vlans vlan-id 10

admin@Switch2# set vlans vlan-id 4088 l3-interface vlan4088

admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching native-vlan-id 4088

admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching port-mode trunk

admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching vlan members 10

admin@Switch2# set interface aggregate-ethernet ae71 family ethernet-switching port-mode trunk

admin@Switch2# set interface aggregate-ethernet ae71 family ethernet-switching vlan members 10

admin@Switch2# set interface aggregate-ethernet ae72 family ethernet-switching port-mode trunk

admin@Switch2# set interface aggregate-ethernet ae72 family ethernet-switching vlan members 10

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch2# set interface aggregate-ethernet ae71 aggregated-ether-options lacp enable true

admin@Switch2# set interface aggregate-ethernet ae72 aggregated-ether-options lacp enable true

Step3 Add member interfaces to a LAG.

admin@Switch2# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae48

admin@Switch2# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae48

admin@Switch2# set interface gigabit-ethernet te-1/1/41 ether-options 802.3ad ae71

admin@Switch2# set interface gigabit-ethernet te-1/1/42 ether-options 802.3ad ae72

Step4 Configure an MLAG domain ID.

admin@Switch2# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify Switch2 as MLAG Node 1.

admin@Switch2# set protocols mlag domain 10 node 1

Step6 Configure the peer IP address and peer link port.

admin@Switch2# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-link ae48

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@Switch2# set l3-interface vlan-interface vlan4088 address 10.10.0.2 prefix-length 24

Step8 Configure link ID for the MLAG member port.

admin@Switch2# set protocols mlag domain 10 interface ae71 link 1

admin@Switch2# set protocols mlag domain 10 interface ae72 link 2

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

admin@Switch2# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-vlan 4088

Step10 Enable DHCP snooping function.

admin@Switch2# set protocols dhcp snooping vlan 10 disable false

Step11 Configure the interface connected to the DHCP server and peer-link port as DHCP snooping trusted interfaces.

admin@Switch2# set protocols dhcp snooping trust-port ae48

admin@Switch2# set protocols dhcp snooping trust-port ae72

Step12 Commit the configuration.

admin@Switch2# commit

Switch3

Step1 Configure the VLANs.

admin@Switch3# set vlans vlan-id 10

admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 10

admin@Switch3# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 10

admin@Switch3# set interface gigabit-ethernet ge-1/1/3 description "to-client"

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch3# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@Switch3# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1

admin@Switch3# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

Step3 Enable DHCP snooping function.

admin@Switch3# set protocols dhcp snooping vlan 10 disable false

Step4 Configure ae1 as DHCP snooping trusted port.

admin@Switch3# set protocols dhcp snooping trust-port ae1

Step5 Commit the configuration.

admin@Switch3# commit

Switch4

Step1 Configure the VLANs.

admin@Switch4# set vlans vlan-id 10

admin@Switch4# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk

admin@Switch4# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 10

admin@Switch4# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 10

admin@Switch4# set interface gigabit-ethernet ge-1/1/3 description "to-server"

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch4# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae2

admin@Switch4# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2

admin@Switch4# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true

Step3 Enable DHCP snooping function.

admin@Switch4# set protocols dhcp snooping vlan 10 disable false

Step4 Configure ge-1/1/3 as DHCP snooping trusted port.

admin@Switch4# set protocols dhcp snooping trust-port ge-1/1/3

Step5 Commit the configuration.

```
admin@Switch4# commit
```

Verify the Configuration

- You can use the **run show mlag domain** command to display the global MLAG domain information.

```
admin@Switch1# run show mlag domain summary
Domain ID: 10    Domain MAC: 48:6E:73:FF:00:0a    Node ID: 0
-------------------------------------------------------------------------
Peer Link  Peer IP  Peer Vlan  Neighbor Status  Config Matched  MAC Synced  # of Links
---------  --------  ------     ---------        --------------  ----------  ----------
ae48      10.10.10.1  4088       ESTABLISHED     Yes              Yes          1
ae48      10.10.10.1  4088       ESTABLISHED     Yes              Yes          2
```

- You can use the **run show mlag link** command to display MLAG link information.

```
admin@Switch1# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer Status   Config Matched   Flood

```

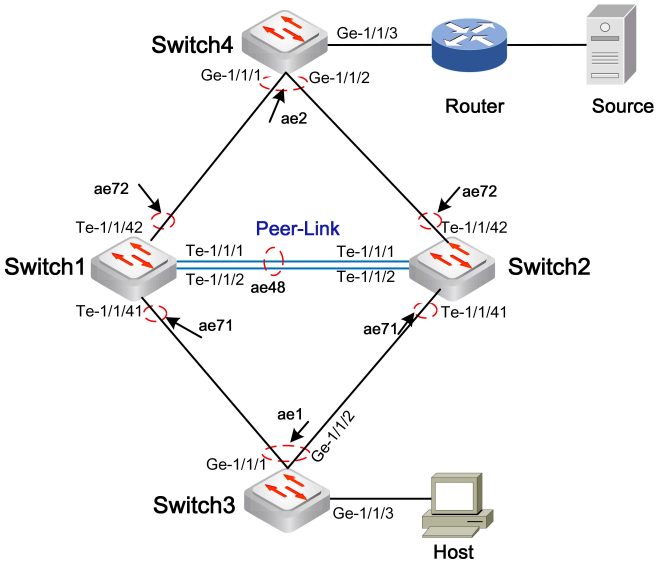
Example for Configuring MLAG with IGMP Snooping

- Networking Requirements
- Procedure
  - Switch1
  - Switch2
  - Switch3
  - Switch4
- Verify the Configuration

Networking Requirements

Figure 1 User Configuration Topology of MLAG with IGMP Snooping



As shown in **Figure 1**, a Host connects to a multicast source through the MLAG topology and a Layer 3 Router to receive multicast data from the Source device. Switch3 and Switch4 have dual access to the network through the MLAG peer devices Switch1 and Switch2.

Perform the following procedures on Switch1, Switch2, Switch3 and Switch4 to implement MLAG with IGMP snooping:

- Deploy basic MLAG configurations on Switch1 and Switch2 to form an MLAG topology.
- Enable global and VLAN-based IGMP snooping function on all the switches.

Configuration Notes:

- IGMP snooping configuration should be identical on both MLAG peer devices
- Only the dynamic Layer 2 multicast forwarding entries are synchronized between the MLAG peers, static entries are not synchronized.
- Generally, it is not necessary to configure mrouter port on the peer link.

Procedure

Switch1

Step1 Configure the VLANs.

```
admin@Switch1# set vlans vlan-id 10
admin@Switch1# set vlans vlan-id 4088 l3-interface vlan4088
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching native-vlan-id 4088
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae48 family ethernet-switching vlan members 10
admin@Switch1# set interface aggregate-ethernet ae71 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae71 family ethernet-switching vlan members 10
admin@Switch1# set interface aggregate-ethernet ae72 family ethernet-switching port-mode trunk
admin@Switch1# set interface aggregate-ethernet ae72 family ethernet-switching vlan members 10
```

Step2 Configure aggregation interfaces with LACP mode.

```
admin@Switch1# set interface aggregate-ethernet ae71 aggregated-ether-options lacp enable true
admin@Switch1# set interface aggregate-ethernet ae72 aggregated-ether-options lacp enable true
```

Step3 Add member interfaces to a LAG.

admin@Switch1# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae48

admin@Switch1# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae48

admin@Switch1# set interface gigabit-ethernet te-1/1/41 ether-options 802.3ad ae71

admin@Switch1# set interface gigabit-ethernet te-1/1/42 ether-options 802.3ad ae72

Step4 Configure an MLAG domain ID.

admin@Switch1# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify Switch1 as MLAG Node 0.

admin@Switch1# set protocols mlag domain 10 node 0

Step6 Configure the peer IP address and peer link port.

admin@Switch1# set protocols mlag domain 10 peer-ip 1.1.1.201 peer-link ae48

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@Switch1# set l3-interface vlan-interface vlan4088 address 1.1.1.166 prefix-length 24

Step8 Configure link ID for the MLAG member port.

admin@Switch1# set protocols mlag domain 10 interface ae71 link 11

admin@Switch1# set protocols mlag domain 10 interface ae72 link 12

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

admin@Switch1# set protocols mlag domain 10 peer-ip 1.1.1.201 peer-vlan 4088

Step10 Enable IGMP snooping function.

admin@Switch1# set protocols igmp-snooping enable true

admin@Switch1# set protocols igmp-snooping vlan-id 10 enable true

Step11 Commit the configuration.

admin@Switch1# commit

Switch2

Step1 Configure the VLANs.

admin@Switch2# set vlans vlan-id 10

admin@Switch2# set vlans vlan-id 4088 l3-interface vlan4088

admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching native-vlan-id 4088

admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching port-mode trunk

admin@Switch2# set interface aggregate-ethernet ae48 family ethernet-switching vlan members 10

admin@Switch2# set interface aggregate-ethernet ae71 family ethernet-switching port-mode trunk

admin@Switch2# set interface aggregate-ethernet ae71 family ethernet-switching vlan members 10

admin@Switch2# set interface aggregate-ethernet ae72 family ethernet-switching port-mode trunk

admin@Switch2# set interface aggregate-ethernet ae72 family ethernet-switching vlan members 10

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch2# set interface aggregate-ethernet ae71 aggregated-ether-options lacp enable true

admin@Switch2# set interface aggregate-ethernet ae72 aggregated-ether-options lacp enable true

Step3 Add member interfaces to a LAG.

admin@Switch2# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae48

admin@Switch2# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae48

admin@Switch2# set interface gigabit-ethernet te-1/1/41 ether-options 802.3ad ae71

admin@Switch2# set interface gigabit-ethernet te-1/1/42 ether-options 802.3ad ae72

Step4 Configure an MLAG domain ID.

admin@Switch2# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify Switch2 as MLAG Node 1.

admin@Switch2# set protocols mlag domain 10 node 1

Step6 Configure the peer IP address and peer link port.

admin@Switch2# set protocols mlag domain 10 peer-ip 1.1.1.166 peer-link ae48

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 VLAN interface IP address for peer link port on local MLAG peer device.

admin@Switch2# set l3-interface vlan-interface vlan4088 address 1.1.1.201 prefix-length 24

Step8 Configure link ID for the MLAG member port.

admin@Switch2# set protocols mlag domain 10 interface ae71 link 11

admin@Switch2# set protocols mlag domain 10 interface ae72 link 12

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

admin@Switch2# set protocols mlag domain 10 peer-ip 1.1.1.166 peer-vlan 4088

Step10 Enable IGMP snooping function.

admin@Switch2# set protocols igmp-snooping enable true

admin@Switch2# set protocols igmp-snooping vlan-id 10 enable true

Step11 Commit the configuration.

admin@Switch2# commit

Switch3

Step1 Configure the VLANs.

admin@Switch3# set vlans vlan-id 10

admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@Switch3# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 10

admin@Switch3# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 10

admin@Switch3# set interface gigabit-ethernet ge-1/1/3 description "to-host"

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch3# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@Switch3# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1

admin@Switch3# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

Step3 Enable IGMP snooping function.

admin@Switch3# set protocols igmp-snooping enable true

admin@Switch3# set protocols igmp-snooping vlan-id 10 enable true

Step4 Commit the configuration.

admin@Switch3# commit

Switch4

Step1 Configure the VLANs.

admin@Switch4# set vlans vlan-id 10

admin@Switch4# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk

admin@Switch4# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 10

admin@Switch4# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 10

admin@Switch4# set interface gigabit-ethernet ge-1/1/3 description "to-server"

Step2 Configure aggregation interfaces with LACP mode.

admin@Switch4# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae2

admin@Switch4# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2

admin@Switch4# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true

Step3 Enable IGMP snooping function.

admin@Switch4# set protocols igmp-snooping enable true

admin@Switch4# set protocols igmp-snooping vlan-id 10 enable true

Step4 Commit the configuration.

admin@Switch4# commit

Verify the Configuration

- You can use the **run show mlag link** command to display MLAG link information.

```
admin@Switch1# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
```

```
11      ae71         FULL         UP             UP            Yes             No
12      ae72         FULL         UP             UP            Yes             No

admin@Switch2# run show mlag link summary
# of Links: 2
------------------------------------------------------------------------------
Link  Local LAG  Link Status  Local Status  Peer Status  Config Matched  Flood
----  ---------  -----------  ------------  -----------  --------------  -----
11    ae71        FULL         UP            UP           Yes              No
12    ae72        FULL         UP            UP           Yes              No
```

- You can use the **run show igmp-snooping groups** command to show the multicast group information.

```
admin@Switch1# run show igmp-snooping groups
Total group count: 1
Vlan      Group               Port List          Type
--------  ------------------  -----------------  ----------------------
10        234.0.0.8            ae71               Dynamic
                               ae72               Mrouter

admin@Switch2# run show igmp-snooping groups
Total group count: 1
Vlan      Group               Port List          Type
--------  ------------------  -----------------  ----------------------
10        234.0.0.8            ae71               Dynamic
                               ae72               Mrouter

admin@Switch3# run show igmp-snooping groups
Total group count: 1
Vlan      Group               Port List          Type
--------  ------------------  -----------------  ----------------------

```

Example for Configuring MLAG with Rapid PVST+

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
- Verify the Configuration

Networking Requirements

As shown in **Figure 1**, we have implemented MLAG on Switch A and Switch B, the downstream Switch C and Switch D has dual-access to network through Switch A and Switch B respectively.

Rapid PVST+ is deployed in the network to eliminate loops. Devices running rapid PVST+ exchange rapid PVST+ bridge protocol data units (BPDUs) to discover loops in the network and block some ports to prune the network into a loop-free tree network.

Figure1. Example Topology of MLAG with Rapid PVST+

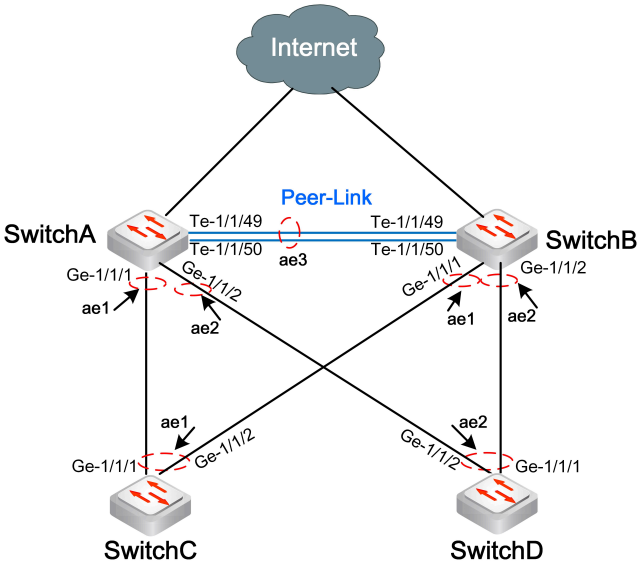

Figure 1 shows the user topology of MLAG with rapid PVST+. Follow the configuration roadmap below to complete the configuration.

- Configure MLAG. Switch A, Switch B and the aggregated port ae1connected to Switch C form an MLAG, link ID is 1; Switch A, Switch B and the aggregated port ae2 connected to Switch D form another MLAG, link ID is 2. MLAG peer-link implements a backup link aggregation group ae3 between Switch A and Switch B to carry MLAG control messages and improve network reliability.
- Configure basic Rapid PVST+ functions to eliminate loops.

Procedure

Configure Switch A, Switch B, Switch C and Switch D according to the networking requirements described above.

Switch A

Step1 Configure the VLANs.

```
admin@SwitchA# set vlans vlan-id 15
admin@SwitchA# set vlans vlan-id 16
admin@SwitchA# set vlans vlan-id 4088 l3-interface 4088
admin@SwitchA# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15
admin@SwitchA# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16
admin@SwitchA# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk
admin@SwitchA# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15
admin@SwitchA# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16
admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching port-mode trunk
admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 4088
admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 15
```

```
admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 16
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 15
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 16
```

Step2 Configure aggregation interfaces with LACP mode.

```
admin@SwitchA# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
admin@SwitchA# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true
```

Step3 Add member interfaces to the LAG.

```
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2
admin@SwitchA# set interface gigabit-ethernet te-1/1/49 ether-options 802.3ad ae3
admin@SwitchA# set interface gigabit-ethernet te-1/1/50 ether-options 802.3ad ae3
```

Step4 Configure an MLAG domain ID.

```
admin@SwitchA# set protocols mlag domain 10
```

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify SwitchA as MLAG Node 0.

```
admin@SwitchA# set protocols mlag domain 10 node 0
```

Step6 Configure the peer IP address and peer link port.

```
admin@SwitchA# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-link ae3
```

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

```
admin@SwitchA# set l3-interface vlan-interface 4088 address 10.10.0.1 prefix-length 24
```

Step8 Configure link ID for the MLAG member port.

```
admin@SwitchA# set protocols mlag domain 10 interface ae1 link 1
admin@SwitchA# set protocols mlag domain 10 interface ae2 link 2
```

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

```
admin@SwitchA# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-vlan 4088
```

Step10 Configure rapid PVST+.

a. Enable spanning tree on Switch A.

```
admin@SwitchA# set protocols spanning-tree enable true
```

By default, spanning tree function is enabled.

b. Configure spanning tree mode in rapid PVST+.

```
admin@SwitchA# set protocols spanning-tree force-version 4
```

c. Enable rapid PVST+ on VLAN instance.

```
admin@SwitchA# set protocols spanning-tree pvst vlan 15 enable true
admin@SwitchA# set protocols spanning-tree pvst vlan 16 enable true
admin@SwitchA# set protocols spanning-tree pvst vlan 4088 enable true
```

Step11 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure the VLANs.

```
admin@SwitchB# set vlans vlan-id 15
admin@SwitchB# set vlans vlan-id 16
admin@SwitchB# set vlans vlan-id 4088 l3-interface 4088
admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching port- mode trunk
admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15
admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16
admin@SwitchB# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk
admin@SwitchB# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15
admin@SwitchB# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16
admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching port-mode trunk
admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 4088
admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 15
admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 16
admin@SwitchB# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 15
admin@SwitchB# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 16
```

Step2 Configure aggregation interfaces with LACP mode.

```
admin@SwitchB# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
admin@SwitchB# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true
```

Step3 Add member interfaces to the LAG.

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2
admin@SwitchB# set interface gigabit-ethernet te-1/1/49 ether-options 802.3ad ae3
admin@SwitchB# set interface gigabit-ethernet te-1/1/50 ether-options 802.3ad ae3
```

Step4 Configure an MLAG domain ID.

```
admin@SwitchB# set protocols mlag domain 10
```

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step5 Specify SwitchB as MLAG Node 1.

```
admin@SwitchB# set protocols mlag domain 10 node 1
```

Step6 Configure the peer IP address and peer link port.

```
admin@SwitchB# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-link ae3
```

NOTE: Peer-link port should be configured as a LAG port.

Step7 Configure the L3 interface IP address for peer link port on local MLAG peer device.

```
admin@SwitchB# set l3-interface vlan-interface 4088 address 10.10.0.2 prefix-length 24
```

Step8 Configure link ID for the MLAG member port.

```
admin@SwitchB# set protocols mlag domain 10 interface ae1 link 1
admin@SwitchB# set protocols mlag domain 10 interface ae2 link 2
```

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step9 Configure MLAG peer VLAN.

```
admin@SwitchB# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-vlan 4088
```

Step10 Configure rapid PVST+.

a. Enable spanning tree on Switch B.

```
admin@SwitchB# set protocols spanning-tree enable true
```

By default, spanning tree function is enabled.

b. Configure spanning tree mode in rapid PVST+.

```
admin@SwitchB# set protocols spanning-tree force-version 4
```

c. Enable rapid PVST+ on VLAN instance.

```
admin@SwitchB# set protocols spanning-tree pvst vlan 15 enable true
admin@SwitchB# set protocols spanning-tree pvst vlan 16 enable true
admin@SwitchB# set protocols spanning-tree pvst vlan 4088 enable true
```

Step11 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step1 Enable the aggregation interface with LACP mode.

```
admin@SwitchC# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
```

Step2 Add the member interfaces to the LAGs.

```
admin@SwitchC# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1
```

Step3 Configure the VLANs.

```
admin@SwitchC# set vlans vlan-id 15
admin@SwitchC# set vlans vlan-id 16
admin@SwitchC# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@SwitchC# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15
admin@SwitchC# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16
```

Step4 Configure rapid PVST+.

a. Enable spanning tree on Switch C.

```
admin@SwitchC# set protocols spanning-tree enable true
```

By default, spanning tree function is enabled.

b. Configure spanning tree mode in rapid PVST+.

```
admin@SwitchC# set protocols spanning-tree force-version 4
```

c. Enable rapid PVST+ on VLAN instance.

```
admin@SwitchC# set protocols spanning-tree pvst vlan 15 enable true
admin@SwitchC# set protocols spanning-tree pvst vlan 16 enable true
```

Step5 Commit the configuration.

```
admin@SwitchC# commit
```

Switch D

Step1 Enable the aggregation interface with LACP mode.

```
admin@SwitchD# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true
```

Step2 Add the member interfaces to the LAG ports.

```
admin@SwitchD# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae2
admin@SwitchD# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2
```

Step3 Configure the VLANs.

```
admin@SwitchD# set vlans vlan-id 15
admin@SwitchD# set vlans vlan-id 16
admin@SwitchD# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk
admin@SwitchD# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15
admin@SwitchD# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16
```

Step4 Configure rapid PVST+.

a. Enable spanning tree on Switch D.

```
admin@SwitchD# set protocols spanning-tree enable true
```

By default, spanning tree function is enabled.

b. Configure spanning tree mode in rapid PVST+.

```
admin@SwitchD# set protocols spanning-tree force-version 4
```

c. Enable rapid PVST+ on VLAN instance.

```
admin@SwitchD# set protocols spanning-tree pvst vlan 15 enable true
admin@SwitchD# set protocols spanning-tree pvst vlan 16 enable true
```

Step5 Commit the configuration.

```
admin@SwitchD# commit
```

Verify the Configuration

- You can use the **run show mlag domain** command to check the configuration information of MLAG domain.

  # Check MLAG information on Switch A.

```
admin@SwitchA# run show mlag domain summary
Domain ID: 10    Domain MAC: 48:6E:73:FF:00:0a    Node ID: 0
------------------------------------------------------------------------
Peer Link  Peer IP             Peer Vlan     Neighbor Status  Config Matched   MAC Synced # of Links
---------  ---------------     ---------     ---------------  --------------   ----------   --------------
ae3         10.10.10.2         4088          ESTABLISHED       Yes             Yes          2
```

Check MLAG information on Switch B.

```
admin@SwitchB# run show mlag domain summary
Domain ID: 10    Domain MAC: 48:6E:73:FF:00:0a    Node ID: 1
------------------------------------------------------------------------
Peer Link  Peer IP          Peer Vlan  Neighbor Status  Config Matched   MAC Synced   # of Links
---------  ---------------  ---------  ---------------  --------------  ----------   ----------
ae3        10.10.10.1       4088       ESTABLISHED      Yes              Yes          2
```

- You can use the **run show mlag link** command to display MLAG link information.

```
admin@SwitchA# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer-Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
1      ae1         IDLE          UP             UNKNOWN       No               No
2      ae2         IDLE          UP             UNKNOWN       No               No
```

- You can use the **run show mlag consistency-parameter** command to display the result of MLAG configuration consistency check, including the global and per MLAG configuration.

```
admin@SwitchA# run show mlag consistency-parameter link 2
Port Configurations:
```

```

  - Configuring MLAG on SwitchA
  - Configuring VXLAN on SwitchA
  - Configuring MLAG on SwitchB
  - Configuring VXLAN on SwitchB
  - Configuring LAG on SwitchC
  - Configuring LAG on SwitchD
- Verifiy the Configuration

Introduction

PICOS-powered Ethernet switches use Multi-Chassis Link Aggregation (MLAG) technology to connect devices, enabling each one to connect to a pair of Pica8 switches with all links running active/active to improve resiliency. There's no need to block certain links, as with the spanning tree protocol (STP), resulting in improved bandwidth utilization and performance. With STP, while redundant links may exist between switches, traffic can only flow over one of them at a time, which effectively cuts the amount of available bandwidth in half. MLAG still supports redundancy, however, because peer switches synchronize forwarding state between them, so if a leaf or spine switch fails, traffic is automatically rerouted for continuous uptime.

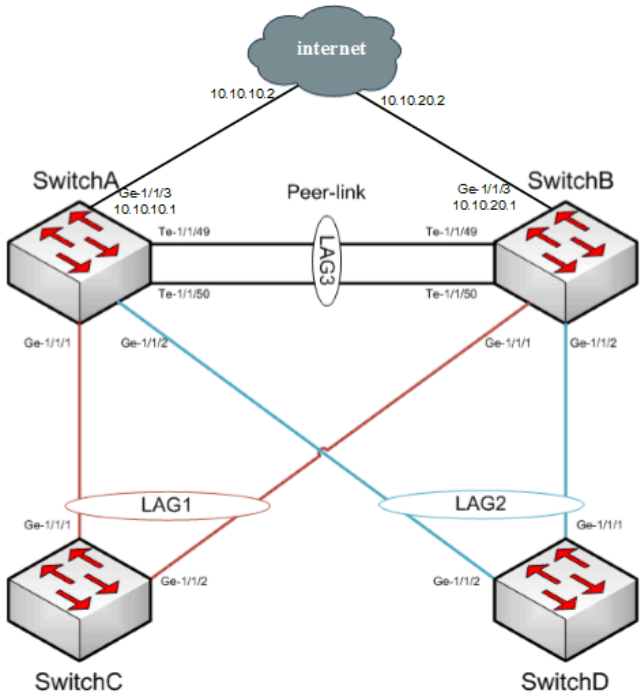
This document describes how to configure MLAG with a Virtual eXtensible LAN (VXLAN), a method for running a Layer 2 overlay network on Layer 3 infrastructure.

Networking Requirements

Figure 1 illustrates an MLAG configured between Switch A and Switch B, the MLAG connections between the neighboring switches, and two downstream Network Devices.

Access Switches SwitchC and SwitchD are dual-homed to an MLAG domain through a VXLAN tunnel, achieving that Layer 2 devices on the access side can communicate with each other over Layer 3 networks.

Figure 1 MLAG Topology with VXLAN



Follow the configuration roadmap below to complete the configuration:

- Configure MLAG. SwitchA, SwitchB and the aggregated port ae1connected to SwitchC form an MLAG, link ID is 1; SwitchA, SwitchB and the aggregated port ae2 connected to SwitchD form another MLAG, link ID is 2. MLAG peer-link implements a backup link aggregation group ae3 between SwitchA and SwitchB to carry MLAG control messages and improve network reliability.
- Configure VXLAN functions on SwitchA and SwitchB.
- Configure LACP LAG ports on Switch C and Switch D to implement dual-homing access.

Procedure

Configuring MLAG on SwitchA

Step1 Configure the aggregation interfaces with LACP mode.

admin@SwitchA# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

admin@SwitchA# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true

Step2 Add member interfaces to a LAG.

admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2

admin@SwitchA# set interface gigabit-ethernet te-1/1/49 ether-options 802.3ad ae3

admin@SwitchA# set interface gigabit-ethernet te-1/1/50 ether-options 802.3ad ae3

Step3 Configure the VLANs.

admin@SwitchA# set vlans vlan-id 15

admin@SwitchA# set vlans vlan-id 16

admin@SwitchA# set vlans vlan-id 4088 l3-interface vlan4088

admin@SwitchA# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@SwitchA# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15

admin@SwitchA# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16

admin@SwitchA# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk

admin@SwitchA# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15

admin@SwitchA# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16

admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching native-vlan-id 4088

admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching port-mode trunk

admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 15

admin@SwitchA# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 16

Step4 Configure the L3 Interface IP Address.

admin@SwitchA# set l3-interface vlan-interface vlan4088 address 10.10.0.1 prefix-length 24

Step5 Configure MLAG domain ID.

admin@SwitchA# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step6 Specify SwitchA as MLAG Node 0.

admin@SwitchA# set protocols mlag domain 10 node 0

Step7 Configure the peer IP address and peer link port.

admin@SwitchA# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-link ae3

NOTE: Peer-link port should be configured as a LAG port.

Step8 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@SwitchA# set l3-interface vlan-interface vlan4088 address 10.10.0.1 prefix-length 24

Step9 Configure link ID for the MLAG member port.

admin@SwitchA# set protocols mlag domain 10 interface ae1 link 1

admin@SwitchA# set protocols mlag domain 10 interface ae2 link 2

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step10 Configure MLAG peer VLAN.

admin@SwitchA# set protocols mlag domain 10 peer-ip 10.10.0.2 peer-vlan 4088

Step11 Commit the configurations.

admin@SwitchA# commit

Configuring VXLAN on SwitchA

Step1 Configure VXLAN soure interface.

admin@SwitchA# set l3-interface loopback lo address 10.10.10.1 prefix-length 32

admin@SwitchA# set vxlans source-interface loopback address 10.10.10.1

Step2 Create VXLAN VNI.

admin@SwitchA# set vxlans vni 100010

Step3 Configure vtep address for VXLAN VNI.

admin@SwitchA# set vxlans vni 100010 flood vtep 20.20.20.1

Step4 Add VXLAN port into VXLAN VNI.

admin@SwitchA# set vxlans vni 100010 vlan 15

Note that, in current version, only one VLAN is supported in one VNI.

Step5 Configure a static route.

admin@SwitchA# set protocols static route 20.20.20.1/24 next-hop 10.10.10.2

Step6 Enable IP routing.

admin@SwitchA# set ip routing enable true

Step7 Commit the configurations.

admin@SwitchA# commit

Configuring MLAG on SwitchB

Step1 Configure the aggregation interfaces with LACP mode.

admin@SwitchB# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

admin@SwitchB# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true

Step2 Add the member interfaces to the LAG ports.

admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2

admin@SwitchB# set interface gigabit-ethernet te-1/1/49 ether-options 802.3ad ae3

admin@SwitchB# set interface gigabit-ethernet te-1/1/50 ether-options 802.3ad ae3

Step3 Configure the VLANs.

admin@SwitchB# set vlans vlan-id 15

admin@SwitchB# set vlans vlan-id 16

admin@SwitchB# set vlans vlan-id 4088 l3-interface vlan4088

admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15

admin@SwitchB# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16

admin@SwitchB# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk

admin@SwitchB# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15

admin@SwitchB# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16

admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching native-vlan-id 4088

admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching port-mode trunk

admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 15

admin@SwitchB# set interface aggregate-ethernet ae3 family ethernet-switching vlan members 16

Step4 Configure the L3 Interface IP Address.

admin@SwitchB# set l3-interface vlan-interface vlan4088 address 10.10.0.2 prefix-length 24

Step5 Configure MLAG domain ID.

admin@SwitchB# set protocols mlag domain 10

NOTE: Currently, only one MLAG domain is allowed to be configured on one MLAG device.

Step6 Specify SwitchB as MLAG Node 1.

admin@SwitchB# set protocols mlag domain 10 node 1

Step7 Configure the peer IP address and peer link port.

admin@SwitchB# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-link ae3

NOTE: Peer-link port should be configured as a LAG port.

Step8 Configure the L3 interface IP address for peer link port on local MLAG peer device.

admin@SwitchB# set l3-interface vlan-interface vlan4088 address 10.10.0.2 prefix-length 24

Step9 Configure link ID for the MLAG member port.

admin@SwitchB# set protocols mlag domain 10 interface ae1 link 1

admin@SwitchB# set protocols mlag domain 10 interface ae2 link 2

NOTE: The paired MLAG member ports must be bound to the same MLAG link ID.

Step10 Configure MLAG peer VLAN.

admin@SwitchB# set protocols mlag domain 10 peer-ip 10.10.0.1 peer-vlan 4088

Step11 Commit the configurations.

admin@SwitchB# commit

Configuring VXLAN on SwitchB

Step1 Configure VXLAN soure interface.

admin@SwitchB# set l3-interface loopback lo address 10.10.10.1 prefix-length 32

admin@SwitchB# set vxlans source-interface loopback address 10.10.10.1

Step2 Create VXLAN VNI.

admin@SwitchB# set vxlans vni 100010

Step3 Configure vtep address for VXLAN VNI.

admin@SwitchB# set vxlans vni 100010 flood vtep 20.20.20.1

Step4 Add VXLAN port into VXLAN VNI.

admin@SwitchB# set vxlans vni 100010 vlan 15

Note that, in current version, only one VLAN is supported in one VNI.

Step5 Configure a static route.

admin@SwitchB# set protocols static route 20.20.20.0/24 next-hop 10.10.20.2

Step6 Enable IP routing.

admin@SwitchB# set ip routing enable true

Step7 Commit the configurations.

admin@SwitchB# commit

Configuring LAG on SwitchC

Step1 Configure the aggregation interface with LACP mode.

admin@SwitchC# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true

Step2 Add the member interfaces to the LAG ports.

admin@SwitchC# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1

admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1

Step3 Configure the VLANs.

admin@SwitchC# set vlans vlan-id 15

admin@SwitchC# set vlans vlan-id 16

admin@SwitchC# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk

admin@SwitchC# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 15

admin@SwitchC# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 16

Step4 Commit the configurations.

admin@SwitchC# commit

Configuring LAG on SwitchD

Step1 Configure the aggregation interface with LACP mode.

admin@SwitchD# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true

Step2 Add the member interfaces to the LAG ports.

admin@SwitchD# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae2

admin@SwitchD# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae2

Step3 Configure the VLANs.

admin@SwitchD# set vlans vlan-id 15

admin@SwitchD# set vlans vlan-id 16

admin@SwitchD# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk

admin@SwitchD# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 15

admin@SwitchD# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 16

Step4 Commit the configurations.

admin@SwitchD# commit

Verifiy the Configuration

- You can use the **run show vxlan vni** and **run show vxlan tunnel** commands to display the information of VXLAN tunnel.

```
admin@SwitchA# run show vxlan vni 100010
Interface    ID             Type           Egress     Vlan ID
-----------  -----------    -----------    -------    --------
ae1          0x80000001     Access         100078     15
```

```
ae2          0x80000002     Access         100083     15
ge-1/1/3     0x80000005     Network(UC)    100085

admin@SwitchA# run show vxlan tunnel
Total number of tunnels: 1

VNI 100010, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:10.10.10.1, dst addr:20.20.20.1, state:UP
  traffic type:all
  nexthops:10.10.10.2
  output ports:ge-1/1/3
```

- You can use the **run show vxlan address-table** and **run show mac-address table** commands to display the VXLAN MAC address information.

```
admin@SwitchA# run show vxlan address-table
VNID           MAC address          Type       Interface          VTEP
-----------    -----------------    -------    ----------------    ---------------
100010         20:04:0f:0f:49:d1    Dynamic                         20.20.20.1
100010         22:22:22:44:44:44    Dynamic                         20.20.20.1

admin@SwitchB# run show vxlan address-table

100010         22:22:22:44:44:44    Sync                            10.10.10.1

admin@SwitchB# run show mac-address table
Total entries in switching table:   3909
Static entries in switching table:  6
Dynamic entries in switching table: 3903

VLAN      MAC address          Type         Age     Interfaces         User
----      -----------------    ---------    ----    ----------------   ----------
15        a0:01:0f:0f:49:f1    Dynamic      300     ae2                xorp
N/A       20:04:0f:0f:49:d1    Peer-Sync    300     vxlan              xorp
N/A       22:22:22:44:44:44    Peer-Sync    300     vxlan              xorp
```

- You can use the **run show mlag domain** command to display the MLAG domain information.

```
admin@SwitchA# run show mlag domain summary
Domain ID: 10    Domain MAC: 48:6E:73:FF:00:0a    Node ID: 0
-------------------------------------------------------------------
Peer Link  Peer IP          Peer Vlan  Neighbor Status  Config Matched   MAC Synced   # of Links
---------  ---------------  ---------  ---------------  --------------  -----------  --------------
ae3        10.10.10.2       4088        ESTABLISHED     Yes              Yes         2
```

- You can use the **run show mlag link** command to display MLAG link information.

```
admin@SwitchA# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer-Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
1      ae1         IDLE          UP             UNKNOWN       No               No
2      ae2         IDLE          UP             UNKNOWN       No               No
```

- After the configuration is complete, the access switches SwitchC and SwitchD can communicate with each other normally.

MLAG Maintenance and Troubleshooting

- How to bind a LAG interface to the MLAG link?
- How to check whether the VLAN configuration on the two peer-link ports are consistent?
- How to confirm whether the MAC address table has been correctly synchronized?
- How to enable MLAG traceoptions
- How to ensure the reliability of the peer link?
- How to verify configurations on MLAG peer are consistent?
- How to verify MLAG link status?
- How to verify MLAG neighbor status?
- How to verify that the peer link connection status is normal?
- How to view and clear MLAG statistics?

How to bind a LAG interface to the MLAG link?

When an MLAG domain is created, you have to associate a pair of MLAG member ports on each MLAG peer device to form an MLAG link by using command **set protocols mlag domain** <*domain-id*> **interface** <*lag-interface*> **link** <*link-id*>.

For example, bind LAG port ae3 to MLAG link 2 of MLAG domain 3.

```
admin@Xorplus# set protocols mlag domain 3 interface ae3 link 2
```

NOTE:

The paired MLAG member ports of the same MLAG must be bound to the same MLAG link ID. Different MLAGs are identified by different link IDs. For example we have two MLAGs in an MLAG Domain then link ID 1 could identify the first MLAG while link ID 2 could identify the second MLAG in the MLAG Domain.

How to check whether the VLAN configuration on the two peer-link ports are consistent?

Any MLAG VLAN and non-MLAG VLAN traffic MUST be allowed on MLAG peer-link. Therefore, the VLAN configurations of the peer-link ports on both ends must be consistent. Run the **run show vlans** command on the MLAG peer devices to check the VLANs of the peer-link port.

For example,

```
admin@PICOS# run show vlans
VlanID  Vlan Name          Tag       Interfaces
------  -----------------  --------  ------------------------------------------------------------
1                          untagged  xe-1/1/1, xe-1/1/2, te-1/1/2, xe-1/1/3, te-1/1/3
                                     xe-1/1/4, te-1/1/4, xe-1/1/5, te-1/1/5, xe-1/1/6
                                     te-1/1/6, te-1/1/7, te-1/1/8, te-1/1/9, te-1/1/10
                                     te-1/1/11, te-1/1/12, te-1/1/13, te-1/1/14, te-1/1/15
                                     te-1/1/16, te-1/1/17, te-1/1/18, te-1/1/19, te-1/1/20
                                     te-1/1/21, te-1/1/22, te-1/1/23, te-1/1/24, te-1/1/25
                                     te-1/1/26, te-1/1/27, te-1/1/28, te-1/1/29, te-1/1/30
                                     te-1/1/31, te-1/1/32, te-1/1/33, te-1/1/34, te-1/1/35
                                     te-1/1/36, te-1/1/37, te-1/1/38, te-1/1/39, te-1/1/40
                                     te-1/1/41, te-1/1/42, te-1/1/43, te-1/1/44, te-1/1/45
                                     te-1/1/46, te-1/1/47, te-1/1/48, ae1
                           tagged

2       default            untagged  te-1/1/1
                           tagged    xe-1/1/3

3                          untagged
                           tagged    xe-1/1/3
```

How to confirm whether the MAC address table has been correctly synchronized?

The MLAG peer switches synchronize MAC address table to each other using MAC synchronization message. Only when MLAG neighbor state changes to ESTABLISHED and there is a change in the MAC table, the MAC Sync message will be sent.

To check whether the MAC address tables on both peer devices are consistent, use **run show mac-address table** command to show MAC address table on each MLAG peer device. A MAC address entry contains the VLAN ID, destination MAC address, entry type, aging time and outbound interface.

For details about how MAC tables are synchronized between the MLAG peer devices, see section **MAC Synchronization** in Principle of MLAG.

For example, when showing MAC address table on each MLAG peer devices after the system automatically completed MAC synchronization, the MAC address should be synced to each other on the MLAG peer devices.

```
admin@SwitchA# run show mac-address table
Total entries in switching table:   3
Static entries in switching table:  0
Dynamic entries in switching table: 3

VLAN      MAC address      Type         Age     Interfaces         User
----         -----------------     ---------        ----     ----------------       ------
1         08:9e:01:61:64:13   Dynamic      300      ge-1/1/2           xorp
1         cc:37:ab:4f:ad:01    Peer-Sync     300      ae1              xorp
4088      8c:ea:1b:88:5b:81    Peer-Sync     300       ae3              xorp

admin@SwitchB# run show mac-address table
Total entries in switching table:   3
Static entries in switching table:  0
Dynamic entries in switching table: 3

VLAN      MAC address      Type         Age     Interfaces         User
----         -----------------     ---------        ----     ----------------       ------
1         8c:ea:1b:88:5b:81   Dynamic      300     ae4              xorp
1         cc:37:ab:4f:ad:01    Dynamic      300      ae1              xorp
4088      08:9e:01:61:64:13    Peer-Sync      300     ae3              xorp
```

How to enable MLAG traceoptions

Use the following commands to enable MLAG traceoptions for checking the MLAG syslogs.

```
admin@Xorplus# set protocols mlag traceoptions
Possible completions:
  <[Enter]>                       Execute this command
  all                             Configure MLAG all events and packets tracing
  configuration                   Configure MLAG configuration tracing
  event                           Configure MLAG event tracing
  packet                          Configure MLAG send/receive packets tracing
  raw-packet                      Configure MLAG raw packet tracing
  state-change                    Configure MLAG state change tracing
  timer                           Configure MLAG timer tracing
```

How to ensure the reliability of the peer link?

If peer-link is down for any reason, MLAG control plane messages cannot be exchanged properly, causing the MLAG system to operate abnormally. To ensure the reliability of peer-link, note the following points when configuring and deploying peer link.

1. Only one peer link connecting the two peer devices is allowed in an MLAG domain.
2. When configuring the peer link, only one LAG port can be used as peer link.
3. Use a LAG port with at least two **directly connected** physical ports to guarantees reliable communication between the peer devices on the peer link. Use of any intermediate transmission device between the two peer devices on the peer link is not allowed. All of the directly connected physical ports should be added into one LAG port to form the peer-link. We don't support more than one L2 connection between MLAG peer switches.
4. 10G or 40G speed ports should be used for peer link to enough bandwidth is provided when the network is deployed.
5. Any manual action to shut down the peer link is strictly forbidden.

For more details, you can refer to the peer link concept in Principle of MLAG.

How to verify configurations on MLAG peer are consistent?

PICOS automatically checks the configuration consistency of the MLAG peer devices to ensure that the MLAG peer devices appear as one device to the downstream device and to make the MLAG function operate normally and smoothly.

After an MLAG related configuration is set, use the following command to show the result of MLAG configuration consistency check result.

run show mlag consistency-parameter { **link** <link-id>| **summary**}

For example,

- Show the result of per MLAG configuration consistency check.

```
admin@Xorplus# run show mlag consistency-parameter link 3
Port Configurations:
-------------------------------------------------------------------
Property                 Local Value      Peer Value       Result
-----------------------  ---------------  ---------------  ------

-- Forward Delay         15               15               PASS
-- Max Age               20               20               PASS

Instance Vlan 2
-- Bridge Priority       32768            32768            PASS
-- Hello Time            2                2                PASS
-- Forward Delay         15               15               PASS
-- Max Age               20               20               PASS

Instance Vlan 3
-- Bridge Priority       32768            32768            PASS
-- Hello Time            2                2                PASS
-- Forward Delay         15               15               PASS
-- Max Age               20               20               PASS

Instance Vlan 4
-- Bridge Priority       32768            32768            PASS
-- Hello Time            2                2                PASS
-- Forward Delay         15               15               PASS
-- Max Age               20               20               PASS

DHCP Snooping Configurations:
----------------------------------------------------------------------
Property            Local Value  Peer Value       Result
----------------------  ---------------  ---------------  ------
Enable               No          No               PASS

IGMP Snooping Configurations:
----------------------------------------------------------------------
Property                 Local Value      Peer Value       Result
----------------------  ---------------  ---------------  ------
Enable                   No               No               PASS
```

In the displayed result, **Result** shows the consistency check results. The value could be **PASS** or **FAIL**:

- If **Result** is PASS, the configurations of the MLAG peer-link devices are consistent.
- If **Result** is FAIL, the configurations of the MLAG peer-link devices are inconsistent.

To ensure that the configuration parameters are consistent, we recommend that you run the MLAG consistency check command to display the configurations and the consistency check results for each MLAG peer device once you set a new MLAG related configuration.

For more details about MLAG consistency check, please refer to **MLAG Consistency Check**.

NOTE:

- Inconsistent configuration may cause MLAG to run abnormally.
- After the configuration is changed from inconsistent to consistent, you need to restart the MLAG peer devices to ensure that MLAG functions normally.

How to verify MLAG link status?

After the MLAG neighbor relationship is correctly established and MLAG link configurations are loaded on the MLAG devices, use the following command to show the MLAG link to verify the MLAG link status.

run show mlag link {*<link-id>*| **summary**}

For example,

```
admin@XorPlus# run show mlag link summary
# of Links: 2
Link   Local LAG   Link Status   Local Status   Peer Status   Config Matched   Flood
----   ---------   -----------   ------------   -----------   --------------   -----
1      ae1         IDLE          UP             UNKNOWN       No               No
2      ae2         IDLE          UP             UNKNOWN       No               No
```

See the command reference of run show mlag link for more details about the explanation of all the output.

In the display result, if **Link Status** is not FULL or **Local Status** is not UP, you can check whether LACP neighbor is established normally between the access devices and MLAG peer device by using the command **run show lacp neighbor**.

For example,

```
admin@Xorplus# run show lacp neighbor
Aggregated interface: ae1
Port Number   Partner System ID    Partner Port Num   Port Priority   Oper Key   State
-----------   -----------------------   ----------------   -------------   --------   -----

Aggregated interface: ae2
Port Number   Partner System ID   Partner Port Num   Port Priority   Oper Key   State
-----------   -----------------------   ----------------   -------------   --------   -----
te-1/1/5      32768,3C:2C:99:89:89:01   2          32768           0x20       0x3D
```

In the displayed result, the **State** value should be **0x3D**. If not, that indicates the LACP neighbor relationship is not successfully established. Then you can check whether a packet is sent to the CoPP or check the LACP configurations.

For example,

```
admin@Xorplus# run show copp statistics forwarding-class lacp-class
lacp-class Traffic statistics:
forwarding-class state: active
Input rate 0 bits/sec, 0 packets/sec
Input Packets.............................0
Input Octets..............................0

Drop rate 0 bits/sec, 0 packets/sec
Drop Packets..............................0
Drop Octets...............................0
```

How to verify MLAG neighbor status?

After completed the MLAG domain configurations, we have to check the MLAG neighbor status to make sure that the MLAG neighbor relationship is correctly established. Use the command run show mlag domain {<*domain-id*>| summary} to show the MLAG domain information, which includes the MLAG neighbor status.

For example,

```
admin@Xorplus# run show mlag domain summary
Domain ID: 1    Domain MAC: 48:6E:73:FF:00:01    Node ID: 0
-------------------------------------------------------------------------------------------
Peer Link  Peer IP  Peer Vlan  Neighbor Status  Config Matched  MAC Synced  # of Links
---------  --------------  ---------  ---------------    --------------      ----------  ----------
ae23       1.1.1.2    4088    ESTABLISHED      Yes       Yes         2
```

See the command reference of run show mlag domain for more details about the explanation of all the output.

If the MLAG neighbor relationship cannot be correctly established on the MLAG peer devices, the Neighbor Status is not ESTABLISHED in the display result. The possible causes and the troubleshooting procedure are as follows:

1. The peer-link connection status is abnormal. See the following link to confirm the peer-link connection status: How to verify that the peer link connection status is normal?
2. The MLAG domain configurations are incorrect or inconsistent on the MLAG peer devices, the configurations involved including domain ID, node ID and peer IP. We have to make sure the configurations are correct and consistent.

How to verify that the peer link connection status is normal?

After completed the peer link configurations, ping peer IP to verify whether the L3 connection is ok on peer link, determining the network status based on the number of Ping packets returned.

For example,

```
admin@Xorplus> ping 10.10.51.1
PING 10.10.51.1 (10.10.51.1) 56(84) bytes of data.
64 bytes from 10.10.51.1: icmp_seq=1 ttl=64 time=1.94 ms
64 bytes from 10.10.51.1: icmp_seq=2 ttl=64 time=2.03 ms
64 bytes from 10.10.51.1: icmp_seq=3 ttl=64 time=2.00 ms

How to view and clear MLAG statistics?

After MLAG is successfully deployed, you can run the MLAG statistics command to check packet statistics about MLAG. The command output helps you to determine whether data is normal or not and to locate faults.

View MLAG packet statistics of COPP:

```
admin@Xorplus# run show copp statistics forwarding-class mlag-class
mlag-class Traffic statistics:
forwarding-class state: active
Input rate 0 bits/sec, 0 packets/sec
Input Packets.....................1
Input Octets.....................153
Drop rate 0 bits/sec, 0 packets/sec
Drop Packets.....................0
Drop Octets.....................0
```

```
admin@Xorplus# run show copp statistics forwarding-class mlag-mac-sync-class
mlag-mac-sync-class Traffic statistics:
forwarding-class state: active
Input rate 0 bits/sec, 0 packets/sec
Input Packets.....................9
Input Octets.....................1511
Drop rate 0 bits/sec, 0 packets/sec
Drop Packets.....................0
Drop Octets.....................0
```

View the MLAG control plane packets statistics:

```
admin@Xorplus# run show mlag statistics
Receive:                                Transmit:
  Total Packets: 0                        Total Packets: 0
  MLAG Control: 0                         MLAG Control: 0
  MAC Sync: 0                             MAC Sync: 0
  STP Sync: 0                             STP Sync: 0
  VXLAN Sync: 0                           VXLAN Sync: 0
  Multicast Control Sync: 0               Multicast Control Sync: 0
  Configuration Consistency: 0            Configuration Consistency: 0
# of input DHCP Sync: 0                       # of Output DHCP Sync: 0
```

To collect statistics about MLAG traffic generated over a certain period, first reset the original statistics.

Clear MLAG control plane packet statistics:

```
admin@Xorplus# run clear mlag statistics
```

VLAN Configuration

Configuring MAC-based VLAN

- Overview
- Configuring MAC-based VLAN
- Example for Configuring MAC-based VLAN
  - Networking Requirements
  - Procedure

Overview

The traditional VLAN assignment method is based on the switch access port of the traffic, MAC-based VLAN assigns VLAN based on the source MAC address of untagged traffic rather than port.

When users have the demand for security and mobility, they can configure MAC-based VLAN. MAC-based VLAN means that MAC addresses are associated with VLANs, VLAN members are defined according to the source MAC address of the packet, then the VLAN Tag is added to the packet before sending it. There is no need to re-assign VLANs when physical location changed, which improves the security and access flexibility of end users.

You define a MAC to VLAN mapping by configuring an entry in the MAC to VLAN table. An entry is specified using a source MAC address and the appropriate VLAN ID. The MAC to VLAN configurations are shared across all ports of the device (i.e., there is a system-wide table that has MAC address to VLAN ID mappings).

MAC-based VLAN only handles untagged packets. Tagged packets are processed the same way as port-based VLAN.

When an untagged packet is received by the interface, the interface will look up the MAC to VLAN table entry based on the source MAC address of the packet.

- If an entry is found, the corresponding VLAN ID is assigned to the packet, and the priority value in the VLAN tag is set to 0 (zero).
- If no entries are found, the untagged packet will be forwarded in the native VLAN of the

For tagged packets, if the VLAN ID carried by the packet is in the list of VLANs allowed to be transmitted through the port, the packet is allowed to pass, otherwise the packet is dropped.

NOTEs:

- The same MAC address can be bound to no more than one VLAN.
- The number of MAC-VLAN entry supported by the whole switch varies in different switch platforms, for details please see the following attached file.

  Maximum Number of MAC VLAN Mapping on Different Platforms.xlsx
- To enable MAC-based VLAN function, add the port to the VLAN with MAC address bound. Do not forget to configure the port mode to **trunk** if there are more than one VLANs transported across this port.
- MAC-based VLAN will not work if 802.1X, voice VLAN or VXLAN is enabled on the same port.
- QinQ will not work if MAC-based VLAN is enabled.
- MAC-based VLAN can work with private VLAN.

Configuring MAC-based VLAN

Step 1 Create VLAN and add port to the VLAN.

set vlans vlan-id <*vlan-id*>

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching vlan members** <*vlan-id*>

Step 2 (Optional) Configure the port mode to **trunk**.

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching port-mode** <*port-mode*>

Step 3 Configure MAC address and VLAN mapping entry.

set mac-map mac-address <*mac-address*> **vlan** <*vlan-id*>

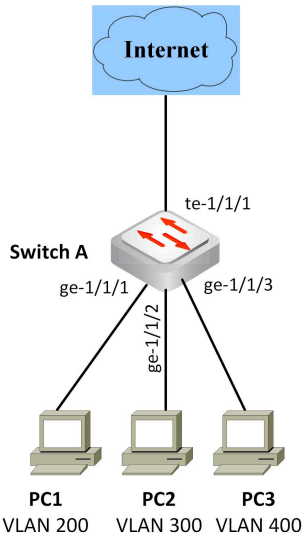
Step 4 View the configuration information of MAC-based VLAN.

run show mac-map [**mac-address** <*mac-address*>]

Example for Configuring MAC-based VLAN

Networking Requirements

Figure 1. MAC-based VLAN Configuration Example



In a company network, the network administrator divides the employees of different departments into different VLANs. In order to improve the information security in the department, only the PCs belonging to the department are allowed to access the network of the department.

As shown in Figure 1, PC1 (00:22:22:22:22:22:20), PC2 (00:33:33:33:33:20) and PC3 (00:44:44:44:44:44:20) are PCs of employees in different departments. It is required that these PCs can only access their respective department networks. If they are replaced by other PCs, they cannot access the network.

You can configure MAC-based VLAN to bind the MAC addresses of PCs in different departments to different VLANs to achieve this requirement.

Procedure

Step 1 Configure VLAN, configure port-mode to trunk port and add to VLAN.

```
admin@SwitchA# set vlans vlan-id 200
admin@SwitchA# set vlans vlan-id 300
admin@SwitchA# set vlans vlan-id 400
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 200
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 300
admin@SwitchA# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 400
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 200,300,400
```

Step 2 Configure MAC address and VLAN mapping entry.

```
admin@SwitchA# set mac-map mac-address 00:22:22:22:22:20 vlan 200
admin@SwitchA# set mac-map mac-address 00:33:33:33:33:20 vlan 300
admin@SwitchA# set mac-map mac-address 00:44:44:44:44:20 vlan 400
```

Step 3 Commit the configurations.

```
admin@SwitchA# commit
```

Step 4 View the configuration information of MAC-based VLAN.

```
admin@SwitchA# run show mac-map
Total entries: 4096
MAC                 VLAN
00:22:22:22:22:20   200
00:33:33:33:33:20   300
00:44:44:44:44:20   400
```

MAC Trace

- Overview
- Configuring MAC Trace
- Configuration Example
  - Networking Requirements
  - Procedure
    - Switch A
    - Switch B
    - Switch C
  - Verification

Overview

MAC Trace function shows L2 path trace based on MAC address, which is similar to the IP layer Traceroute. It is used to detect the Ethernet link connection fault, providing an effective method for Ethernet fault detection and location.

The device determines the path by using the MAC address tables of the switches in the path.

The packets are based on CFM (IEEE802.1ag), CFM is a connection checking mechanism that uses its own Ethernet frames (its Ethernet type is 0x8902 and has its own MAC address) to verify the operational status of the service instance.

The TTL (time to live) value is 64, which specifies the lifetime of the packet and sets the maximum number of hops that the packet will go through.

NOTEs:

- To make MAC trace function work, you need to enable MAC trace function on both ends of the link under test and the intermediate devices; only after this, the devices can reply to the received MAC trace messages.
- MAC trace function supports only unicast destination MAC addresses.

Configuring MAC Trace

Step 1 Enable MAC trace function.

Enable MAC trace function on both ends of the link under test and on intermediate devices.

set tracemac disable <**true | false**>

By default, the MAC Trace function is disabled.

Only when the MAC Trace function is enabled, MAC Trace operation can be performed on the device; the device can reply to the received MAC Trace messages.

Step 2 Commit the configuration.

commit

Step 3 Perform MAC Trace detection.

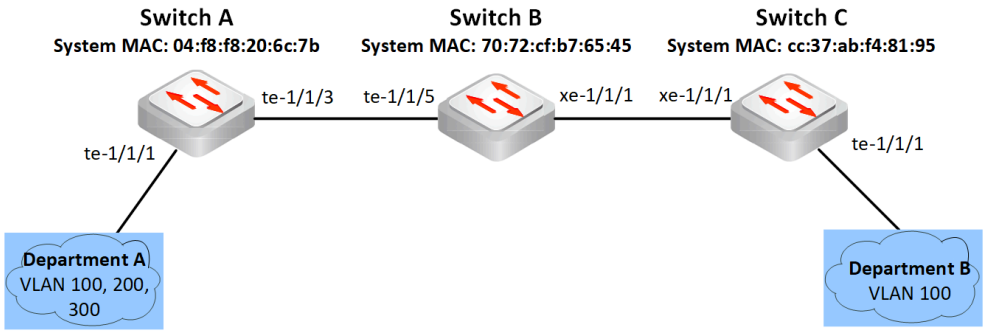
Perform MAC Trace on any end of the link under test to locate the connectivity failures between the device and the destination device.

run tracemac destination <*mac-address*> **vlan** <*vlan-id*>

Configuration Example

Networking Requirements

Figure 1. MAC Trace Configuration Example



As shown in **Figure 1**, Department A (belonging to VLAN 100, 200, 300) and Department B (belonging to VLAN 100) of a company are connected by multiple switches. This example uses command **run tracemac destination** <*mac-address*> **vlan** <*vlan-id*> to check the connectivity between the current device and the destination device, which is called a MAC Trace.

Procedure

Switch A

Step 1 Configure VLAN and port mode.

```
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 200, 300
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 100
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 200, 300
```

Step 2 Enable MAC trace function.

```
admin@SwitchA# set tracemac disable false
```

Step 3 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step 1 Configure VLAN and port mode.

```
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 100
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching vlan members 200, 300
admin@SwitchB# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchB# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching vlan members 200, 300
```

Step 2 Enable MAC trace function.

```
admin@SwitchB# set tracemac disable false
```

Step 3 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step 1 Configure VLAN and port mode.

```
admin@SwitchC# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchC# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching vlan members 200, 300
admin@SwitchC# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
```

Step 2 Enable MAC trace function.

```
admin@SwitchC# set tracemac disable false
```

Step 3 Commit the configurations.

```
admin@SwitchC# commit
```

Verification

- Run command **run show mac-address table** to check the MAC address table.
  - On Switch A:

VLAN	MAC address	Type	Age	Interfaces	User
100	22:11:11:11:11:11	Dynamic	300	te-1/1/1	xorp
100	70:72:cf:b7:65:45	Dynamic	300	te-1/1/3	xorp

  - On Switch B:

```
VLAN      MAC address          Type         Age     Interfaces          User
----      -----------------    ---------    ----    ----------------    ----------
100       04:f8:f8:20:6c:7b    Dynamic      300     te-1/1/5            xorp
100       22:11:11:11:11:11    Dynamic      300     te-1/1/5            xorp
```

- On Switch C:

```
VLAN      MAC address          Type         Age     Interfaces          User
----      -----------------    ---------    ----    ----------------    ----------
100       22:11:11:11:11:11    Dynamic      300     xe-1/1/1            xorp
100       70:72:cf:b7:65:45    Dynamic      300     xe-1/1/1            xorp
```

- On Switch C, trace MAC destination device with MAC address 20:11:11:11:11:11 and belonging to VLAN 100.

```
admin@SwitchC# run tracemac destination 22:11:11:11:11:11 vlan 100
Hop   Hostname    Ingress port     Ingress mac        Egress port    Egress mac
----  ----------- --------------   ------------       ------------   ------------
1     SwitchB       xe-1/1/1       70:72:cf:b7:65:45  te-1/1/5       70:72:cf:b7:65:45
2     SwitchA       te-1/1/3       04:f8:f8:20:6c:7b  te-1/1/1       04:f8:f8:20:6c:7b
```

Configuring Port-based VLAN

Virtual Local Area Network (VLAN) technology divides a physical LAN into multiple broadcast domains, each of which is called a VLAN. VLAN tagging (IEEE 802.1Q) is a networking standard that defines the VLAN. Hosts within a VLAN can communicate with each other but cannot communicate directly with hosts in other VLANs. Consequently, broadcast packets are confined to within a single VLAN.

You can configure a physical port as either a trunk or an access port. With the native VLAN ID, you can add the port (in trunk mode) to more than one VLAN. Access ports only belong to native VLAN, while trunk ports belong to more than one VLAN, including the native VLAN.

If hosts in different VLANs need to communicate, configure inter-VLAN communication. A VLAN interface is a Layer 3 logical interface and can implement inter-VLAN Layer 3 connectivity. Each VLAN corresponds to a VLAN interface. An IP address can be assigned to each VLAN interface. For details about VLAN interface configuration, see Layer 3 VLAN Interface Configuration.

NOTE:

When configuring VLAN member, use VLAN ID or VLAN range, but NOT other strings.

Configure the Access/Trunk Mode

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode access
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configure the Native VLAN ID

NOTE:

VLAN IDs (VLAN 1-4094) have been pre-configured in the system from version 4.3.2 and are not user-deletable. Users no longer need to use command **set vlans vlan-id** <*vlan-id*> to create VLAN IDs.

The native VLAN ID is the ID of the default VLAN (usually vlan-id 1) in which the port belongs. Every port should be included in at least one VLAN.

```
admin@XorPlus# set vlans vlan-id 5
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 5
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show vlans vlan-id 5
VLAN ID: 5
VLAN type: Static
VLAN Name: default
Description:
Vlan-interface:
Routed-interface:
Number of member ports: 1
```

```
Untagged port: ge-1/1/1
Tagged port: None
admin@XorPlus#
```

Add a Port to a VLAN with Tagged Packet

```
admin@XorPlus# set vlans vlan-id 5
admin@XorPlus# set vlans vlan-id 6
admin@XorPlus# set vlans vlan-id 7
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 5
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 6
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 7
admin@XorPlus# commit
Commit OK.
Save done.

admin@XorPlus# run show vlans
VlanID   Vlan Name     Tag        Interfaces

VLAN Configuration Example

In the following topology, the VLANs are configured for each switch.

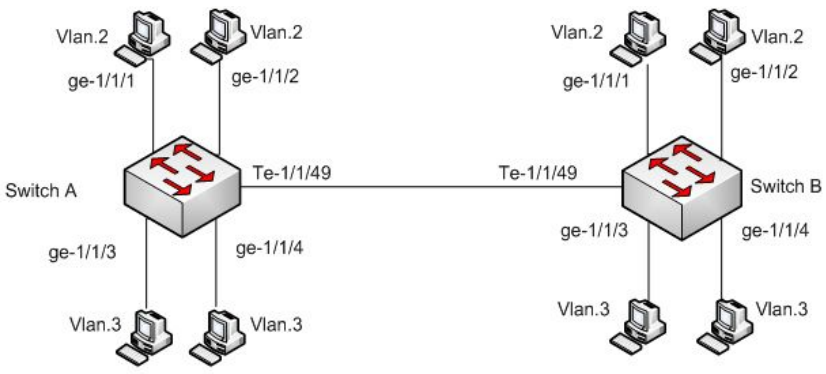

Figure 4-1.VLAN configuration.

Configuring Switch A

For Switch A, you should configure ge-1/1/1 through ge-1/1/4 as access ports and te-1/1/49 as the trunk port because the 10Gbit link will trunk the traffic of VLAN-2 and VLAN-3.

```
admin@XorPlus# set vlans vlan-id 2
```

```
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode access
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode access
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode access
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode access
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 3
admin@XorPlus#set interface gigabit-ethernet te-1/1/49 family ethernet-switching port-mode trunk
admin@XorPlus#set interface gigabit-ethernet te-1/1/49 family ethernet-switching vlan members 2
admin@XorPlus#set interface gigabit-ethernet te-1/1/49 family ethernet-switching vlan members 3
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
admin@XorPlus# run show vlans
VlanID    Vlan Name    Tag                    Interfaces

GVRP

- Overview of GVRP
- Configuring GVRP
- Example for Configuring GVRP

Overview of GVRP

> **NOTE:**
> GVRP and MVRP are mutually exclusive which can not be configured at the same time.

To manually create or delete VLANs for all the devices in a large and complex network, the workload will be very heavy, and it is very easy to make a configuration mistakenly for network administrator. In this case, users can complete the VLAN configuration through GVRP dynamic VLAN creation function.

GARP VLAN Registration Protocol (GVRP) is an application of Generic Attribute Registration Protocol (GARP) that is used to propagate and register VLAN configuration information on interfaces among devices. After the device enables GVRP, it sends the local VLAN configuration information to other devices, and also receives VLAN configuration information from other devices, so as to dynamically updates local VLAN configuration information to keep consistent with other devices in the network, which greatly reduces the VLAN configuration work for network administrator.

When the network topology changes, GVRP re-propagates and registers VLAN configuration information according to the new topology, so as to make VLAN configuration information on all the GVRP devices be updated synchronously with the network topology.

GVRP Timer

> **NOTE:**
> It is highly recommended to KEEP the default configuration of GVRP Timers to ensure the system and network stability. Modifying timers to inappropriate values might cause an imbalance in the operation of GVRP.

The supported GVRP timers are shown in the following table.

Timer Name	Function	Description
Join Timer	It is used to control the sending of Join messages.	To ensure that join messages are transmitted to other participants, an MRP participant waits for the specified period of the join timer before sending a join message. If a JoinIn message is received within one Join timer time, a second Join message is not sent; if not received, another Join message is sent.
Leave Timer	It is used to control the VLAN registrar state machine change.	The Leave timer is started when a Leave message or LeaveAll message is received on the interface. The VLAN registrar state machine waits in the Leave All state before transiting to the MT state before the Leave timer expires.
LeaveAll Timer	It is used to specify the frequency with which the Leave All state machine generates Leave All messages.	When GVRP is enabled, the device starts the LeaveAll timer. When the timer expires, the device sends a LeaveAll message externally, which is used to deregister all VLAN attributes on the GVRP device in the network.

GVRP edge-switch

For the GVRP access switch connected the host, when this switch forms a loop with other devices, it causes the GVRP messages received by this device to be forwarded cyclically over the same set of links, which consumes bandwidth and causes overutilization. To solve this problem, users can configure the following command to enable GVRP edge-switch function on the host-side switch, then the edge switch will not forward the received GVRP messages.

```
admin@PICOS# set protocols gvrp edge-switch true
admin@PICOS# commit
```

Configuring GVRP

- Configuration Notes and Constraints
- Configuring GVRP

Configuration Notes and Constraints

When configuring GVRP, pay attention to the following notes:

- GVRP and MVRP are mutually exclusive which can not be configured at the same time.
- The GVRP function can only work on **Trunk** type interfaces.
- GVRP is not allowed to be enabled on the host-side interfaces of the access devices at both ends of the network. However, users have to enable GVRP on all uplink interfaces of the access devices and all interfaces of intermediate devices.
- GVRP function conflicts with VLAN member function. That is, the static configuration of VLAN member is not allowed on the interface that enables GVRP function.
- On a single device, GVRP supports allocating up to 256 VLANs.
- STP/RSTP/MSTP blocking interface does not block GVRP PDUs.
- GVRP and Rapid PVST+ cannot be configured at the same time.
- It is not supported to deploy GVRP in MLAG topology.
- In the topology with loops, even if spanning tree is enabled, dynamic VLANs may not be removed by GVRP Leave/LeaveAll process.
- GVRP cannot be enabled on the routed interface or a member port of a LAG port.
- It is highly recommended to KEEP the default configurations of GVRP Timers to ensure the system and network stability. Modifying timers to inappropriate values might cause an imbalance in the operation of GVRP.

Configuring GVRP

Step1 Enable GVRP function globally.

set protocols gvrp enable <**true | false**>

Step2 Configure the port mode to **trunk**.

set interface gigabit-ethernet *<interface-name>* **family ethernet-switching port-mode** *<port-mode>*

Step3 Enable GVRP function on a specific interface.

> **NOTE:**
> To enable GVRP function, users need to enable GVRP function BOTH globally and at the per-interface level.

set protocols gvrp interface <*interface-name*> **enable** <**true | false**>

Step4 (Optional) Enable GVRP edge-switch function on the edge switch to prevent loops.

> **NOTE:**
> This command can be enabled only on the edge switches.

set protocols gvrp edge-switch <**true | false**>

Step5 (Optional) Configure GVRP timers.

set protocols gvrp join-timer *<join-timer>*

set protocols gvrp leave-timer *<leave-timer>*

set protocols gvrp leaveall-timer*<leaveall-timer>*

Step6 Commit the configuration.

commit

Step7 View the configuration information of GVRP.

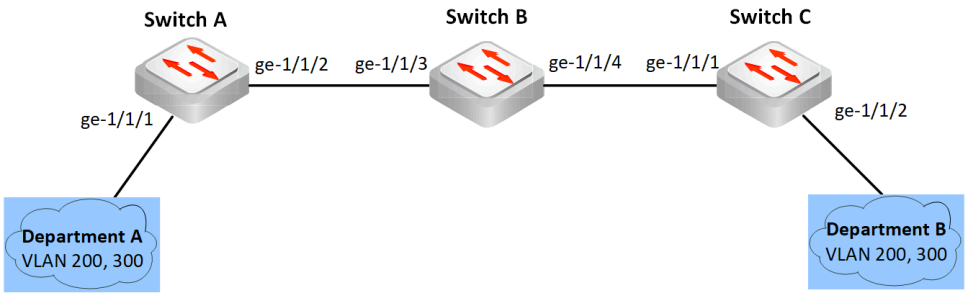
run show gvrp interface *<interface-name>*

Example for Configuring GVRP

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Switch C
- Verification

Networking Requirements

Figure 1. GVRP Configuration Example



As shown in **Figure 1**, Department A and Department B (belonging to VLAN 200, 300) of a company are connected by multiple switches, which requires mutual communication between the two departments.

We can enable GVRP function for dynamic VLAN creation to reduce the workload of VLAN configuration. To achieve GVRP dynamic VLAN registration, first statically configure the access interface of Switch A and Switch C to join VLAN 200 and 300, then enable global GVRP function and the interface GVRP function on Switch A, Switch B and Switch C.

> **NOTEs:**
> - GVRP is not allowed to be enabled on the host-side interfaces of the access devices, say ge-1/1/1 on Switch A and ge-1/1/2 on Switch C. However, GVRP needs to be enabled on ge-1/1/2 of Switch A, ge-1/1/1 of Switch C and all interfaces of Switch B .
> - The port mode of GVRP interfaces should be **Trunk** type.

Procedure

Switch A

Step1 Configure VLAN and port mode.

```
admin@SwitchA# set vlans vlan-id 200
admin@SwitchA# set vlans vlan-id 300
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 200
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 300
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
```

Step2 Enable GVRP function globally.

```
admin@SwitchA# set protocols gvrp enable true
```

Step3 Enable GVRP function on the interface.

```
admin@SwitchA# set protocols gvrp interface ge-1/1/2 enable true
```

Step4 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure port-mode to **trunk**.

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
```

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode trunk
```

Step2 Enable GVRP function globally.

```
admin@SwitchB# set protocols gvrp enable true
```

Step3 Enable GVRP function on the interfaces.

```
admin@SwitchB# set protocols gvrp interface ge-1/1/3 enable true
admin@SwitchB# set protocols gvrp interface ge-1/1/4 enable true
```

Step4 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN and port mode.

```
admin@SwitchC# set vlans vlan-id 200
admin@SwitchC# set vlans vlan-id 300
admin@SwitchC# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 200
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 300
```

Step2 Enable GVRP function globally.

```
admin@SwitchC# set protocols gvrp enable true
```

Step3 Enable GVRP function on the interfaces.

```
admin@SwitchC# set protocols gvrp interface ge-1/1/1 enable true
```

Step4 Commit the configurations.

```
admin@SwitchC# commit
```

Verification

- After the configuration, users belonging to VLAN 200 (or 300) of department A and department B can communicate with each other.
- On Switch A, use command **run show gvrp interface** <*interface-name*> to view GVRP information on a specific interface, including GVRP Status, Registrar State, Timers and VLANs learned by the interface through GVRP.

```
admin@SwitchA# run show gvrp interface ge-1/1/2
Port            Leave Timer(ms)  LeaveAll Timer(s)  Join Timer(ms)
ge-1/1/2        1000             10                 200

Port            Vlans Added
ge-1/1/2        200, 300
```

- On Switch A, use command **run show gvrp interface** <*interface-name*> **statistics** to view the statistics of GVRP PDUs on the interface.

```
admin@SwitchA# run show gvrp interface ge-1/1/2 statistics
packet_received: 245
packet_sent:    248
```

GVRP information on Switch B and Switch C can be viewed in the similar way and will not be repeated here.

MVRP

- Overview of MVRP
- Configuring MVRP
- Example for Configuring MVRP

Overview of MVRP

> **NOTE:**
> GVRP and MVRP are mutually exclusive and can not be configured at the same time.

To manually create or delete VLANs for all the devices in a large and complex network, the workload will be very heavy, and it is very easy to make a configuration mistakenly for network administrator. In this case, users can complete the VLAN configuration through MVRP dynamic VLAN creation function.

Multiple VLAN Registration Protocol (MVRP) is an application of Multiple Registration Protocol (MRP) that is used to propagate and register VLAN configuration information on interfaces among devices. After the device enables MVRP, it sends the local VLAN configuration information to other devices, and also receives VLAN configuration information from other devices, so as to dynamically updates local VLAN configuration information to keep consistent with other devices in the network, which greatly reduces the VLAN configuration work for network administrator.

When the network topology changes, MVRP re-propagates and registers VLAN configuration information according to the new topology, so as to make VLAN configuration information on all the MVRP devices be updated synchronously with the network topology.

MVRP Timer

> **NOTE:**
> It is highly recommended to KEEP the default configuration of MVRP Timers to ensure the system and network stability. Modifying timers to inappropriate values might cause an imbalance in the operation of MVRP.

The supported MVRP timers are shown in the following table.

Timer Name	Function	Description
Join Timer	It is used to control the sending of Join messages.	To ensure that join messages are transmitted to other participants, an MRP participant waits for the specified period of the join timer before sending a join message. If a JoinIn message is received within one Join timer time, a second Join message is not sent; if not received, another Join message is sent.
Leave Timer	It is used to control the VLAN registrar state machine change.	The Leave timer is started when a Leave message or LeaveAll message is received on the interface. The VLAN registrar state machine waits in the Leave All state before transiting to the MT state before the Leave timer expires.
LeaveAll Timer	It is used to specify the frequency with which the Leave All state machine generates Leave All messages.	When MVRP is enabled, the device starts the LeaveAll timer. When the timer expires, the device sends a LeaveAll message externally, which is used to deregister all VLAN attributes on the MVRP device in the network.

MVRP edge-switch

For the MVRP access switch connected the host, when this switch forms a loop with other devices, it causes the MVRP messages received by this device to be forwarded cyclically over the same set of links, which consumes bandwidth and causes overutilization. To solve this problem, users can configure the following command to enable MVRP edge-switch function on the host-side switch, then the edge switch will not forward the received MVRP messages.

```
admin@PICOS# set protocols mvrp edge-switch true
admin@PICOS# commit
```

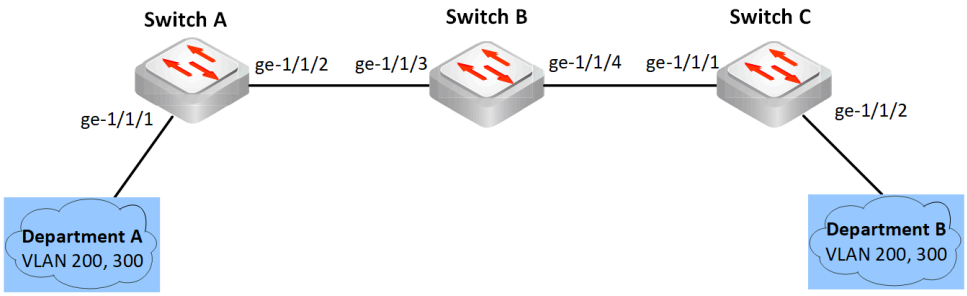
Networking Requirements

Figure 1. MVRP Configuration Example



As shown in **Figure 1**, Department A and Department B (belonging to VLAN 200, 300) of a company are connected by multiple switches, which requires mutual communication between the two departments.

We can enable MVRP function for dynamic VLAN creation to reduce the workload of VLAN configuration. To achieve MVRP dynamic VLAN registration, first statically configure the access interface of Switch A and Switch C to join VLAN 200 and 300, then enable global MVRP function and the interface MVRP function on Switch A, Switch B and Switch C.

NOTEs:

- MVRP is not allowed to be enabled on the host-side interfaces of the access devices, say ge-1/1/1 on Switch A and ge-1/1/2 on Switch C. However, MVRP needs to be enabled on ge-1/1/2 of Switch A, ge-1/1/1 of Switch C and all interfaces of Switch B .
- The port mode of MVRP interfaces should be **Trunk** type.
- VLANs need to be statically configured on the access interfaces of the access devices at both ends of the network, in order to implement MVRP bidirectional VLAN registration process.

Procedure

Switch A

Step1 Configure VLAN and port mode.

```
admin@SwitchA# set vlans vlan-id 200
admin@SwitchA# set vlans vlan-id 300
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 200
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 300
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
```

Step2 Enable MVRP function globally.

```
admin@SwitchA# set protocols mvrp enable true
```

Step3 Enable MVRP function on the interface.

```
admin@SwitchA# set protocols mvrp interface ge-1/1/2 enable true
```

Step4 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure port-mode to **trunk**.

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode trunk
```

Step2 Enable MVRP function globally.

```
admin@SwitchB# set protocols mvrp enable true
```

Step3 Enable MVRP function on the interfaces.

```
admin@SwitchB# set protocols mvrp interface ge-1/1/3 enable true
admin@SwitchB# set protocols mvrp interface ge-1/1/4 enable true
```

Step4 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN and port mode.

```
admin@SwitchC# set vlans vlan-id 200
admin@SwitchC# set vlans vlan-id 300
admin@SwitchC# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 200
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 300
```

Step2 Enable MVRP function globally.

```
admin@SwitchC# set protocols mvrp enable true
```

Step3 Enable MVRP function on the interfaces.

```
admin@SwitchC# set protocols mvrp interface ge-1/1/1 enable true
```

Step4 Commit the configurations.

```
admin@SwitchC# commit
```

Verification

- After the configuration, users belonging to VLAN 200 (or 300) of department A and department B can communicate with each other.
- On Switch A, use command **run show mvrp interface** <*interface-name*> to view MVRP information on a specific interface, including MVRP Status, Registrar State, Timers and VLANs learned by the interface through MVRP.

```
admin@SwitchA# run show mvrp interface ge-1/1/2
Port            Leave Timer(ms)  LeaveAll Timer(s)  Join Timer(ms)
ge-1/1/2        1000             10                  200

Port            Vlans Added
ge-1/1/2        200, 300
```

- On Switch A, use command **run show mvrp interface** <*interface-name*> **statistics** to view the statistics of MVRP PDUs on the interface.

```
admin@SwitchA# run show mvrp interface ge-1/1/2 statistics
packet_received: 245
packet_sent:    248
```

MVRP information on Switch B and Switch C can be viewed in the similar way and will not be repeated here.

Q-in-Q Basic Port Configuration

Q-in-Q tunneling allows service providers on Ethernet access networks to extend a Layer2 Ethernet connection between two customer sites. Q-in-Q tunneling can also be used to segregate or bundle customer traffic into fewer VLANs, or different VLANs, by adding another layer of 802.1Q tags.
Q-in-Q tunneling is useful when there are overlapping VLAN IDs because the 802.1Q VLAN tags are prepended by the service VLAN tag. The L2/L3 implementation of Q-in-Q tunneling supports the IEEE 802.1ad standard.
The Q-in-Q tunneling external mode belongs to basic Q-in-Q, while the Q-in-Q tunneling internal mode belongs to selective Q-in-Q.

Configuring the Q-in-Q Tunneling Internal/External Mode

By default, Q-in-Q is disabled. User can enable it as shown below:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching dot1q-tunneling mode
internal
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching dot1q-tunneling mode
external
admin@XorPlus# commit
Commit OK.
Save done.

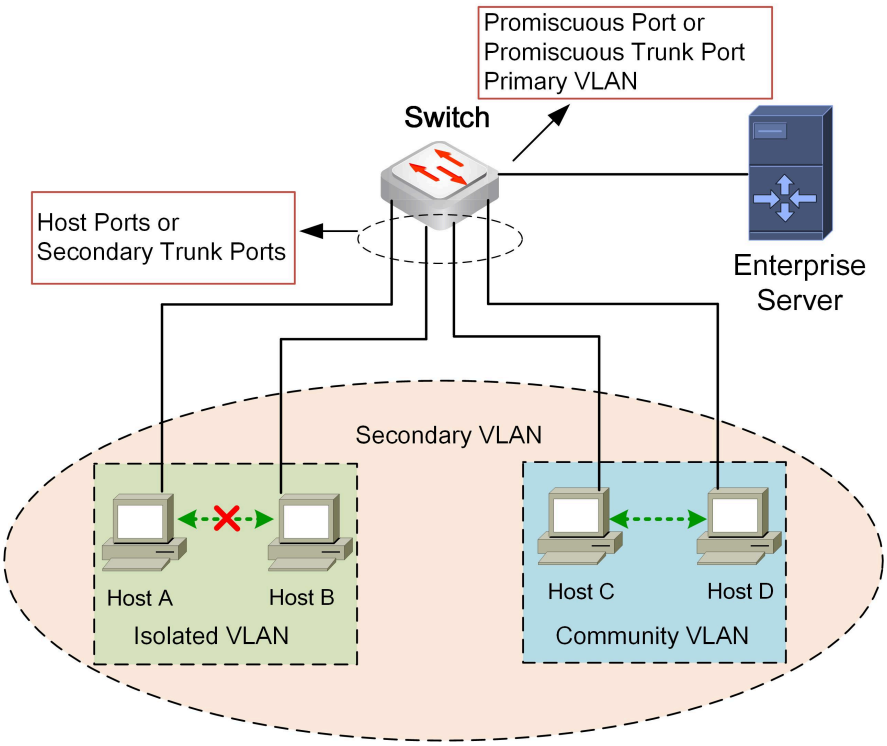
Overview

Private VLAN (PVLAN) is a technology that divides a VLAN broadcast domain into multiple discrete broadcast subdomains by defining secondary VLANs (community VLANs and an isolated VLAN) inside a primary VLAN, achieving port isolation within a VLAN while sharing a single layer-3 router port and the same IP subnet.

For example, in **Figure 1**, access-side VLANs are divided into Isolated VLAN and Community VLAN. Community VLAN users can communicate with each other, while Isolated VLAN users are isolated and cannot communicate with each other. However, both Community VLAN users and Isolated VLAN users can access the Primary VLAN where the enterprise servers are located. All of this can be accomplished by deploying PVLAN.

Figure 1. PVLAN Application Diagram



PVLAN has the following characteristics and advantages,

- By deploying PVLANs and configuring isolated VLANs on the access side, it is possible to isolate the traffic of different users in the same VLAN. This improves the network security as well as conserving VLANs.
- As all secondary VLAN users inside a primary VLAN share one IP subnet, PVLAN can be deployed to conserve IP addresses.

PVLAN Concepts and Terminology

PVLAN Types

PVLAN defines two VLAN types: primary VLAN and secondary VLAN. One pair of PVLAN consists of only one primary VLAN and at least one secondary VLAN. One switch can configure multiple pairs of PVLAN.

Note that, secondary VLANs need to be associated with a primary VLAN to form a pair of PVLANs.

- **Primary VLAN**

Ports within a primary VLAN are connected to the uplink devices, and the corresponding ports are PVLAN promiscuous ports or promiscuous trunk ports. These ports are used to transmit traffic from the promiscuous ports to the host ports and to other promiscuous ports.

A pair of PVLAN has only one primary VLAN.

A primary VLAN can be associated with multiple community VLANs and only one isolated VLAN.

- **Secondary VLAN**

Ports within a secondary VLAN are connected to the hosts or downlink devices, and the corresponding ports are PVLAN host ports or secondary trunk ports. These ports are used to transmit traffic from hosts to other allowed hosts or to upstream routers.

There are two types of secondary VLANs: Isolated VLAN and Community VLAN.

Secondary VLANs should be configured to associate with a primary VLAN. One secondary VLAN (isolated or community) can be associated with only one primary VLAN.

> **NOTE:**
>
> In the CLI configuration, the configurable values are "**isolated**" and "**community**", but not "**secondary**".

- **Isolated VLAN**

An isolated VLAN is a secondary VLAN, which is used to transmit traffic from the hosts toward the promiscuous ports and the gateway. Ports within an isolated VLAN cannot communicate with each other at the Layer 2 level. Traffic received from an isolated port is forwarded only to promiscuous ports.

A pair of PVLAN can configure not more than one Isolated VLAN.

- **Community VLAN**

A community VLAN is a secondary VLAN that transmits upstream traffic from the host ports to the promiscuous port gateways and to other host ports in the same community VLAN. Ports within a community VLAN can communicate with each other and the primary VLAN but cannot communicate with ports in other communities at the Layer 2 level or isolated VLAN.

Users can configure multiple community VLANs in a pair of PVLAN.

PVLAN Port Modes

Ethernet interfaces are classified into four PVLAN types depending on the devices connected to them and the way they process the frames.

> **NOTE:**
>
> - Only when configured with the PVLAN port mode, a port can be added into a PVLAN.
> - After modifying the port mode, the port will be restarted automatically.

- **PVLAN Host Port**

A PVLAN host port connects to a user device. For host mode ports, make sure that their native VLAN is a secondary VLAN, otherwise the ports won't be able to forward packets from primary VLAN. One host port can be added into only one secondary VLAN.

Packets sent from this port are untagged.

- **PVLAN Secondary Trunk Port**

A PVLAN secondary trunk port is used to connect to the downstream devices. One secondary trunk port can be added into more than one secondary VLAN. Secondary trunk mode is applicable to scenarios where multiple secondary VLANs need to pass through the downlink port while Host mode is applicable to cases where only one secondary VLAN passes through the downlink port.

The primary VLAN ID carried by the packets is replaced with the corresponding secondary VLAN ID on the outbound side of the secondary trunk mode port, thus masking the primary VLAN for the downstream device. By default, packets sent from this port will be tagged (tagged/untagged can be configured through CLI command).

> **NOTE:**
>
> - Secondary trunk mode ports can be added to only one secondary VLAN of the same primary VLAN, but can be added to multiple secondary VLANs associated with different primary VLANs.
> - PVLAN secondary trunk port can also be added to normal VLANs in addition to the secondary VLANs.

- **PVLAN Promiscuous Port**

PVLAN promiscuous ports are used to connect to the uplink devices. Uplinks are typically ports that connect to routers, firewalls, servers or provider networks.

Promiscuous ports belong to the primary VLAN, which can communicate with all PVLAN ports, including host/secondary trunk ports and other promiscuous/promiscuous trunk ports within the same primary VLAN.

A promiscuous port can serve only one primary VLAN, one isolated VLAN, and multiple community VLANs.

Make sure that the native VLAN of the promiscuous port is the primary VLAN, otherwise the port will not forward packets sent from a secondary VLAN.

Promiscuous port mode is used when there is only one primary VLAN passing through the uplink port. Packets sent from this port are untagged.

- **PVLAN Promiscuous Trunk Port**

PVLAN promiscuous trunk ports are used to connect to the uplink devices. Promiscuous trunk port mode is used when there are more than one primary VLAN passing through the uplink port.

The secondary VLAN ID carried by the message is replaced with the corresponding primary VLAN ID on the outbound side of the port, thus masking the secondary VLAN for the uplink device. By default, packets sent from this port will be tagged (tagged/untagged can be configured through CLI command).

> **NOTE:**
>
> PVLAN Promiscuous trunk ports can also be added to normal VLANs in addition to the primary VLANs.

Communication Restriction between PVLAN Ports

PVLANs limit the Layer 2 communication within a pair of Private VLANs, a port defined in a PVLAN cannot communicate with ports in other pairs of PVLANs or normal VLANs.

The following table summaries the Layer 2 communication restriction between the PVLAN ports.

PVLAN	PVLAN Mode	Port Mode	Communication Restriction

Primary VLAN	Primary VLAN	Promiscuous Port Promiscuous Trunk Port	The port within the primary VLAN can communicate with all ports in a pair of PVLAN.
Secondary VLAN	Isolated VLAN	Host Port Secondary Trunk Port	Ports within an isolated VLAN cannot communicate with each other at the Layer 2 level. Each isolated VLAN must be bound to a primary VLAN.
	Community VLAN	Host Port Secondary Trunk Port	Ports within a community VLAN can communicate with each other but cannot communicate with ports in other communities at the Layer 2 level. Each community VLAN must be bound to a primary VLAN.

Configuration Synchronization for PVLAN Port

In order for users in the secondary VLAN to communicate with users in the Primary VLAN, the system synchronizes Private VLAN configurations for the PVLAN ports.

If the PVLAN port has been configured to add to the primary VLAN (or secondary VLAN), the port will be added to the corresponding secondary VLAN (or primary VLAN) based on the following rules while maintaining the original configuration.

- The downlink ports in host mode or secondary trunk mode will be added to the corresponding primary VLAN. The primary VLAN ID carried by the packets is replaced with the corresponding secondary VLAN ID on the outbound side of the port, thus masking the primary VLAN for the downstream device.

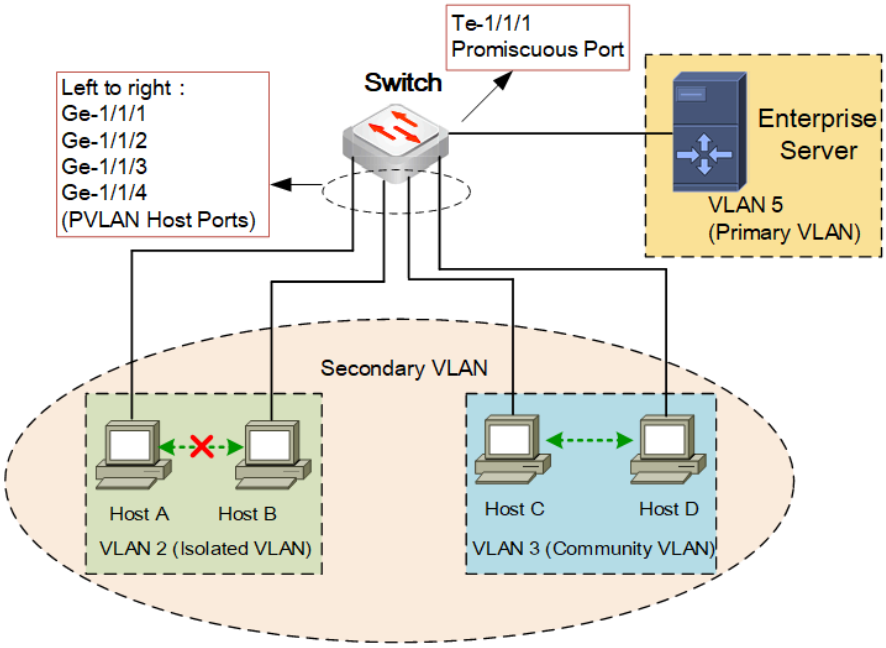
Messages sent from the secondary trunk mode ports could be tagged or untagged, which is determined by the tagged/untagged configuration of the secondary VLAN.

- The uplink ports in promiscuous mode or promiscuous trunk mode will be added to the corresponding secondary VLAN. The secondary VLAN ID carried by the packets is replaced with the corresponding primary VLAN ID on the outbound side of the port, thus masking the secondary VLAN for the upstream device.

Messages sent from the promiscuous trunk mode ports could be tagged or untagged, which is determined by the tagged/untagged configuration of the primary VLAN.

The following example illustrates configuration synchronization for PVLAN ports in detail.

Figure 2. Diagram for Configuration Synchronization for PVLAN Ports



To configure the topology shown above:

```
set vlans vlan-id 2 private-vlan mode isolated
set vlans vlan-id 3 private-vlan mode community
set vlans vlan-id 5 private-vlan mode primary
set vlans vlan-id 5 private-vlan association 2-3
set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode pvlan-promiscuous
set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 3
set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 3
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 5
```

The system will synchronize private VLAN configurations for the PVLAN ports after completing the configuration, as shown in the following table.

Port	Port Mode	Native VLAN	VLANs Allowed to Pass

Ge-1/1/1	pvlan-host	2	• Added to VLAN 2, 5 • Allow packets of VLAN 2, 5 to pass
Ge-1/1/2	pvlan-host	2	• Added to VLAN 2, 5 • Allow packets of VLAN 2, 5 to pass
Ge-1/1/3	pvlan-host	3	• Added to VLAN 3, 5 • Allow packets of VLAN 3, 5 to pass
Ge-1/1/4	pvlan-host	3	• Added to VLAN 3, 5 • Allow packets of VLAN 3, 5 to pass
Te-1/1/1	pvlan-promiscuous	5	• Added to VLAN 2, 3, 5 • Allow packets of VLAN 2, 3, 5 to pass

Users can run the command **run show vlans** to view the VLAN information. In the output, synchronized VLANs of the PVLAN ports are marked with a **(pv).**

```
admin@Xorplus# run show vlans
VlanID  Vlan Name    Tag        Interfaces
------  ------------ --------   ------------------------------------------------------
2       default      untagged   ge-1/1/1, ge-1/1/2, te-1/1/1(pv)
                     tagged
3       default      untagged   ge-1/1/3, ge-1/1/4, te-1/1/1(pv)
                     tagged
5       default      untagged   ge-1/1/1(pv), ge-1/1/2(pv), ge-1/1/3(pv), ge-1/1/4(pv)
                     tagged
```

MAC Address Duplication

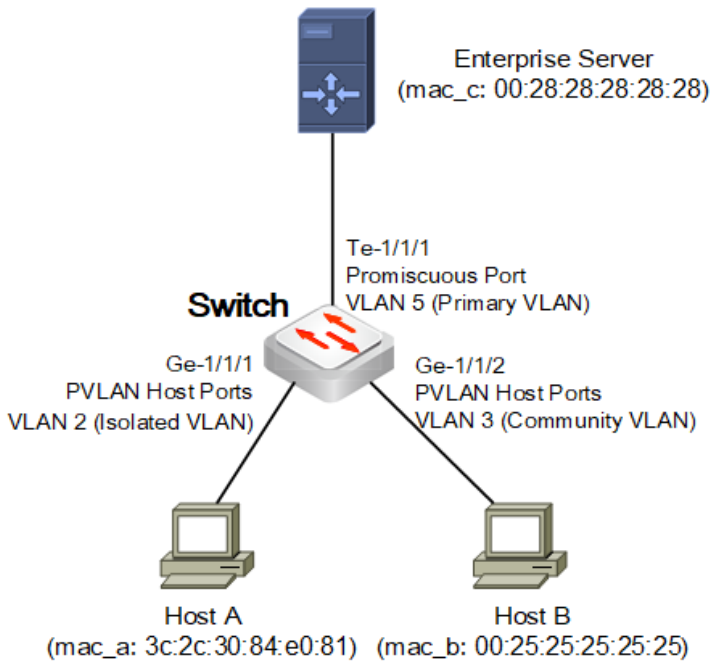
To avoid flooding of packets received from the PVLAN port, PVLAN performs MAC address duplication, including:

- Secondary VLAN to Primary VLAN duplication, that is, MAC addresses dynamically learned or statically configured on ports in the Secondary VLAN are duplicated to the corresponding Primary VLAN.
- Primary VLAN to Secondary VLAN duplication, that is, MAC addresses dynamically learned or statically configured on ports in the Primary VLAN are duplicated to all the corresponding Secondary VLANs.

Note that, for the normal trunk ports between two or multiple switches, MAC addresses dynamically learned or statically configured on ports in the private VLAN will also be duplicated following the rules stated above.

The following example illustrates PVLAN MAC address duplication in detail.

Figure 3. Diagram for PVLAN MAC Address Duplication



From the topology shown above, the resulting MAC address tables before and after the duplication are shown below.

MAC Address Table Before MAC Duplication

Source MAC Address	VLAN	Outgoing Interface

mac_c	5	Te-1/1/1
mac_a	2	Ge-1/1/1
mac_b	3	Ge-1/1/2

MAC Address Table After MAC Duplication

Source MAC Address	VLAN	Outgoing Interface
mac_c	5	Te-1/1/1
mac_c	2	Te-1/1/1
mac_c	3	Te-1/1/1
mac_a	2	Ge-1/1/1
mac_a	5	Ge-1/1/1
mac_b	3	Ge-1/1/2
mac_b	5	Ge-1/1/2

Users can run the command **run show mac-address table** to view the MAC address table. In the output, duplicated MAC address entries are marked with a **(pv)**.

```
admin@Xorplus# run show mac-address table
Total entries in switching table:   7
Static entries in switching table:  0
Dynamic entries in switching table: 7

VLAN    MAC address            Type         Age     Interfaces    User
----      -----------------    ---------    ----    -----------   ----------
5         00:28:28:28:28:28    Dynamic      300     te-1/1/1       xorp
2         00:28:28:28:28:28    Dynamic(pv)  300     te-1/1/1       xorp
3         00:28:28:28:28:28    Dynamic(pv)  300     te-1/1/1       xorp
2         3c:2c:30:84:e0:81    Dynamic      300     ge-1/1/1       xorp
5         3c:2c:30:84:e0:81    Dynamic(pv)  300     ge-1/1/1       xorp
3         00:25:25:25:25:25    Dynamic      300     ge-1/1/2       xorp
3         00:25:25:25:25:25    Dynamic(pv)  300     ge-1/1/2       xorp
```

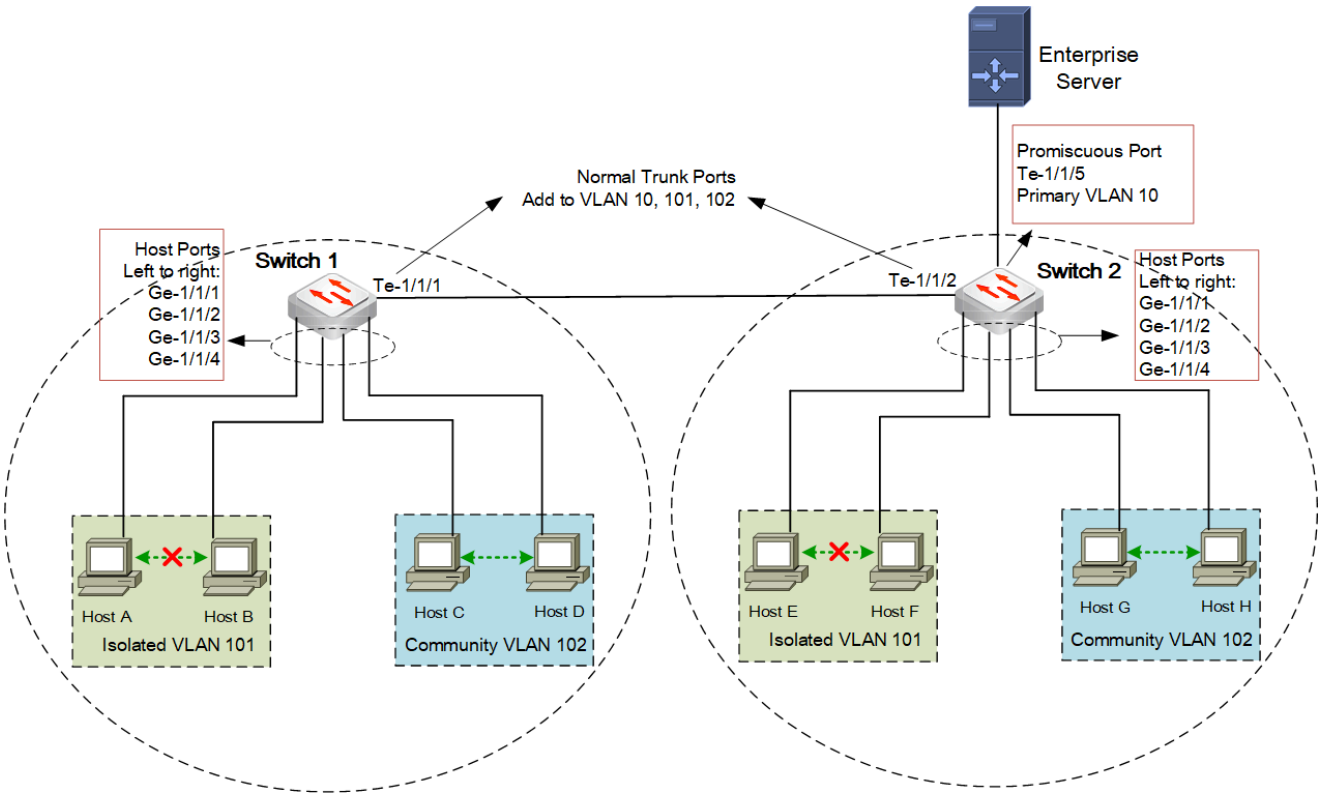
NOTE:
For the secondary VLANs configured on the normal trunk port, the static MAC entries configured on these secondary VLANs are NOT duplicated to the primary VLAN.

However, for the primary VLAN configured on the normal trunk port, the static MAC entries configured on this primary VLAN are duplicated to the secondary VLANs.

PVLAN Across Multiple Switches

Users can configure normal trunk ports between two or multiple switches to enable PVLAN cross-device communication.

Figure 4. Diagram for PVLAN Across Multiple Switches



As shown in the topology above, we want to achieve the following:

- Hosts connecting to the same switch or across multiple switches in the same Community VLAN can communicate with each other. In the figure, Host C, Host D, Host G and Host H in the same Community VLAN (VLAN 102) can communicate with each other.
- Hosts connecting to the same switch or across multiple switches in the same Isolated VLAN cannot communicate with each other. In the figure, Host A, Host B, Host E and Host F in the same Isolated VLAN (VLAN 101) cannot communicate with each other.

Besides the basic PVLAN configurations, we have to configure ports Te-1/1/1 and Te-1/1/2 as normal trunk ports, connecting Switch 1 to Switch 2. And then add Te-1/1/1 and Te-1/1/2 to all the private VLAN IDs (VLAN 10, 101 and 102 in this example) and normal VLAN IDs (if have) to carry packets needed to forward through the trunk link.

To configure the topology shown above:

```
# Switch 1
set vlans vlan-id 10 private-vlan mode primary
set vlans vlan-id 102 private-vlan mode community
set vlans vlan-id 101 private-vlan mode isolated
set vlans vlan-id 10 private-vlan association 101-102
set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 101
set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 101
set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 102
set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 102
set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 10
set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 101-102
```

```
# Switch 2
set vlans vlan-id 10 private-vlan mode primary
set vlans vlan-id 102 private-vlan mode community
set vlans vlan-id 101 private-vlan mode isolated
set vlans vlan-id 10 private-vlan association 101-102
set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode pvlan-host
set interface gigabit-ethernet te-1/1/5 family ethernet-switching port-mode pvlan-promiscuous
set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 101
```

```
set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 101
set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 102
set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 102
set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 10
set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 10
set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 101-102
```

From the configurations above, we can note that PVLAN configurations, as well as the binding configuration of primary VLAN and secondary VLAN need to be consistent on all switches.

Deploy DHCP Snooping with PVLAN

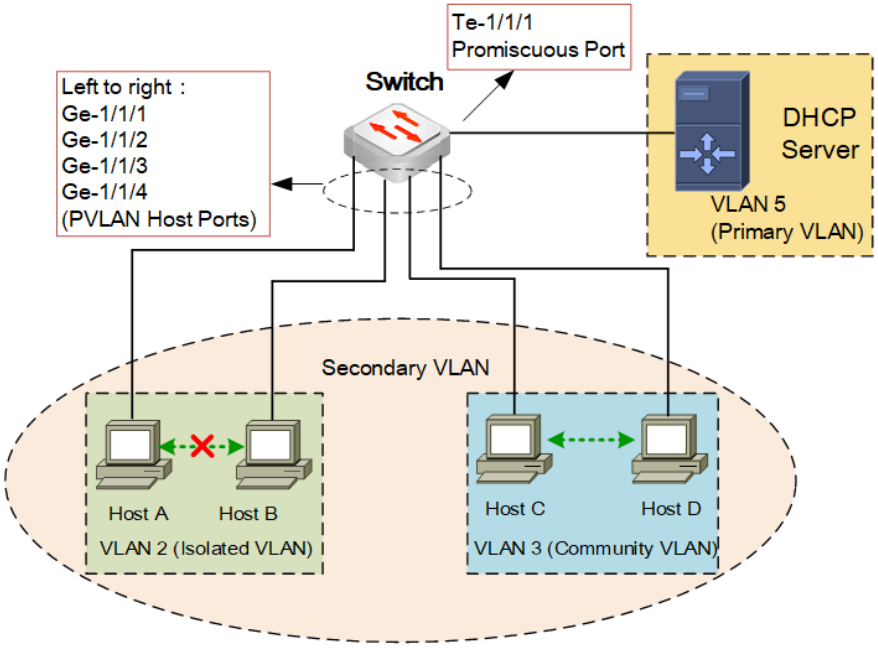
PicOS supports deploying DHCP snooping in a PVLAN topology. Depending on whether the DHCP client and server are on the same PVLAN switch, this section is divided into two parts:

- DHCP Client and Server Deployed on a Single Switch
- DHCP Client and Server Deployed Across Multiple Switches

DHCP Client and DHCP Server Deployed on a Single Switch

In the following PVLAN topology, Switch acts as a user gateway and forwards DHCP messages to the DHCP server, so that DHCP clients Host A, Host B, Host C and Host D can request for IP address lease and other related configuration information from the DHCP server. In order to provide better service to DHCP users, network administrators can configure DHCP Snooping to prevent DHCP attacks.

Figure 5. Diagram for Deploying DHCP Snooping with PVLAN on a Single Switch



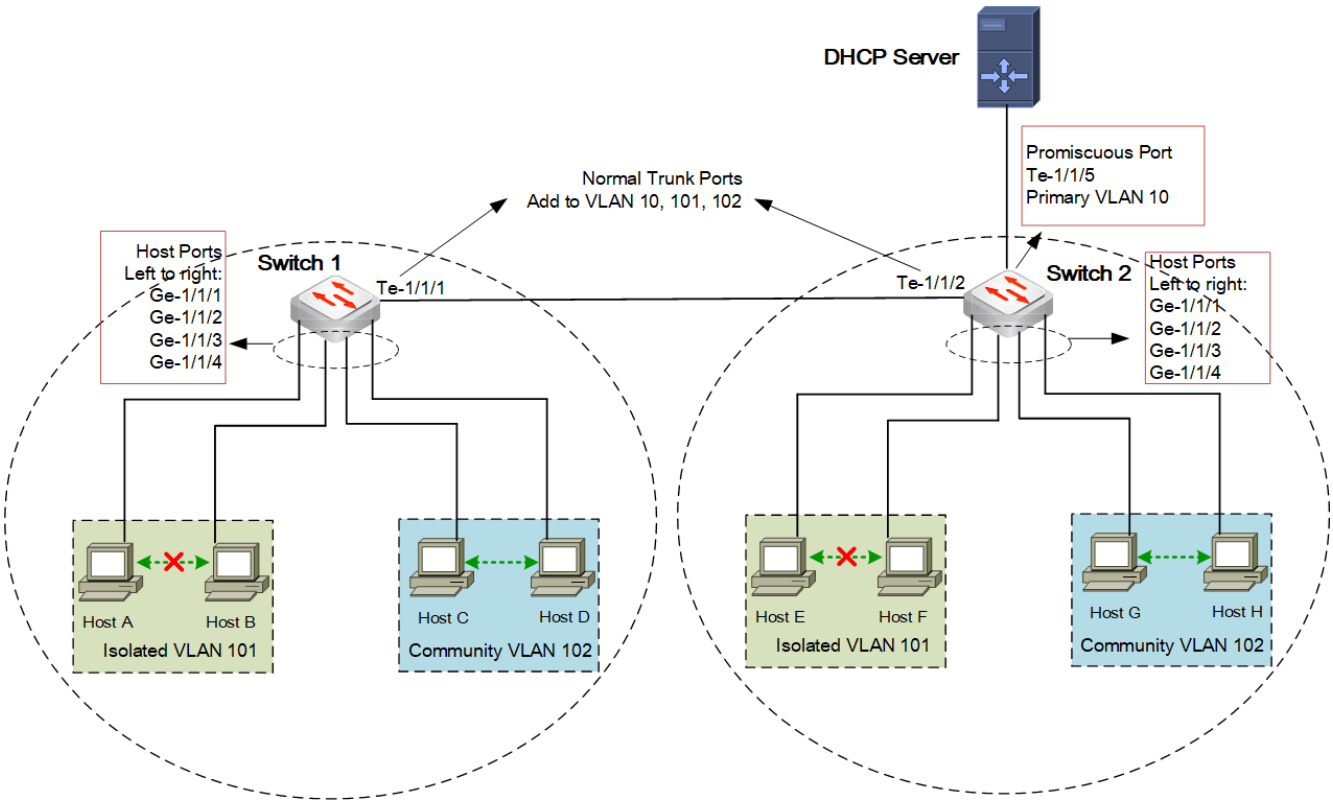
In the above topology, besides the basic PVLAN configurations, you need to do the following DHCP snooping configuration to enable DHCP snooping and configure the trust port.

```
set protocols dhcp snooping vlan 5 disable false
set protocols dhcp snooping trust-port te-1/1/1
```

DHCP Client and Server Deployed Across Multiple Switches

In the following PVLAN topology, DHCP clients Host A, Host B, Host C, Host D and the DHCP server are deployed across two PVLAN switches.

Figure 6. Diagram for Deploying DHCP Snooping with PVLAN Across Multiple Switches



In this example, you can refer to PVLAN Across Multiple Switches to complete the basic PVLAN configurations. When configuring DHCP snooping, pay attention to the following points:

- Enable DHCP snooping in VLAN 10 on both Switch 1 and Switch 2.
- In addition to configuring port Te-1/1/5 on Switch 2 as a trust port, which is connected to the DHCP server, users also have to configure Te-1/1/1 on Switch 1 as a trust port.

Configuration Notes of PVLAN

When configuring PVLAN on a device, pay attention to the following points:

- One pair of PVLAN consists of only one primary VLAN and at least one secondary VLAN. One switch can configure multiple pairs of PVLAN.
- One primary VLAN can be associated with multiple community VLANs and only one isolated VLAN.
- A secondary VLAN (isolated or community) can be associated with one and only one primary VLAN, but not multiple primary VLANs.
- PVLAN supports to be deployed in conjunction with MSTP or rapid PVST+. A pair of primary VLAN and secondary VLANs should be in the same MSTP instance when MSTP is deployed with PVLAN.
- PVLAN supports to be deployed with DHCP snooping.
- Both primary VLAN and secondary VLAN should be in the same MSTP instance when MSTP is deployed with PVLAN.
- Layer 3 routing on private VLAN is not supported.
- VLAN 1 is not allowed to be configured as a private VLAN.
- If you want to change a private VLAN to a normal VLAN, you need to remove the configurations for PVLAN-related binding relationship before you can remove the PVLAN mode configuration. For example, if you use the **set vlans vlan-id** <*vlan-id*> **private-vlan association** <*secondary-vlan-list*> command for PVLAN association, remove the binding relationship first before you can change the private VLAN to a normal VLAN.

  Similarly, it is also required to remove the private VLAN related configuration (e.g. static MAC address configurations on private VLAN) before changing the role of a private VLAN to another PVLAN type, e.g. when changing the PVLAN type from primary VLAN to secondary VLAN.
- Before modifying or deleting PVLAN association configuration, you need to delete all the PVLAN settings of the involved Private VLANs.
- For the secondary VLANs configured on the normal trunk port, the static MAC entries configured on these secondary VLANs are NOT duplicated to the primary VLAN. However, for the primary VLAN configured on the normal trunk port, the static MAC entries configured on this primary VLAN are duplicated to the secondary VLANs.

Configuring PVLAN

By default, the Private VLAN is disabled. To configure a PVLAN, follow these steps:

1. Create the secondary VLANs, i.e. isolated VLAN or community VLAN.
2. Create the primary VLAN.
3. Associate the secondary VLAN with the primary VLAN. (Only one isolated VLAN can be associated with a primary VLAN, but more than one community VLAN can be associated with a primary VLAN).
4. Configure the port connected to the host or the downlink devices as a PVLAN host port or secondary trunk port.
5. Configure the port connected to the uplink device as a PVLAN promiscuous port or promiscuous trunk port.
6. Add PVLAN ports to the private VLAN and set the native VLAN of the port as the private VLAN.
7. Verify PVLAN configurations.

Procedure

Step1 Create the secondary VLANs.

set vlans vlan-id <*vlan-id*> **private-vlan mode community**

set vlans vlan-id <*vlan-id*> **private-vlan mode isolated**

Step2 Create the primary VLAN.

set vlans vlan-id <*vlan-id*> **private-vlan mode primary**

Step3 Associate the secondary VLAN with the primary VLAN.

set vlans vlan-id <*vlan-id*> **private-vlan association** <*secondary-vlan-list*>

Step4 Configure the port connected to the uplink device as a promiscuous port or promiscuous trunk port.

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching port-mode** <*port-mode*>

Step5 Configure the port connected to the host or the downlink device as a host port or secondary trunk port.

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching port-mode** <*port-mode*>

Step6 Add the PVLAN ports to the private VLAN and set the native VLAN of the port as the private VLAN.

set interface gigabit-ethernet <*port*> **family ethernet-switching native-vlan-id** <*vlan-id*>

Step7 Commit the configurations.

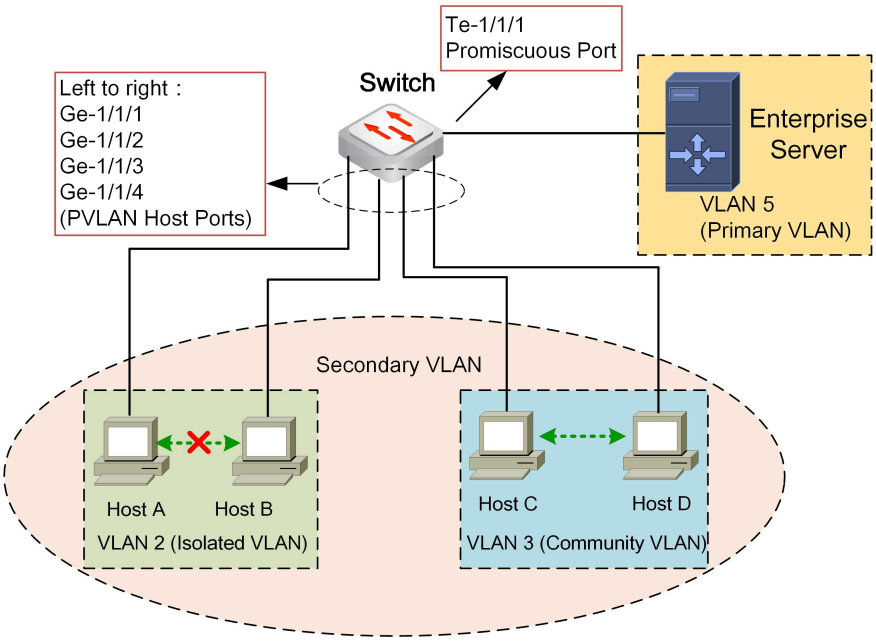
Commit

Example for Configuring PVLAN

- Networking Requirements
  - Figure 1. PVLAN Configuration Example
- Procedure
- Verify the Configuration

Networking Requirements

Figure 1. PVLAN Configuration Example



As shown in **Figure 1**, in an enterprise network, all employees have access authorization to the enterprise server. However, it is desirable that some employees within the enterprise can communicate with each other, while some employees are isolated from each other.

In order to achieve this, PVLAN feature can be deployed on the switch that connects the terminal and the enterprise server. PVLAN not only meets the network isolation demands, but also addresses the problem of VLAN ID shortage, and is easy to maintain by the network administrator.

Complete the following configurations on the Switch:

- To isolate the communication between Host A and Host B, configure the VLAN of Host A and Host B (VLAN 2) as the Isolated VLAN; To make sure Host C and Host D can communicate with each other, configure the VLAN of Host C and Host D (VLAN 3) as the Community VLAN.
- Configure the VLAN of the server as the Primary VLAN.
- The access ports of Host A, Host B, Host C, and Host D are configured as the PVLAN host ports.
- Add the access ports of Host A and Host B (ge-1/1/1 and ge-1/1/2) into Isolated VLAN. Add the access ports of Host C and Host D (ge-1/1/3 and ge-1/1/4) to the Community VLAN.
- The port connected to the server is configured as promiscuous port and is added into the primary VLAN (VLAN 5).

Procedure

Step1 Create the secondary VLANs.

```
admin@XorPlus# set vlans vlan-id 2 private-vlan mode isolated
admin@XorPlus# set vlans vlan-id 3 private-vlan mode community
```

Step2 Create the primary VLAN.

```
admin@XorPlus# set vlans vlan-id 5 private-vlan mode primary
```

Step3 Associate the secondary VLAN with the primary VLAN.

```
admin@XorPlus# set vlans vlan-id 5 private-vlan association 2-3
```

Step4 Configure the ports connected to the hosts as the PVLAN host ports.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode pvlan-host
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode pvlan-host
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode pvlan-host
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode pvlan-host
```

Step5 Configure the port connected to the Server as the promiscuous port.

```
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode pvlan-promiscuous
```

Step6 Add the host ports into the secondary VLAN and set the native VLAN of the host port as the secondary VLAN ID.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 3
```

Step7 Add the promiscuous port into the primary VLAN and set the native VLAN of the promiscuous port as the primary VLAN ID.

```
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 5
```

Step8 Commit the configurations.

```
admin@XorPlus# commit
```

Verify the Configuration

- You can use the **run show vlans private-vlan** command to view the PVLAN configuration information.

```
admin@Xorplus# run show vlans private-vlan
Primary   Secondary  Type            Tag         Interfaces
-------   ---------  -----------     --------    -------------------------
5                    primary         untagged    te-1/1/1
                                       tagged
          2          isolated        untagged    ge-1/1/1, ge-1/1/2
                                       tagged
          3          community       untagged    ge-1/1/3, ge-1/1/4
                                       tagged
```

- You can use the **run show vlans private-vlan type** command to view the PVLAN type information.

```
admin@Xorplus# run show vlans private-vlan type
Vlan Type
---- -----------
5    primary
2    isolated
3    community
```

- Check device connection status.

The Server, Host A, Host B, Host C and Host D are on the same subnet.

Host A, Host B, Host C and Host D can communicate with the Server.

Host A and Host B cannot communicate with each other at Layer 2.

Host C and Host D can communicate with each other at Layer 2.

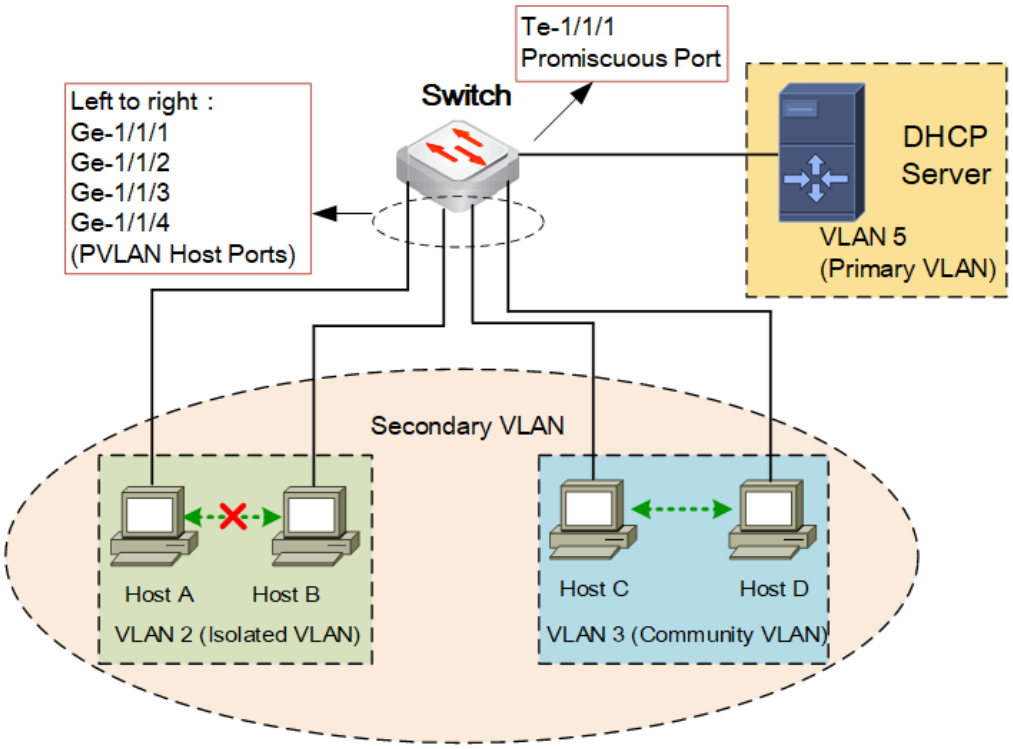
Host A and Host B cannot communicate with Host C and Host D at Layer 2.

Example for Configuring DHCP Snooping with PVLAN

- Networking Requirements
  - Figure 1. DHCP Snooping with PVLAN Configuration Example
- Procedure
- Verify the Configuration

Networking Requirements

Figure 1. DHCP Snooping with PVLAN Configuration Example



As shown in **Figure 1**, in the PVLAN topology, the Switch acts as a user gateway and forwards DHCP messages to DHCP server, so that DHCP clients Host A, Host B, Host C and Host D can apply for IP address lease and other related configuration information from the DHCP server. In order to provide better service to DHCP users, network administrators can configure DHCP Snooping to prevent DHCP attacks.

Complete the following configurations on the Switch:

- Configure PVLAN on the Switch. For details, please refer to 8.3.1 Example for Configuring PVLAN.
- Enable DHCP snooping on the primary VLAN, where the PVLAN pvlan-promiscuous port Te-1/1/1 connects to the DHCP server.
- Configure the PVLAN pvlan-promiscuous port Te-1/1/1 connecting to the DHCP server as a trust port.

Procedure

Step1 Create the secondary VLANs.

```
admin@XorPlus# set vlans vlan-id 2 private-vlan mode isolated
admin@XorPlus# set vlans vlan-id 3 private-vlan mode community
```

Step2 Create the primary VLAN.

```
admin@XorPlus# set vlans vlan-id 5 private-vlan mode primary
```

Step3 Associate the secondary VLAN with the primary VLAN.

```
admin@XorPlus# set vlans vlan-id 5 private-vlan association 2-3
```

Step4 Configure the ports connected to the hosts as the PVLAN host ports.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode pvlan-host
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode pvlan-host
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode pvlan-host
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode pvlan-host
```

Step5 Configure the port connected to the Server as the promiscuous port.

```
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode pvlan-promiscuous
```

Step6 Add the host ports into the secondary VLAN and set the native VLAN of the host port as the secondary VLAN ID.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 3
```

Step7 Add the promiscuous port into the primary VLAN and set the native VLAN of the promiscuous port as the primary VLAN ID.

```
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 5
```

Step8 Configure DHCP snooping.

```
admin@XorPlus# set protocols dhcp snooping vlan 5 disable false
admin@XorPlus# set protocols dhcp snooping trust-port te-1/1/1
```

Step9 Commit the configurations.

```
admin@XorPlus# commit
```

Verify the Configuration

- You can use the **run show vlans private-vlan** command to view the PVLAN configuration information.

```
admin@Xorplus# run show vlans private-vlan

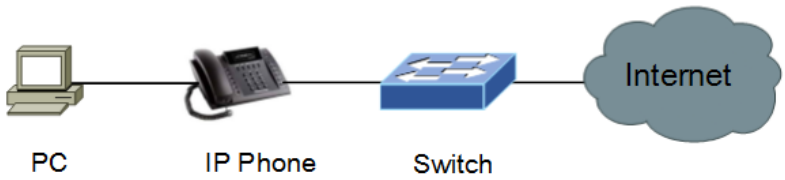
- Data and Voice Packet Operation Process

Introduction

Voice over Internet Protocol (VoIP) is widely used today, but the performance of voice calls is greatly affected by the network quality. To make the quality of voice calls solid, you can use the voice VLAN technique which refers to a dedicated VLAN designed to handle the voice traffic. By configuring a voice VLAN on the switch to transmit voice data and setting QoS parameters of voice VLAN, we can make sure the voice data is given preference when congestion occurs.

Figure 1. Connecting a PC and an IP Phone to a Switch



As shown in Figure 1, a PC and an IP phone can be connected to the switch so that both data and voice services can be transmitted.

The switch can determine whether the data stream is a voice data stream according to the source MAC address field in the data packet of the ingress interface. The switch identifies the data packets as voice data when the source MAC address matches the system pre-configured Organizationally Unique Identifier (OUI).

OUI

OUI refers to the first 24 bits (binary) of the MAC address that can be used to represent a MAC address segment, which is a globally unique identifier assigned by the IEEE to different device vendors. Each device vendor then allocates another 24 bits to form a 48-bit MAC address. Voice packets sent by IP phones can be identified by its OUI.

In voice VLAN, the OUI is not necessarily 24 bits long which depends on the mask value. The OUI is the result of the AND operation between the MAC address and the mask value in the **set vlans voice-vlan mac-address mask** command.

The system uses three types of OUI: default OUI, user-defined OUI and learned OUI. The system has predefined seven OUIs, Table 1 lists all the default OUIs. User-defined OUI is configured by using **set vlans voice-vlan mac-address mask** command. Learned OUI is the OUI learned by the system if LLDP function or LLDP compliance with CDP function is enabled. Please note that in PICOS 2.11.4 and the later version , there is no default OUI.

Table 1. List of Default OUI

Default OUI	Description
00:01:e3:00:00:00	Siemens phone
00:03:6b:00:00:00	Cisco phone
00:04:0d:00:00:00	Avaya phone
00:60:b9:00:00:00	Philips/NEC phone
00:d0:1e:00:00:00	Pingtel phone
00:e0:75:00:00:00	Polycom phone
00:e0:bb:00:00:00	3com phone

Auto and Manual Mode

Auto and manual mode determine the way of the port when added to the voice VLAN.

Auto Mode

In auto mode, the system utilizes the voice packets or the protocol packets such as PICA8 supported LLDP, LLDP-MED and CDP sent by the IP phone to determine whether to add the port to voice VLAN. If the source MAC address of the packets matches the OUI address, the system will automatically add the ingress port of the voice packet into the voice VLAN, and implement the QoS priority to the voice VLAN. If the source MAC address of the packets matches no OUI address, the system will learn the source MAC address of the LLDP, LLDP-MED or CDP packet as the learned OUI and add the port to the voice VLAN.

If the IP phone supports one of the protocols of LLDP, LLDP-MED or CDP, please refer to section Voice VLAN with LLDP and Voice VLAN with LLDP Compliance CDP for details about the process of protocol packets.

You can set voice VLAN aging time of the device in auto mode. Until the aging time expires, if no voice packet is received from the ingress port, the system will delete the port from the voice VLAN after the aging time. The process of adding/deleting a port to the voice VLAN is implemented automatically by the voice VLAN feature.

Manual Mode

In manual mode, the ports are added to voice VLAN by manual configuration. If the source MAC address of the packets matches the OUI address, the system will implement the QoS priority of the voice VLAN. The process of adding/deleting a port to the voice VLAN is implemented manually by the administrator. This type of port is not affected by the aging time of the voice VLAN. When the aging time expires, the port will not be deleted from the voice VLAN.

802.1p Priority and DSCP Value

User can modify the 802.1p and DSCP priorities to meet the QoS requirement for voice traffic in the network. The default value of 802.1p and DSCP priorities of the voice VLAN feature are 6 and 46 respectively.

802.1p Priority

802.1p priority is the value of the priority field in the VLAN frame in IEEE 802.1Q standard, which contains the layer 2 priority to be used for the specified application type. This 3 bits field could specify one of eight priority levels (0 through 7), as defined by IEEE 802.1D-2004.

DSCP Value

Differentiated Services Code Point (DSCP) value is used to provide Diff-Serv (Differentiated Service) node behavior for the specified application type as defined in IETF RFC 2474. This 6 bits field may contain one of 64 code point values (0 through 63). The 6 bits Type of Service (TOS) field in the IPv4 data packet header is referred to as DSCP.

> **NOTE :**
>
> If the DSCP value of the voice VLAN is not set, the system does not modify the DSCP value carried by the packet by default.

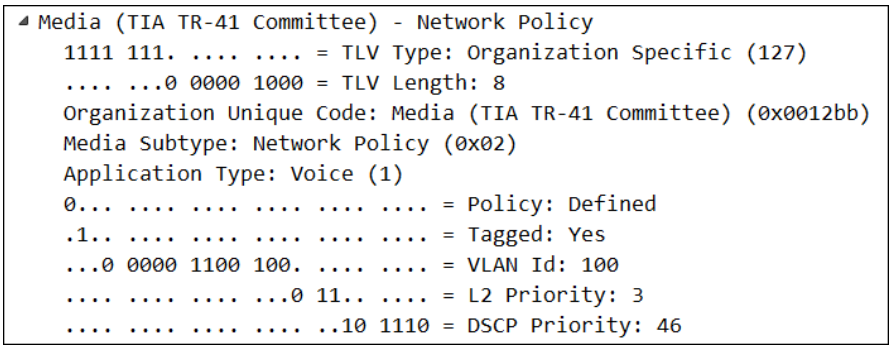
Voice VLAN with LLDP

Voice VLAN with LLDP means that PICA8 switch could learn OUI address from the source MAC address of the LLDP packet if LLDP is enabled between IP phone and PICA8 switch.

When receiving an LLDP packet, the system checks the Capabilities TLV in the LLDP packet. If the **telephone** value in both the **Capabilities** and **Enabled Capabilities** fields is **Capable**, the system considers the device connected to the switch as an IP phone. Afterwards, the system learns the source MAC address of the LLDP packet and saves it to the learned OUI table. The port is then added to the voice VLAN. You can view the learned OUI entries by using the **run show vlans voice-vlan oui** command and the **run show vlans** command to check whether the port has been added to the voice VLAN.

Besides the basic LLDP, the system also supports LLDP-MED for voice VLAN. Figure 2 is the content of the Network Policy TLV in LLDP-MED, mainly including the fields: Policy, Tagged, VLAN ID, L2 Priority and DSCP Priority. Network Policy TLV is used to exchange VLAN configuration between switches and terminal devices. A switch uses the TLV to advertise the local configuration of voice VLAN ID and QoS priority to an IP phone. Then the IP phone could totally decide what packets are sent according to the received information. “**run show lldp local_info detail**” and “**run show lldp neighbor detail**” commands can be used to view each field value of LLDP packet coming from the switch or the IP Phone.

Figure 2. Content of Network Policy TLV in LLDP-MED



Voice VLAN with LLDP Compliance CDP

When an IP phone in the network does not support LLDP but CDP protocol, a proprietary link discovery protocol of Cisco, you can enable LLDP compliance CDP function in order to be compatible with CDP protocol and guarantee that the switch can discover and identify this type of neighbor node. You have to enable LLDP function before using LLDP compliance CDP function.

Data and Voice Packet Operation Process

Data packets and voice packets may arrive at the same port. Even if both traffics are untagged packets, we could use the ingress ACLs based on OUI to separate these two types of packets. Any untagged VoIP traffic will be tagged with voice VLAN ID and the 802.1P priority and DSCP value will be modified when transmitted to the egress port if it successfully matches an ingress ACL. As a result, we can separate these two types of untagged traffic into two different VLANs and both data packets and voice packets can be transmitted in parallel.

Configuration Notes of Voice VLAN

When configuring Voice VLAN on a device, pay attention to the following points:

- Voice VLAN could not be configured as PVID or VLAN members on a port, in other words, PVID or VLAN members on a port could not be configured as voice VLAN.
- Voice VLAN could not be configured on the LAG interface.
- Voice VLAN MUST be configured on the port with trunk port-mode.
- Only one VLAN can be configured as voice VLAN on an interface at a time.
- The system supports a maximum of 10 OUIs, including the default 7 OUIs. In PICOS 2.11.4 and the later version, there is no default OUI, the user is allowed to configure a maximum of 10 OUIs.
- A chassis switch supports a maximum of 4 voice VLANs.

Configuring Voice VLAN

Procedure

Step1 Configure VLAN, configure the port mode to **trunk**.

a) Create a VLAN.

set vlans vlan-id <*vlan-id*>

b) Configure the port mode to **trunk**.

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching port-mode <***port-mode*>

Step2 Configure an interface into voice VLAN.

set interface gigabit-ethernet <*interface-name*> **voice-vlan vlan-id <***vlan-id*>

Step3 Configure the mode for how an interface is added to a voice VLAN.

set interface gigabit-ethernet <*interface-name*> **voice-vlan mode** {**auto | manual**}

Step4 Configure the tagged mode for the outgoing packet of a voice VLAN interface.

set interface gigabit-ethernet <*interface-name*> **voice-vlan tagged mode** <**tag | untag | auto**>

Step5 Configure the aging time for voice VLAN.

set vlans voice-vlan aging <*aging-time*>

Step6 Configure an OUI for the voice VLAN.

set vlans voice-vlan mac-address <*mac-address*> **mask** <*oui-mask*>

The system supports a maximum of 10 OUIs, including the default 7 OUIs. After PICOS version 2.11.4, there is no default OUI, the user is allowed to configure a maximum of 10 OUIs.

Step7 (Optional) Configure description information for the OUI address.

set vlans voice-vlan mac-address <*mac-address*> **description** <*text*>

Step8 Configure the 802.1p priority and DSCP value for a voice VLAN.

set vlans voice-vlan local-priority <*priority-value*>

set vlans voice-vlan dscp <*dscp-value*>

Step9 Enable LLDP function to support IP phone of LLDP, LLDP-MED and CDP.

set protocols lldp enable <**true | false**>

Step10 Enable LLDP compliance with CDP to support IP phone of CDP.

a) Enable global LLDP compliance with CDP.

set protocols lldp compliance cdp <**true | false**>

b) Enable interface-based LLDP compliance with CDP.

set protocols lldp interface <*interface-name*> **compliance cdp** <**true** | **false**>

NOTE:

- To enable LLDP compliance with CDP on a specific interface, you need to enable both the global and interface-based LLDP compliance with CDP functions.
- To avoid unnecessary trouble, you should only configure CDP compliance on access port intended for VoIP phones, but do not configure CDP on other interfaces.

Configuration Example of Voice VLAN

Procedure

Step1 Configure the VLAN, configure port mode to **trunk**.

```
admin@XorPlus# set vlans vlan-id 10
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
```

Step2 Configure an interface into voice VLAN.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 voice-vlan vlan-id 10
```

Step3 Configure the mode for how an interface is added to a voice VLAN.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 voice-vlan mode manual
```

Step4 Configure the tagged mode for the outgoing packet of a voice VLAN interface.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 voice-vlan tagged mode tag
```

Step5 Configure the aging time for voice VLAN.

```
admin@XorPlus# set vlans voice-vlan aging 600
```

Step6 Configure an OUI for the voice VLAN.

```
admin@XorPlus# set vlans voice-vlan mac-address 00:11:11:00:00:01 mask ff:ff:ff:00:00:00
```

Step7 (Optional) Configure description information for the OUI address.

```
admin@Xorplus# set vlans voice-vlan mac-address 00:11:11:00:00:01 description CompanyPhone
```

Step8 Configure the 802.1p priority and DSCP priority for a voice VLAN.

```
admin@XorPlus# set vlans voice-vlan local-priority 6
admin@XorPlus# set vlans voice-vlan dscp 63
```

Step9 Enable LLDP function to support IP phone of LLDP, LLDP-MED and CDP.

```
admin@XorPlus# set protocols lldp enable true
```

Step10 Enable LLDP compliance with CDP to support IP phone of CDP.

a) Enable global LLDP compliance with CDP.

```
admin@XorPlus# set protocols lldp compliance cdp true
```

b) Enable interface-based LLDP compliance with CDP.

```
admin@XorPlus# set protocols lldp interface ge-1/1/1 compliance cdp true
```

NOTE:

- To enable LLDP compliance with CDP on a specific interface, you need to enable both the global and interface-based LLDP compliance with CDP functions.
- To avoid unnecessary trouble, you should only configure CDP compliance on access port intended for VoIP phones, but do not configure CDP on other interfaces.

Verify the Configuration

- You can use the **run show vlans voice-vlan oui** command to view the OUI addresses of voice VLAN, including default OUI, user-configured OUI and learned OUI.

```
admin@XorPlus# run show vlans voice-vlan oui
Oui_Address          Mask                 Description
0:1:e3:0:0:0         ff:ff:ff:0:0:0       Siemens phone
0:3:6b:0:0:0         ff:ff:ff:0:0:0       Cisco phone
0:4:d:0:0:0          ff:ff:ff:0:0:0       Avaya phone
0:60:b9:0:0:0        ff:ff:ff:0:0:0       Philips/NEC phone
0:d0:1e:0:0:0        ff:ff:ff:0:0:0       Pingtel phone
0:e0:75:0:0:0        ff:ff:ff:0:0:0       Polycom phone
0:e0:bb:0:0:0        ff:ff:ff:0:0:0       3com phone
00:11:11:00:00:01 ff:ff:ff:0:0:0      CompanyPhone
Learned_Oui_Address     Mask
22:22:22:22:11:11    ff:ff:ff:ff:ff:ff
22:22:22:22:22:22    ff:ff:ff:ff:ff:ff
22:22:22:22:33:33    ff:ff:ff:ff:ff:ff
22:22:22:22:44:44    ff:ff:ff:ff:ff:ff
```

- You can use the **run show vlans voice-vlan** command to view the configuration information of a voice VLAN.

```
admin@XorPlus# run show vlans voice-vlan vlan-id 10
Voice Vlan ID:10
Voice Vlan local priority:6
Voice Vlan dscp:63
Voice Vlan aging time:600 minutes
Current voice vlan enabled port mode:
Port       Mode      Tagged    Mac_Address     Status
-------------------------------------------------------------------------
ge-1/1/1    manual      true    00:11:11:00:00:01   Working
```

- You can use the **run show vlans vlan-id** <*vlan-id*> command to check whether the port has been added to the voice VLAN.

```
admin@XorPlus# run show vlans vlan-id 10
VLAN ID: 10
VLAN Name: default
Description: CompanyPhone

Link Aggregation Configuration

- Static Link Aggregation (LAG) Configuration
- Link Aggregation Control Protocol (LACP) Configuration
- LAG Hashing Configuration
  - LAG Hashing Configuration and Example
  - LAG Hash Mapping
  - Resilient LAG Hashing Configuration and Example
- LACP Fallback
- Configuring LACP Fast Rate
- LAG Specification of Different Platforms

Static Link Aggregation (LAG) Configuration

- Both static and LACP LAGs can support the hashing of traffic using the Src/Dst MAC address, the Src/DstIP address, and Layer 4 port information.
- If all member ports of a LAN are link-down, the LAG will be link-down. The LAG will become link-up when at least one member port is link-up.
- The logical function and configuration of LAGs are same as those of a physical port.

Configuring Static LAGs

The name of the LAG interface is a string in the format of **ae***x*, where x is an integer ranging from 1 to 4094.

> The maximum LAGs per switch is limited by the interface capacity.

```
admin@XorPlus# set interface aggregate-ethernet ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 ether-options 802.3ad ae1
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Displaying Static LAG Information

```
admin@XorPlus# run show interface aggregate-ethernet ae1

ge-1/1/2 Down Auto
ge-1/1/3 Up Auto
ge-1/1/4 Up Auto
```

Link Aggregation Control Protocol (LACP) Configuration

LACP (802.3ad) provides the dynamic link aggregation function.

The LACPDU includes the LACP system priority, the system MAC, the port priority, and I.D. The port, included in the LACP LAG, will transmit the LACPDU to its neighbors.

The configuration of the LACP LAG is similar to that of the static LAG.

The **min-selected-port** label denotes that the LAG is up only when no fewer than the defined number of ports are up. Below, our defined number is 4.

Configuring LACP LAGs

```
admin@XorPlus# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
admin@XorPlus# set interface aggregate-ethernet ae1 aggregated-ether-options min-selected-port 4
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 ether-options 802.3ad ae1

```

LAG Hashing Configuration

The IEEE 802.3ad link aggregation protocol groups multiple Ethernet interfaces and forms a single link layer interface known as LAG (link aggregation group). Traffic is balanced across the member links in the LAG to make use of all available bandwidth. The balancing is done by the LAG hashing algorithm. The LAG hashing algorithm determines the member link to be used for an incoming frame on the basis of certain values in the frame header.

- LAG Hashing Configuration and Example
- LAG Hash Mapping
- Resilient LAG Hashing Configuration and Example

LAG Hashing Configuration and Example

This example configures the LAG hash mapping mode as **ethernet-destination-only**.

Configuration:

```
set interface aggregate-ethernet ae1 hash-mapping mode ethernet-destination-only
```

Examples:

Configure one LAG with three ports.

```
set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae10
set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae10
set interface gigabit-ethernet ge-1/1/3 ether-options 802.3ad ae10
```

Examples:

Configure the LAG hash mapping mode as **ethernet-destination-only**.

```
set interface aggregate-ethernet ae10 hash-mapping mode ethernet-destination-only
```

LAG Hash Mapping

User can configure the LAG hash mapping field according to the requirement.

Configure one LAG with three ports.

```
set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae10
set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae10
set interface gigabit-ethernet ge-1/1/3 ether-options 802.3ad ae10
```

Configure the LAG hash mapping mode as **ethernet-destination-only**.

```
set interface aggregate-ethernet ae10 hash-mapping mode ethernet-destination-only
```

Configure the LAG hash mapping field.

```
set interface aggregate-balancing hash-mapping field ethernet-destination-address disable false
set interface aggregate-balancing hash-mapping field ethernet-source-address disable false
```

Resilient LAG Hashing Configuration and Example

Configure the LAG hashing mode as **advanced-resilient**. By default, the hash-mapping field is **disable false all**.

Without resilient mode, each traffic flow (the flow definition depends on the hash-mapping configuration) is load balanced on one port of the LAG. This distribution is done via a hashing algorithm. If a port on this LAG is added or removed (link up/down), the hash will change all flows to be re-distributed on the remaining ports. It is typically not important if the device on the other side of the LAG is a router or a switch but could be important if the LAG is sending traffic to equipment (like a cluster of servers) that handles traffic differently on each port (for example, distributing http sessions on multiple servers).

In resilient mode, a removed link does not trigger the redistribution of traffic on the remaining ports. Only the traffic from the removed port will be distributed to the remaining ports. An added link does not trigger redistribution of traffic on the remaining ports. The added link will share the traffic on the remaining ports.

> ⚠ Currently, only switch models of Trident, Trident II, Trident II+, and Trident3-X5 support the resilient LAG hashing feature.

Configuration:

```
set interface aggregate-ethernet ae10 hash-mapping mode advanced-resilient
```

Examples:

Configure one lag with three ports

```
set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae10
set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae10
set interface gigabit-ethernet ge-1/1/3 ether-options 802.3ad ae10
```

Configure the lag hash mode advanced-resilient

```
set interface aggregate-ethernet ae10 hash-mapping mode advanced-resilient
```

Configure the hash-mapping field

```
  set interface aggregate-balancing hash-mapping field ip-destination disable false
  set interface aggregate-balancing hash-mapping field ip-source disable false
```

LACP Fallback

- Overview
  - Application Scenarios
  - Timer
  - Port Election
- Configuring LACP Fallback
  - Prerequisite Configurations
  - Enable LACP Fallback
- Configuration Example
  - Procedure

NOTE:
Some PXE servers cannot send DHCP discover messages continuously, which may result in failure to obtain IP addresses, thus affecting device communication.

When such an issue is encountered, you can try the following two methods to solve the problem.

1. Set the LACP fallback timer to 0 by using the following command.

```
admin@Xorplus# set interface aggregate-ethernet ae1 aggregated-ether-options lacp fallback timeout 0
admin@Xorplus# commit
```

By default, the LACP fallback timer is 10 seconds. After LACP configurations are finished, you have to wait for the timer to expire before the LACP fallback port can forward packets.

2. Disable spanning tree function by using the following command.

```
admin@Xorplus# set protocols spanning-tree enable false
admin@Xorplus# commit
```

Spanning tree is enabled by default, which will wait 9 seconds before the port can forward packets.

However, if you do not want to disable spanning tree, you can use the following command to configure *manual-forwarding* on the LAG port, so that messages can be forwarded immediately after the LAG port is up.

```
admin@Xorplus# set protocols spanning-tree mstp interface ae1 manual-forwarding true
admin@Xorplus# commit
```

Overview

The LACP fallback feature sets the LACP LAG port to fallback mode and brings up one of the member ports to the active (up) state before any LACP PDUs is received by the LAG port. The fallback mode will not exit until one LACP PDU is received by any one of the member ports from the peer device.

Application Scenarios

This feature is useful for scenarios where the peer device is a Preboot Execution Environment (PXE) booting client and connected through a LAG interface on Pica8 switch. With LACP fallback feature enabled on Pica8 switch, a PXE booting client can complete the PXE booting process and system configurations by connecting to the DHCP server/TFTP server through one of the active LAG member ports on Pica8 switch.

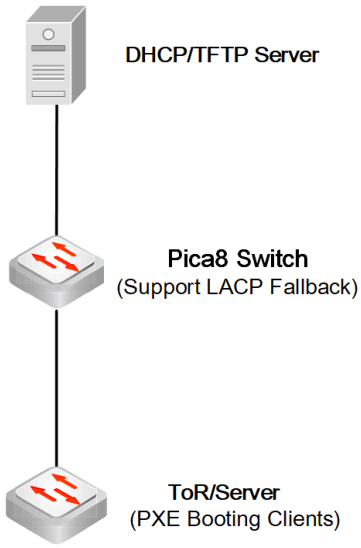
The following sections describe in detail the application scenarios of LACP Fallback in both non-MLAG and MLAG networks.

Non-MLAG Networks

As shown in Figure 1, in Non-MLAG networks, where the peer device connected to the Pica8 Switch is a Server or ToR through an LACP LAG port on Pica8 Switch.

Such Server and ToR are PXE booting clients, which cannot send and process LACP messages during the PXE phase. This causes the connected LAG port on Pica8 Switch to be inactive and unable to communicate with the PXE booting clients. These clients need the link to be active so that they can reach the DHCP or TFTP server to get the necessary installation files.

Figure 1. LACP Fallback Applied in Non-MLAG Networks

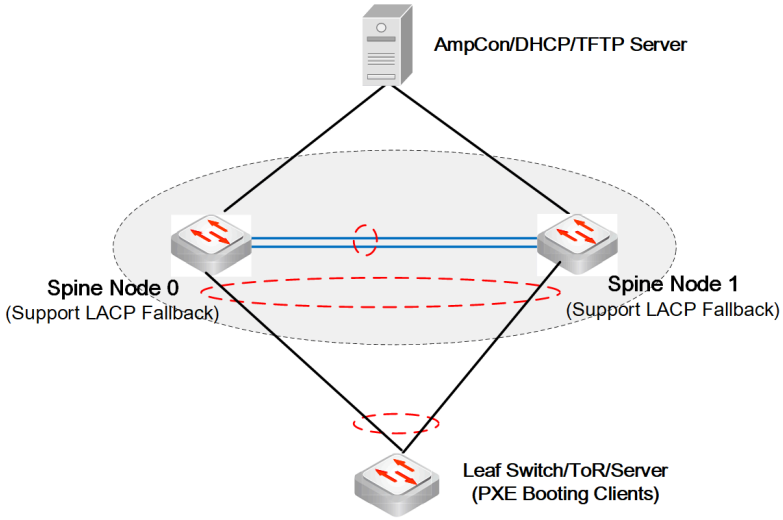


With LACP fallback feature, a Pica8 Switch will allow the system to bring up the LAG (before receiving any LACP PDUs from the PXE booting clients) and keeps one of the member ports active until receiving an LACP PDU by one of the member ports from the peer. This allows the PXE booting clients to establish a connection, download its boot image and then continue the boot process. When the boot process is complete, the server will fully support to form an LACP LAG.

MLAG Networks

As shown in Figure 2, in MLAG networks or an AmpCon application scenario, LACP Fallback can be configured on the spine switches. The newly deployed Leaf switch/ToR/Server in bare metal state with no NOS installed, will not be able to send and process LACP messages during the PXE phase. This causes the LAG port connected on the Spine switches to be inactive and hence making it impossible for the Leaf switch/ToR/Server to reach the AmpCon/DHCP/TFTP server to complete the system installation.

Figure 2. LACP Fallback Applied in MLAG Networks



With LACP fallback feature, Spine switches allow the system to bring up the LAG (before receiving any LACP PDUs from the Leaf switch/ToR/Server) and keeps one of the member ports active until receiving an LACP PDU on any one of the member ports from the Leaf switch/ToR/Server. This allows the newly installed Leaf switches/ToR/Server to establish a connection, reaching the AmpCon server to get provisioned.

NOTEs:

- Upon receiving the first LACP PDU, the system will exit the fallback mode. The system will not start the LACP Fallback process again afterwards, even if no LACP PDUs are received from the peer later for an LACP fallback timer. But there are some special cases, that is, all LAG member ports are down or the peer device is replaced after the system has exited from the LACP fallback mode. Only in these special cases, the LACP Fallback process can be started again.
- For MLAG environment, the LACP fallback configurations should be consistent on MLAG peers.

Timer

The switch starts LACP fallback timer when LACP configurations are finished and LACP fallback is enabled on the switch. If no LACP PDUs are received from the peer device on any of the member ports of the LAG when this timer expires, the switch will set the LAG to fallback mode and bring up one member port to active (up) state.

The switch will not exit LACP fallback mode until it receives an LACP PDU from the peer device.

Use the following command to configure the LACP fallback timer. The default value is 10 seconds.

set interface aggregate-ethernet <*lag-interface*> **aggregated-ether-options lacp fallback timeout** <*timer*>

Port Election

Since only one member port of the LAG can be chosen as the active port, the port election rules are:

- The port with *lowest LACP port priority value* will be chosen as the active port.
- If LACP port priorities are the same, port with *lowest port index* will be chosen as the active port.

The following command can be used to set priority of the LACP member port:

set protocols lacp interface <*physical-port*> **priority** <*priority-value*>

For non-MLAG environment, the port election rule is as described above.

For MLAG environment, port election is first performed on each MLAG peer device. Then the elected ports information is exchanged between MLAG peers. And finally, an active port is elected from these two ports according to the port election rules described above.

LACP Fallback supports fallback port preemption. A port with a higher priority can always preempt the active fallback port as the new active fallback port. During LACP fallback mode, when a non-fallback port is configured with a higher priority, the system will perform port re-election, as a result, the higher priority port will replace the elected port as the active port.

Configuring LACP Fallback

Prerequisite Configurations

1. Create a LAG interface.
2. Add member ports to the LAG interface.
3. Enable LACP protocol on the LAG interface.

> **NOTEs:**
> LACP fallback can only be applied on the LACP LAG interface, but not on a static LAG.

Enable LACP Fallback

- Enable LACP fallback.

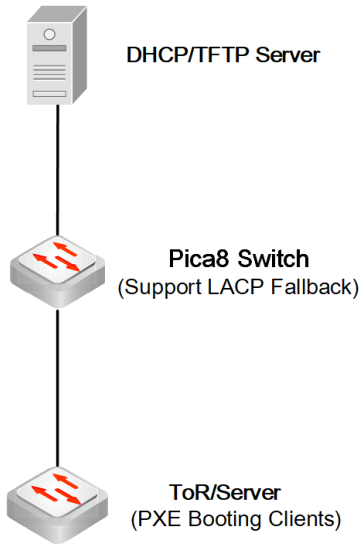
set interface aggregate-ethernet <*lag-interface*> **aggregated-ether-options lacp fallback enable** <**true | false**>

- (Optional) Configure LACP fallback timer. The default value is 10 seconds.

set interface aggregate-ethernet <*lag-interface*> **aggregated-ether-options lacp fallback timeout** <*timer*>

Configuration Example

As shown in the following figure, Pica8 Switch and the PXE Booting Clients (ToR or Server) are connected through an LACP LAG interface. You can enable LACP fallback function on Pica8 Switch, which will allow the PXE Booting Client to connect to the DHCP/TFTP Server through one active port on Pica8 Switch during the PXE phase.



Procedure

Step 1 Create a LAG interface **ae1**, add physical ports and enable LACP protocol on the LAG.

```
admin@XorPlus# set interface aggregate-ethernet ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 ether-options 802.3ad ae1
admin@XorPlus# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
```

Step 2 Enable LACP fallback on LAG interface **ae1**.

```
admin@Xorplus# set interface aggregate-ethernet ae1 aggregated-ether-options lacp fallback enable true
```

Step 3 Commit the configurations.

```
admin@XorPlus# commit
```

Step 4 Verify the configurations.

Run the command **run show interface aggregate-ethernet** <*lag-interface*> to display configuration information and status of the LAG interface, "*Fallback: Enabled*" shows that LACP fallback is enabled.

```
admin@XorPlus# run show interface aggregate-ethernet ae1
Physical interface: ae1, Enabled, error-discard False, Physical link is Up
Interface index: 80, Mac Learning Disabled
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1518, Speed: 1Gb/s, Duplex: Auto
Source filtering: Disabled, Flow control: Disabled
Auto-negotiation: Disabled

  ge-1/1/3      Up(active)      1Gb/s
```

LAG Specification of Different Platforms

The following specifications supportd by LAG are model dependent, we have collected them in page Collection of Feature Specification of Different Platforms:

- the maximum number of LAGs supported by a switch
- the maximum number of member ports supported by a switch

Symmetric Hash for LAG Configuration Example

Symmetric Hash support for LAG. Symmetric hash need the hashing field must be symmetric. For example, packet 1 and packet 2 are symmetric in table 1 and table 2 as below, and then packet 1 and packet2 will go out from the same physical port. Now Our symmetric Hash use IP layer and L4 field to hash when packets are transmitted on LAG port. Only matching symmetric condition, two packets can be transmitted on the same member port of LAG interface.

IP Packet	Source IP Address	Destination IP Address
Packet1	10.1.1.1	20.1.1.1
Packet2	20.1.1.1	10.1.1.1

Table 1.

Layer 4 Packet	Source IP Address	Destination IP Address	Source Port Number	Destination Port Number
Packet1	10.1.1.1	20.1.1.1	100	200
Packet2	20.1.1.1	10.1.1.1	200	100

Table 2.

Symmetric Hash field as below:

1. ip-source
2. ip-destination
3. port-source
4. port-destination

By default, Enable hash field on LAG interface:

1. ingress-interface
2. ethernet-source-address
3. ethernet-destination-address
4. ethernet-type
5. vlan
6. ip-protocol
7. ip-source
8. ip-destination
9. port-source
10. port-destination

> LAG interface enables 10 fields to hash more than symmetric hashing 4 fields in the default case. So if to need symmetric hash work on lag interface，please it is best to disable the following field：
>
> 1. ingress-interface
> 2. ethernet-source-address
> 3. ethernet-destination-address
> 4. ethernet-type
> 5. vlan
> 6. ip protocol

> Symmetric hashing is supported on Helix4 **,** Trident2, Trident2+, Trident3 and Tomahawk platform switches.

LAG Hashing Configuration

```
set interface aggregate-ethernet ae1 hash-mapping mode advanced
set interface aggregate-balancing hash-mapping symmetric true
```

LAG Hashing Examples:

configure one lag with three ports:

```
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 199
set interface aggregate-ethernet ae1 family ethernet-switching native-vlan-id 299
set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae1
set interface gigabit-ethernet te-1/1/3 ether-options 802.3ad ae1
set interface gigabit-ethernet te-1/1/4 ether-options 802.3ad ae1
set protocols static route 100.100.100.0/24 next-hop 182.168.1.100
set protocols static route 172.168.1.0/24 next-hop 182.168.1.100
```

```
set l3-interface vlan-interface vlan199 address 172.168.1.1 prefix-length 24
set l3-interface vlan-interface vlan299 address 182.168.1.1 prefix-length 24
set l3-interface vlan-interface vlan399 address 100.100.100.1 prefix-length 24
set vlans vlan-id 199 l3-interface vlan199
set vlans vlan-id 299 l3-interface vlan299
set vlans vlan-id 399 l3-interface vlan399
```

Configure the symmetric hash true

```
set interface aggregate-ethernet ae1 hash-mapping mode advanced
set interface aggregate-balancing hash-mapping symmetric true
set interface aggregate-balancing hash-mapping field ingress-interface disable true
set interface aggregate-balancing hash-mapping field ethernet-source-address disable true
set interface aggregate-balancing hash-mapping field ethernet-destination-address disable true
set interface aggregate-balancing hash-mapping field ethernet-type disable true
set interface aggregate-balancing hash-mapping field vlan disable true
set interface aggregate-balancing hash-mapping field ip-protocol disable true
```

LLDP Configuration (Link Layer Discovery Protocol)

LLDP is a standard link-layer discovery protocol which can broadcast its capability, IP address, ID, and interface name as TLVs (Type/Length/Value) in LLDP PDUs (Link Layer Discovery Protocol Data Units).

An LLDP PDU includes 4 basic TLVs and several optional TLVs.

Basic TLVs include the Chassis ID, Port ID, TTL and End TLVs.

In L2/L3, you can select the following optional TLVs:

TLV Name	Description
mac-phy-cfg	MAC address of the system
management-address	Management IP address of the system
port-description	The port description of system
port-vlan	The VLAN ID of the port
system-capabilities	System capability (e.g. switching, routing)
system-description	System description
system-name	System name

Configuring the LLDP Mode

LLDP supports 4 modes: TxRx, Tx_only, Rx_only, and Disabled. By default, LLDP is disabled.

In TxRx mode, the system transmits *and* receives LLDPDUs. In Tx_only, the system only transmits LLDPDUs. In Rx_only, the system only receives LLDPDUs. In Disabled, the system will not transmit or receive any LLDPDUs.

After enabling LLDP, each interface will be in tx_rx mode by default.

You can configure the system as shown below:

Selecting Optional TLVs

```
admin@XorPlus# set protocols lldp tlv-select mac-phy-cfg true
admin@XorPlus# set protocols lldp tlv-select management-address true
admin@XorPlus# set protocols lldp tlv-select port-description true
admin@XorPlus# set protocols lldp tlv-select system-capabilities true
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Displaying LLDP Information

```
admin@XorPlus# show protocols lldp
```

```
    enable: true
>   interface "xe-1/1/3" {
>       compliance {
>           cdp: true
>       }
>   }
>   tlv-select {
>   }
admin@XorPlus# run show lldp neighbor all detail
Local Port: te-1/1/1
LLDP info:
------------------------------------------------------------------------------

  802.3 Power via MDI :Not available

LLDP MED is not Enabled.

Total entries displayed: 1
```

Configuring Other Parameters

You can configure other parameters, such as advertisement-interval, hold-time-multiplier, reinit-delay, and transmit-delay, in a similar manner.

LLDP MED Configuration

In LLDP-MED protocol, it provides extra Organizationally Specific TLVs. The TLVs lists that Pica8 switch support are as follows :

M Mandatory for this TLV to be included in all outgoing LLDP-MED LLDPDUs,

C Conditionally required, mandatory for this TLV to be included in outgoing LLDP-MED LLDPDUs under the described conditions,

LLDP-MED TLV Subtype	TLV Name	LLDPDU Usage
1	LLDP-MED Capabilities	M
2	Network Policy	C1
3	Location Identification	C1
4	Extended Power-via-MDI	C2

Note 1: Transmission of these mandatory TLVs only applies if the associated TLV data contents have been administratively configured and apply on a given port.

Note 2: Extended Power-via-MDI TLV is mandatory for IEEE 802.3af compliant PSE Network Connectivity Devices. This TLV is not applicable for non-PoE capable ports, and should not be included in outgoing LLDP-MED LLDPDUs on such ports.

Basic Configuration:

Enable LLDP

```
set protocols lldp enable true
```

Configure lldp med tlvs

- basiclly these tlvs are selected by default:

```
set protocols lldp med-tlv-select inventory-management true/false
set protocols lldp med-tlv-select network-policy true/false
set protocols lldp med-tlv-select extended-power-via-mdi true/false
```

- Configure the lldp med fast start repeat count:
- The LLDP-MED fast start repeat count specifies the number of LLDP packets that will be sent during the LLDP-MED fast start period.

```
set protocols lldp med-fast-start-repeat-count 5
```

The LLDP MED function will only be active by receiving lldp med packets.

Show the med working status:

```
admin@XorPlus# run show lldp detail
LLDP: Enable

MSTP Configuration

802.1D, 802.1w, and 802.1s are spanning tree protocols that can avoid the loop in Layer2. You can configure the parameters of MSTP, including bridge-priority, forward-delay, max-age, and hello-time interval.

NOTE:

- A chassis switch supports a maximum of 16 MST instances.
- Once the spanning tree protocol is enabled on the network, the port starts to perform spanning tree calculation. Parameters such as the device priority and port priority affect spanning tree calculation, and the change of these parameters may cause network flapping. To ensure fast and stable spanning tree calculation, configure parameters such as the device priority and port priority before enabling spanning tree protocols.

Enabling Spanning Tree Mode in MSTP

```
admin@XorPlus# set protocols spanning-tree force-version 3
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Basic Global Parameters of MSTP

When configuring global parameters, make sure to set the forward delay to greater than Max-Age/2 + 1, or the commit will fail.

```
admin@XorPlus# set protocols spanning-tree mstp bridge-priority 4096
admin@XorPlus# set protocols spanning-tree mstp forward-delay 20

Configuring Root Guard

Configure Root Guard to protect devices or links. If a port is enabled with the root guard function, its port role on all instances can only be the designated port. Once the port that is enabled with root guard receives BPDUs with a higher priority, the port enters the Discarding state and does not forward packets. If the port does not receive any BPDUs with a higher priority for a long time, the port automatically returns to the Forwarding state.

```
admin@XorPlus# set protocols spanning-tree mstp interface te-1/1/3 root-guard true
admin@XorPlus# commit
```

MSTP Configuration Example

There are two examples of MSTP configuration. In our first example, VLAN 100 is mapped to MSTI-1 and VLAN 200 is mapped to MSTI-2. The entire topology belongs to only one MSTP domain named **region1**. Switch A is the root of the network.

To achieve load balancing, VLAN 100 should be in MSTI-1 (Fig. 4-4), and VLAN 200 should be in MSTI-2 (Fig. 4-5).

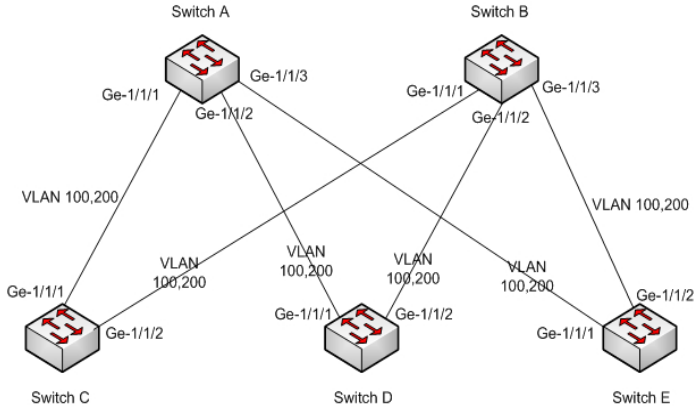

Figure 4-3. MSTP configuration.

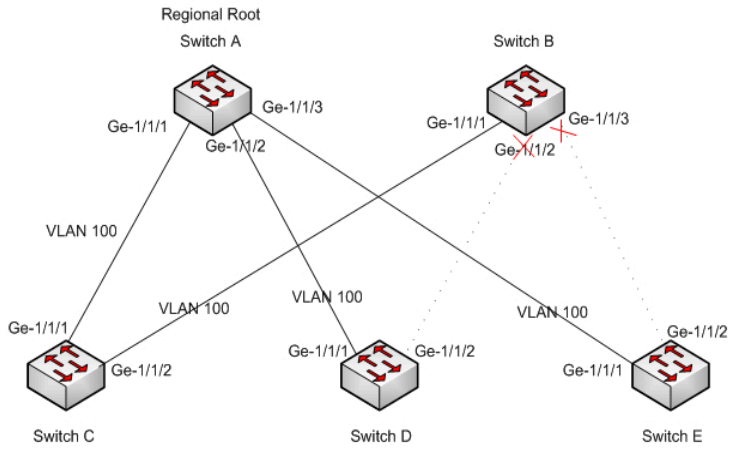

Figure 4-4. MSTI-1 topology for VLAN 100.

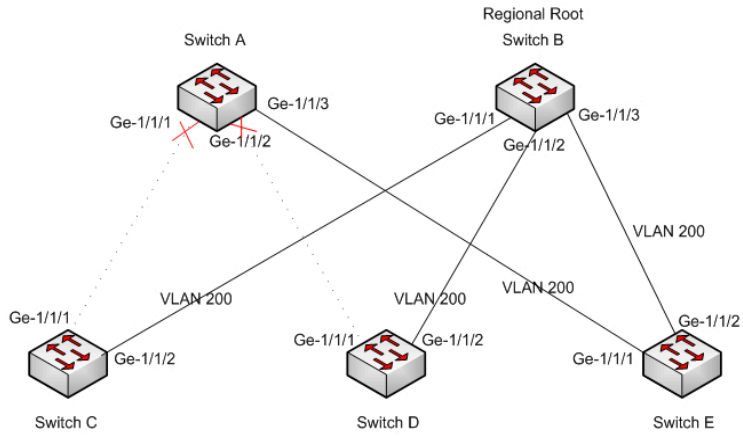

Figure 4-5. MSTI-2 topology for VLAN 200.

Configuring Switch A, Example 1

For Switch A, configure ge-1/1/1~ge-1/1/3 as trunk ports and as members of VLAN 100 and VLAN 200.

```
admin@XorPlus# set vlans vlan-id 100
```

```
admin@XorPlus# set vlans vlan-id 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 200

In the second example, there are two regions. In region 1, VLAN 100 is mapped to MSTI-1, VLAN 200 is mapped to MSTI-2, and VLAN 300 is mapped to MSTI-3. In region 2, VLAN 200 is mapped to MSTI-2 and VLAN 400 is mapped to MSTI-4. Switch A is the root of the entire network. The topologies of the VLANs are presented in Fig. 4-6 through 4-10.

Rapid PVST+ Configuration

802.1D, 802.1w, and 802.1s are spanning tree protocols that avoid the loop in Layer 2. You can configure the parameters of rapid-PVST+, including bridge-priority, forward-delay, max-age, and hello-time interval.

NOTE:

- On a chassis switch, a maximum of 64 VLANs can be enabled for rapid-PVST+ mode.
- Once the spanning tree protocol is enabled on the network, the port starts to perform spanning tree calculation. Parameters such as the device priority and port priority affect spanning tree calculation, and the change of these parameters may cause network flapping. To ensure fast and stable spanning tree calculation, configure parameters such as the device priority and port priority before enabling spanning tree protocols.
- For rapid-PVST+ in PICOS switches, the value of **Organization Code** field in the BPDUs is 00:00:00. The peer devices with a different value should ignore the compatibility check of this field, otherwise, it may cause device connection problems due to compatibility issues.
- Rapid PVST+ blocks traffic from the dynamic VLAN delivered from the RADIUS authentication server.

When using rapid-PVST+, pay attention to the following two points:

- For the trunk port
  - In VLAN 1 and the native VLAN, the rapid-PVST+ device sends standard RSTP and rapid-PVST+ packets (untagged, the destination MAC address is 01-80-C2-00-00-00) to negotiate with the peer.
  - In other VLANs, the rapid-PVST+ device sends rapid-PVST+ packets (the destination MAC address is 01-00-0C-CC-CC-CD) to negotiate with the peer.
- For the access port
  - In all VLANs, the rapid-PVST+ device sends only standard RSTP packets to negotiate with the peer.

Enabling Spanning Tree Mode in Rapid PVST+

```

Disabling/Enabling Rapid PVST+

You cannot disable the spanning tree protocol rapid-PVST+ with just the **enable false** command. To disable PVST, *first* configure the spanning tree mode in MSTP/RSTP/STP. Then, disable the spanning tree. After the spanning tree is disabled, the port will stay in "forwarding" status and cease to send BPDUs.

```
admin@XorPlus# set protocols spanning-tree enable false

Configuring Root Guard

Configure Root Guard to protect devices or links. If a port is enabled with the root guard function, its port role on all instances can only be the designated port. Once the port that is enabled with root guard receives BPDUs with a higher priority, the port enters the Discarding state and does not forward packets. If the port does not receive any BPDUs with a higher priority for a long time, the port automatically returns to the Forwarding state.

```
admin@XorPlus# set protocols spanning-tree pvst interface te-1/1/3 root-guard true
admin@XorPlus# commit
```

Rapid PVST+ Configuration Example

The following topology is an example of a rapid-PVST+ configuration. Switches A and B are in the aggregation layer, and switches C and D are in the access layer. Configure switch A as the root bridge of VLAN 100 and VLAN 200, switch B as the root bridge of VLAN 300, and switch C as the root bridge of VLAN 400.

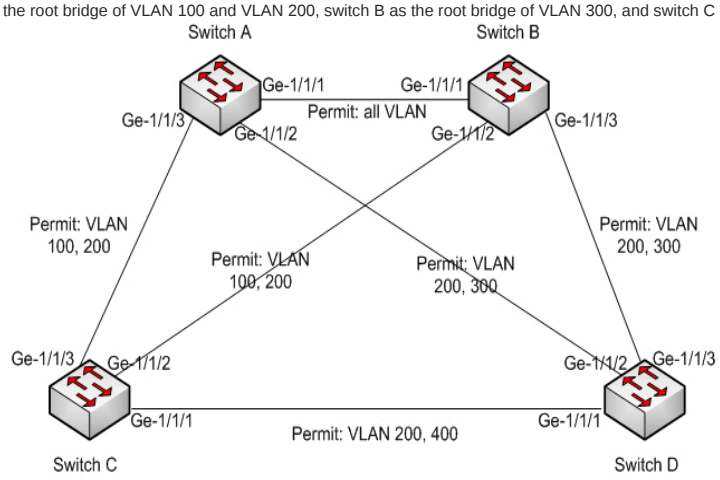

Figure 4-11. PVST configuration.

Configuring Switch A

For Switch A, configure ge-1/1/1~ge-1/1/3 as trunk ports; ge-1/1/1 as a member of VLANs 100, 200, 300, and 400; ge-1/1/2 as a member of VLANs 200 and 300; and ge-1/1/3 as a member of VLANs 100 and 200.

```
admin@XorPlus# set vlans vlan-id 100
admin@XorPlus# set vlans vlan-id 200
admin@XorPlus# set vlans vlan-id 300
admin@XorPlus# set vlans vlan-id 400
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 300
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 400
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 300
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 200

BPDU Tunneling Configuration

Introduction

As a Layer 2 tunneling technology, BPDU tunneling enables Layer 2 protocol packets from geographically dispersed customer networks to be transparently transmitted over a BPDU tunnel on the ISP (Internet Service Provider) network.

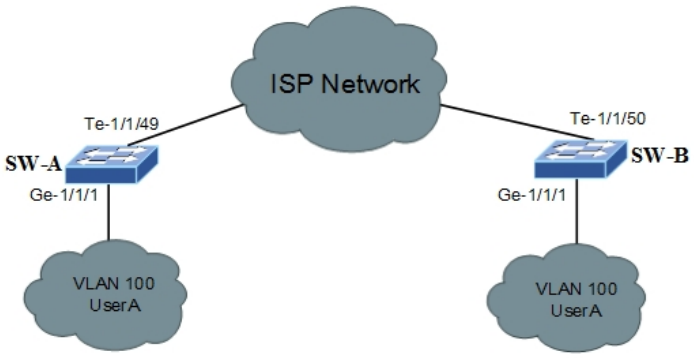

Figure 1 Transparent Transmission of Layer 2 Protocol Packets through BPDU Tunnel

PicOS currently supports Layer 2 protocol packets of STP and LACP that can be transmitted through BPDU tunneling. Transparent transmission of Layer 2 protocol packets through BPDU tunnel is based on the following processes:

1. On the BPDU tunnel ingress switch SW-A, destination multicast MAC address of the received Layer 2 protocol packet is replaced with a specified destination multicast MAC address.

2. Layer 2 protocol packets are transparently transmitted through the ISP network.

3. When the packet arrives at the BPDU tunnel egress switch SW-B, the destination multicast MAC address is checked and the packet is considered as a tunneled packet. Then the destination multicast MAC address of the packet is restored to standard destination multicast MAC address on the BPDU tunnel egress interface, and the packet is further processed and forwarded.

Configuration Notes

- BPDU Tunneling cannot be configured on a LAG port or a physical port that belongs to a LAG. When we need to configure BPDU tunneling on the physical port that belongs to a LAG, we must first remove the physical port from the LAG port before configuration.
- When configuring BPDU tunneling destination multicast MAC address, the following multicast MAC addresses cannot be used:

  01:80:C2:00:00:00 to 01:80:C2:00:00:2f.
- The destination multicast MAC address configured on the tunnel ingress switch and the egress switch must be the same value.

Configuring BPDU Tunneling

Procedure

Step1 Configure VLAN.

a) Configure VLAN ID.

set vlans <*vlan-id*>

b) Configure the interface to VLAN.

set interface gigabit-ethernet <*port-id*> **family ethernet-switching vlan members** <*vlan-id*>

Step2 Enable the BPDU tunneling function of the Layer 2 protocol.

set interface gigabit-ethernet <*port-id*> **family ethernet-switching bpdu-tunneling protocol** <*protocol-type*>

Step3 Configure the BPDU tunneling destination multicast MAC address to replace the original destination multicast MAC address.

set interface bpdu-tunneling destination-mac <*destination-mac*>

Configuration Example

Network Requirements

1. Private networks of User A and User B are located on two sides of the ISP network, as shown in Figure 2, SwitchA1, SwitchA2, SwitchB1 and SwitchB2 are the edge devices of the user network, SW-A and SW-B are the edge devices of the ISP network.
2. The User A network belongs to VLAN 100 and the User B network belongs to VLAN 200.

3. The BPDU tunneling function of the STP protocol is enabled so that Layer 2 protocol packets of User A and User B can cross the ISP network to complete the spanning tree calculation.

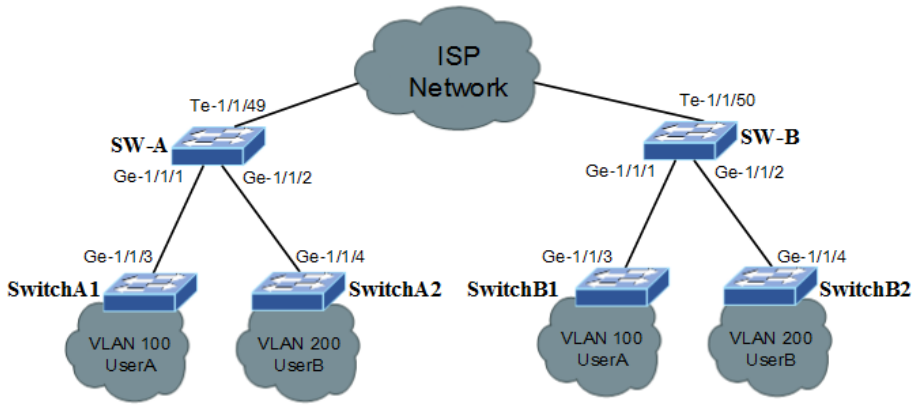

Figure 2 Networking Diagram for Configuring Transparent Transmission of Layer 2 Protocol Packets through BPDU Tunnel

Procedure

Step1 Enable STP function on SwitchA1, SwitchA2, SwitchB1 and SwitchB2.

 # Configure SwitchA1

```
admin@XorPlus# set vlans vlan-id 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 100
admin@XorPlus# set protocols spanning-tree enable true
```

 # Configure SwitchA2

```
admin@XorPlus# set vlans vlan-id 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching vlan members 200
admin@XorPlus# set protocols spanning-tree enable true
```

 # Configure SwitchB1

```
admin@XorPlus# set vlans vlan-id 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan  members 100
admin@XorPlus# set protocols spanning-tree enable true
```

 # Configure SwitchB2

```
admin@XorPlus# set vlans vlan-id 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching vlan members 200
admin@XorPlus# set protocols spanning-tree enable true
```

Step2 Configure VLAN on SW-A and SW-B.

 # Configure SW-A

```
admin@XorPlus# set vlans vlan-id 100
admin@XorPlus# set vlans vlan-id 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 200
admin@XorPlus# set interface gigabit-ethernet te-1/1/49 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/49 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet te-1/1/49 family ethernet-switching vlan members 200
```

 # Configure SW-B

```
admin@XorPlus# set vlans vlan-id 100
admin@XorPlus# set vlans vlan-id 200
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 100
```

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 200
admin@XorPlus# set interface gigabit-ethernet te-1/1/50 family ethernet-switching port- mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/50 family ethernet-switching vlan members 100
admin@XorPlus# set interface gigabit-ethernet te-1/1/50 family ethernet-switching vlan members 200
```

Step3 Enable the BPDU tunneling function of STP on SW-A and SW-B of different inbound interface.

 # Configure SW-A

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching bpdu-tunneling protocol stp
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family Ethernet-switching bpdu-tunneling protocol stp
```

 # Configure SW-B

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching bpdu-tunneling protocol stp
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching bpdu-tunneling protocol stp
```

Step4 Configure the BPDU tunneling destination multicast MAC address to replace the original destination multicast MAC address.

 # Configure SW-A

```
admin@XorPlus# set interface bpdu-tunneling destination-mac 01:90:00:00:00:1a
```

 # Configure SW-B

```
admin@XorPlus# set interface bpdu-tunneling destination-mac 01:90:00:00:00:1a
```

> **NOTE:**
>
> The destination multicast MAC address configured on the tunnel ingress switch and the egress switch must be the same value.

Configuring Flex Links Preemption Delay

User can configure two physical ports or two LAGs as Flex Links or configure one physical port and one LAG as Flex Links.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 backup-port interface ae1
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 backup-port delay 10
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# set interface aggregate-ethernet ae2 backup-port interface ae3
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

Configuring the Preemption Mode

By default, the preemption mode is set, and the active interface is preferred. Beyond that, user can configure the "bandwidth" or "off" mode. The "bandwidth" mode calls for a higher bandwidth interface, and the "off" mode turns off preemption.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 backup-port mode bandwidth
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Showing Flex Links on All Interfaces

User can view the state of user's Flex Links interfaces:

```
admin@XorPlus# run show interface flexlink
Active Interface Backup Interface Mode Delay(seconds)
---------------- ---------------- --------- --------------
ge-1/1/1(up) ge-1/1/2(standby) bandwidth 10
admin@XorPlus#
```

UDLD Configuration

UDLD (Unidirectional Link Detection) using for detecting optical fiber unidirectional link. It supports two modes of operation: normal mode(the default) and aggressive mode. In normal mode, UDLD can detect unidirectional links due to mis-connected interfaces. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic, twisted-pair links, and mis-connected interfaces. You can enable UDLD globally or on specific ports. When UDLD detectes uni-directional fault, the port status will be setted Disabled(UDLD) and down, and there is no udld neighbor. In addition, UDLD can detect the self loop port and disable this port. Self loop means TX links to RX on the same port.

Caution:

- For the case of TX-RX (RX indicates the receiving end, and TX indicates the sending end) self-loops on one ethernet port, the port status will be set to Disabled (UDLD) and down, and there will be no UDLD neighbor.
- Do not configure up-mode with UDLD, as this may cause the peer interface to be disabled unexpectedly by UDLD.

Configure UDLD normal mode on global

```
admin@XorPlus# set protocols udld disable false
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure UDLD aggressive mode on global

```
admin@XorPlus# set protocols udld disable false
admin@XorPlus# set protocols udld aggressive true
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure UDLD normal mode on Specific Port

```
admin@XorPlus# set protocols udld interface te-1/1/27 disable false
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure UDLD aggressive mode on Specific Port

```
admin@XorPlus# set protocols udld interface te-1/1/27 disable false
admin@XorPlus# set protocols udld interface te-1/1/27 aggressive true
admin@XorPlus# commit
Merging the configuration.
Commit OK.
Save done.
```

Configure UDLD Message-interval

```
admin@XorPlus# set protocols udld message-interval 20
admin@XorPlus# commit
Commit OK.
Save done.
```

UDLD status as follows when the link is good

```
admin@Xorplus# run show udld neighbors
  Port       Device Name     Device ID        Port ID     state
--------     -----------    -----------    ------------   ---------------
```

```
te-1/1/27    3295           QTFQXI10700003  te-1/1/49      bi-directional

admin@Xorplus# run show udld interface te-1/1/27
Interface te-1/1/27
---------------------------------------
Udld enabled, aggressive mode
Current bidirectional state: bi-directional
Current phase: advertisement
Message interval: 15s

Traffic statistics:
  5 sec input rate 0 bits/sec, 0 packets/sec
  5 sec output rate 0 bits/sec, 0 packets/sec
  Input Packets.............................16
  Output Packets............................1360
  Input Octets..............................1797
  Output Octets............................157178
```

UDLD status when self loop link

The example is that tx connect with rx on the same port te-1/1/27. The udld status will be transmit-to-receive loop, and the port status will be setted Disabled(UDLD) and down, and there is no udld neighbor.

```
admin@Xorplus# run show udld neighbors
  Port       Device Name     Device ID        Port ID     state
--------     -----------    -----------    ------------   ---------------

admin@Xorplus# run show udld interface te-1/1/27
Interface te-1/1/27
---------------------------------------
Udld enabled, aggressive mode
Current bidirectional state: transmit-to-receive loop
Current phase: linkdown
Message interval: 7s
```

```
Timeout interval: 5s

admin@XorPlus# run show interface gigabit-ethernet te-1/1/27
Physical interface: te-1/1/27, Disabled(UDLD), error-discard False, Physical link is Down
Interface index: 27, SFP type: SR/850
Description:
Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Full
Source filtering: Disabled, Flow control: Disabled, Auto-negotiation: Enabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress:unlimited, egress:unlimited
Interface burst limit ingress:unlimited, egress:unlimited
Precision Time Protocol mode:none
Current address: 00:90:4c:06:a5:73, Hardware address: 00:90:4c:06:a5:73
Traffic statistics:
  5 sec input rate 0 bits/sec, 0 packets/sec
  5 sec output rate 0 bits/sec, 0 packets/sec
  Input Packets.............................16
  Output Packets............................1360
  Input Octets..............................1797
  Output Octets............................157178
```

Recover port status Disabled(UDLD)

You can through down, up the port to recover the status Disabled(UDLD)

```
admin@XorPlus# set interface gigabit-ethernet te-1/1/27 disable true
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set interface gigabit-ethernet te-1/1/27 disable false
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show interface gigabit-ethernet te-1/1/27
Physical interface: te-1/1/27, Enabled, error-discard False, Physical link is Up
Interface index: 27, SFP type: SR/850
Description:
Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Full
Source filtering: Disabled, Flow control: Disabled, Auto-negotiation: Enabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress:unlimited, egress:unlimited
Interface burst limit ingress:unlimited, egress:unlimited
Precision Time Protocol mode:none
Current address: 00:90:4c:06:a5:73, Hardware address: 00:90:4c:06:a5:73
Traffic statistics:
  5 sec input rate 0 bits/sec, 0 packets/sec
  5 sec output rate 0 bits/sec, 0 packets/sec
  Input Packets.............................16
  Output Packets............................1360
  Input Octets..............................1797
  Output Octets............................157178
```

Or you can using follow command to recover the status Disabled(UDLD)

```
admin@XorPlus# run clear udld
admin@XorPlus# run show interface gigabit-ethernet te-1/1/27
Physical interface: te-1/1/27, Enabled, error-discard False, Physical link is Up
Interface index: 27, SFP type: SR/850
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Full
Source filtering: Disabled, Flow control: Disabled, Auto-negotiation: Enabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress:unlimited, egress:unlimited
Interface burst limit ingress:unlimited, egress:unlimited
Precision Time Protocol mode:none
Current address: 00:90:4c:06:a5:73, Hardware address: 00:90:4c:06:a5:73

```

```
5 sec output rate 0 bits/sec, 0 packets/sec
Input Packets.....................16
Output Packets....................1360
Input Octets......................1797
Output Octets.....................157178
```

LFS Configuration

Abstract

Link fault signaling (LFS) operates between the remote RS and the local RS. Faults detected between the remote RS and the local RS are received by the local RS as Local Fault. RS is the only layer that can generate Remote Fault signals.

Sublayers within the PHY are capable of detecting faults that render a link unreliable for communication. Upon recognition of a fault condition, a PHY sublayer indicates Local Fault status on the data path. When this Local Fault status reaches an RS, the RS stops sending MAC data, and continuously generates a Remote Fault status on the transmit data path (possibly truncating a MAC frame being transmitted). When Remote Fault status is received by an RS, the RS stops sending MAC data, and continuously generates Idle control characters. When the RS no longer receives fault status messages, it returns to normal operation, sending MAC data.

The RS reports the fault status of the link. Local Fault indicates a fault detected on the receive data path between the remote RS and the local RS. Remote Fault indicates a fault on the transmit path between the local RS and the remote RS.

The fault status is as follows:

a) link_fault = OK

The RS shall send MAC frames as requested through the PLS service interface. In the absence of MAC frames, the RS shall generate Idle control characters.

b) link_fault = Local Fault

The RS shall continuously generate Remote Fault Sequence ordered_sets.

c) link_fault = Remote Fault

The RS shall continuously generate Idle control characters.

Link Fault Signaling

If ignore local fault is set as false: When link local fault is triggered, the RS shall continuously generate Remote Fault Sequence ordered_sets. Otherwise, the RS will not generate Remote Fault Sequence ordered_sets.

If ignore remote fault is set as false: When link remote fault is received, the RS shall continuously generate Idle control characters. Otherwise, the RS shall send MAC frames as requested through the PLS service interface and generate Idle control characters in the absence of MAC frames

LFS Commands

The following is the configuration command as sample:

```
set interface gigabit-ethernet te-1/1/1 link-fault-signaling ignore-local-fault true/false
set interface gigabit-ethernet te-1/1/1 link-fault-signaling ignore-remote-fault true/fals
```

Up Mode

The force up command forcibly brings up a fiber Ethernet port and enables the port to forward packets unidirectionally over a single link. In this way, transmission links are well utilized.

Up Mode Commands

The following is the configuration commad as sample:

```
set interface gigabit-ethernet te-1/1/1 up-mode true/false
```

> ⚠ Up-mode true command should be configured with ignore-local-fault true command together. If user only configures up-mode true and does not configure ignore-local-fault command, traffic cannot transmit from TX link.

Storm Control in Ethernet Port Configuration

You can configure unicast, multicast, and broadcast storm control in packets per second, kilobits per second or percentage of physical link speed. The storm control function can permit the max rate of unicast, multicast, and broadcast traffics on ingress port.

- Storm-control function is invalid for the known unicast traffic. It works on the unknown unicast, all multicast and broadcast traffic.
- pps, kbps and ratio are mutually exclusive and can not be configured at the same time.
- When the value of the storm control is set to 0, it means that data packets are not allowed to pass.
- For storm control in kbps, the actual value of storm control and the configured value are not exactly the same, the correspondence is:

  When the configured value is between 64*n and 64*n+63, where n is an integer, the actual value of the storm control is 64*n. For example, when the configured value is 200 kbps (between 64*3 and 255), the actual value of the storm control is 64*3=192 kbps. There is a special case, when the configured value is between 0 and 63, the actual value of the flow control is 64 kbps.

Configuring Storm Control in packet per second on ingress port

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 storm-control broadcast pps 10000
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 storm-control multicast pps 10000
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 storm-control unicast pps 10000
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Storm Control in ratio on ingress port

The ratio means the percentage of the physical link speed.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 storm-control broadcast ratio 10
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 storm-control multicast ratio 20
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 storm-control unicast ratio 30
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Storm Control in kilobits per second on ingress port

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 storm-control broadcast kbps 1000
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 storm-control multicast kbps 1000
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 storm-control unicast kbps 1000
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Ethernet Ring Protection Switching (ERPS)

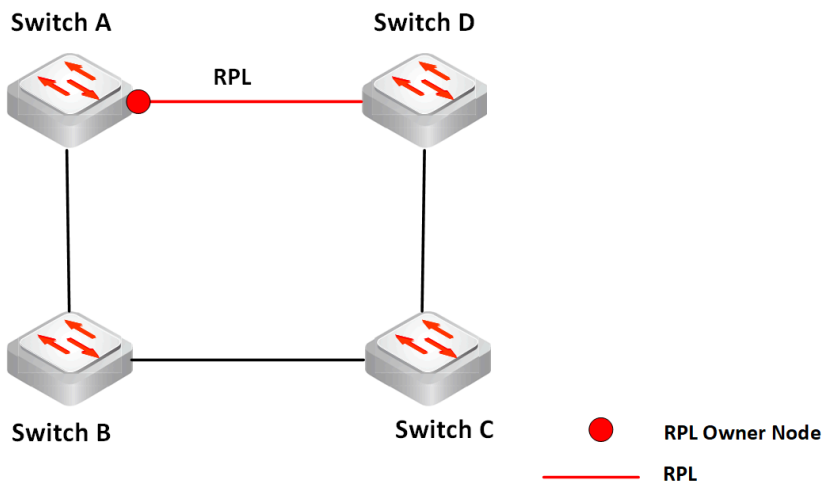
- Overview of ERPS
- Configuration Notes and Constraints of ERPS
- Configuring ERPS
- Example for Configuring ERPS (Single Ring)
- Example for Configuring ERPS (Intersection Rings)

Overview of ERPS

- Terminology
  - Ring, Major Ring and Sub-ring
  - Ring Instance
  - Node
  - Port Role
  - Control VLAN
  - Data VLAN
  - Protected Instance
  - ERPS Timer
  - Revertive/Non-revertive Mode
  - Port Blocking Switching Method
- Virtual-Channel Sub-ring RAPS Message Transmission Method
- Non-Virtual-Channel Sub-ring RAPS Message Transmission Method
- Connect Ring for Sub-ring
- Tcn-propagation
- ERPS Operation Mechanism
  - Link Failure
  - Recovery of Link Failure

Redundant links (e.g., ring networks) are often used in Ethernet switching networks for link backup and to improve network reliability. However, redundant links always form loops in the network, which may cause broadcast storms and unstable MAC address tables, and result in undesirable network communication interruption for users.

Figure 1. ERPS Diagram



As shown in **Figure 1**, Ethernet Ring Protection Switching (ERPS) is a layer 2 ring protection protocol standard defined by ITU-T under the standard number ITU-T G.8032/Y1344. It defines the Ring Auto Protection Switching (RAPS) protocol message and ring protection mechanism.

PICOS supports both versions of ERPSv1 and ERPSv2. ERPSv2 is fully compatible with ERPSv1 and has the following extensions:

- Sub-ring supporting
- Sub-ring virtual channel/non-virtual channel transmission of RAPS messages
- Manual switching of port blocking, including Forced Switch and Manual Switch
- ERPS ring revertive/non-revertive modes are configurable
- Sub-ring topology change notifications

ERPSv1 only supports major ring networking, while ERPSv2 supports not only major ring, but also supports sub-ring network, and the mixed networking of major ring and sub-ring.

ERPS leverages the advantages of ring protection technologies such as STP, with optimized detection mechanism and faster convergence; it also has good compatibility to allow interoperability with the switches, also support ERPS protocol, of other manufacturers within the ring.

Terminology

Ring, Major Ring and Sub-ring

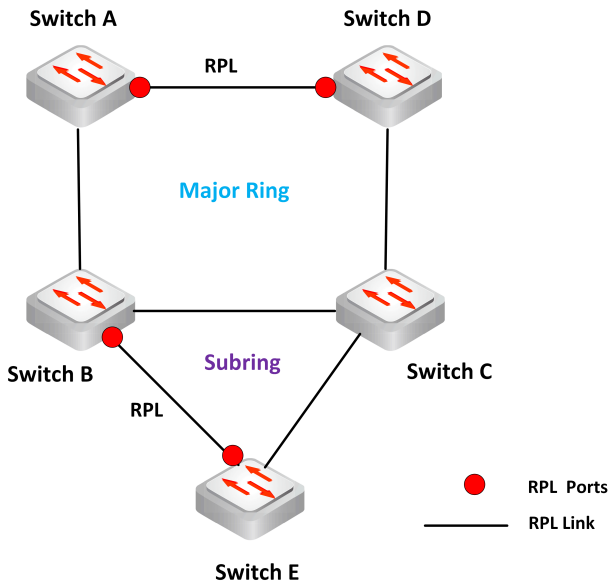
A group of interconnected Layer 2 switching devices configured with the same control VLAN and is the basic unit of the ERPS protocol forms an ERPS ring.

An ERPS ring can be a major ring or a sub-ring. By default, an ERPS ring is a major ring. The major ring is a closed ring, and the sub-ring is a non-closed ring which needs to be defined by CLI command **set protocols erps ring** *<ring-id>* **sub-ring** <**true | false**>. The configuration of the sub-ring is supported only in ERPSv2 version.

The Ethernet ring control module supports multiple rings in each node (two interfaces are part of each ring). The ring control module also supports the intersection of multiple rings. Intersection of two rings means that two rings might share the same link or share the same node.

As shown in **Figure 2**, Switch A, Switch B, Switch C and Switch D form an ERPS major ring, Switch B, Switch C and Switch E form an ERPS sub-ring. The ring ID is a unique identifier for each physical ring which can be configured by command **set protocols erps ring** *<ring-id>*.

Figure 2. ERPS Major Ring and Sub-ring



The protocol messages of the major ring are transmitted only on the major ring, and the protocol messages of the sub-ring will terminate at the intersecting nodes and will not enter the major ring. However, when there is a link fault in the sub-ring, it is necessary to advertise the topology change information of the sub-ring to the major ring at the intersecting nodes Switch B and Switch C, which is fulfilled by the tcn-propagation function.

Users can plan and deploy ERPS major ring and sub-ring by accordance with the actual network topology and usage environment.

Ring Instance

The ERPS ring is a physical ring, and the ring instance can be understood as a logical ring on the physical ring. A maximum of eight ERPS rings (including both major ring and sub-ring) are supported on a device, and a maximum of two instances can be configured for each ring. Additionally, at least one instance should be configured for each ring.

To improve link utilization, ERPS supports the configuration of up to two logical ERPS rings on a single physical ring, i.e., two instances. Usually, different instances should have unique configurations such as port roles, control VLANs, etc. Each instance has its own blocking port, which will be blocked or unblocked separately, without affecting other instances. Topology calculation for different instances will not affect each other.

For example, different protected instances can be configured for different ring instances, data traffic belonging to different VLANs can then be transmitted through different paths, thus achieving load sharing and link backup of traffic and maximizing the utilization of link resources.

Node

The Layer 2 switching devices that join the ERPS ring are called ERPS nodes. No more than two ports per node can join the same ERPS ring, which are named ERPS **port0** and **port1**.As shown in **Figure 2**, Switch A, Switch B Switch C and Switch D are the nodes of the major ring, Switch B, Switch C and Switch E are the nodes of the sub-ring.

Port Role

There are three types of ERPS port role: RPL Owner Port, RPL Neighbor Port and Ordinary Port.

- RPL Owner Port

Each ERPS ring instance has only one RPL owner port, which is determined by user configuration. By blocking the RPL owner port to forward user traffic, it prevents network loops in the ERPS ring. RPL owner port state is discarding, it can only send and receive ERPS protocol packets.

When the device of the RPL owner port receives a link failure message and learns that other nodes or links on the ERPS ring are down, it will automatically unblock the RPL owner port. RPL owner port state changes to forwarding, which will resume receiving and sending traffic, ensuring that traffic will not be interrupted.

The link where the RPL owner port located is the Ring Protection Link (RPL), which is normally NOT allowing traffic to pass.

- RPL Neighbor Port

RPL neighbor port refers to the port on the RPL link that is directly connected to the RPL owner port. It needs to be specified by the user configuration.

In normal condition, both the RPL owner port and the RPL neighbor port are blocked to prevent network loop.

When a link failure occurs, both the RPL owner port and the RPL neighbor port will be unlocked.

- Ordinary Port

The ERPS port is an ordinary port if not specified as an RPL owner port or RPL neighbor port.

The ordinary ports are responsible for monitoring the link status of the ERPS ring and informing other ring nodes.

Control VLAN

In an ERPS ring, the control VLAN is used to transmit ERPS protocol packets.

- Each ERPS ring instance must be configured with a control VLAN.
- Different ERPS ring instances cannot use the same control VLAN.

- The same control VLAN must be configured for all devices in the same ERPS ring instance.

Data VLAN

Data VLANs are a group of VLAN(s) that is used in the ring for transmission of user traffic, which should be defined in MSTP instance and VLAN mapping.

Protected Instance

Protected instance is the MSTP instance of data VLAN mapping that needs the ERPS ring protection. Before configuring ERPS, users need to configure protected MSTP instance and VLAN mapping by using command **set protocols spanning-tree mstp msti** <*msti*> **vlan** <*vlan-id*>. Then, configure the MSTP instance as the protected-instance of the ERPS ring instance by using command **set protocols erps ring** <*ring-id*> **instance** <*instance-id*> **protected-instance** <*msti*>.

The control VLAN and data VLAN must be configured in the protected instance, only then the ERPS protocol can process messages of these VLANs.

> **NOTE**:
>
> When users want to share the forwarding path of data traffic between intersecting rings, it is important to note that when configuring ERPS, the control VLAN and data VLAN of the intersecting rings should be configured in the same protected instance.
>
> For example, let's assume that two intersecting rings with different control VLANs (such as VLAN 200, VLAN 300), and they share the same data VLAN (such as VLAN 100), it's necessary to configure the control VLANs and data VLAN (VLAN 100, VLAN 200, VLAN 300) into the same protected instance to enable data forwarding between the intersecting rings.
>
> You can refer to Example for Configuring ERPS (Intersection Rings) for detailed configuration.

ERPS Timer

There are three timers used in ERPS protocol: Guard Timer, WTR (Wait to Restore) Timer and Holdoff Timer.

- Guard Timer

The device involved in the signal failure (SF) sends R-APS (NR) messages to other nodes after the failure is recovered or the clearing of SF condition operation is detected. The guard timer is started at the same time, and the R-APS (NR) messages are not processed until this timer expires, with the purpose of preventing the reception of outdated R-APS (NR) messages. If R-APS (NR) messages from other ports are still received after the guard timer expired, the state of this port is changed to Forwarding state.

The guard timer can be configured. The default time interval is 500 milliseconds; the time interval ranges from 10 to 2000 milliseconds.

- Wait-to-Restore (WTR) Timer

When recovering from a signal failure (SF) condition, the WTR timer is used to prevent frequent operation of protection switching due to intermittent SF defects.

The WTR timer can be configured. The delay timer must be long enough to allow the recovering network to become stable. The default time interval is 5 minutes; the time interval ranges from 1 to 12 minutes.

- Holdoff Timer

If the holdoff timer is specified, a defect is not reported to the ring protection mechanism immediately. Instead, the hold-off timer is started. On expiration of the timer, if the defect still exists, it is reported to protection switching.

The holdoff timer can be configured. The default time interval is 0 millisecond; the time interval ranges from 0 to 1000 milliseconds.

- WTB timer

When clearing the forced switching or manual switching state of a port, WTB timer is started. As there may be multiple manually switching blocking nodes in a ERPS ring, and the clearing operation works only when the WTB timer expires, which prevents blocking-point oscillations caused by immediate blocking of the RPL owner port.

WTB Timer cannot be configured directly via CLI, it obtains from the configuration of Guard Timer value plus 5 seconds. The default value is 7 seconds.

Revertive/Non-revertive Mode

ERPS revertive/non-revertive mode determines whether the RPL owner port is re-blocked when the failed link recovers.

- In **revertive mode**, if the failed link recovers, the RPL owner port is re-blocked after waiting for the WTR timer interval. The RPL link is reverted to
- In **non-revertive mode**, if the failed link recovers, the WTR timer is not started, and the blocking link remains on the original failed link and does not revert to RPL link.

By default, the ERPS ring is in revertive mode.

ERPSv2 supports the configuration of revertive and non-revertive modes, while ERPSv1 supports only revertive mode.

Port Blocking Switching Method

Since the RPL link may have higher bandwidth, users can consider blocking the link with low bandwidth to allow data traffic to transmit through the RPL link.

ERPS supports two switching methods to manually configure port blocking: Force Switch and Manual Switch.

- **Forced Switch**: Ports configured for forced switch are blocked immediately, regardless of whether other links on the ring are faulty or not.
- **Manual Switch**: Ports configured for manual switch are blocked if the state of the ring is Idle or Pending, otherwise they are not blocked.

In addition to forced switch and manual switch, ERPS also supports clear operation, which is used in the following three cases:

- Clearing the locally configured manual switch and forced switch configurations.
- When the ERPS ring is in the revertive mode, the revert action is triggered manually before the WTB Timer or WTR Timer expires.
- When the ERPS ring is in non-revertive mode, the revert action is triggered manually.

Users can use the **run show erps ring** <*ring-id*> [**instance** <*instance-id*>] command to view the detailed information of the ERPS ring instances. If force switch (or manual switch) is set successfully, the ***Node state*** in the show result displays **Forced Switch** (or **Manual Switch**).

```
admin@PICOS# run show erps ring 1
Ring ID: 1
Port0: te-1/1/19
```

```
Port1: te-1/1/7
Ring-MAC: false
Sub-ring: No
Virtual-channel: No

Instance ID: 1
Enable: Yes
Active: true
Node state: Forced Switch
Description:

Protected instance: 1
Protected VLAN: 100-101,111,4094
……
```

Port blocking manual switching is an ERPSv2 feature which is not supported in ERPSv1.

Virtual-Channel Sub-ring RAPS Message Transmission Method

When ERPS protocol is deployed in multi-ring networking, the transmission methods of RAPS messages on sub-ring nodes are categorized into **Virtual-Channel (VC)** and **Non-Virtual-Channel (NVC)**.

For Virtual-Channel method, the RAPS protocol messages of the sub-ring will transmit in the major ring through the intersecting node. That is, the intersecting node does not terminate the protocol messages of the sub-ring. In this topology, the RPL owner port of the sub-ring blocks both RAPS protocol messages and data traffic of the sub-ring.

R-APS messages from sub-rings are forwarded over virtual channels to be broadcast or multicast over the interconnected network.

R-APS messages forwarded by a sub-ring over a virtual channel need to be distinguishable from R-APS messages of other rings, which can be achieved by using separate control VLANs for the R-APS virtual channels of different sub-rings.

To enable Virtual-Channel method, the following configurations are required:

1. Enable virtual channel on all the devices of the sub-ring, where the *<ring-id>* is the sub-ring ID.

   set protocols erps ring *<ring-id>* **virtual-channel** <**true | false**>

2. Add the ports of major ring, which are used for forwarding R-APS messages from the sub-ring, to the control VLAN of the sub-ring.

Non-Virtual-Channel Sub-ring RAPS Message Transmission Method

For Non-Virtual-Channel method, the RAPS protocol messages of the sub-ring will terminate on the intersecting node, and the RPL owner port of the sub-ring will block only the data traffic but not the RAPS protocol messages of the sub-ring.

If link failure occurs on any link of the sub-ring, the RAPS channel of the sub-ring may be segmented, which prevents RAPS messages from being exchanged between sub-ring links.

By default, the sub-ring RAPS message is transmitted with non-virtual channel method.

Connect Ring for Sub-ring

On a multi-ring network, associate a ring (this is the connect ring, e.g. ring A) with a sub-ring (e.g. sub-ring B) if you want to advertise topology changes in the sub-ring (sub-ring B) to the ring (ring A).

Before using the tcn-propagation function to forward a topology change notification to the connect ring whenever the topology of the sub-ring changed, you need to configure connect ring for the sub-ring. By default, a sub-ring has no connect ring.

Tcn-propagation

Tcn-propagation (topology change notification propagation) function enables sub-ring topology change notifications. When the topology of the sub-ring changes, the FDB refresh of the port will generate a Topology Change (TC) signal. When the tcn-propagation function is enabled, the intersecting node sends an event flush message to the connect ring when it receives the TC signal.

By default, this feature is disabled.

To enable sub-ring topology change notifications, the following configurations are required:

1. Configure the connect ring for a sub-ring on all intersecting nodes.

   set protocols erps ring *<ring-id>* **instance** *<instance-id>* **connect ring** *<ring-id>* **instance** *<instance-id>*

2. Enable tcn-propagation function to advertise topology changes to the connect ring on all intersecting nodes.

   set protocols erps tcn-propagation <**true | false**>

ERPS Operation Mechanism

In normal condition, the communication is normal between devices on the loop, all ports can forward traffic normally except the RPL owner port is blocked by ERPS to prevent network loops. When link failure occurs, there are two ERPS operation process involved: **Link Failure** and **Recovery of Link Failure**, which are described below.

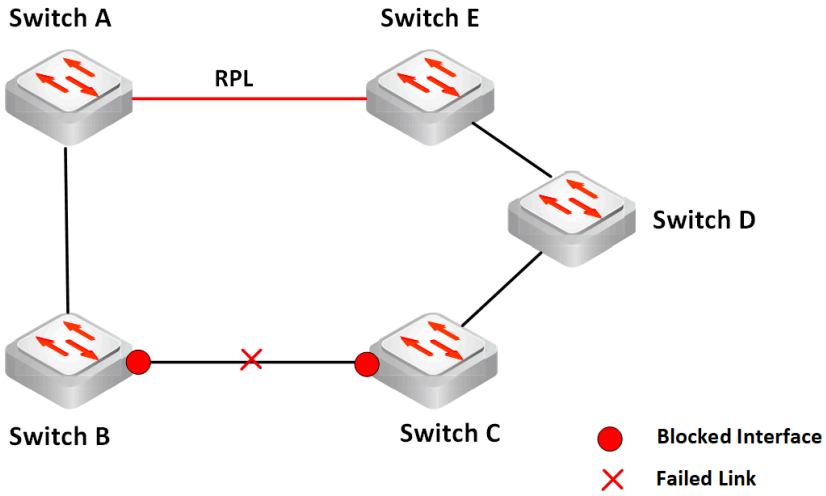
Link Failure

As shown in **Figure 3**, when the link between Switch B and Switch C fails, the ERPS protocol initiates a protection reversal mechanism to block the ports at both ends of the failed link, and then unblocks the RPL owner port, which resumes receiving and sending user traffic, thus ensuring uninterrupted traffic. The detailed process is as follows:

1. Switch B and Switch C detect a link failure, block the port on the failed link, and perform the FDB flush.

2. Switch B and Switch C then start sending R-APS (SF) messages periodically with the (node ID, BPR) pair on both ring ports, while the SF condition persists.
3. When the other devices receive the R-APS (SF) message from Switch B and Switch C, they all perform the FDB flush. When Switch A device (the device where the RPL owner port is located) receives this RAPS message, it unblocks the RPL owner port and RPL neighbor port, performs the FDB flush.

Figure 3. ERPS Link Failure



Recovery of Link Failure

After the link has been recovered from the failure, it can be used to transmit user traffic again, and the RPL owner port will be blocked again. The detailed recovery process is as follows:

1. When the link between Switch B and Switch C is recovered, Switch B and Switch C start a Guard Timer to prevent reception of outdated R-APS (NR) messages, and do not receive other R-APS protocol messages until the timer expires. At the same time Switch B and Switch C sends R-APS (NR) messages to other nodes.
2. When Switch A (the device where the RPL owner port is located) receives the R-APS (NR) message, it starts the WTR Timer. On expiration of the WTR timer, the RPL owner node blocks its end of the RPL, sends an R-APS (NR, RB) message with the (node ID, BPR) pair and performs the FDB flush.
3. When Switch B and Switch C receive the NR-RB (No request, RPL block) R-APS message from Switch A, they remove the block on its blocked ring ports, stop sending R-APS (NR) messages and perform the FDB flush. In addition to this, ethernet ring nodes B to E perform the FDB flush when receiving an R-APS (NR, RB) message due to the node ID and BPR-based mechanism.

Configuration Notes and Constraints of ERPS

When configuring ERPS, consider the following points:

- A maximum of eight ERPS rings (including both major ring and sub-ring) are supported on a device, and a maximum of two instances can be configured for each ring.
- The ERPS port must be a trunk port.
- Before enabling ERPS, users need to disable spanning tree protocol on specific port.
- Traffic from VLANs other than the control VLAN or data VLAN will be dropped by the ERPS ports.
- Make sure that the control VLAN and data VLANs of an ERPS ring have all been added to the MSTP instance (ERPS protected-instance) and VLAN
- When the ERPS ring instance is enabled, the traffic of MSTP instance 0 will be blocked.
- Control VLAN should be assigned as a tagged VLAN.
- Different ERPS ring instances cannot use the same control VLAN.
- The same control VLAN must be configured for all devices in the same ERPS ring instance.
- To ensure the fast convergence of ERPS, it is recommended not to configure the intersecting link as an RPL link in the configuration of the intersecting ring.
- ERPS only works with MSTP, but not STP/RSTP/PVST.
- MLAG configuration on ERPS ring ports is not supported.
- On such deployments, where gateways are serving VLANs across the ring, VRRP is recommended.

Configuring ERPS

PICOS supports both versions of ERPSv1 and ERPSv2. ERPSv2 is fully compatible with ERPSv1 and has the following extensions:

- Sub-ring supporting
- Sub-ring virtual channel/non-virtual channel transmission of RAPS messages
- Manual switching of port blocking, including Forced Switch and Manual Switch
- ERPS ring revertive/non-revertive modes are configurable
- Sub-ring topology change notifications

Procedure

Step1 Disable spanning-tree protocol on the interface where you want to enable ERPS.

set protocols spanning-tree interface <*interface-name*> **enable false**

Step2 Configure protected MSTP instance (i.e., ERPS protected-instance) and VLAN mapping before configuring ERPS. The ERPS control VLAN must be in one of the protected-msti.

set protocols spanning-tree mstp msti <*msti*> **vlan** <*vlan-id*>

Step3 Configure the port mode to **trunk**, configure VLAN member.

NOTEs:

- Both the control VLAN and data VLAN have to be configured as the VLAN member of the ERPS port.
- Control VLAN should be assigned as a tagged VLAN. If not explicitly specified, VLAN is tagged in VLAN member configuration by default.

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching port-mode** <*port-mode*>

set interface gigabit-ethernet <*interface-name*> **family ethernet-switching vlan members** <*vlan-id*>

Step4 Enable ERPS function globally. By default, ERPS is disabled.

set protocols erps enable <**true | false**>

Step5 (Optional) Configure ERPS version. The default version is ERPSv2.

set protocols erps version <1 | 2>

Step6 Create an ERPS ring with a given ID. By default, ERPS ring is a major ring. A maximum of eight ERPS rings are supported on a device.

set protocols erps ring <*ring-id*>

Step7 (Optional) Create an ERPS sub-ring with a given ID.

set protocols erps ring <*ring-id*> **sub-ring** <**true | false**>

Step8 Configure ERPS ring ports: port0 and port1.

set protocols erps ring <*ring-id*> **port0 interface** <*interface-name*>

set protocols erps ring <*ring-id*> **port1 interface** <*interface-name*>

Step9 Create an instance for the ERPS ring. A maximum of two instances can be configured for each ring.

set protocols erps ring <*ring-id*> **instance** <**1** | **2**>

Step10 Configure RPL port role for the ERPS ring instance. Each ERPS ring instance has only one RPL owner port and neighbor port.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **rpl** <**port0** | **port1**> <**owner** | **neighbor**>

Step11 Configure a control VLAN. Note that the same control VLAN must be configured for all devices in the same ERPS ring instance.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **control-vlan** <*control-vlan*>

Step12 Configure the MSTP instance of VLANs that are protected by the ERPS ring instance.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **protected-instance** <*msti*>

Step13 (Optional) Configure the guard timer, holdoff timer and WTR timer duration for a ring instance.

By default, guard timer is 500 milliseconds, holdoff timer is 0 millisecond and WTR timer is 5 minutes.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **guard-timer** <*guard-timer*>

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **holdoff-timer** <*holdoff-timer*>

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **wtr-timer** <*wtr-timer*>

Step14 (Optional) Configure the ring ID as the last byte of the destination MAC address for R-APS packets.

set protocols erps ring <*ring-id*> **r-aps ring-mac**

Step15 (Optional) Configure the Automatic Protection Switching (APS) message level for the node on the Ethernet ring.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **r-aps level** <*level-id*>

Step16 (Optional) Configure ERPS revertive/non-revertive mode. By default, the ERPS ring is in revertive mode.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **non-revertive** <**true | false**>

Step17 (Optional) Configure virtual-channel sub-ring RAPS message transmission method. By default, the sub-ring RAPS message is transmitted with the non-virtual channel method.

set protocols erps ring <*ring-id*> **virtual-channel** <**true | false**>

Step18 (Optional) Configure the connect ring for a sub-ring, enable tcn-propagation function to advertise topology changes to the connect ring.

set protocols erps ring <*ring-id*> **instance** <*instance-id*> **connect ring** <*ring-id*> **instance** <*instance-id*>

set protocols erps tcn-propagation <**true | false**>

Step19 Commit the configuration.

commit

Step20 (Optional) In operational mode, block a specific ring interface in one of the two following ways:

- Force: The switch blocks a specific ring interface regardless of the protection switching state of the ring instance.
- Manual: The switch blocks a specific ring interface if no other protection switch event is active on the ring instance.

erps switch force ring <*ring-id*> **instance** <*instance-id*> <**port0** | **port1**>

erps switch manual ring <*ring-id*> **instance** <*instance-id*> <**port0** | **port1**>

erps clear ring <*ring-id*> **instance** <*instance-id*>

Step21 View the configuration information and status of ERPS.

run show erps interface ring <*ring-id*> **instance** <*instance-id*>

run show erps brief

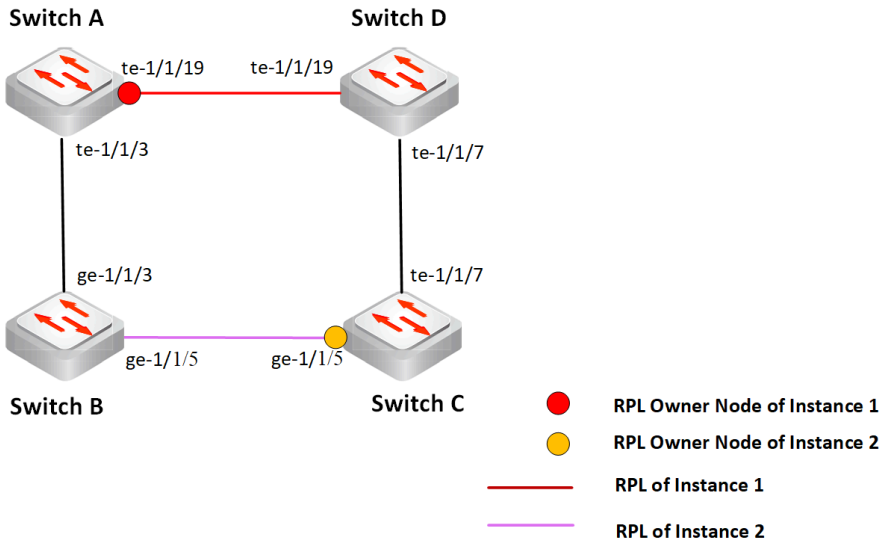
run show erps ring <*ring-id*> [**instance** <*instance-id*>]

Example for Configuring ERPS (Single Ring)

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
  - Verifying the Configuration

Networking Requirements

Figure 1. ERPS Configuration Example



To solve the loop problem caused by redundant links in the network, ERPS protocol can be deployed on the devices that form the ring network. As shown in **Figure 4**, taking the deployment of a single-ring multi-instance ERPS ring as an example.

- Switch A, Switch B, Switch C and Switch D form an ERPS ring, on which two instances are configured.
- The RPL Owner Node of instance 1 is the interface te-1/1/19 (port1) on Switch A. The RPL is the link between Switch A and Switch D. The control VLAN is VLAN 4001 and the data VLANs are VLAN 100-200.
- The RPL Owner Node of instance 2 is the interface ge-1/1/5 (port0) on Switch C. Its RPL is the link between Switch B and Switch C. The control VLAN is VLAN 4002 and the data VLANs are VLANs 300-400.

NOTEs:

- The ERPS port must be a trunk port and disable spanning tree protocol.
- Different ERPS ring instances cannot use the same control VLAN.
- The same control VLAN must be configured for all devices in the same ERPS ring instance.

Procedure

Switch A

Step1 Disable spanning-tree protocol on the interface where you want to enable ERPS.

```
admin@SwitchA# set protocols spanning-tree interface te-1/1/3 enable false
admin@SwitchA# set protocols spanning-tree interface te-1/1/19 enable false
```

Step2 Configure protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: The ERPS control VLAN must be in one of the protected MSTP instance.

```
admin@SwitchA# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchA# set protocols spanning-tree mstp msti 1 vlan 4001
admin@SwitchA# set protocols spanning-tree mstp msti 2 vlan 300-400
admin@SwitchA# set protocols spanning-tree mstp msti 2 vlan 4002
```

Step3 Configure VLAN and port mode.

```
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 100-200,300-400,4001
admin@SwitchA# set interface gigabit-ethernet te-1/1/19 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/19 family ethernet-switching vlan members 100-200,300-400,400
```

Step4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchA# set protocols erps enable true
```

Step5 Create the ERPS ring with a given ID.

```
admin@SwitchA# set protocols erps ring 1
```

Step6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchA# set protocols erps ring 1 port0 interface te-1/1/3
admin@SwitchA# set protocols erps ring 1 port1 interface te-1/1/19
```

Step7 Create instance for the ERPS ring.

```
admin@SwitchA# set protocols erps ring 1 instance 1
admin@SwitchA# set protocols erps ring 1 instance 2
```

Step8 Configure port te-1/1/19 (port1) on Switch A as the RPL Owner Node for ERPS ring 1 instance 1.

```
admin@SwitchA# set protocols erps ring 1 instance 1 rpl port1 owner
```

Step9 Configure the control VLAN.

```
admin@SwitchA# set protocols erps ring 1 instance 1 control-vlan 4001
admin@SwitchA# set protocols erps ring 1 instance 2 control-vlan 4002
```

Step10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchA# set protocols erps ring 1 instance 1 protected-instance 1
admin@SwitchA# set protocols erps ring 1 instance 2 protected-instance 2
```

Step11 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Disable spanning-tree protocol on the interface where you want to enable ERPS.

```
admin@SwitchB# set protocols spanning-tree interface ge-1/1/3 enable false
admin@SwitchB# set protocols spanning-tree interface ge-1/1/5 enable false
```

Step2 Configure protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: The ERPS control VLAN must be in one of the protected MSTP instance.

```
admin@SwitchB# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchB# set protocols spanning-tree mstp msti 1 vlan 4001
admin@SwitchB# set protocols spanning-tree mstp msti 2 vlan 300-400
admin@SwitchB# set protocols spanning-tree mstp msti 2 vlan 4002
```

Step3 Configure VLAN and port mode.

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 100-200,300-400,4001
admin@SwitchB# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 100-200,300-400,4001
```

Step4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchB# set protocols erps enable true
```

Step5 Create the ERPS ring with a given ID.

```
admin@SwitchB# set protocols erps ring 1
```

Step6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchB# set protocols erps ring 1 port0 interface ge-1/1/3
admin@SwitchB# set protocols erps ring 1 port1 interface ge-1/1/5
```

Step7 Create instance for the ERPS ring.

```
admin@SwitchB# set protocols erps ring 1 instance 1
admin@SwitchB# set protocols erps ring 1 instance 2
```

Step8 Configure port ge-1/1/5 (port1) on Switch C as the RPL Neighbor Node for ERPS ring 1 instance 2.

```
admin@SwitchB# set protocols erps ring 1 instance 2 rpl port1 neighbor
```

Step9 Configure the control VLAN.

```
admin@SwitchB# set protocols erps ring 1 instance 1 control-vlan 4001
admin@SwitchB# set protocols erps ring 1 instance 2 control-vlan 4002
```

Step10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchB# set protocols erps ring 1 instance 1 protected-instance 1
admin@SwitchB# set protocols erps ring 1 instance 2 protected-instance 2
```

Step11 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Disable spanning-tree protocol on the interface where you want to enable ERPS.

```
admin@SwitchC# set protocols spanning-tree interface te-1/1/7 enable false
admin@SwitchC# set protocols spanning-tree interface ge-1/1/5 enable false
```

Step2 Configure MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: The ERPS control VLAN must be in one of the protected MSTP instance.

```
admin@SwitchC# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchC# set protocols spanning-tree mstp msti 1 vlan 4001
admin@SwitchC# set protocols spanning-tree mstp msti 2 vlan 300-400
admin@SwitchC# set protocols spanning-tree mstp msti 2 vlan 4002
```

Step3 Configure VLAN and port mode.

```
admin@SwitchC# set interface gigabit-ethernet te-1/1/7 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet te-1/1/7 family ethernet-switching vlan members 100-200,300-400,4001
admin@SwitchC# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 100-200,300-400,4001
```

Step4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchC# set protocols erps enable true
```

Step5 Create the ERPS ring with a given ID.

```
admin@SwitchC# set protocols erps ring 1
```

Step6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchC# set protocols erps ring 1 port0 interface ge-1/1/5
admin@SwitchC# set protocols erps ring 1 port1 interface te-1/1/7
```

Step7 Create instance for the ERPS ring.

```
admin@SwitchC# set protocols erps ring 1 instance 1
admin@SwitchC# set protocols erps ring 1 instance 2
```

Step8 Configure port ge-1/1/5 (port0) on Switch C as the RPL Owner Node for ERPS ring 1 instance 2.

```
admin@SwitchC# set protocols erps ring 1 instance 2 rpl port0 owner
```

Step9 Configure the control VLAN.

```
admin@SwitchC# set protocols erps ring 1 instance 1 control-vlan 4001
admin@SwitchC# set protocols erps ring 1 instance 2 control-vlan 4002
```

Step10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchC# set protocols erps ring 1 instance 1 protected-instance 1
admin@SwitchC# set protocols erps ring 1 instance 2 protected-instance 2
```

Step11 Commit the configurations.

```
admin@SwitchC# commit
```

Switch D

Step1 Disable spanning-tree protocol on the interface where you want to enable ERPS.

```
admin@SwitchD# set protocols spanning-tree interface te-1/1/7 enable false
admin@SwitchD# set protocols spanning-tree interface te-1/1/19 enable false
```

Step2 Configure the protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: The ERPS control VLAN must be in one of the protected MSTP instance.

```
admin@SwitchD# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchD# set protocols spanning-tree mstp msti 1 vlan 4001
admin@SwitchD# set protocols spanning-tree mstp msti 2 vlan 300-400
admin@SwitchD# set protocols spanning-tree mstp msti 2 vlan 4002
```

Step3 Configure VLAN and port mode.

```
admin@SwitchD# set interface gigabit-ethernet te-1/1/7 family ethernet-switching port-mode trunk
admin@SwitchD# set interface gigabit-ethernet te-1/1/7 family ethernet-switching vlan members 100-200,300-400,4001
admin@SwitchD# set interface gigabit-ethernet te-1/1/19 family ethernet-switching port-mode trunk
admin@SwitchD# set interface gigabit-ethernet te-1/1/19 family ethernet-switching vlan members 100-200,300-400,400
```

Step4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchD# set protocols erps enable true
```

Step5 Create the ERPS ring with a given ID.

```
admin@SwitchD# set protocols erps ring 1
```

Step6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchD# set protocols erps ring 1 port0 interface te-1/1/7
```

```
admin@SwitchD# set protocols erps ring 1 port1 interface te-1/1/19
```

Step7 Create instance for the ERPS ring.

```
admin@SwitchD# set protocols erps ring 1 instance 1
admin@SwitchD# set protocols erps ring 1 instance 2
```

Step8 Configure port te-1/1/19 (port1) on Switch D as the RPL Neighbor port for ERPS ring 1 instance 1.

```
admin@SwitchD# set protocols erps ring 1 instance 1 rpl port1 neighbor
```

Step9 Configure the control VLAN.

```
admin@SwitchD# set protocols erps ring 1 instance 1 control-vlan 4001
admin@SwitchD# set protocols erps ring 1 instance 2 control-vlan 4002
```

Step10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchD# set protocols erps ring 1 instance 1 protected-instance 1
admin@SwitchD# set protocols erps ring 1 instance 2 protected-instance 2
```

Step11 Commit the configurations.

```
admin@SwitchD# commit
```

Verifying the Configuration

- The command **run show erps brief** can be used to check the brief configuration information of the ERPS ring. Take Switch A as an example:

```
admin@SwitchA# run show erps brief
Enable: true
Version: 2
Tcn-propagation: No

D: Discarding
F: Forwarding
R: RPL Owner
N: RPL Neighbour
FS: Forced Switch
MS: Manual Switch
Ring ID    Instance ID    Control VLAN    Port0            Port1
------------------------------------------------------------------------------
1          1              4001            te-1/1/3(F)      te-1/1/19 (D,R)
1          2              4002            te-1/1/3(F)      te-1/1/19(F)
```

- The command **run show erps ring** *<ring-id>* can be used to check the detailed information of the ERPS ring. Take Switch A as an example:

```
admin@SwitchA# run show erps ring 1
Ring ID: 1
Port0: te-1/1/3
Port1: te-1/1/19
Ring-MAC: false
Sub-ring: No
Virtual-channel: No

Instance ID: 1
Enable: Yes
Active: true
Node state: Idle
Description:
Control VLAN: 4001
Protected instance: 1
Protected VLAN: 100-200
Guard timer: 500 ms
Hold-off timer: 0 ms
WTR timer: 5 min
Revertive mode: Revertive
```

```
R-APS level : 7
Connect(ring/instance): -
Forced Switch Port: -
Manual Switch Port: -
Interface      Port Role      Port State       Signal Failure
--------------------------------------------------------------------------------
te-1/1/3       Common         Forwarding     Non-failed
te-1/1/19      RPL Owner      Discarding      Non-failed

Instance ID: 2
Enable: Yes
Active: true
Node state: Idle
Description:
Control VLAN: 4002
Protected instance: 2
Protected VLAN: 300-400
Guard timer: 500 ms
Hold-off timer: 0 ms
WTR timer: 5 min
Revertive mode: Revertive
R-APS level : 7
Connect(ring/instance): -
Forced Switch Port: -
Manual Switch Port: -
Interface      Port Role      Port State       Signal Failure
------------------------------------------------------------------
te-1/1/3       Common         Forwarding       Non-failed
te-1/1/19      Common         Forwarding       Non-failed
```

From the show result, we can see that port te-1/1/19 on Switch A is the Owner node in Instance 1, with the ERPS ring in the Idle state, the RPL owner port blocked, and the port state of the non-RPL owner port is forwarding.

In Instance 2, port0 and port1 are Normal nodes, the ERPS ring is in the Idle state, and the port state of the non-RPL owner ports are forwarding.

Example for Configuring ERPS (Intersection Rings)

- Networking Requirements

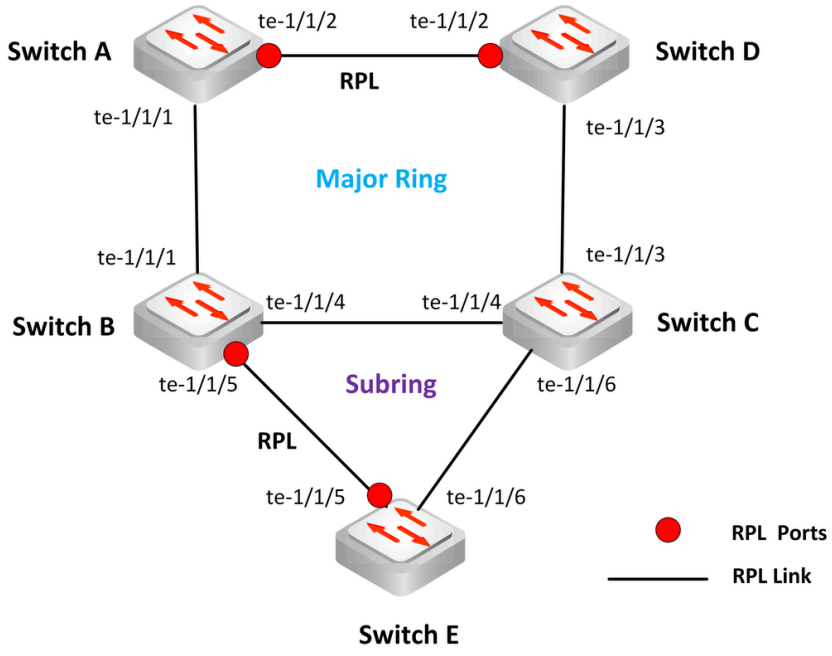
Networking Requirements

Figure 1. ERPS Configuration Example



To solve the loop problem caused by redundant links in the network, ERPS protocol can be deployed on the devices that form the ring network. As shown in **Figure 1**, taking the deployment of the interconnection ERPS ring as an example.

- Switch A, Switch B, Switch C and Switch D form an ERPS major ring, ring ID is 1 and protected instance is 1; Switch B, Switch C and Switch E form a sub-ring, ring ID is 2 and protected instance is 2.
- Configure the control VLAN ID of ERPS ring 1 to be 4001 and the control VLAN ID of ERPS ring 2 to be 4002. ERPS ring 1 and ring 2 transmit data packets for the same user VLAN 100 to 200.
- Users wish to share the forwarding path between the intersecting rings for the data traffic, in such case, it is necessary to configure the control VLANs and data VLANs (VLAN 4001, 4002, 100 to 200) into the same protected instance to achieve data forwarding between the intersecting rings.
- Configure network topology change notification on intersecting nodes Switch B and Switch C. The following configurations are required:

  1. Configure the connect ring for a sub-ring on all intersecting nodes.

  set protocols erps ring <*ring-id*> **instance** <*instance-id*> **connect ring** <*ring-id*> **instance** <*instance-id*>

  2. Enable tcn-propagation function to advertise topology changes to the connect ring on all intersecting nodes.

set protocols erps tcn-propagation <**true | false**>

NOTEs:

- The ERPS port must be a trunk port and disable spanning tree protocol.
- Different ERPS ring instances cannot use the same control VLAN.
- The same control VLAN must be configured for all devices in the same ERPS ring instance.

Procedure

Switch A

Step 1 Disable spanning-tree protocol on the interface before configuring ERPS ring on the interface.

```
admin@SwitchA# set protocols spanning-tree interface te-1/1/1 enable false
admin@SwitchA# set protocols spanning-tree interface te-1/1/2 enable false
```

Step 2 Configure protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: The ERPS control VLAN must be in one of the protected MSTP instance.

```
admin@SwitchA# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchA# set protocols spanning-tree mstp msti 1 vlan 4001
```

Step 3 Configure VLAN and port mode.

```
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 100-200,4001
admin@SwitchA# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 100-200,4001
```

Step 4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchA# set protocols erps enable true
```

Step 5 Create the ERPS ring with a given ID.

```
admin@SwitchA# set protocols erps ring 1
```

Step 6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchA# set protocols erps ring 1 port0 interface te-1/1/1
admin@SwitchA# set protocols erps ring 1 port1 interface te-1/1/2
```

Step 7 Create instance for the ERPS ring.

```
admin@SwitchA# set protocols erps ring 1 instance 1
```

Step 8 Configure port te-1/1/2 (port1) on Switch A as the RPL Owner Node for ERPS ring 1 instance 1.

```
admin@SwitchA# set protocols erps ring 1 instance 1 rpl port1 owner
```

Step 9 Configure the control VLAN.

```
admin@SwitchA# set protocols erps ring 1 instance 1 control-vlan 4001
```

Step 10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchA# set protocols erps ring 1 instance 1 protected-instance 1
```

Step 11 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step 1 Disable spanning-tree protocol on the interface before configuring ERPS ring on the interface.

```
admin@SwitchB# set protocols spanning-tree interface te-1/1/1 enable false
admin@SwitchB# set protocols spanning-tree interface te-1/1/4 enable false
admin@SwitchB# set protocols spanning-tree interface te-1/1/5 enable false
```

Step 2 Configure protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: Configure the control VLAN and data VLAN of ring 1 and ring 2 (VLAN 4001, 4002, 100 to 200) into the same protected instance to achieve data forwarding between the intersecting rings.

```
admin@SwitchB# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchB# set protocols spanning-tree mstp msti 1 vlan 4001
admin@SwitchB# set protocols spanning-tree mstp msti 1 vlan 4002
```

Step 3 Configure VLAN and port mode.

```
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 100-200,4001
admin@SwitchB# set interface gigabit-ethernet te-1/1/4 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/4 family ethernet-switching vlan members 100-200,4001
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching vlan members 100-200,4002
```

Step 4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchB# set protocols erps enable true
```

Step 5 Create the ERPS ring 1 and 2, and specify ring 2 as a sub-ring.

```
admin@SwitchB# set protocols erps ring 1
admin@SwitchB# set protocols erps ring 2 sub-ring true
```

Step 6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchB# set protocols erps ring 1 port0 interface te-1/1/1
admin@SwitchB# set protocols erps ring 1 port1 interface te-1/1/4
admin@SwitchB# set protocols erps ring 2 port0 interface te-1/1/5
```

Step 7 Configure port te-1/1/5 (port0) on Switch B as the RPL Owner Node for ERPS ring 2 instance 2.

```
admin@SwitchB# set protocols erps ring 2 instance 2 rpl port0 owner
```

Step 8 Create instance for the ERPS ring.

```
admin@SwitchB# set protocols erps ring 1 instance 1
admin@SwitchB# set protocols erps ring 2 instance 2
```

Step 9 Configure the control VLAN.

```
admin@SwitchB# set protocols erps ring 1 instance 1 control-vlan 4001
```

```
admin@SwitchB# set protocols erps ring 2 instance 2 control-vlan 4002
```

Step 10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchB# set protocols erps ring 1 instance 1 protected-instance 1
admin@SwitchB# set protocols erps ring 2 instance 2 protected-instance 1
```

Step 11 Configure the connect ring for sub-ring 2, and enable network topology change notification on intersecting nodes Switch B and Switch C.

```
admin@SwitchB# set protocols erps ring 2 instance 2 connect ring 1 instance 1
admin@SwitchB# set protocols erps tcn-propagation true
```

Step 12 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step 1 Disable spanning-tree protocol on the interface before configuring ERPS ring on the interface.

```
admin@SwitchC# set protocols spanning-tree interface te-1/1/3 enable false
admin@SwitchC# set protocols spanning-tree interface te-1/1/4 enable false
admin@SwitchC# set protocols spanning-tree interface te-1/1/6 enable false
```

Step 2 Configure MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: Configure the control VLAN and data VLAN of ring 1 and ring 2 (VLAN 4001, 4002, 100 to 200) into the same protected instance to enable data forwarding between the intersecting rings.

```
admin@SwitchC# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchC# set protocols spanning-tree mstp msti 1 vlan 4001
admin@SwitchC# set protocols spanning-tree mstp msti 1 vlan 4002
```

Step 3 Configure VLAN and port mode.

```
admin@SwitchC# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 100-200,4001
admin@SwitchC# set interface gigabit-ethernet te-1/1/4 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet te-1/1/4 family ethernet-switching vlan members 100-200,4001
admin@SwitchC# set interface gigabit-ethernet te-1/1/6 family ethernet-switching port-mode trunk
admin@SwitchC# set interface gigabit-ethernet te-1/1/6 family ethernet-switching vlan members 100-200,4002
```

Step 4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchC# set protocols erps enable true
```

Step 5 Create the ERPS ring with a given ID.

```
admin@SwitchC# set protocols erps ring 1
admin@SwitchC# set protocols erps ring 2 sub-ring true
```

Step 6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchC# set protocols erps ring 1 port0 interface te-1/1/3
admin@SwitchC# set protocols erps ring 1 port1 interface te-1/1/4
admin@SwitchC# set protocols erps ring 2 port0 interface te-1/1/6
```

Step 7 Create instance for the ERPS ring.

```
admin@SwitchC# set protocols erps ring 1 instance 1
admin@SwitchC# set protocols erps ring 2 instance 2
```

Step 8 Configure the control VLAN.

```
admin@SwitchC# set protocols erps ring 1 instance 1 control-vlan 4001
admin@SwitchC# set protocols erps ring 2 instance 2 control-vlan 4002
```

Step 9 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchC# set protocols erps ring 1 instance 1 protected-instance 1
admin@SwitchC# set protocols erps ring 2 instance 2 protected-instance 1
```

Step 10 Configure the connect ring for sub-ring 2, and enable network topology change notification on intersecting nodes Switch B and Switch C.

```
admin@SwitchC# set protocols erps ring 2 instance 2 connect ring 1 instance 1
admin@SwitchC# set protocols erps tcn-propagation true
```

Step 11 Commit the configurations.

```
admin@SwitchC# commit
```

Switch D

Step 1 Disable spanning-tree protocol on the interface before configuring ERPS ring on the interface.

```
admin@SwitchD# set protocols spanning-tree interface te-1/1/2 enable false
admin@SwitchD# set protocols spanning-tree interface te-1/1/3 enable false
```

Step 2 Configure the protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

NOTE: The ERPS control VLAN must be in one of the protected MSTP instance.

```
admin@SwitchD# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchD# set protocols spanning-tree mstp msti 1 vlan 4001
```

Step 3 Configure VLAN and port mode.

```
admin@SwitchD# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@SwitchD# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 100-200,4001
admin@SwitchD# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@SwitchD# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 100-200,4001
```

Step 4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchD# set protocols erps enable true
```

Step 5 Create the ERPS ring with a given ID.

```
admin@SwitchD# set protocols erps ring 1
```

Step 6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchD# set protocols erps ring 1 port0 interface te-1/1/2
admin@SwitchD# set protocols erps ring 1 port1 interface te-1/1/3
```

Step 7 Create instance for the ERPS ring.

```
admin@SwitchD# set protocols erps ring 1 instance 1
```

Step 8 Configure port te-1/1/2 (port0) on Switch D as the RPL Neighbor port for the ERPS ring 1 instance 1.

```
admin@SwitchD# set protocols erps ring 1 instance 1 rpl port0 neighbor
```

Step 9 Configure the control VLAN.

```
admin@SwitchD# set protocols erps ring 1 instance 1 control-vlan 4001
```

Step 10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchD# set protocols erps ring 1 instance 1 protected-instance 1
```

Step 11 Commit the configurations.

```
admin@SwitchD# commit
```

Switch E

Step 1 Disable spanning-tree protocol on the interface before configuring ERPS ring on the interface.

```
admin@SwitchE# set protocols spanning-tree interface te-1/1/5 enable false
admin@SwitchE# set protocols spanning-tree interface te-1/1/6 enable false
```

Step 2 Configure the protected MSTP instance (ERPS protected-instance) and VLAN mapping before configuring ERPS.

```
admin@SwitchE# set protocols spanning-tree mstp msti 1 vlan 100-200
admin@SwitchE# set protocols spanning-tree mstp msti 1 vlan 4002
```

Step 3 Configure VLAN and port mode.

```
admin@SwitchE# set interface gigabit-ethernet te-1/1/5 family ethernet-switching port-mode trunk
admin@SwitchE# set interface gigabit-ethernet te-1/1/5 family ethernet-switching vlan members 100-200,4002
admin@SwitchE# set interface gigabit-ethernet te-1/1/6 family ethernet-switching port-mode trunk
admin@SwitchE# set interface gigabit-ethernet te-1/1/6 family ethernet-switching vlan members 100-200,4002
```

Step 4 Enable ERPS function globally. By default, ERPS is disabled.

```
admin@SwitchE# set protocols erps enable true
```

Step 5 Create the ERPS ring with a given ID.

```
admin@SwitchE# set protocols erps ring 2 sub-ring true
```

Step 6 Configure port0 and port1 of the ERPS ring.

```
admin@SwitchE# set protocols erps ring 2 port0 interface te-1/1/5
admin@SwitchE# set protocols erps ring 2 port1 interface te-1/1/6
```

Step 7 Create instance for the ERPS ring.

```
admin@SwitchE# set protocols erps ring 2 instance 2
```

Step 8 Configure port te-1/1/5 (port0) on Switch D as the RPL Neighbor port for the ERPS ring 2 instance 2.

```
admin@SwitchE# set protocols erps ring 2 instance 2 rpl port0 neighbor
```

Step 9 Configure the control VLAN.

```
admin@SwitchE# set protocols erps ring 2 instance 2 control-vlan 4002
```

Step 10 Configure the MSTP instance of VLANs that are protected by this ring instance.

```
admin@SwitchE# set protocols erps ring 2 instance 2 protected-instance 1
```

Step 11 Commit the configurations.

```
admin@SwitchE# commit
```

Verifying the Configuration

- The command **run show erps brief** can be used to check the brief configuration information of the ERPS ring. Take Switch A and Switch B as an example:

```
admin@SwitchA# run show erps brief
Enable: true
Version: 2
Tcn-propagation: No

D: Discarding
F: Forwarding
R: RPL Owner
N: RPL Neighbour
FS: Forced Switch
MS: Manual Switch
Ring ID    Instance ID    Control VLAN      Port0           Port1
------------------------------------------------------------------------------
1               1           4001            te-1/1/1(F)     te-1/1/2 (D,R)

admin@SwitchB# run show erps brief
Enable: Yes
Version: 2
Tcn-propagation: Yes

D: Discarding
F: Forwarding
R: RPL Owner
N: RPL Neighbour
FS: Forced Switch
MS: Manual Switch
Ring ID       Instance ID        Control VLAN      Port0               Port1
-------       -----------       ------------       -----------------   -----------------
1               1                 4001             te-1/1/1(F)         te-1/1/4 (D,R)
2               2                 4002             te-1/1/5(D,R)       -
```

- The command **run show erps ring** *<ring-id>* can be used to check the detailed information of the ERPS ring. Take Switch A as an example:

```
admin@SwitchA# run show erps ring 1
Ring ID: 1
Port0: te-1/1/1
Port1: te-1/1/2
Ring-MAC: false
Sub-ring: No
Virtual-channel: No

Instance ID: 1
Enable: Yes
```

```
Active: true
Node state: Idle
Description:
Control VLAN: 4001
Protected instance: 1
Protected VLAN: 100-200
Guard timer: 500 ms
Hold-off timer: 0 ms
WTR timer: 5 min
Revertive mode: Revertive
R-APS level : 7
Connect(ring/instance): -
Forced Switch Port: -
Manual Switch Port: -
Interface      Port Role       Port State     Signal Failure
-------------------------------------------------------------
te-1/1/1       Common          Forwarding     Non-failed
te-1/1/2       RPL Owner       Discarding     Non-failed
```

From the show result, we can see that port te-1/1/2 on Switch A is the Owner node in Instance 1, with the ERPS ring in the Idle state, the RPL port blocked, and the non-RPL port state is forwarding.

Loopback Detection

- Overview of Loopback Detection
- Configuring Loopback Detection

Overview of Loopback Detection

Overview
Detection Message
Loopback Detection Action

Overview

Loopback detection is a network technology used to identify and prevent switching loops within a network infrastructure. Switching loops occur when there is more than one path for data to travel between network devices, causing packets to continuously circulate and potentially overwhelm the network.

Loopback detection works by sending loopback detection messages out on interfaces and then monitoring for these messages to return. If the message returns to the originating switch, it indicates that a loop is present.

- If the loopback detection message is received from the sending interface, it is considered that the interface is self-looped or there is a loop in the network connected to the interface.
- If the loopback detection message is received by other interfaces on this device, it is considered that the network where the interface is located has a loop, or the device itself has a self-loop.

If a loop is detected, the switch takes action to mitigate it by disabling the affected interfaces and changing their state to ***err-disable***. This helps maintain network stability and prevents performance degradation caused by excessive traffic looping.

> **NOTE**:
>
> The loopback detection message is sent only on the native VLAN. Upon receiving a loopback detection message, the device checks the source MAC address to determine if the message originated from itself, disregarding the VLAN tag.

Detection Message

The format of loopback detection message is depicted below.

DMAC	SMAC	802.1Q Tag	Protocol-Type	PortIndex

Field	Description
DMAC	The value of the destination MAC address is set to all Fs, regardless of whether the packet is tagged or untagged. This ensures that detection packets can be looped back to the device when a loop occurs on an interface or in the network.
SMAC	The source MAC address is set to the system MAC address of the local device to uniquely identify the packets sent by this device.
802.1Q Tag	It includes the Tag Protocol Identifier (TPID), with a value of 0x8100, indicating an 802.1Q tagged frame.
Protocol-Type	The protocol type field has a value of 0x9000, indicating a loopback detection message.
PortIndex	It represents the interface information of the sender of the detection message, allowing the device to compare interfaces and determine whether the message was sent from one of its own interfaces.

Loopback Detection Action

When the ingress interface receives a Loopback Detection (LBD) message sent from this device, then a loop is detected, the ingress interface will be set to the ***err-disable*** state, causing the physical link to go down. Additionally, the loop information will be logged.

You can clear the ***err-disable*** state of the interface through the following methods:

- Use the command **run clear loopback-detection interface** to clear the ***err-disable*** state of the interface.
- Delete the loopback detection configuration can clear the state of the interface.
- Administratively reset the interface by disabling and then enabling it using the configuration commands.
- Disable the loopback detection protocol to clear the state of the interface.

When loops occur within interfaces or networks, they can negatively impact routine business operations. Loopback detection, as a technology designed for detecting loops at a single node, possesses limited capabilities for resolving such loops. Consequently, it is recommended that users address loop-related problems promptly upon detection.

Configuring Loopback Detection

Configuration Notes and Constraints
Configuring Loopback Detection
Example for Configuring Loopback Detection
Networking Requirements
Procedure

Configuration Notes and Constraints

When configuring loopback detection, consider the following points:

- The loopback detection message is sent in the native VLAN. When a loopback detection message is received, the device considers the source MAC address to determine if the message was sent from this device, without considering the VLAN tag.
- Loopback detection can be enabled on a physical interface or a Link Aggregation Group (LAG) interface but cannot be enabled on the member interfaces of a LAG.
- To enable the loopback detection function, users need to enable loopback detection BOTH globally and at the per-interface level.
- Loopback detection is not supported in Multi-Chassis Link Aggregation (MLAG) scenarios.

Configuring Loopback Detection

Step 1 Enable loopback detection function globally.

set protocols loopback-detection enable <**true** | **false**>

Step 2 Enable loopback detection function on a specific interface.

set protocols loopback-detection interface <*interface-name*> **enable** <**true** | **false**>

Step 3 (Optional) Configure the loopback detection message transmission period.

set protocols loopback-detection message-interval <*message-interval*>

Step 4 (Optional) Clear the ***err-disable*** state of the loopback-detection interface.

run clear loopback-detection interface {<*interface-name*> | **all**}

Step 5 Commit the configuration.

commit

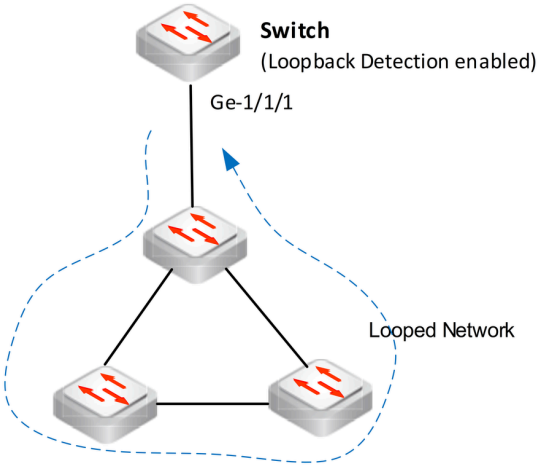
Step 6 View the configuration information and status information of loopback detection.

run show loopback-detection

Example for Configuring Loopback Detection

Networking Requirements

Figure 1. Loopback Detection Configuration Example



As shown in **Figure 1**, if there is a loop in the network connected to interface ge-1/1/1 of the device Switch, it will cause a broadcast storm, and communication on the Switch and the entire network may be affected.

Users hope to detect loops in the downstream network connected to the Switch and reduce the impact of the loop to the networks by blocking the downlink interface. Users can achieve this by enabling loopback detection function on ge-1/1/1 of the Switch. Once a loop is detected, interface state of ge-1/1/1 will be set to ***err-disable***, resulting in the disconnection of the interface. This action helps to reduce the impact of the loop on the device and the network.

Procedure

Step 1 Enable loopback detection function globally.

```
admin@Switch# set protocols loopback-detection enable true
```

Step 2 Enable loopback detection function on a specific interface.

```
admin@Switch# set protocols loopback-detection interface ge-1/1/1 enable true
```

Step 3 Commit the configurations.

```
admin@Switch# commit
```

Step 4 View the configuration information and status information of loopback detection.

```
admin@Switch# run show loopback-detection
Loopback-detection: enabled
message-interval: 30s
Interface       LBD Tx         Status                From_Port
----------      -----------    ------------          -----------
ge-1/1/1        true           LoopDetected          ge-1/1/1
ge-1/1/2        false          Normal
......

admin@Switch# run show interface gigabit-ethernet xe-1/1/1
Physical interface: ge-1/1/1, Enabled, error-discard True(LBD), Physical link is Down
Interface index: 73, QSFP+ type: 40G_BASE_SR4, Mac Learning Enabled
Port mode: access
Description:
…….
```

From the show result, we can see that,

- **Status** of interface ge-1/1/1 is “***LoopDetected***” and “***error-discard True(LBD)***, ***Physical link is Down***”, indicating a loop is detected and the interface is disabled.
- When a loopback is detected, the field **From_Port** indicates the sending interface of loopback detection packets.

Layer 3 Routing Configuration

This chapter describes the configuration steps of Layer 3 routing, including static routing, RIPv2, OSPFv2, VRRP, and ECMP.

ARP Configuration

- Configuring ARP
- Dynamic ARP Inspection (DAI)
- Flushing ARP and the Neighbor Table

Configuring ARP

> **NOTE:**
> A chassis switch supports a maximum of 12000 ARP entries in the ARP table, including both IPv4 ARP entries and IPv6 neighbor entries. Both of which are saved in the same system resource on the switch. One IPv6 neighbor entry takes up two ARP entries.

Configuring ARP Aging Time

In the default setting, the ARP aging time is 1200 seconds.

```
admin@XorPlus# set protocols arp aging-time 600
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring a Static ARP Entry

PicOS supports configuring static ARP on VLAN interface, routed interface or sub-interface. The following example shows how to configure a static ARP entry on the VLAN interface.

Step1 Configure a VLAN.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 192.168.1.1 prefix-length 24
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

Step2 Configure a static MAC entry to create a hardware forwarding entry, where the **interface** is the outbound physical interface.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 static-ethernet-switching mac-address 22:22:22:22:22:22 vlar
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

Step3 Configure a static ARP entry.

```
admin@XorPlus#set protocols arp interface vlan-2 address 192.168.1.1 mac-address 22:22:22:22:22:22
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
```

Dynamic ARP Inspection (DAI)

  - Example for Configuring Static ARP Inspection

Introduction

The ARP Inspection feature is used to defend against man-in-the-middle attack scenarios, preventing ARP table entries to be maliciously modified by a forged ARP message sent by an attacker.

Trust Port

ARP inspection divides interfaces into ARP trusted and untrusted ports. On trusted ports, the system does not perform ARP inspection on incoming ARP messages, allowing the ARP messages to pass. However, ARP inspection is required for ARP messages received on the untrusted port interface.

By default, all the interfaces are untrusted ports. You can use the command **set protocols arp inspection trust-port** *<port-name>* to configure an interface as trusted port and use **run show arp inspection interface** to show the trust state of all the interfaces for ARP inspection.

ARP Inspection contains two functions: ARP message validity checking and user legitimacy checking.

ARP Packets Validity Checking

For ARP trusted ports, packets validity checking is not performed; for ARP untrusted ports, the system checks the validity of MAC address and IP address in the ARP packets:

- Check that if the source MAC address in the ARP message and the source MAC address in the Ethernet header are consistent. If so, pass, otherwise discard.
- Check if the source MAC address in the ARP message is all 0 or all 1. All 0 and all 1 source MAC addresses are invalid and the message will be discarded.
- Check if the source IP in the ARP message is all 0, all 1, or the multicast IP address, these IP addresses are invalid and the message will be discarded.

User Legitimacy Checking

For ARP trusted ports, user legitimacy checking is not performed; for ARP untrusted ports, a user legitimacy checking is performed to prevent attacks from spoofing users.

ARP inspection user legitimacy checking is to check the validity of ARP message which supports two of the following implementation and application modes:

1. Dynamic ARP inspection based on DHCP snooping binding table. DHCP snooping is required in this scenario.

However, if ARP inspection is enabled in the VLAN with DHCP relay enabled, DHCP snooping is also required in this same VLAN for ARP inspection to work properly. The system uses the DHCP snooping table to generate ARP entries for ARP inspection.

You can run the command **run show ARP inspection dhcp-binding** to view the ARP entries generated from the DHCP snooping and DHCP relay table.

2. ARP access lists for non-DHCP environments which needs the administrator to configure by CLI commands.

When the switch receives an ARP message, it compares the source IP address and source MAC address of the ARP message with the entries in the ARP access lists (if configured) and the DHCP binding table:

- If the message matches, the user who sent the ARP message is considered as a legitimate user and allows the ARP message to pass.
- Otherwise, it is considered as an attack and the ARP message is discarded.

run show arp inspection statistics vlan command displays the statistics of ARP inspection, such as, discarded and permitted ARP packets.

NOTE:

- If both ARP access lists and dynamic ARP inspection are enabled, the system checks ARP access lists first, if there is no match then the system checks DHCP binding table.
- When ARP inspection is enabled on MLAG peers, we recommend that you don't enable ARP inspection in the peer-link VLAN which is dedicated to transmitting MLAG control plane messages.

However, if ARP inspection is enabled in peer link VLAN, an ARP access list must be configured by the following commands for ARP inspection to make MLAG work normally,

set protocols arp inspection access-list *<acl-name>* **ip** *<ipv4-addr>* **mac-address** *<mac-addr>*

set protocols arp inspection vlan *<peer-vlan-id>* **access-list** *<acl-name>*

where IP, MAC address and VLAN should be configured as the corresponding values of peer link port on the MLAG peer device.

Configuring Dynamic ARP Inspection

Dynamic ARP Inspection checks ARP messages based on DHCP binding table. Therefore, you need to enable the DHCP snooping function for this feature to work properly.

Procedure

Step1 Enable ARP inspection in a VLAN.

set protocols arp inspection vlan <*vlan-id*> **disable** <**true | false**>

Step2 Enable DHCP snooping.

a) Enable DHCP snooping in a VLAN.

set protocols dhcp snooping vlan <*vlan-id*> **disable** <**true** | **false**>

b) Configure the interface connected to the DHCP server as DHCP snooping trusted interface.

set protocols dhcp snooping trust-port <*interface-name*>

Step3 (Optional) Configure an interface as a trust port on which ARP inspection will not be implemented.

set protocols arp inspection trust-port <*port-name*>

Step4 Commit the configurations.

commit

Example for Configuring Dynamic ARP Inspection

Networking Requirements

- On Pica8 Switch, the interfaces ge-1/1/1 and ge-1/1/2 are in VLAN 2.
- Enable DHCP snooping on VLAN 2.
- Configure the interface connected to the DHCP server (ge-1/1/2) as the DHCP snooping trust interface.
- To prevent man-in-the-middle attacks and prevent the ARP table entries of legitimate users on the device being maliciously modified, enable ARP inspection in VLAN 2.

Figure 1 Dynamic ARP Inspection Network

Procedure

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
```

Step2 Enable ARP inspection in VLAN 2.

```
admin@Xorplus# set protocols arp inspection vlan 2 disable false
```

Step3 Enable DHCP snooping.

```
admin@XorPlus# set protocols dhcp snooping vlan 2 disable false
admin@XorPlus# set protocols dhcp snooping trust-port ge-1/1/2
```

Step4 Commit the configurations.

```
admin@XorPlus# commit
```

Step5 Verify the configurations.

- Run the command **run show arp inspection vlan** <*vlan-id*> to display ARP inspection configured information of a VLAN.

```
admin@Xorplus# run show arp inspection vlan 2
Vlan  Configuration      Static ACL
----   -------------     ----------
2     Enabled            -
```

- Run the**run show arp inspection dhcp-binding** command to view the ARP inspection table. This table includes the ARP entries generated from the DHCP snooping or DHCP relay table.

```
admin@Xorplus# run show arp inspection dhcp-binding
Vlan  IP Address        Mac Address
----  ---------------  -----------------
 2    100.1.1.1         14:18:77:18:2c:b9
```

Configuring ARP Inspection Access List

ARP inspection supports to statically configure ARP access lists through CLI commands in non-DHCP environments, so it does not require to enable DHCP snooping.

NOTE:

When configuring the ARP access list for ARP Inspection, the same IP-MAC cannot exist in multiple access lists.

Procedure

Step1 Enable ARP **inspection** in a VLAN.

set protocols arp inspection vlan <*vlan-id*> **disable** <**true | false**>

Step2 Configure ARP access list for ARP inspection.

set protocols arp inspection access-list <*acl-name*> **ip** <*ipv4-addr*> **mac-address** <*mac-addr*>

Step3 Apply the ARP inspection access list to a VLAN.

set protocols arp inspection vlan <*vlan-id*> **access-list** <*acl-name*>

Step4 (Optional) Configure an interface as a trust port on which ARP inspection will not be implemented.

set protocols arp inspection trust-port <*port-name*>

Step5 Commit the configurations.

commit

Example for Configuring Static ARP Inspection

Configuring ARP access lists is an effective defense against man-in-the-middle attacks and preventing ARP table entries of legitimate users on the device being maliciously modified.

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 100
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 100
```

Step2 Enable ARP inspection in VLAN 100.

```
admin@Xorplus# set protocols arp inspection vlan 100 disable false
```

Step3 Configure ARP inspection static access list.

```
admin@Xorplus# set protocols arp inspection access-list test1 ip 10.0.0.1 mac-address 00:B0:BC:00:00:00
```

Step4 Apply the ARP inspection access list to a VLAN.

```
admin@Xorplus# set protocols arp inspection vlan 100 access-list test1
```

Note that:

Configure the access-list first and then apply to a VLAN, otherwise it will prompt access-list does not exist when committing this command.

Step5 Commit the configurations.

```
admin@XorPlus# commit
```

Step6 Verify the configurations.

- Run the command **run show arp inspection vlan** <*vlan-id*> to display ARP inspection configured information of a VLAN.

```
admin@Xorplus# run show arp inspection vlan 100
Vlan  Configuration      Static ACL
----   -------------     ----------
100     Enabled          test1
```

- Run command **run show arp inspection vlan** <*vlan-id*> **access-list** <*acl-name*> to display the information for ARP inspection static access list.

```
admin@Xorplus# run show arp inspection access-list test1
Static ACL  IP Address       Mac Address
----------  ---------------  -----------------
Test1       10.0.0.1         00:B0:BC:00:00:00
Static ACL  Applied Vlans
----------  -------------------
Test1       100
```

Flushing ARP and the Neighbor Table

You can manually flush the ARP entry and the IPv6 neighbor table.

Flushing the ARP Entry

```
admin@XorPlus> flush arp all
admin@XorPlus> flush arp ip-address 192.168.1.1
```

Configuring IP Routing

NOTE:

- Layer 3 packets cannot be forwarded normally if IP routing function is disabled.
- Enable IP routing function before using VXLAN.
- IP routing affects only Layer 3 data forwarding, but takes no effect on non-Layer 3 data forwarding of the interface. Therefore, inband management (such as login via SSH) has nothing to do with whether IP routing is enabled or not.
- If the following commit failed message appears when you enable IP routing, the Enterprise License is not installed, and you need to purchase and install the Enterprise License before the L3 feature can be used properly.

```
admin@Xorplus# set ip routing enable true
admin@Xorplus# commit
Command failed: L3 feature is not covered by the installed license key.
Commit failed.
```

To allow users to communicate with users in different VLANs through Layer 3 routing, in addition to configuring Layer 3 interfaces for VLANs, you also need to enable IP routing function on Layer 3 switches.

By default, IP routing function is disabled. If you want to implement the Layer 3 inter-VLAN routing function of the switch, you need to enable the IP routing function first. Similarly, you can configure the system to disable IP routing if you want to disable the Layer 3 inter-VLAN routing function on the switch. When the IP routing function is disabled, the switch can function only as a Layer 2 switch.

Configuring IP Routing

Procedure

- Use the following command to enable or disable IP routing function.

  set ip routing enable [**true | false**]

  The default setting is **set ip routing enable false**. The command takes effect immediately after committing.

Configuration Example

Network Requirement

As shown in Figure 1, User1 and User2 are in the same department of the company but belong to different VLANs and are located on different network segments. Follow the configuration steps below to achieve User1 and User2 can communicate with each other.
1. Create a VLAN and specify the VLAN to which the user belongs.
2. Add an interface to the VLAN.
3. Create a Layer 3 interface and configure the IP address.
4. Enable IP routing function to achieve inter-VLAN routing.

NOTE:

On User1 and User2, add a route with the default gateway to be the IP address of the corresponding Layer 3 VLAN interface.

Figure 1. Network of Inter-VLAN Routing

Procedure

Step1 Create VLAN2 and VLAN3 on Switch.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
```

Step2 Add interfaces connected to user terminals to different VLANs.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 3
```

Step3 Associate a Layer 3 interface with the VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
```

Step4 Configure IP address of the Layer 3 interface.

```
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 192.168.2.2 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 192.168.3.2 prefix-length 24
```

Step5 Enable IP routing function.

```
admin@XorPlus# set ip routing enable true
```

Step6 Commit the Configuration.

```
admin@XorPlus# commit
```

Step7 Verify the Configuration.

- After the configuration is complete, User1 in VLAN2 and User2 in VLAN3 can communicate with each other.
- When IP routing function is disabled on the Switch, User1 in VLAN2 and User2 in VLAN3 will be unreachable when pinging each other.
- Use **show route forward-route brief** command to view the information of IP routing table. If IP routing function is disabled, the command results "**Ip routing is disable**".

```
admin@Xorplus# run show route forward-route brief
Ip routing is disable
```

Static Routing Configuration

This chapter describes the functions, purposes, and applications of static routes, and explains how they can be configured.

- Configuring Static Routes
- Example for Configuring IPv4 Static Routes

Configuring Static Routes

NOTE:

- Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.
- The static route that specifies the next hop address and the one that specifies the outgoing interface are not considered for ECMP load sharing, even if they have equal cost.
- If you are configuring a default route in the default VRF, you need to enable management VRF (After enabled by using command set system management-vrf enable true, eth0 will automatically be moved to management VRF from default VRF) to ensure the normal access to eth0 management port.

In L2/L3, all routing entries will be configured to the ASIC switching chip if the outgoing interface is link-up, and the outgoing physical port is learning. The outgoing interface is an L3 interface which can be VLAN interface, routed interface, loopback interface or sub-interface.

Traffic that can be routed will have a route entry in the RIB and the ARP of the next hop; the outgoing interface should be link-up. The traffic will then be soft-routed (i.e., routed by the switch's CPU).

When the switch learns the MAC address of the next-hop, the switch will forward the traffic with the ASIC chip.

Configure static route:

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 192.168.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 192.168.2.1 prefix-length 24
admin@Xorplus# set ip routing enable true
admin@XorPlus# set protocols static route 10.10.1.0/24 next-hop 192.168.2.5
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show route static
RIB entry for static

Total route count:2
```

Example for Configuring IPv4 Static Routes

Unicast routing involves sending data from a single sender to a single receiver, making it a point-to-point routing protocol. Examples of unicast protocols include TCP and HTTP. Various forms of Layer 3 routing are considered unicast, including static routing. Static routing is used to manually configure a routing entry rather than rely on dynamic routing. As the name implies, static routes are fixed routes that do not change. They may be used as a backup to dynamic routing, to ensure a valid path exists between two points.

This document describes an example of how to configure a static route between two hosts in a network using open white box switches running the Pica8 PICOS network operating system.

- Configuration Example
  - Configuring Switch A
  - Configuring Switch B
  - Configuring Switch C

Configuration Example

An example of configuration with static routing is shown in Fig. 5-1. Host A and Host B should be able to communicate with each other. Host A and Host B should be able to communicate with the gateway (e.g., access Internet).

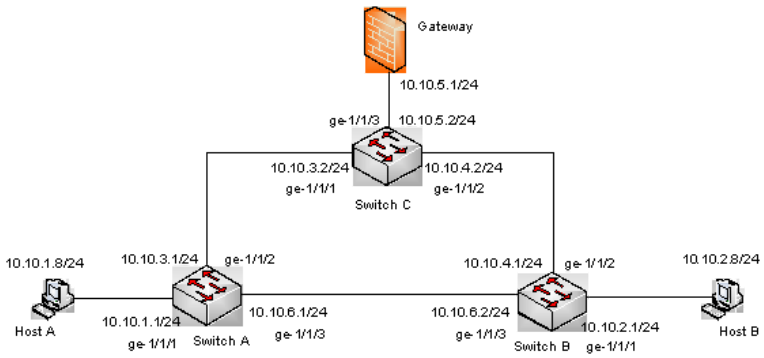

Figure 5-1. Static routing configuration.

Configuring Switch A

For Switch A, configure 3 VLAN interfaces for networks 10.10.1.1/24, 10.10.3.1/24, and 10.10.6.1/24. Also configure a static route to 10.10.2.0/24 and a default route.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set vlans vlan-id 4
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 4
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set vlans vlan-id 4 l3-interface vlan-4
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.3.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-4 address 10.10.6.1 prefix-length 24
admin@XorPlus# set ip routing enable true
admin@XorPlus# set protocols static route 10.10.2.0/24 next-hop 10.10.6.2
admin@XorPlus# set protocols static route 0.0.0.0/0 next-hop 10.10.3.2
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Verify the static route entry in the RIB as follows:

```
admin@XorPlus# run show route static
RIB entry for static
====================
Codes: K - kernel route, C - connected, S - static, R - RIP,
```

```
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

S>* 10.10.2.0/24 [1/0] via 10.10.6.1, vlan-4, weight 1, 00:40:35
S>* 0.0.0.0/0 [1/0] via 10.10.3.1, vlan-3, weight 1, 05:00:04
```

Configuring Switch B

Configure 3 VLAN interfaces for networks 10.10.2.1/24, 10.10.4.1/24, and 10.10.6.2/24. Then, configure a static route to 10.10.1.0/24 and a default route.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set vlans vlan-id 4
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 4
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3

VRF Configuration Guide

- Introduction to VRF
- Configuration Notes of VRF
- Configuring a User-defined VRF
- Enabling Management VRF
- Example for Configuring Basic VRF

Introduction to VRF

NOTE:

PICOS supports only VRF-Lite, a lighter version of VRF, referring to VRF without MPLS.

- VRF Characteristics
- Application Scenarios
- Default VRF
  - In-band Management Interface
- Management VRF
- Management Services
- User-defined VRF

VRF (Virtual Routing and Forwarding) is a technology that virtualizes a single physical routing device into multiple virtual routing devices, each of them being (relatively) independent of each other, allowing for overlapping subnets, separate routing tables to make Layer 3 segregated, separate ARP tables and separate sets of Layer 3 interfaces assigned to each VRF.

Figure 1 Multiple VRF Process Modules on One Pica8 Switch

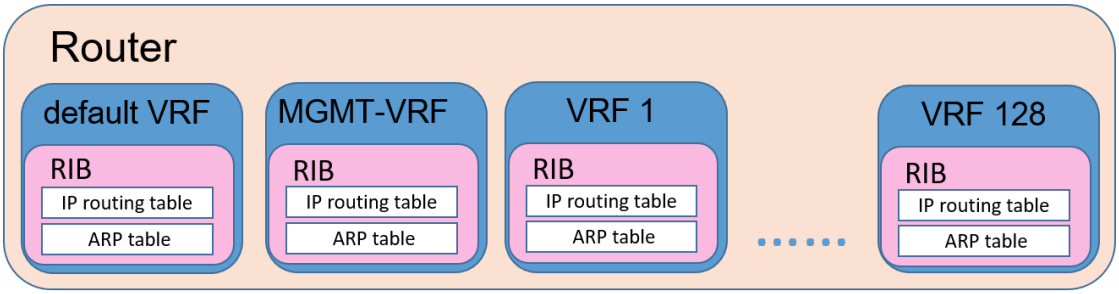

Figure 1 shows multiple VRF process modules on one Pica8 switch. Pica8 switches support multiple VRF instances: one default VRF, one management VRF and multiple user-defined VRFs. IP routing and traffic is separated between the VRFs. By default, PICOS starts up with only default VRF, which cannot be deleted. User can create other VRFs based on the requirements for route separation. The command **set system management-vrf enable** <true | false> can be used to enable management VRF and **set ip vrf** <*vrf-name*> [**description** <*string*>] can be used to create the user-defined VRFs. A maximum of 128 user-defined VRFs can be created on a Pica8 switch.

Currently, default VRF and user-defined VRFs support static routing and other routing protocols (BGP, OSPF, RIP, PIM). However, Management VRF does not support any routing protocols, including static routing.

The following sections describe the VRF characteristics and application scenarios, then details how to use default VRF, management VRF and user-defined VRFs.

VRF Characteristics

- Each VRF has an independent routing table and ARP table to implement independent routing and forwarding functions.
- Each VRF has an independent address space. This allows address overlapping between different VRFs without address conflicts occurring on the same device.
- Users in the same VRF can communicate with each other, but users in different VRFs cannot communicate with each other.
- As with the introduction of management VRF, Out of Band (OOB) management flow is completely separate from data flow, which enhances the security of the management network.

Application Scenarios

This document lists several use cases which can be deployed with VRFs as follows,

- User can deploy VRF function to solve the problem of insufficient IP addresses, as different VRFs have different address spaces which allows address overlapping between different VRFs.
- User can deploy VRF function to achieve traffic isolation of different users and increase data communication security, as the communication between different tenants is segregated in different VRFs.
- User can enable management VRF to separate the Out of Band management traffic from the data traffic, thus to enhance the security of the management network.
- VRF virtualizes a single physical routing device into multiple virtual routing devices; this can save hardware costs.

Default VRF

By default, all the L3 interfaces (VLAN interface, loopback interface, routed interface or sub-interface) and Ethernet0 management interface, and their IP route tables share one VRF - the default VRF. When a L3 interface is created, it is in the default VRF if not explicitly bound to any VRF. However, user can bind an existing Layer 3 interface to a user-defined VRF.

Ethernet0 is used for Out of Band (OOB) management, the L3 interfaces can be used for in-band (IB) management or transmission of data traffic.

Default VRF supports static routing and other routing protocols (BGP, OSPF, RIP, PIM).

In-band Management Interface

By default, the user cannot remotely log in and manage the switch through an L3 interface. PICOS provides in-band management in default VRF. In-band management provides a method of access to the switch even if the Ethernet0 interface is down. You can enable in-band management function to perform the SSH, TELNET, SNMP and HTTP services through any one of the L3 interfaces in the default VRF.

For example,

Set VLAN interface VLAN400 in the default VRF as the in-band management port.

```
admin@Xorplus# set system inband vlan-interface VLAN400
admin@Xorplus# commit
```

In-band management provides a method of access to the switch even if the Ethernet0/1 interface is down.

NOTE:

- Only the L3 interface in the default VRF can be set as the in-band management port. If a L3 interface has been set as an in-band management port, it cannot be bound to other VRFs.
- A maximum of four L3 VLAN interfaces in the default VRF can be set as the in-band management ports by using **set system inband vlan-interface**<*vlan-interface*> command.
- By default, all the management services (including **802.1X / OVSDB management protocol / SNMP trap / sFlow / syslog / NTP / TACACS+/RADIUS**) run in default VRF. If management VRF is enabled, you have to consider which VRF (default VRF or management VRF) will be used to run management services, see the **Management Services** for details.

Management VRF

By default, PICOS starts up with only default VRF, management VRF function is disabled. To enhance the security of the management network, and prevent attacks by illegal users, users can use command **set system management-vrf enable** true to enable management VRF.

Once management VRF is enabled, a VRF with fixed name **mgmt-vrf** is created automatically by the system, and the Eth0 management interface is automatically moved from the default VRF to the management VRF. As long as the management VRF is not disabled, Eth0 is always in the management VRF. Eth0 will return from the management VRF to the default VRF only when management VRF is disabled by setting **set system management-vrf enable** false.

Management VRF is dedicated to transmit the OOB management traffic. Other VRFs are used to transmit the data traffic, thus separating the OOB management traffic from the data traffic effectively.

The management services (including **802.1X / OVSDB management protocol / SNMP trap / sFlow / syslog / NTP / TACACS+/RADIUS**) are running in default VRF by default. However, when management VRF is enabled and Eth0 is used for management services, the management services need to be manually moved from the default VRF into the management VRF by using relevant CLI commands.

For example, if you want to enable management VRF and use the Eth0 management interface for NTP service, the VRF-related configurations are as follows. For more details, see **Management Services.**

```
admin@Xorplus# set system management-vrf enable true
admin@Xorplus# set system ntp vrf vrf mgmt-vrf
admin@Xorplus# commit
```

Management VRF configuration notes:

- Only Eth0 management interfaces can run in the management VRF, no other L3 interfaces or loopback interfaces can run in the management VRF.
- Management VRF supports neither static routing nor any other dynamic routing protocol.

Management Services

To properly use management services, the following descriptions in this section provide a guidance.

By default, all the management services (including **802.1X / OVSDB management protocol / SNMP trap / sFlow / syslog / NTP / TACACS+/RADIUS**) run in default VRF. If management VRF is enabled, Eth0 interface is automatically moved from the default VRF to the management VRF, you have to decide which VRF (default VRF or management VRF) will be used to run the management services.

1. syslog/NTP/TACACS+/RADIUS/SNMP Trap/sFlow/NAC/OVSDB

Management services (referring to syslog/NTP/TACACS+/RADIUS/SNMP Trap/sFlow/NAC /OVSDB) are bound to default VRF at system startup. They can move from default VRF to management VRF and vice versa by using the following CLI commands.

set system syslog vrf mgmt-vrf

set system ntp vrf mgmt-vrf

set system aaa radius vrf mgmt-vrf

set system tacacs-plus radius vrf mgmt-vrf

set protocols snmp trap-group vrf mgmt-vrf

set protocols sflow collector *<ip-address>* **vrf mgmt-vrf**

set protocols dot1x aaa vrf mgmt-vrf

set protocols ovsdb controller *<controller-name>* **vrf mgmt-vrf**

These management services cannot be bound to a user-defined VRF.

Whether the management service is in the default VRF or the management VRF, you need to ensure that the server relevant to the management service (e.g. syslog server, TACACS+ server) is route reachable in the VRF running the management service.

For example,

If you want to enable management VRF and use the Eth0 management interface for NTP service, NTP service needs to be manually moved from the default VRF into the management VRF by using CLI command **set system ntp vrf mgmt-vrf**. The VRF-related configurations are as follows:

```
admin@Xorplus# set system management-vrf enable true
```

```
admin@Xorplus# set system ntp vrf mgmt-vrf
admin@Xorplus# commit
```

2. ssh/scp/tftp/ping/traceroute/apt-get

When executing ssh/scp/tftp/ping/traceroute/apt-get commands, the system looks for the next-hop route in default VRF by default. If management VRF is enabled, and Eth0 is used as the route interface, you have to add the VRF parameter in the command to specify that finding the next-hop route in the management VRF.

- At the Linux prompt

If management VRF is enabled, and you want to find the next-hop route in management VRF when running the commands **traceroute/SCP/ping/apt get/SSH** at Linux prompt, that is, using Eth0/1 management interface as the route interface, you have to add **ip vrf exec mgmt-vrf** before the commands.

The example format of these commands is shown below:

sudo ip vrf exec <**mgmt-vrf|***vrf-name*> **traceroute** 10.10.51.11

sudo ip vrf exec <**mgmt-vrf|***vrf-name*> **scp** admin@10.10.51.18:/home/Pica8.pm

sudo ip vrf exec <**mgmt-vrf|***vrf-name*> ping 10.10.51.1

sudo ip vrf exec <**mgmt-vrf|***vrf-name*> apt-get update

sudo ip vrf exec <**mgmt-vrf|***vrf-name*> ssh <*ip-address*>

ip vrf exec <**mgmt-vrf|***vrf-name*> is added to specify which VRF to run the command in. If not specified, find the next hop routing information from the default VRF.

- At PICOS CLI prompt

If management VRF is enabled, and you want to find the next-hop route in management VRF when running the commands ping/traceroute/tftp at PICOS CLI prompt, that is, using Eth0/1 management interface as the route interface, you need to add **vrf mgmt-vrf** before the commands.

ping/traceroute/tftp commands are shown below,

ping <ip-address> [<packets>] [**vrf** <**mgmt-vrf** | *vrf-name*>] [**source** <source-ip-address >] [**deadline** <deadline-time>] [**ttl** <ttl-value>] [**interval** <interval-value>] [**pattern** <pattern-value>] [**size** <size-value>] [**tos** <tos-value>]

traceroute <ipv4-address> [**vrf** <**mgmt-vrf** | *vrf-name*>]

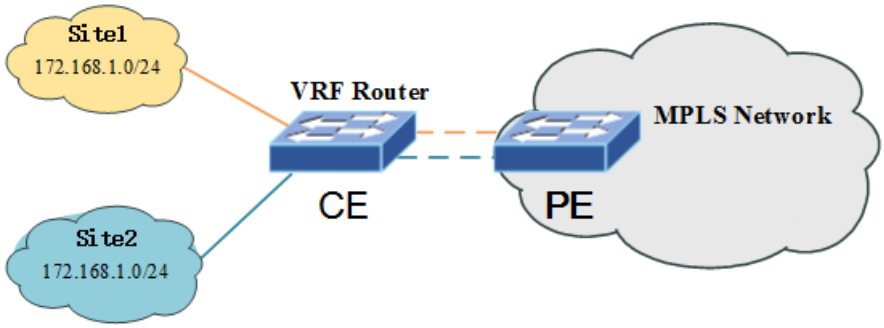
file tftp get remote-file <*remote-file-path*> [**local-file** *local-file-path*] **ip-address** <*ip-address*> [**vrf** <**mgmt-vrf** | *vrf-name*>]

[**vrf** <**mgmt-vrf** | *vrf-name*>] is used to specify which VRF to run the command in. If no VRF is specified, find the next hop routing information from the default VRF. For details about the usage of each parameter, see section Command Reference.

User-defined VRF

By default, all the L3 interfaces and their IP route tables are in the default VRF. User can create multiple new VRFs with the VRF definition command **set ip vrf** <*vrf-name*> [**description** <*string*>], and then add the Layer 3 interfaces and their route settings to different VRFs to run services in these VRFs. The system segregates the IP routing table, ARP table, hardware forwarding table, and host hardware forwarding table of different VRFs on one customer edge (CE) device. A maximum of 128 user-defined VRFs can be created.

Figure 2 Networking diagram of VRF



In **Figure 2**, when implementing VRF function on the CE device for different L3 access interfaces, users from Site1 and Site2 can use overlapping IP addresses when accessing the internet through the CE and have segregated users' routing spaces on the CE device.

When the CE switch receives the data packets, it looks up the IP routing table divided by the VRF, which is bound to the ingress Layer 3 interface, and then forwards the data packets based on the routing entry in this VRF.

VRF implements data traffic segregation among different customers while sharing the same physical router device, that is to say, users in the same VRF could communicate with each other, but it could not communicate with each other in different VRFs.

Configuration Notes of VRF

When configuring VRF on a device, pay attention to the following points:

- Enable IP routing function before using VRF function.
- Currently, default VRF supports static routing and other routing protocols (BGP, OSPF, RIP, PIM), the user-defined VRFs support static routing and OSPF routing protocol. However, management VRF supports neither static routing nor any other dynamic routing protocols.
- VRRP supports VRF function by binding the Layer 3 interface to a specified VRF.
- A switch supports a maximum of 128 VRFs.
- A Layer 3 interface can't belong to more than one VRF, but one VRF can be bound to multiple Layer 3 interfaces. This is limited by the maximum number of Layer 3 VLAN interfaces a switch supports. A switch supports a maximum of 255 Layer 3 interfaces.
- Loopback interface can be configured in the default VRF, management VRF or the user-defined VRFs.
- If a VLAN interface changes the configuration to bind to another VRF, the IPv6 addresses of the interface need to be reconfigured to make it valid.
- For AmpCon environment, PICOS will restart the OpenVPN connection between the switch and AmpCon Server, switching the OpenVPN connection to the management VRF, if Eth0 is used to connect to the AmpCon Server and management VRF is enabled. This may cause a short interruption in communication between AmpCon Server and the switch.

Configuring a User-defined VRF

The VRF configuration process is in the following steps:

1. Enable IP routing function before using VRF function.
2. Create a VRF for the tenant.
3. Bind one or more L3 interfaces (VLAN interfaces, loopback interfaces, routed interfaces or sub-interfaces) to the VRF.
4. Configure static routes or OSPF routing protocol into the VRF table.

Procedure

Step1 Enable IP routing function before using VRF function.

set ip routing enable <**true** | **false**>

Step2 Create a VRF for the tenant.

set ip vrf <*vrf-name*> [**description** <*string*>]

Step3 Bind one or more L3 interfaces to the VRF.

- Bind one or more VLAN interfaces to the VRF.

  a) Configure VLAN ID.

  set vlans vlan-id <*vlan-id*>

  b) Configure the interface to a VLAN.

  set interface gigabit-ethernet <*port*> **family ethernet-switching native-vlan-id** <*vlan-id*>

  c) Configure the IP address of the Layer 3 interface.

  set l3-interface vlan-interface <*interface-name*> **address** <*address*> **prefix-length** <*number*>

  d) Associate a Layer 3 interface with a VLAN.

  set vlans vlan-id <*vlan-id*> **l3-interface** <*interface-name*>

  e) Bind the Layer 3 VLAN interface to a VRF.

  set l3-interface vlan-interface <*interface-name*> **vrf** <*vrf-name*>

- Bind one or more routed interfaces/sub-interfaces to the VRF.

  a) Enable routed interface.

  set interface gigabit-ethernet <*interface-name*> **routed-interface enable** <**true | false**>

  set interface gigabit-ethernet <*interface-name*> **routed-interface name** <*string*>

  b) Configure reserved-vlan for the routed interface.

  set vlans reserved-vlan <*reserved-vlan*>

  c) (Optional) Create the sub-interface and add it into a VLAN.

  set interface aggregate-ethernet <*interface-name*> **routed-interface sub-interface** <*sub-interface-name*> **vlan-id** <*vlan-id*>

  d) Configure the IP address of the routed interface.

  set l3-interface routed-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*prefix-number*>

  e) Bind the routed interface to a VRF.

  set l3-interface routed-interface <*interface-name*> **vrf** <*vrf-name*>

- Bind one or more loopback interfaces to the VRF.

  a) Create a loopback interface and configures its IP address.

  set l3-interface loopback <*loopback-name*> **address** <*ip-address*> **prefix-length** <*int*>

  b) Bind the loopback interface to a VRF.

  set l3-interface loopback <*interface-name*> **vrf** <*vrf-name*>

Step4 (Optional) Configure a static route entry into the VRF.

set protocols static [**vrf** <*vrf-name*>] **route** <*ip-address*> **next-hop** <*nexthop-address*>

Step5 (Optional) Configure static ARP entries.

set protocols arp interface <*interface-name*> **address** <*ip-address*> **mac-address** <*mac-address*>

The ARP entries are associated with the VRF by binding the Layer 3 VLAN interface to the VRF.

Enabling Management VRF

Procedure

Step1 Enable IP routing function before using VRF function.

set ip routing enable <**true** | **false**>

Step2 Enable management VRF.

set system management-vrf enable <true | false>

Step3 (Optional) Set static IP addresses for management interface eth0.

set system management-ethernet eth0 ip-address {**IPv4** | **IPv6}** <*ip_address*>

> **NOTE:**
> If the static IP address is not assigned, the system will try to dynamically obtain the management port IP address from the DHCP server which is also the factory setting.

Step4 Set the gateway address for management interface eth0.

set system management-ethernet eth0 ip-gateway {IPv4 | IPv6}<*ip_address*>

Step5 Configure to run the management services in the management VRF.

When management VRF is enabled, the management services (including **802.1X / OVSDB management protocol / SNMP trap / sFlow / syslog / NTP / TACACS+/RADIUS**) are still running in default VRF by default. If Eth0 is used for management services, the management services need to be moved into the management VRF manually by using relevant CLI commands.

set system syslog vrf <mgmt-vrf | default>

set system ntp vrf <**mgmt-vrf** | **default>**

set system aaa radius vrf <mgmt-vrf | default>

set system tacacs-plus radius vrf <mgmt-vrf | default>

set protocols snmp trap-group vrf <mgmt-vrf | default>

set protocols sflow collector <*ip-address*> **vrf** <**mgmt-vrf** | **default**>

set protocols dot1x aaa vrf <mgmt-vrf | default>

set protocols ovsdb controller <*controller-name*> **vrf <mgmt-vrf | default>**

Step6 You can use the **run show system management-ethernet eth0** command to view the information of the management interface.

Once management VRF is enabled, a VRF with fixed name **mgmt-vrf** is created automatically by the system, and the Eth0 management interface is automatically moved from the default VRF to the management VRF.

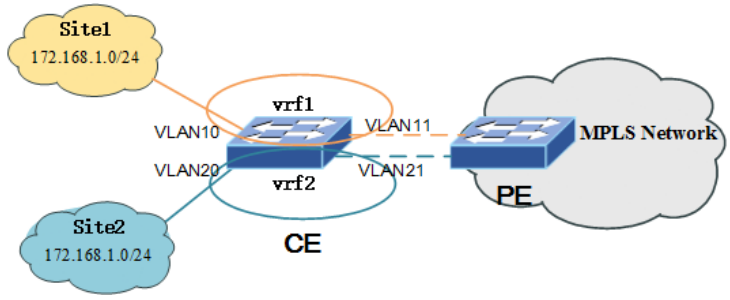
```
admin@Xorplus# run show system management-ethernet
eth0    Hwaddr: e0:07:1b:c9:20:9a   State: UP
    Master: mgmt-vrf
    Gateway  : 10.10.51.1
    Inet addr:
               10.10.51.166/24
               fe80::e207:1bff:fec9:209a/64
    Traffic statistics
    Input Packets.....................4685
    Input Bytes.......................305542
    Output Packets....................109
    Output Bytes......................8566
```

Example for Configuring Basic VRF

- Networking Requirements
- Procedure
- Verify the Configuration

Networking Requirements

Figure 1. VRF Configuration Example



As shown in Figure 1, users of Site1 and Site2 use overlapping IP addresses when accessing the internet from an interface of CE. Deploy VRF function on the CE to segregate the users' routing spaces on Site1 and Site2.

- Configure VRFs vrf1 and vrf2 on CE.
- Create Layer 3 VLAN interfaces VLAN10 and VLAN20 on user access interface te-1/1/3, Layer 3 VLAN interfaces VLAN11 and VLAN21 on the interface te-1/1/4 connected to PE. Set the overlapping IP address 172.168.1.1 to VLAN10 and VLAN20, 192.168.2.1 to VLAN11 and VLAN21.
- Bind the Layer 3 VLAN interfaces VLAN10 and VLAN11 to vrf1, VLAN20 and VLAN21 to vrf2.
- Configure a static route for each VRF for data forwarding. For example, the destination network segment is 10.10.1.0/24, the next hop is 172.168.1.3.

Procedure

Step1 Enable IP routing function before using VRF function.

```
admin@XorPlus# set ip routing enable true
```

Step2 Create two VRFs.

```
admin@Xorplus# set ip vrf vrf1 description East
admin@Xorplus# set ip vrf vrf2 description West
```

Step3 Configure the VLAN and L3 VLAN interface.

```
admin@XorPlus# set vlans vlan-id 10
admin@XorPlus# set vlans vlan-id 20
admin@XorPlus# set vlans vlan-id 11
admin@XorPlus# set vlans vlan-id 21
admin@XorPlus#set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@XorPlus#set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 10
admin@XorPlus#set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 20
admin@XorPlus#set interface gigabit-ethernet te-1/1/4 family ethernet-switching port-mode trunk
admin@XorPlus#set interface gigabit-ethernet te-1/1/4 family ethernet-switching vlan members 11
admin@XorPlus#set interface gigabit-ethernet te-1/1/4 family ethernet-switching vlan members 21
admin@XorPlus# set l3-interface vlan-interface vlan10 address 172.168.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan20 address 172.168.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan11 address 192.168.2.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan21 address 192.168.2.1 prefix-length 24
admin@XorPlus# set vlans vlan-id 10 l3-interface vlan10
admin@XorPlus# set vlans vlan-id 20 l3-interface vlan20
admin@XorPlus# set vlans vlan-id 11 l3-interface vlan11
admin@XorPlus# set vlans vlan-id 21 l3-interface vlan21
```

Step4 Bind the Layer 3 VLAN interface to the VRF.

```
admin@XorPlus# set l3-interface vlan-interface vlan10 vrf vrf1
admin@XorPlus# set l3-interface vlan-interface vlan11 vrf vrf1
admin@XorPlus# set l3-interface vlan-interface vlan20 vrf vrf2
admin@XorPlus# set l3-interface vlan-interface vlan21 vrf vrf2
```

Step5 (Optional) Configure a static route entry into the VRF, the destination network segment is 10.10 1.0/24, the next hop is 172.168.1.3.

```
admin@XorPlus# set protocols static vrf vrf1 route 10.10.1.0/24 next-hop 172.168.1.3
admin@XorPlus# set protocols static vrf vrf2 route 10.10.1.0/24 next-hop 172.168.1.3
```

Verify the Configuration

- You can use the **run show vrf** command to view the binding information between VRFs and the Layer 3 VLAN interfaces.

```
admin@Xorplus# run show vrf
Vrf          Description       Interfaces
----------   ---------------   --------------------
vrf1                           vlan10,vlan11
vrf2                           vlan20,vlan21
```

- You can use the **run show route vrf** command to check the routing table information of the specific VRF.

```
admin@XorPlus# run show route vrf vrf1
show ip route vrf vrf1
=======================
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,

Overview

Dynamic Host Configuration Protocol (DHCP) dynamically configures and uniformly manages network parameters of the hosts in a TCP/IP network, and allocates IP addresses to the network hosts. PICOS switch supports two basic DHCP functions: DHCP snooping and DHCP relay.

DHCP snooping is a network security feature, which is used to ensure that DHCP clients obtain IP addresses from legitimate DHCP servers, and record the binding relationship between IP addresses and MAC addresses of DHCP clients, so as to prevent DHCP attacks on the network.

Device enabled with DHCP snooping forwards the DHCP request messages from the DHCP client to the legitimate DHCP server through the trust interface, then generates a DHCP snooping binding table according to the DHCP Ack message responded by the DHCP server. The DHCP snooping binding table will be synchronized to ARP inspection table to validate ARP packets in a network to prevent ARP attacks and ARP request message flood, for details about Dynamic ARP Inspection (DAI), please refer to Dynamic ARP Inspection (DAI).

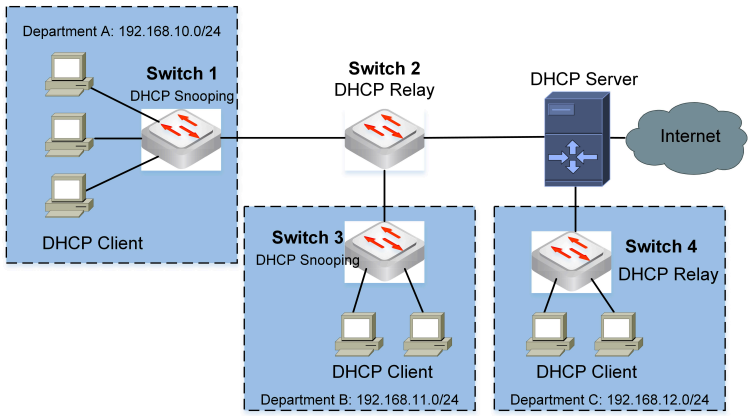
> NOTE:
>
> If Dynamic ARP Inspection (DAI) is to be deployed on the device, when configuring from the CLI, it is required to enable DAI before DHCP snooping can be enabled to make the two features function normally.

DHCP relay is a Layer 3 feature. When the DHCP client and DHCP server are not in the same physical subnet, DHCP relay can be deployed on the Layer 3 device laid between the DHCP client and DHCP server to forward DHCP messages, implementing allocation of IP addresses to the network hosts across different Layer 3 subnets.

DHCP Snooping and DHCP Relay Networking Applications

As shown in figure 1, an enterprise has Department A, Department B and Department C, the gateway server of the enterprise network serves as the DHCP server. The hosts in the three departments are not in the same subnet with the DHCP server. The enterprise wants to dynamically assign IP addresses to the hosts of all the departments by the same DHCP server. The network administrator can deploy a DHCP relay agent between the hosts and the DHCP server to achieve this.

Figure 1 DHCP snooping and DHCP relay networking



Usually, the DHCP relay agent is deployed on the gateway device of the departments, the DHCP server can be deployed on the gateway of the enterprise, or a dedicated DHCP server.

As DHCP request messages are broadcasted in the same subnet, there are often DHCP attacks in the network (e.g., DHCP Server Spoofing, Denial of Service attacks, etc.). In order to prevent attacks by DHCP messages and to improve security, DHCP snooping can be deployed between the DHCP clients and DHCP server to ensure that DHCP clients obtain IP address from the legitimate DHCP server. DHCP snooping is generally deployed on devices close to the DHCP client (e.g., switch 1 and switch 3).

> NOTE:
>
> DHCP snooping and DHCP relay are two modules which are working independently and in parallel. If both DHCP snooping and DHCP relay are enabled on one switch, the DHCP messages will be processed and forwarded by the two modules independently.

DHCP Option 82

Option 82 records the location information of the DHCP client, it can be configured on a DHCP relay or DHCP snooping device. For the DHCP packet received from the DHCP client, the Option 82 carried in that packet will be processed according to the Option 82 policy before sending to the DHCP server.

DHCP server allocates IP addresses and other parameters to the clients based on the Option 82 information carried in the DHCP packet, which provides more flexible address allocation schemes.

Option 82 contains two common sub-options: Circuit ID and Remote ID. Circuit ID is mainly used to identify the VLAN and the interface of the client, Remote ID identifies the device from which the client accessed, usually the MAC address of the device.

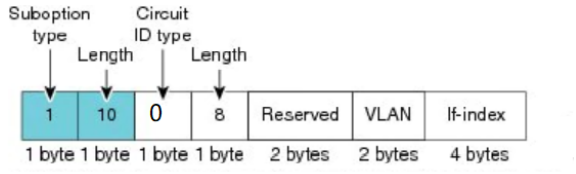
Packet Format

Circuit ID Sub-option

Circuit ID includes three types: Type 0 (value is port index), Type 1 (value is port name + VLAN ID) and Type 2 (value is port description + VLAN ID). The format is listed below by types.

- Type 0 (port index)

Circuit ID type is 0, where physical or LAG interface is used for Circuit ID sub-option.

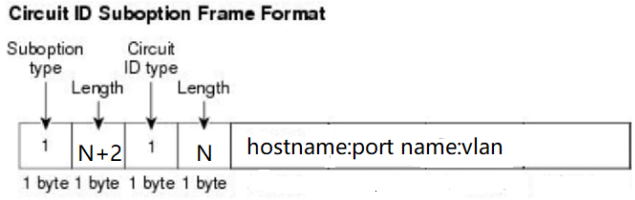


When configuring DHCP snooping and DHCP relay in MLAG topology, MLAG Link ID and Port Index are used for circuit ID field with an offset, see the following table for details:

	MLAG Port	Non-MLAG Port
MLAG Node 0	512 + MLAG Link ID	Local Port Index
MLAG Node 1	512 + MLAG Link ID	1024 + Local Port Index

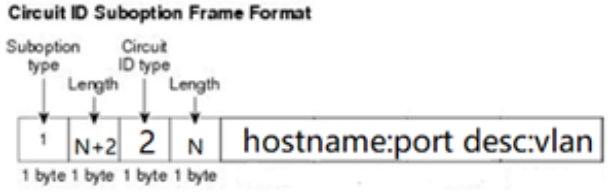
- Type 1 (port name)

Circuit ID type is 1, where port name and VLAN ID make up the Circuit ID sub-option value.



- Type 2 (port description)

Circuit ID type is 1, where port name and VLAN ID make up the Circuit ID sub-option value.

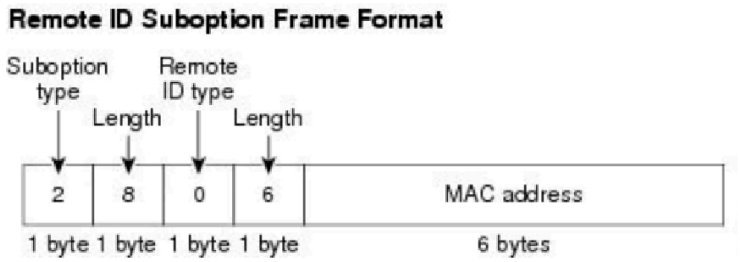


Remote ID Sub-option

Remote ID includes two types: Type 0 (value is system MAC) and Type 1 (value is host name). The format is listed below by types.

- Type 0 (system MAC)

Remote ID type is 0, where system MAC is used for Remote ID sub-option.



Note that: The format of DHCP Option 82 sub-options remote ID is fixed as MLAG domain MAC address in MLAG topology.

- Type 1 (hostname)

Remote ID type is 1, where hostname is used for Remote ID sub-option.

How to Handle Option 82?

The system handles Option 82 in the received DHCP packets according to the following rules:

- When a DHCP Discover/Request/Release/Decline/Inform message **without giaddr** but **with Option 82** is received,
  - If Option 82 trust-all is disabled, then drop the message.
  - If Option 82 trust-all is enabled, such kind of message is processed according to the user configuration of Option 82 policy. There are four types of operations that can be set for Option 82 policy: **Keep**, **Drop**, **Insert** and **Replace**. The default operation is **Keep** which means Option 82 in the DHCP message received from the DHCP client remains unchanged and forwarded.
- When a DHCP Discover/Request/Release/Decline/Inform message of any other type but the one above, the message is allowed on receiving and processed depending on the Option 82 policy.
- When a DHCP Offer/Ack/Nak message **without Option 82** is received, the message is forwarded without Option 82.
- When a DHCP Offer/Ack/Nak message **with Option 82** is received, Option 82 is removed before the message is forwarded.

Option 82 settings are supported respectively on both DHCP relay agent or on the Layer 2 access device enabled with DHCP snooping function. The related commands are listed below:

Set Option policy for DHCP snooping:

set protocols dhcp snooping vlan <*vlan-id*> **option82-policy** <**drop | keep | insert | replace**>

When option82-policy is set to “insert” or “replace”, you can use the following commands to set the format of sub-options circuit ID and remote ID:

set protocols dhcp snooping option82 circuit-id <**port-index | port-name | port-description**>

set protocols dhcp snooping option82 remote-id <system-mac | hostname>

Set Option policy for DHCP Relay:

set protocols dhcp relay interface <*vlan-interface-name*> **option82-policy** <**drop | keep | insert | replace**>

When option82-policy is set to “insert” or “replace”, you can use the following commands to set the format of sub-options circuit ID and remote ID:

set protocols dhcp relay option82 circuit-id <**port-index | port-name | port-description**>

set protocols dhcp relay option82 remote-id <system-mac | hostname>

We can use the following table to summarize the Option 82 policy.

Received Packet / Option82 Policy	No Option82	Only Circle ID	Only Remote ID	Circle ID + Remote ID
drop	The packet is forwarded without changing option 82.	The packet is dropped.	The packet is dropped.	The packet is dropped.
keep	The packet remains unchanged and forwarded.	The packet remains unchanged and forwarded.	The packet remains unchanged and forwarded.	The packet remains unchanged and forwarded.
insert	The packet is forwarded. Circle ID: inserted with the value configured. Remote ID: inserted with the value configured.	The packet is forwarded. Circle ID: unchanged. Remote ID: inserted with the value configured.	The packet is forwarded. Circle ID: inserted with the value configured. Remote ID: unchanged.	The packet is forwarded. Circle ID: unchanged. Remote ID: unchanged.
replace	The packet is forwarded. Circle ID: inserted with the value configured. Remote ID: inserted with the value configured.	The packet is forwarded. Circle ID: replaced with the value configured. Remote ID: inserted with the value configured.	The packet is forwarded. Circle ID: inserted with the value configured. Remote ID: replaced with the value configured.	The packet is forwarded. Circle ID: replaced with the value configured. Remote ID: replaced with the value configured.

NOTE:

DHCP snooping and DHCP relay can handle Option 82 independently and in parallel since they are two completely separated modules.

Option 82 trust-all

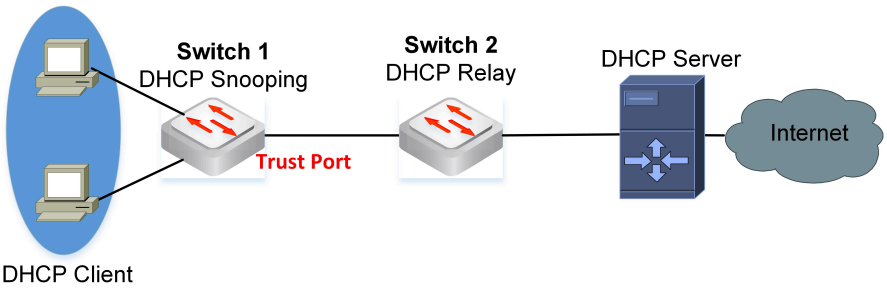
DHCP Discover/Request/Release/Decline/Inform packets received on the switch without giaddr but containing Option 82 are dropped by default. However, if Option 82 trust all function is enabled, such packets will be allowed and processed.

Therefore, when configuring the Option 82 policy, you need to take into consideration the network topology and the configuration of trust all together, especially if there is a switch between the client and the relay agent/the DHCP snooping enabled device that may insert Option 82. Enable DHCP Option 82 trust all on this device to ensure that these packets do not get dropped.

For example, in the following topology, the configurations on Switch 1 and Switch 2 are:

- DHCP snooping is enabled on Switch 1, and DHCP relay is enabled on Switch 2.
- DHCP snooping trust port is configured on the physical or L2 aggregated port towards Switch 2 on Switch 1.

Figure 2 DHCP Snooping and DHCP Relay Topology



DHCP snooping Option 82 can be enabled on Switch 1, and DHCP relay Option 82 can be enabled on Switch 2. It is optional. But if Option 82 is inserted on Switch 1, DHCP relay Option 82 trust all should be enabled on Switch 2.

Interaction with Other Protocols

MLAG

Devices in the MLAG topology support enabling DHCP snooping or DHCP relay function on the MLAG peer devices to implement address allocation for the DHCP clients.

When configuring DHCP snooping and DHCP relay in MLAG topology, pay attention to the following points:

- DHCP snooping configurations, such as Option 82 policy, VLANs enabled or disabled DHCP snooping, should be configured identically on both MLAG peer devices, the inconsistent configuration can cause undesirable behavior in the traffic flow.
- If the VLANs enabled or disabled DHCP snooping are not identical on MLAG peer devices or the MLAG global configuration are not identical on MLAG peer devices, the DHCP binding table entries will be cleared.
- When configuring DHCP snooping, the ports directly or indirectly connect the DHCP server should be configured as trust port on the network device between the DHCP Client and the Server, including the MLAG peer devices.
- DHCP relay configurations should be configured identically on both MLAG peer devices.

DHCP snooping and DHCP relay in MLAG topology present the following characteristics:

1. DHCP snooping binding table and DHCP relay table of the MLAG member ports will be synchronized to the associated member ports on MLAG peer device.
2. If both the MLAG configuration consistency check as well as the DHCP snooping configuration consistency check pass, the MLAG system syncs the DHCP snooping binding table and DHCP relay table; If any of the MLAG or DHCP snooping configuration consistency check fails, the DHCP binding table entries will be cleared.
3. DHCP snooping binding table and DHCP relay table of the single-homed ports will not be synchronized to the MLAG peer device.
4. When receiving a DHCP message (especially for broadcast messages), the message will be forwarded by DHCP relay, and at the same time flooded in the same VLAN.
5. MLAG flood control module processes DHCP packets just like other packets: When the MLAG member port is in the FULL state, DHCP packets received from the peer link port cannot be forwarded out from the MLAG member port; However, when the MLAG interface state changes to AS_LOCAL, the prohibition is lifted.
6. The format of DHCP Option 82 sub-options remote ID and circuit ID is fixed in MLAG topology,

- MLAG domain MAC address is used to fill in remote ID field.
- MLAG Link ID and Port Index are used for circuit ID field with an offset, see the following table for details:

	MLAG Port	Non-MLAG Port
MLAG Node 0	512 + MLAG Link ID	Local Port Index
MLAG Node 1	512 + MLAG Link ID	1024 + Local Port Index

Note that, when configuring Option 82 in MLAG environment, remote ID should be set to “system-mac” and circuit ID should be set to “port-index”.

VRRP

The DHCP relay feature can be implemented in the VRRP network, allowing the VRRP Master and Backup devices to act as the DHCP relay agents.

When configuring DHCP relay in VRRP topology, pay attention to the following points:

- DHCP relay configurations must be identical on both *VRRP Master/Backup* devices, such as the DHCP server address.
- In VRRP topology, DHCP relay only works on the L3 VLAN interface with single IP address and single VRID.
- DHCP relay agent address is required in VRRP topology, and it must be specified as the virtual IP address of the VRRP group. The command **set protocols dhcp relay interface** *<vlan-interface-name>* **relay-agent-address** *<agent-ipv4-address>* can be used to set the *DHCP relay agent address*. It is used to fill in the giaddr field to identify the client gateway in the DHCP relay Discover/Request/Inform/Release/Decline message where the giaddr is zero. For those DHCP messages in which the giaddr isn't zero, the giaddr remains unchanged.
- Dynamic ARP Inspection (DAI) is supported in the Active-Active VRRP mode, but NOT supported in the standard VRRP mode.

Configuration Notes of DHCP

When configuring DHCP snooping and DHCP relay, pay attention to the following notes:

- DHCP relay only works on the L3 VLAN interface with single IP address and single VRID if VRRP is used.
- DHCP relay supports VRF function by binding DHCP client VLAN interface to a specified VRF.
- Inter-VRF routing isn't support by DHCP relay.
- Dynamic ARP Inspection (DAI) is supported in the Active-Active VRRP mode, but NOT supported in the standard VRRP mode.
- Enable IP routing function before using DHCP relay.
- When a DHCP Offer/Ack/Nak message with Option 82 is received, Option 82 is removed before the message is forwarded.
- The DHCP snooping function is only practicable to the clients directly connected in the local L2 domain, rather than connected through a router.
- There will be compatibility issues with DHCP features when upgrading from a version before PICOS 3.7.0, so upgrading from a version before 3.7.0 to this version is not supported.
- When configuring Option 82 in MLAG environment, remote ID should be set to “system-mac” and circuit ID should be set to “port-index”.

Configuring DHCP Server (IPv4)

- Introduction
- Configuration Notes
- Configuring DHCP Server
  - Procedure
- Configuration Example
  - Networking Requirements
  - Procedure
  - Verify the Configuration

Introduction

Dynamic Host Configuration Protocol (DHCP) is a protocol that dynamically configures and centrally manages the network parameters of the hosts based on TCP / IP protocol, which can be used to:

- Dynamically assign IP addresses to network hosts. Assign an IP address to a host via DHCP with an expiration time (often called a lease time). The default lease time is one hour.
- Provide other network parameters for network hosts, such as the IP address of the DNS server, domain name information and default gateway address.

Configuration Notes

Pay attention to the following points when configuring DHCP server:

- Enabling DHCP client, DHCP relay or DHCP server functions in block VLAN is not supported.
- Enabling DHCP client, DHCP snooping/relay and DHCP server functions in the same VLAN is not supported. Where DHCP snooping and DHCP relay don't have this limitation, they can be enabled in the same VLAN.
- Enabling both DHCP relay and DHCP server functions in the same VRF is supported.
- If both DHCP server and DHCP relay are deployed on the same switch, don't use the VLAN interface enabled with DHCP server to connect to the remote DHCP server.
- DHCP server feature supports only IPv4, and doesn't support IPv6.
- DHCP server supports VRF by binding the address pool and the VLAN interface (which is connected to the DHCP client side) to the same VRF.
- One VRF will run a DHCP server instance. So different VRFs will have different DHCP server instances.
- In each VRF, at most 1000 DHCP clients are allowed.
- Multiple address pools can be configured in the same VRF, but there cannot be address overlap between individual pools. However, address pools in different VRFs do not have this restriction.
- When multiple address ranges are configured under one address pool, there should be no address overlap between these ranges.
- The default router is the default gateway of the DHCP client, which is required to be on the same network segment as the address pool.
- In a VRRP topology, if the DHCP server function is enabled, the address pool configured on the master cannot overlap with that configured on the backup switch.
- Adding, deleting and modifying any parameter in the DHCP address pool will result in the deletion of DHCP server binding table in this VRF.

Configuring DHCP Server

Procedure

Step 1 Create an address pool and specify the IPv4 network segment that can be dynamically allocated to the DHCP clients.

set protocols dhcp server pool <*pool-name*> **network** <*IPv4Net*>

Step 2 Configure the VLAN interface connected to the DHCP client.

set vlans vlan-id <*vlan-id*>

set vlans vlan-id <*vlan-id*> l3-interface <*interface-name*>

set l3-interface vlan-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*number*>

Step 3 (Optional) Associate the VLAN interface with a VRF.

If you want to configure the DHCP server for a user-defined VRF, you need to configure this step.

set l3-interface vlan-interface <*interface-name*> **vrf** <*vrf-name*>

Step 4 (Optional) Configure the lower and upper boundaries of an address range in the address pool.

set protocols dhcp server pool <*pool-name*> **range** <*range-name*> **low** <*ipv4-address*>

set protocols dhcp server pool <*pool-name*> **range** <*range-name*> **high** <*ipv4-address*>

NOTEs:

- The address range is optional. If not configured, it means that all the IP addresses in the address pool are available for address assignment. However, if configured, only addresses in the range can be used for address assignment.
- When multiple address ranges are configured under an address pool, there should be no address overlap between different ranges.

Step 5 (Optional) Configure a lease time for the IP addresses in an address pool.

set protocols dhcp server pool <*pool-name*> **lease-time** <*lease-time*>

By default, the lease time is 60 minutes.

Step 6 (Optional) In a DHCP relay scenario, the following command needs to be used to enable the DHCP server function on the Layer 3 interface.

set protocols dhcp server interface <*interface-name*> **disable** <**true** | **false**>

Step 7 (Optional) Configure the IP address of the DNS server and domain name for the DHCP address pool.

a) Configure the IP address of the DNS server.

set protocols dhcp server pool <*pool-name*> **dns-server** <*dns-server-ip*>

NOTEs:

- By default, no DNS server IP address is configured in a DHCP address pool.
- Each address pool can be configured with a maximum of eight DNS server IP addresses.

b) Configure a domain name for the DHCP clients.

set protocols dhcp server pool <*pool-name*> **domain-name** <*domain-name*>

Step 8 (Optional) Configure a default gateway address for the DHCP clients.

set protocols dhcp server pool <*pool-name*> **default-router** <*router-ip address*>

Step 9 (Optional) Assign a DHCP address pool to a VRF.

set protocols dhcp server pool <*pool-name*> **vrf** <*vrf-name*>

By default, no VRF is configured for an address pool, the address pool belongs to the default VRF.

Step 10 (Optional) Configure the IP address for the TFTP server. After the client sends request packets to the DHCP server, the TFTP server with this IP address will be replied.

set protocols dhcp server pool <*pool-name*> **tftp-server** <*tftp-server-ip*>

Step 11 (Optional) Configure the IP address for the Syslog server. After the client sends request packets to the DHCP server, the Syslog server with this IP address will be replied.

set protocols dhcp server pool <*pool-name*> **log-server** <*log-server-ip*>

Step 12 (Optional) Configure the file name with path on the TFTP server or the file name with URL on the HTTP server. After the client sends request packets to the DHCP server, the file name with path or URL will be replied.

set protocols dhcp server pool <*pool-name*> **bootfile-name** {**file-path** <*file-path*> | **url** <*url*>}

Step 13 (Optional) Configure the file name with path on the TFTP server or the file name with URL on the HTTP server. After the client sends request packets to the DHCP server, the file name with path or URL will be replied.

set protocols dhcp server pool <*pool-name*> **bootfile-name** {**file-path** <*file-path*> | **url** <*url*>}

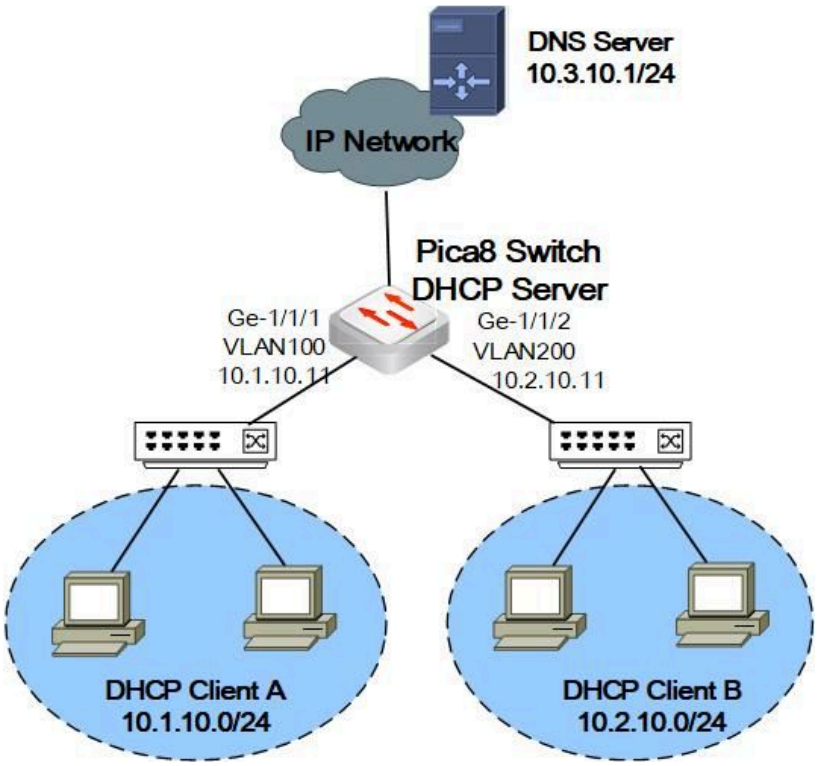
NOTEs:

- If commands of **set protocols dhcp server pool tftp-server** and **set protocols dhcp server pool bootfile-name url** are both configured, the TFTP server is valid, and error prompt appears for the script in the TFTP server cannot be obtained.
- Commonly, the commands of TFTP server and Syslog server are applied for the ZTP function. For details of ZTP, see Zero Touching Provisioning (ZTP).
- By default, no TFTP and Syslog server IP address is configured in a DHCP address pool.
- Each address pool can be respectively configured with one TFTP server address and one Syslog server address.
- If you configure the IP address of TFTP server or Syslog server through ZTP provision script, it will be used in preference to the configurations in the DHCP server.

Configuration Example

Networking Requirements

Figure 1. DHCP Server Configuration Example



As shown in **Figure 1**, an enterprise has planned two network segments for the office terminals. PCs in the network segment 10.1.10.0/24 are the fixed terminals, and the network segment 10.2.10.0/24 is used for temporary users accessing to the network. To facilitate unified administration, the enterprise terminals can automatically obtain IP address and DNS server address from the DHCP server.

By configuring DHCP server on Pica8 switch, IP address and DNS server address can be dynamically assigned to the terminals in the two separate network segments of the enterprise. Among them, the PCs in network segment 10.1.10.0/24 are the fixed office terminal, and the IP lease time is 30 days; the network segment 10.2.10.0/24 provides temporary accesses to the network for business travelers, and the IP lease time is 2 days.

Procedure

Step 1 Configure the VLAN interface connected to the DHCP client.

```
admin@Xorplus# set vlans vlan-id 100
admin@Xorplus# set vlans vlan-id 200
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 100
admin@Xorplus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 200
admin@Xorplus# set vlans vlan-id 100 l3-interface vlan100
admin@Xorplus# set vlans vlan-id 200 l3-interface vlan200
admin@Xorplus# set l3-interface vlan-interface vlan100 address 10.1.10.11 prefix-length 24
admin@Xorplus# set l3-interface vlan-interface vlan200 address 10.2.10.11 prefix-length 24
```

Step 2 Create two address pools and specify the IPv4 network segment that can be dynamically allocated to the DHCP clients.

```
admin@Xorplus# set protocols dhcp server pool pool1 network 10.1.10.0/24
admin@Xorplus# set protocols dhcp server pool pool2 network 10.2.10.0/24
```

Step 3 Configure the lease time for the IP addresses in the address pool.

```
admin@Xorplus# set protocols dhcp server pool pool1 lease-time 43200
admin@Xorplus# set protocols dhcp server pool pool2 lease-time 2880
```

By default, the IP address lease is one hour.

Step 4 Configure the IP address of the DNS server and domain name for the DHCP clients.

a) Configure the IP address of the DNS server for each address pool.

By default, no DNS server is configured in an address pool.

b) Configure domain name for the DHCP clients.

```
admin@Xorplus# set protocols dhcp server pool pool1 domain-name company.com
```

Verify the Configuration

- The IP address and DNS server address of the 10.1.10.0/24 network segment can be obtained from the DHCP server by the PCs in the zone of DHCP client A, and the IP address and DNS server address of the 10.2.10.0/24 network segment can be obtained from the DHCP server by the PCs in the zone of DHCP client B.
- Run the command **run show dhcp server binding** on the switch to view the allocated IP address binding information.

```
admin@Xorplus# set protocols dhcp server pool pool1 dns-server 10.3.10.1
admin@Xorplus# set protocols dhcp server pool pool2 dns-server 10.3.10.1
```

```
admin@Xorplus# run show dhcp server binding
2 bound clients

IP address       MAC address          Server        Interface
10.1.10.89       00:0a:12:00:12:12    10.1.10.11    vlan100
10.2.10.88       00:0a:12:00:12:34    10.2.10.11    vlan200

admin@Xorplus# run show dhcp server binding interface vlan100
Client Interface: vlan100
    MAC address:          00:0a:12:00:12:12
    Client IP Address:      10.1.10.89

    DHCP Options :
    Name: dhcp-lease-time, Value: 43200 minutes
    Name: name-server, Value: [10.3.10.1]
    Name: server-identifier, Value: 10.1.10.11
    Name: router, Value: [ 10.1.10.11 ]
    Name: domain-name, Value: company.com
```

Configuring DHCP Relay

- Configuring DHCP Relay (IPv4)
- Example for Configuring DHCPv6 Relay
- Example for Configuring DHCP Relay over GRE Tunnel

Configuring DHCP Relay (IPv4)

As DHCP is used to send the request packet during the dynamic acquisition of IP address, DHCP is only applicable to the case where the DHCP client and the server are on the same subnet.

For this reason, you have to set up a DHCP server on each network segment for dynamic host configuration, which is obviously very uneconomical. The introduction of DHCP relay function solves this problem: the client can communicate with the DHCP server of other network segment through DHCP relay agent, to obtain the IP address finally. In this way, DHCP clients on multiple networks can share the same DHCP server, which saves the cost as well facilitates centralized management.

Note that: the configuration and processing of DHCP relay function have nothing to do with the DHCP snooping trust port.

NOTE:

- DHCP relay supports VRF function by binding DHCP client VLAN interface to a specified VRF.
- When configuring DHCP relay, the VLAN interface connected to the clients and the VLAN interface connected to the DHCP server should be in the same VRF.

Procedure

Step 1 Configure VLAN.

a). Configure VLAN ID.

set vlans vlan-id <*vlan-id*>

b). Add an interface to the VLAN.

set interface gigabit-ethernet <*port*> **family ethernet-switching native-vlan-id** <*vlan-id*>

c). Associate a Layer 3 interface with a VLAN.

set vlans vlan-id <*vlan-id*> **l3-interface** <*interface-name*>

d). Configure the IP address for the VLAN interface to implement Layer 3 connectivity.

set l3-interface vlan-interface <*interface-name*> **address** <*address*> **prefix-length** <*number*>

Step 2 Enable IP routing function when using DHCP relay.

set ip routing enable <true | **false>**

Step 3 Enable the DHCP relay function on the L3 VLAN interface connected to the client.

set protocols dhcp relay interface <*vlan-interface-name*> **disable** <**true** | **false**>

Step 4 Configure the IP address of the DHCP server.

set protocols dhcp relay interface<*vlan-interface-name*> **dhcp-server-address** <*ipv4-address*>

Note that the VLAN interface is L3 VLAN interface that connected to the client.

Step 5 (Optional) Configure the IP address of the DHCP relay agent.

set protocols dhcp relay interface <*vlan-interface-name*> **relay-agent-address** <*agent-ipv4-address*>

NOTE:

DHCP relay agent address is a required configuration in VRRP topology, when the VRRP Master/Backup devices are used as the DHCP relay agents, you must configure the DHCP relay agent address to the virtual IP address of the VRRP group.

The interface name here should be configured with the L3 VLAN interface which is enabled with DHCP relay and VRRP group.
However, in a non-VRRP topology, there's no need to configure the DHCP relay agent address. By default, the system sets the IP address of the L3 VLAN interface that enabled DHCP relay as the DHCP relay agent address.

Step 6 (Optional) Configure the DHCP relay Option 82 policy and the sub-options.

set protocols dhcp relay interface <*vlan-interface-name*> **option82-policy** <**drop | keep | insert | replace**>

set protocols dhcp relay option82 circuit-id <**port-index | port-name | port-description**>

set protocols dhcp relay option82 remote-id <**system-mac | hostname**>

Step 7 (Optional) Enable Option 82 trust-all function for DHCP relay.

set protocols dhcp relay option82 trust-all <**true | false**>

Step 8 (Optional) Configuring DHCP relay in a VRF.

To enable DHCP relay in a VRF, the configuration method is to bind the DHCP client side VLAN interface to a user-defined VRF by using the following command.

set l3-interface vlan-interface <*interface-name*> **vrf** <*vrf-name*>

By default, the VLAN interface is bound to the default VRF if not specified to a user-defined VRF.

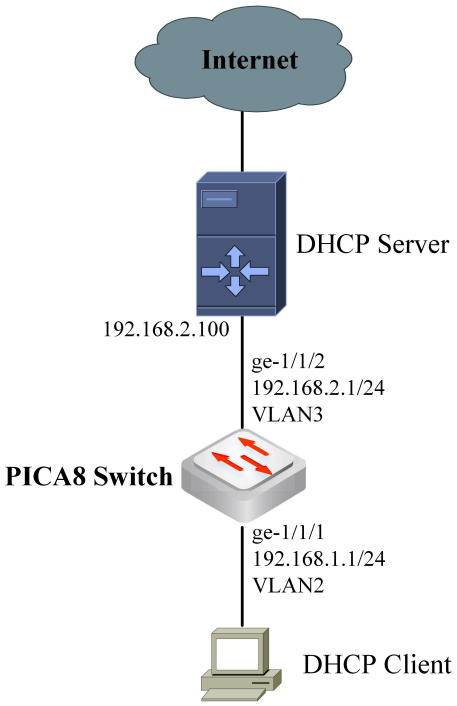
If DHCP relay is deployed in a VRF, this step is required. The VLAN interface connected to the clients and the VLAN interface connected to the DHCP server should be in the same VRF. Otherwise, the DHCP client cannot obtain the IP address normally.

Configuration Example

Networking Requirements

- On PICA8 Switch, the interfaces ge-1/1/1 belongs to VLAN 2 and ge-1/1/2 belongs to VLAN 3.
- The L3 VLAN interface associated with VLAN 2 is vlan-2, the interface IP is 192.168.1.1/24; The L3 VLAN interface associated with VLAN 3 is vlan-3, the interface IP is 192.168.2.1/24.
- Enable DHCP relay function on the L3 VLAN interface vlan-2.
- The IP address of DHCP server is 192.168.2.100.

Figure 1 DHCP Relay Network



Procedure

Step 1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 192.168.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 192.168.2.1 prefix-length 24
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
```

Step 2 Enable IP routing function when using DHCP relay.

```
admin@XorPlus# set ip routing enable true
```

Step 3 Enable the DHCP relay function on L3 VLAN interface vlan-2.

```
admin@XorPlus# set protocols dhcp relay interface vlan-2 disable false
```

Step 4 Configure the IP address of DHCP server 192.168.2.100.

```
admin@XorPlus# set protocols dhcp relay interface vlan-2 dhcp-server-address 192.168.2.100
```

Step 5 Commit the configuration.

```
admin@XorPlus# commit
```

Step 6 Verify the configuration.

- After the configuration is complete, run the **show protocols dhcp relay** command to view the configuration of DHCP relay.

```
admin@Xorplus# show protocols dhcp relay
    interface vlan-2 {
        disable: false
        dhcp-server-address 192.168.2.100
        relay-agent-address: 192.168.1.1
   }
```

- DHCP client can obtain the IP address normally.

Example for Configuring DHCPv6 Relay

A DHCPv6 relay agent enables the DHCPv6 client and server on different links to exchange DHCPv6 messages. The DHCPv6 relay agent forwards DHCP messages to the destination DHCPv6 server on a different network segment. DHCPv6 clients on multiple networks can share one DHCPv6 server.

Multiple DHCPv6 relays can be configured between the DHCPv6 client and server. If a device functions as a DHCPv6 relay and it is directly connected to the DHCPv6 server then you need to specify the IPv6 address of the DHCPv6 server when enabling the DHCPv6 relay feature. If the DHCPv6 relay device is connected to a next-hop relay device then you need to specify the IPv6 address of the next-hop relay device. All the intermediate relay devices are configured with the next-hop device's IPv6 address until the server's IPv6 address is configured on the last relay device in the chain which has a direct connection to the DHCP6 server.

> **NOTE:**
> DHCPv6 relay supports VRF function by binding the VLAN interface to a specified VRF.

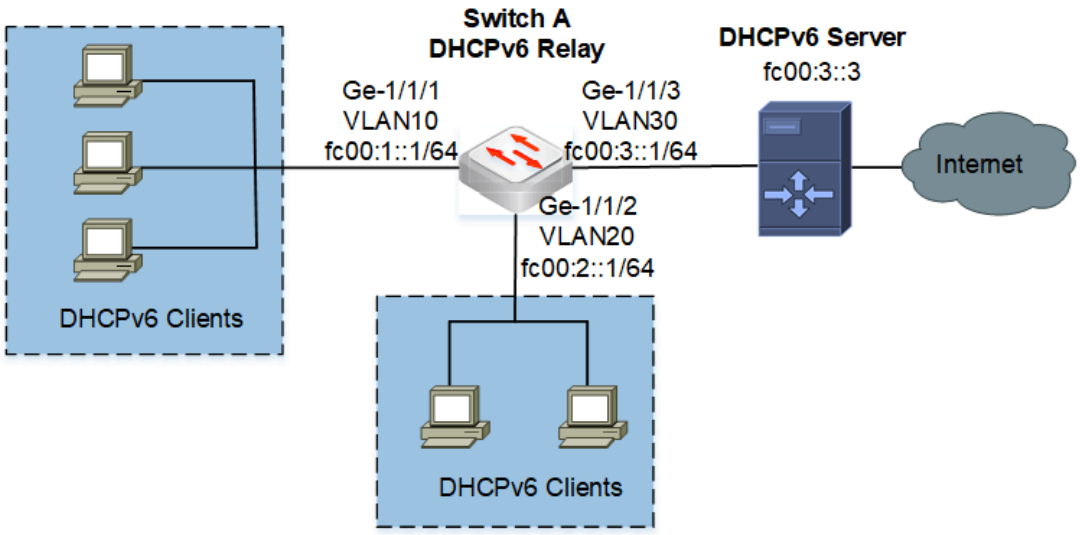
The following configuration example shows how to configure a DHCPv6 relay to assign IPv6 addresses to the clients in multiple network segments.

- Networking Requirements
  - Figure 1. Networking diagram for configuring DHCPv6 relay
- Procedure

Networking Requirements

As shown in Figure 1, the DHCPv6 clients in two network segments fc00:1::/64 and fc00:2::/64 want to dynamically obtain IPv6 addresses from the DHCPv6 server when the DHCPv6 server and clients are in different subnets. The addresses fc00:1::1/64 and fc00:2::1/64 on Switch A are used as the gateway addresses of the clients in network segments fc00:1::/64 and fc00:2::/64.

Figure 1. Networking diagram for configuring DHCPv6 relay



Configure the DHCPv6 relay function on Switch A to forward DHCPv6 packets between the DHCPv6 server and clients so that the clients can dynamically obtain IPv6 addresses.

Switch A is used as a DHCPv6 relay device. DHCPv6 clients can communicate with the DHCPv6 server in a different subnet through DHCPv6 relay to obtain IPv6 addresses from the DHCPv6 server's IPv6 address pool and other configuration information. Using a common DHCPv6 server in this manner not only saves the cost but also facilitates centralized management.

To enable DHCPv6 relay, there are two key steps that should be configured:

1. Enable the DHCPv6 relay function on L3 VLAN interface.
2. Configure the IP address of DHCPv6 server or the next-hop DHCPv6 relay device.

Procedure

Step 1 Configure VLAN interfaces.

```
admin@Xorplus# set vlans vlan-id 10
admin@Xorplus# set vlans vlan-id 20
admin@Xorplus# set vlans vlan-id 30
admin@Xorplus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@Xorplus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@Xorplus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@Xorplus# set vlans vlan-id 10 l3-interface vlan10
admin@Xorplus# set vlans vlan-id 20 l3-interface vlan20
```

```
admin@Xorplus# set vlans vlan-id 30 l3-interface vlan30
admin@Xorplus# set l3-interface vlan-interface vlan10 address fc00:1::1 prefix-length 64
admin@Xorplus# set l3-interface vlan-interface vlan20 address fc00:2::1 prefix-length 64
admin@Xorplus# set l3-interface vlan-interface vlan30 address fc00:3::1 prefix-length 64
```

Step 2 Enable IP routing function when using DHCPv6 relay.

```
admin@XorPlus# set ip routing enable true
```

Step 3 Enable the DHCPv6 relay function on L3 VLAN interface vlan10 and vlan20.

```
admin@XorPlus# set protocols dhcp6 relay interface vlan10 disable false
admin@XorPlus# set protocols dhcp6 relay interface vlan20 disable false
```

Step 4 Configure the IP address of DHCPv6 server.

```
admin@XorPlus# set protocols dhcp6 relay interface vlan10 destination fc00:3::3
admin@XorPlus# set protocols dhcp6 relay interface vlan20 destination fc00:3::3
```

Step 5 Configure to advertise RA messages and configure the M flag bit.

```
admin@XorPlus# set l3-interface vlan-interface vlan10 ipv6-nd suppress-ra false
admin@XorPlus# set l3-interface vlan-interface vlan10 ipv6-nd prefix fc00:1::0/64 router-address
admin@XorPlus# set l3-interface vlan-interface vlan10 ipv6-nd managed-config-flag
```

Step 6 Commit the configuration.

```
admin@XorPlus# commit
```

Step 7 Verify the configuration.

- After the configuration is complete, run the show protocols dhcp6 relay command to view the configuration of DHCPv6 relay.

```
admin@XorPlus# show protocols dhcp6 relay
    interface vlan10 {
        disable: false
        destination fc00:3::3
    }
    interface vlan20 {
        disable: false
        destination fc00:3::3
    }
```

- Run the **run show dhcp6 relay-stats** command to view DHCPv6 relay running status and statistics.

```
admin@Xorplus# run show dhcp6 relay-stats
Vif Name        Rx        Tx
-----------------------------------
vlan10          6866      1626
vlan20          2455      896
Total 2 Vif(s) enabled with DHCP6 relay
```

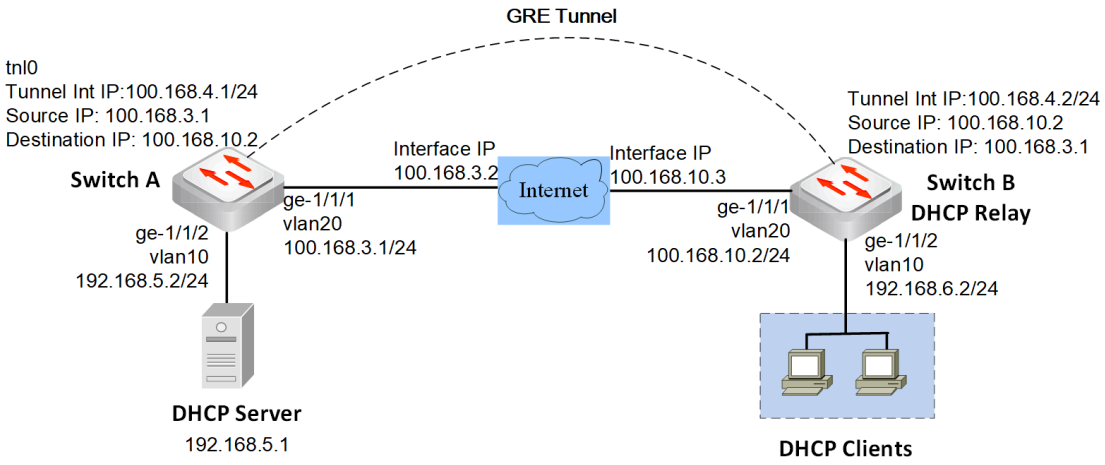
- DHCPv6 client can obtain the IP address normally.

Example for Configuring DHCP Relay over GRE Tunnel

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Verifying the Configuration

Networking Requirements

Figure 1. DHCP Relay over GRE Tunnel Configuration Example



As shown in **Figure 1**, the DHCP server and DHCP clients are deployed in different areas, and are belonged to different network segments. DHCP server accesses the network through Switch A, DHCP clients access the network through Switch B. In this scenario, DHCP relay needs to be configured on Switch B.

To enable communication between DHCP server and DHCP clients through the public network, a Generic Routing Encapsulation (GRE) tunnel needs to be deployed between Switch A and Switch B.

Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchA# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 10
admin@SwitchA# set l3-interface vlan-interface vlan10 address 192.168.5.2 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan20 address 100.168.3.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step3 Configure GRE tunnel name, IP, source IP, destination IP etc.

```
admin@SwitchA# set l3-interface tunnel tnl0 address 100.168.4.1 prefix-length 24
admin@SwitchA# set l3-interface tunnel tnl0 tunnel-mode gre-ip
admin@SwitchA# set l3-interface tunnel tnl0 source 100.168.3.1
admin@SwitchA# set l3-interface tunnel tnl0 destination 100.168.10.2
```

Step4 Create static routes for the GRE tunnel.

```
admin@SwitchA# set protocols static route 192.168.6.0/24 next-hop 100.168.4.2
admin@SwitchA# set protocols static route 100.168.10.0/24 next-hop 100.168.3.2
```

Or we can create the static route using the tunnel name as the next hop.

```
admin@SwitchA# set protocols static interface-route 192.168.6.0/24 interface tnl0
```

Step5 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchB# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 10
admin@SwitchB# set l3-interface vlan-interface vlan10 address 192.168.6.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan20 address 100.168.10.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step3 Configure GRE tunnel name, IP, source IP and destination IP.

```
admin@SwitchB# set l3-interface tunnel tnl0 address 100.168.4.2 prefix-length 24
admin@SwitchB# set l3-interface tunnel tnl0 tunnel-mode gre-ip
admin@SwitchB# set l3-interface tunnel tnl0 source 100.168.10.2
admin@SwitchB# set l3-interface tunnel tnl0 destination 100.168.3.1
```

Step4 Create static routes for the GRE tunnel.

```
admin@SwitchB# set protocols static route 192.168.3.0/24 next-hop 100.168.10.3
admin@SwitchB# set protocols static route 192.168.5.0/24 next-hop 100.168.4.1
```

Or we can create the static route using the tunnel name as the next hop.

```
admin@SwitchB# set protocols static interface-route 192.168.5.0/24 interface tnl0
```

Step5 Enable the DHCP relay function on VLAN interface vlan10 and specifies the DHCP server address for the relay.

```
admin@SwitchB# set protocols dhcp relay interface vlan10 disable false
admin@SwitchB# set protocols dhcp relay interface vlan10 dhcp-server-address 192.168.5.1
```

Step6 Commit the configuration.

```
admin@SwitchB# commit
```

Verifying the Configuration

- After the configuration is complete, run the **show protocols dhcprelay** command to view the configuration of DHCP relay.

```
admin@SwitchB# show protocols dhcp relay
    interface vlan10 {
        disable: false
        dhcp-server-address 192.168.5.1
   }
```

- Run command **run show l3-interface tunnel** to display information about the GRE tunnel interface.

```
admin@SwitchB# run show l3-interface tunnel tnl0
tnl0         State:UP
            Tunnel Source: 100.168.3.1
            Tunnel Destnation:: 100.168.10.2
            Tunnel protocol/transport: gre-ip
            Inet addr: 100.168.4.1
```

```
Traffic statistics:
  5 sec input rate IPv4 1400 packets/sec, IPv6 0 packets/sec
  5 sec forwarding rate IPv4 28 packets/sec, IPv6 0 packets/sec
  IPv4 Input Packets.....................28
  IPv4 Forwarding Packets.....................5
  IPv6 Input Packets.....................0
  IPv6 Forwarding Packets.....................0
```

- DHCP clients can obtain the IP address normally.

Configuring DHCP Snooping

- Configuring DHCP Snooping (IPv4)
- Configuring DHCPv6 Snooping (IPv6)

Configuring DHCP Snooping (IPv4)

DHCP snooping creates a binding table, which includes the client IP address, MAC address, VLAN ID, physical port and the lease time. DHCP snooping is disabled by default. The steps below explain how to enable DHCP snooping and configure the trust port (by default all the ports are untrusted ports), DHCP snooping binding file and the delay timer for writing the DHCP snooping entries from memory to the binding file, and how to configure DHCP snooping Option 82 policy.

Procedure

Step 1 Configure DHCP snooping on a VLAN.

set protocols dhcp snooping vlan <*vlan-id*> **disable** <**true** | **false**>

> **NOTE：**
>
> DHCP snooping should be enabled in the VLAN, it takes effect only on DHCP messages received from interfaces in this VLAN. Packets that are not received from this VLAN won't be processed by DHCP snooping module and will be processed and forwarded as ordinary packets.

Step 2 Configure the interface connected to the DHCP server as DHCP snooping trusted interface.

set protocols dhcp snooping trust-port <*interface-name*>

> **NOTE：**
>
> - The port can be either physical port or aggregated port.
> - By default, all the ports are untrusted ports.
> - When DHCP snooping is enabled in a VLAN without configuring the trust interface, the DHCP packets received from the DHCP server in this VLAN will be dropped.

Step 3 (Optional) Configure the DHCP snooping binding file and the delay timer for writing the DHCP snooping entries from memory to the binding file.

set protocols dhcp snooping binding file <*file-path*>
set protocols dhcp snooping binding write-delay <*write-delay-timer*>

Step 4 (Optional) Configure the DHCP snooping Option 82 policy and the sub-options.

set protocols dhcp snooping vlan <*vlan-id*> **option82-policy** <**drop | keep | insert | replace**>

set protocols dhcp snooping option82 circuit-id <**port-index | port-name | port-description**>

set protocols dhcp snooping option82 remote-id <**system-mac | hostname**>

Step 5 (Optional) Enable Option 82 trust-all function for DHCP snooping.

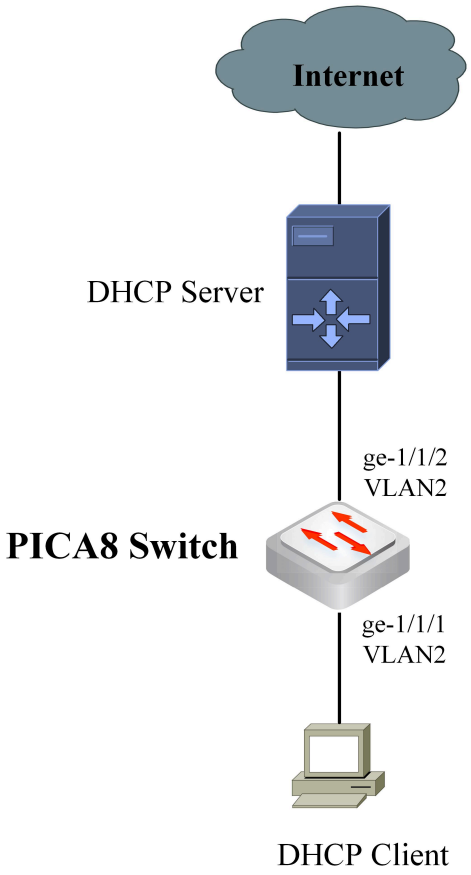
set protocols dhcp snooping option82 trust-all <**true | false**>

Configuration example

Networking Requirements

- On PICA8 Switch, the interfaces ge-1/1/1 and ge-1/1/2 are in VLAN 2.
- Enable DHCP snooping on VLAN 2.
- Configure the interface connected to the DHCP server (ge-1/1/2) as the DHCP snooping trust interface.

Figure 1 DHCP Snooping Networks



Procedure

Step 1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
```

Step 2 Configure DHCP snooping on VLAN 2.

```
admin@XorPlus#set protocols dhcp snooping vlan 2 disable false
```

Step 3 Configure the interface connected to the DHCP server as DHCP snooping trusted interface.

```
admin@XorPlus# set protocols dhcp snooping trust-port ge-1/1/2
```

Step 4 (Optional) Configure /tmp/run/dhcp_bind as the DHCP snooping binding file and the value of delay timer for writing the DHCP snooping entries from memory to the binding file is 30s.

```
admin@XorPlus# set protocols dhcp snooping binding file /tmp/run/dhcp_bind
admin@XorPlus# set protocols dhcp snooping binding write-delay 30
```

Step 5 Commit the configuration.

```
admin@XorPlus# commit
```

Step 6 Verify the configuration.

- After the configuration is complete, run the **run show dhcp snooping** command to view the DHCP snooping binding table.

```
admin@Xorplus# run show dhcp snooping binding
Total count:     1
MAC Address         IP Address     Port            VLAN ID   Lease(sec)
-------------------------------------------------------------------------------------------------
14:18:77:18:2c:b9   100.1.1.1      ge-1/1/1        2         599/600
```

- DHCP client can obtain the IP address normally.

Configuring DHCPv6 Snooping (IPv6)

DHCPv6 snooping creates a binding table, which includes the client IP address, MAC address, VLAN ID, physical port and the lease time. DHCPv6 snooping is disabled by default. The steps below explain how to enable DHCPv6 snooping and configure the trust port (by default all the ports are untrusted ports), DHCPv6 snooping binding file and the delay timer for writing the DHCPv6 snooping entries from memory to the binding file, and how to configure DHCPv6 snooping Option policy.

Procedure

Step 1 Configure DHCPv6 snooping on a VLAN.

set protocols dhcp6 snooping vlan <*vlan-id*> **disable** <**true** | **false**>

NOTE：

- DHCPv6 relay and DHCPv6 snooping cannot be configured on the same VLAN.
- DHCPv6 snooping should be enabled in the VLAN, it takes effect only on DHCPv6 messages received from interfaces in this VLAN. Packets that are not received from this VLAN won't be processed by DHCPv6 snooping module and will be processed and forwarded as ordinary packets.

Step 2 Configure the interface connected to the DHCP server as DHCPv6 snooping trusted interface.

set protocols dhcp6 snooping trust-port <*interface-name*>

NOTE：

- The port can be either physical port or aggregated port.
- By default, all the ports are untrusted ports.
- When DHCPv6 snooping is enabled in a VLAN without configuring the trust interface, the DHCPv6 packets received from the DHCP server in this VLAN will be dropped.

Step 3 (Optional) Configure the DHCPv6 snooping binding file and the delay timer for writing the DHCPv6 snooping entries from memory to the binding file. For non-X86 devices, the path of the binding file is **/mnt/open/dhcp6_bind**; for X86 devices, the binding file path should not be under **/tmp**.

set protocols dhcp6 snooping binding file <*file-path*>
set protocols dhcp6 snooping binding write-delay <*write-delay-timer*>

Step 4 (Optional) Configure the DHCPv6 snooping Option policy and the sub-options.

set protocols dhcp6 snooping vlan <*vlan-id*> **option-policy** <**drop | keep | insert | replace**>

set protocols dhcp6 snooping option18 interface-id <port-index | port-name | port-description>

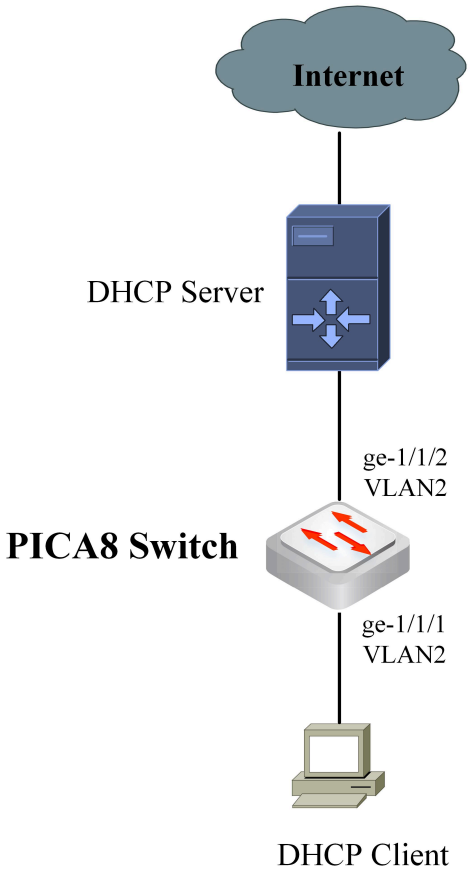
set protocols dhcp6 snooping option37 remote-id <*remote-id*>

Configuration example

Networking Requirements

- On PICA8 Switch, the interfaces ge-1/1/1 and ge-1/1/2 are in VLAN 2.
- Enable DHCPv6 snooping on VLAN 2.
- Configure the interface connected to the DHCP server (ge-1/1/2) as the DHCPv6 snooping trust interface.

Figure 1 DHCPv6 Snooping Networks



Procedure

Step 1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
```

Step 2 Configure DHCPv6 snooping on VLAN 2.

```
admin@XorPlus#set protocols dhcp6 snooping vlan 2 disable false
```

Step 3 Configure the interface connected to the DHCP server as DHCPv6 snooping trusted interface.

```
admin@XorPlus# set protocols dhcp6 snooping trust-port ge-1/1/2
```

Step 4 (Optional) Configure /tmp/run/dhcpv6_bind as the DHCPv6 snooping binding file and the value of delay timer for writing the DHCPv6 snooping entries from memory to the binding file is 30s.

```
admin@XorPlus# set protocols dhcp6 snooping binding file /mnt/open/dhcp6_bind
admin@XorPlus# set protocols dhcp6 snooping binding write-delay 30
```

Step 5 Commit the configuration.

```
admin@XorPlus# commit
```

Step 6 Verify the configuration.

- After the configuration is complete, run the **run show dhcp6 snooping binding** command to view the DHCPv6 snooping binding table.

```
admin@Xorplus# run show dhcp6 snooping binding
Total count:     1
MAC Address         IPv6 Address     Port            VLAN ID   Lease(sec)
-------------------------------------------------------------------------------------------------
14:18:77:18:2c:b9   100::1:1:1       ge-1/1/1        2         599/600
```

- DHCPv6 client can obtain the IPv6 address normally.

Typical Configuration Example for DHCP Relay and DHCP Snooping

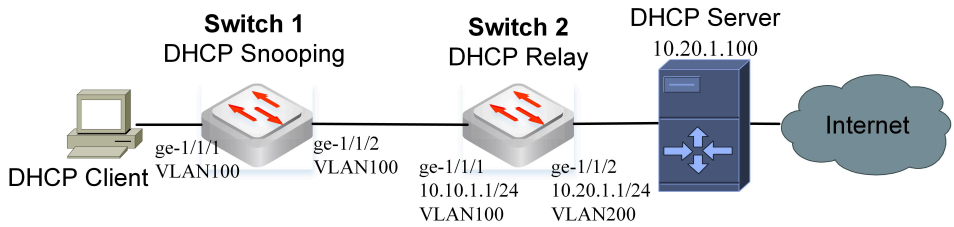
- Networking Requirements
- Procedure
  - Switch 1
  - Switch 2
- Verify the Configuration

Networking Requirements

As shown in figure 5, Switch 1 is a Layer 2 device and Switch 2 is the gateway that acts as a DHCP relay agent to forward DHCP packets between DHCP client and DHCP server, allowing the DHCP client to get configuration parameters such as IP address from the DHCP server.

In order to provide better service to DHCP clients, network administrator can configure DHCP snooping feature on Switch 1 to implement DHCP attack prevention.

Figure 1 User Topology of DHCP Snooping and DHCP Relay



Configure the DHCP Snooping and DHCP Relay by completing the following tasks on each Switch 1 and Switch 2:

- Switch 1 is a Layer 2 device, the interfaces ge-1/1/1 and ge-1/1/2 belong to VLAN 100.
- On Switch 1, enable DHCP snooping in VLAN 100 and configure the interface ge-1/1/2 as the DHCP snooping trust interface.
- On Switch 2, ge-1/1/1 interface belongs to VLAN 100, the IP address of the associated L3 VLAN interface is 10.10.1.1/24; ge-1/1/2 interface belongs to VLAN 200, the IP address of the associated L3 VLAN interface is 10.20.1.1/24.
- Enable DHCP relay on Switch 2 on the L3 VLAN interface VLAN100.
- DHCP server and DHCP relay agent are in the same subnet. The IP address of the DHCP server is 10.20.1.100.

Procedure

Switch 1

Step 1 Configure the VLANs.

```
admin@Switch1# set vlans vlan-id 100
admin@Switch1# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 100
admin@Switch1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 100
```

Step 2 Enable DHCP snooping on VLAN 100.

```
admin@Switch1#set protocols dhcp snooping vlan 100 disable false
```

NOTE:

The DHCP snooping function is only practicable to the clients directly connected to the local L2 domain, rather than connected through a router.

Step 3 Configure the interface ge-1/1/2 as DHCP snooping trust interface.

```
admin@Switch1# set protocols dhcp snooping trust-port ge-1/1/2
```

Step 4 Commit the configuration.

```
admin@Switch1# commit
```

Switch 2

Step 1 Configure the VLANs.

```
admin@Switch2# set vlans vlan-id 100
```

```
admin@Switch2# set vlans vlan-id 200
admin@Switch2# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 100
admin@Switch2# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 200
admin@Switch2# set vlans vlan-id 100 l3-interface VLAN100
admin@Switch2# set vlans vlan-id 200 l3-interface VLAN200
admin@Switch2# set l3-interface vlan-interface VLAN100 address 10.10.1.1 prefix-length 24
admin@Switch2# set l3-interface vlan-interface VLAN200 address 10.20.1.1 prefix-length 24
```

Step 2 Enable IP routing function when using DHCP relay.

```
admin@Switch2# set ip routing enable true
```

Step 3 Enable DHCP relay on the L3 VLAN interface VLAN100.

```
admin@Switch2#set protocols dhcp relay interface VLAN100 disable false
```

Step 4 Configure the IP address for the DHCP server.

```
admin@Switch2#set protocols dhcp relay interface VLAN100 dhcp-server-address 10.20.1.100
```

Step 5 Commit the configuration.

```
admin@Switch2# commit
```

Verify the Configuration

- After the configuration is complete, run the **run show dhcp snooping** command on Switch1 to view the information of DHCP snooping binding table.

```
admin@Switch1# run show dhcp snooping binding
Total count:     1
MAC Address         IP Address     Port           VLAN ID   Lease(sec)
-------------------------------------------------------------------------------------------------------
E3:44:56:a2:00:2c   10.10.1.12     ge-1/1/1        100     60/600
```

The format of lease time for the IP address is **Remaining Lease Time/Total Lease Time**.

- DHCP client can obtain the IP address normally.

DHCPv6 Guard Configuration

- Overview of DHCPv6 Guard
- Configuring DHCPv6 Guard
- Example for Configuring DHCPv6 Guard

Overview of DHCPv6 Guard

DHCPv6 Guard is a security mechanism used to protect the DHCPv6 environment from malicious DHCPv6 servers or intermediate devices that adversely affect DHCPv6 clients. It ensures the security and reliability of DHCPv6 services by detecting and blocking unauthorized DHCPv6 traffic.

DHCPv6 Guard works in the following ways:

- Flow measurement: Monitor DHCPv6 traffic on the network, including communication between DHCPv6 servers and clients.
- Authorization verification: Check whether the DHCPv6 traffic is sent from an authorized DHCPv6 server. You can check the source address, the DUID (DHCPv6 Unique Identifier), or other relevant fields of the DHCPv6 message.
- Blocking traffic: If traffic is detected from an unauthorized DHCPv6 server, DHCPv6 Guard blocks it to ensure that the DHCPv6 client does not receive configuration information.

Characteristics

Terminologies

Functional Procedure

- IPv6 Address/Prefix Assignment Process
- Matching Rules for DHCPv6 Guard

Characteristics

- Security: By blocking unauthorized DHCPv6 traffic, DHCPv6 Guard improves the security of DHCPv6 environment and reduces potential security risks.
- Reliability: DHCPv6 Guard improves the reliability of the DHCPv6 service by ensuring that DHCPv6 clients receive configuration information only from authorized DHCPv6 servers.
- Flexibility: DHCPv6 Guard can be configured according to the network environment and security requirements to adapt to different application scenarios

Terminologies

- **Policy**

"Policy" usually refers to a set of rules defined by a network administrator to control and manage how to handle DHCPv6 traffic on the network through DHCPv6 Guard. These policies determine which DHCPv6 servers are considered legitimate while blocking illegal or unauthorized DHCPv6 server activities.

- **IA-Prefix**

“IA-Prefix” is one of the Identity Association (IA) types in DHCPv6 and is used for prefix delegation. Prefix delegation allows a DHCPv6 client to request one or more IPv6 prefixes from a DHCPv6 server to assign IPv6 addresses with these prefixes on the client's subnet.

IA-Prefix Unique Identity Association Identifier (IAID) is an identifier used to distinguish different IAs, generated by the client and sent to the server in a DHCPv6 message. In addition to IAID, IA-Prefix includes parameters such as the length of the requested prefix, T1 and T2 times (for prefix renewal and rebinding).

When the DHCPv6 client needs to assign an IPv6 address to its subnet, it sends a DHCPv6 request message to the DHCPv6 server with the IA-Prefix option. After receiving the request, the server assigns one or more IPv6 prefixes to the client based on its configuration and policies, and sends these information to the client in the DHCPv6 reply message. After receiving the prefixes, the client can use these prefixes to assign IPv6 addresses to other devices on its sub-network.

- **Preference**

“Preference” indicates the relative priority of the DHCPv6 server. When a DHCPv6 client selects a DHCPv6 server among multiple servers, it evaluates the preference values. A server with a higher preference value is the preferred choice.

The preference value is usually an integer, and its range can vary from implementation to implementation. In some implementations, a larger number represents a higher priority, while in others the opposite may be true. If the preference value is not explicitly set, the DHCPv6 server may use the default value, which may vary from implementation to implementation.

The working principle is as follows:

When a DHCPv6 client starts, it sends Solicit message to request available DHCPv6 servers. Multiple DHCPv6 servers may respond with an Advertise message containing their configuration information and preference values. The DHCPv6 client selects the server with the highest priority based on their preference value from responding servers. With the server selected, the DHCPv6 client will send a Request message with the IP address and other configuration information. The selected DHCPv6 server responds by sending a Reply message containing the IP address assigned to the client and other configuration parameters.

- **Device-role**

"Device-role" refers to the functional positioning of network devices in DHCPv6 protocol interactions. The DHCPv6 Guard mechanism involves two main device roles:

1. DHCPv6 Server: The DHCPv6 server responds to client address requests and provides IPv6 addresses, prefixes, and other network configuration parameters. In a DHCPv6 Guard environment, legitimate DHCPv6 servers are clearly identified by the network administrator so that the Guard mechanism can distinguish between legitimate servers and potentially malicious servers.
2. DHCPv6 Client: The DHCPv6 client is a device that requests for IPv6 addresses and network configuration information. A client initiates the DHCPv6 process by sending Solicit message and then receives an Advertise or Reply message from a legitimate DHCPv6 server.

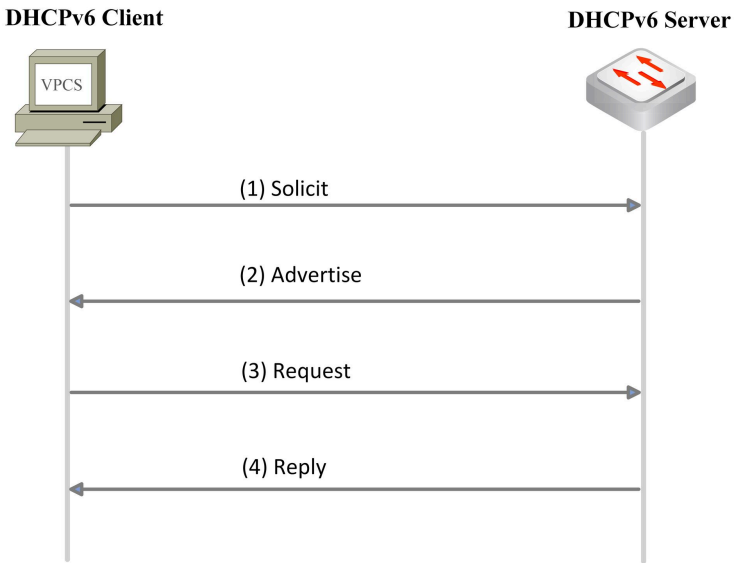
- **Trust-port**

"Trust-port" refers to a port on a network device that is clearly marked to connect to a legitimate DHCPv6 server. If a port is set to Trust-port, all DHCPv6 Advertise and Reply packets received by the port are regarded as legitimate and reliable. The DHCPv6 Guard allows these messages to be forwarded to corresponding clients.

Functional Procedure

IPv6 Address/Prefix Assignment Process

Figure 1. The distribution process of four exchanged messages



The DHCPv6 protocol is used to assign IPv6 addresses to users in a stateful manner, which involves four basic packets, as shown in the figure above.

- Solicit packet: Corresponding to the Discover packet of DHCPv4. The initial request sent by the client to determine the location of the DHCPv6 server. The source port is UDP port 546 and the destination port is 547.

- Advertise packet: Corresponding to the Offer packet of DHCPv4. The response sent by the server declares that it can provide DHCPv6 services and contain an IPv6 address or other configuration information that can be assigned to the client.
- Request packet: Corresponding to the Request packet of DHCPv4. If the client accepts the information provided by the server, it sends this message to request a specific IPv6 address or configuration information.
- Reply packet: Corresponding to the ACK packet of DHCPv4. The final response sent by the server to inform the client that the requested IPv6 address or other configuration information has been assigned.

Matching Rules for DHCPv6 Guard

After receiving DHCPv6 packets, the DHCPv6 Guard processes the packets according to the packet type and port role.

- DHCPv6 request packets: forwarded directly.
- DHCPv6 reply packets: processed according to the port role.

  If the port is trust-port, all packets on the port are directly forwarded.

  If the port role is client, all packets on the port are discarded.

  If the port role is server, the packet will be filtered based on rules.

To ensure the proper functioning of the DHCPv6 Guard feature on network devices, especially when a compliant DHCPv6 server is interfaced, you must designate the device's role within the DHCPv6 Guard policy as a DHCPv6 server. Upon receipt of DHCPv6 response packets, either through a server-bound interface or across a VLAN, the DHCPv6 Guard capability of facilitating packet filtration predicated on these established policies:

- For Advertise messages: The DHCPv6 Guard screens and discards any inappropriate response packets originating from the DHCPv6 server, utilizing Access Control List (ACL) rules for validation. Additionally, responses from the DHCPv6 server that fail to meet predefined priority criteria can also be filtered out.
- For Reply messages: The DHCPv6 Guard filters DHCPv6 Reply packets that contain unauthorized addresses or prefixes through Access Control List (ACL) rules. This ensures that only valid and authorized network configurations are distributed to requesting devices, enhancing network security and stability.

In essence, the DHCPv6 Guard policy implements fine-grained control over DHCPv6 traffic, enabling administrator to maintain a secure and managed network environment by selectively permitting or blocking DHCPv6 packets based on server legitimacy and adherence to configured policies.

The DHCPv6 reply packet can be forwarded to the DHCPv6 client only after passing all DHCPv6 Guard policy checks.

Configuring DHCPv6 Guard

Configuration Notes and Constraints
Procedure

Configuration Notes and Constraints

When configuring DHCPv6 Guard, you should pay attention to the following notes:

- You can configure only one guard policy on an interface. A guard policy can be configured on multiple interfaces.
- By default, the value of device-role is “client”.
- In the guard device-role, if the server and trust-port conflicts with each other, you need to delete one to configure the other.
- If guard device-role is “server”, the default value for preference-min is 0, and preference-max is 255.
- If guard device-role is “client”, all packets in the reply direction are discarded on the port configured with this policy.
- If guard policy is “trust-port”, all DHCPv6 packets on the port configured with the policy are directly forwarded.
- The source-address of matching servers in the guard policy filters only the source address in the Advertise packet but not the source address in the Reply packet.
- DHCPv6 snooping and guard can be placed in the same VLAN. The relay and guard cannot be placed in the same VLAN.
- DHCPv6 Guard does not support the Multi-chassis Link Aggregation Group (MLAG) topology.

Procedure

Step 1 (Optional) Set a matching condition that specifies the source addresses of DHCPv6 servers to matched.

set protocols dhcp6 guard policy <*policy-name*> **match server source-address** <*IPv6Net*>

Step 2 (Optional) The specified IPv6 prefix or network matched by the policy is assigned to the client. The prefix defines the range of IPv6 addresses that can be used by clients.

set protocols dhcp6 guard policy <*policy-name*> **match reply ia-prefix** <*IPv6Net*>

Step 3 (Optional) Set a maximum limit for a preferred value in the DHCPv6 Guard policy to ensure that the DHCPv6 server only considers DHCPv6 responses whose preferred value is lower than or equal to the specified value.

set protocols dhcp6 guard policy <*policy-name*> **preference-max** <*max-value*>

Step 4 (Optional) The minimum limit on the preferred value specified by the user.

set protocols dhcp6 guard policy <*policy-name*> **preference-min** <*min-value*>

Step 5 Configuration options allow different security policies to be defined depending on the source of DHCPv6 messages (server or client), giving more precise control over messages which should be detected, logged, or blocked.

set protocols dhcp6 guard policy <*policy-name*> **device-role** <*server/client*>

Step 6 (Optional) Set a trusted port for DHCPv6 Guard policy to control precisely DHCPv6 messages which should be trusted and processed, limiting trust to messages from a specific port.

set protocols dhcp6 guard policy <*policy-name*> **trust-port**

Step 7 Associate the specified DHCPv6 Guard policy with a specific network interface.

set protocols dhcp6 guard policy <*policy-name*> **interface** <*interface-name*>

Step 8 Commit the configuration.

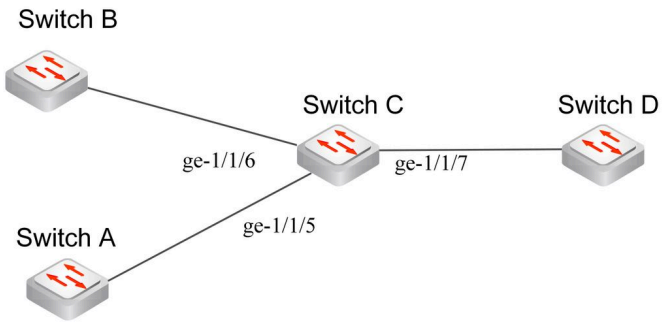
commit

Example for Configuring DHCPv6 Guard

- Network Requirements
- Procedure
- Verifying the Configuration

Network Requirements

Figure 1. DHCPv6 Guard Configuration Example



To maintain the DHCPv6 service properly, the DHCPv6 Guard protocol can be deployed on the device between the DHCPv6 server and the client.

As shown in **Figure 1**, the DHCPv6 Guard is deployed between multiple servers and a single client. You can configure Switch A and Switch B as DHCPv6 servers, configure Switch D as the DHCPv6 client, and configure DHCPv6 guard on Switch C to protect networks from rogue DHCPv6 servers.

Procedure

Switch C

Step 1 Configure policies p1, p2, and p3 on the ports connected to switch A, switch B, and switch D.

```
admin@SwitchC# set protocols dhcp6 guard policy p1 interface ge-1/1/5
admin@SwitchC# set protocols dhcp6 guard policy p2 interface ge-1/1/6
admin@SwitchC# set protocols dhcp6 guard policy p3 interface ge-1/1/7
```

Step 2 Configure a trusted port on the port connected to switch A.

```
admin@SwitchC# set protocols dhcp6 guard policy p1 trust-port
```

Step 3 Configure port roles for the ports that connect to switch B and switch D.

```
admin@SwitchC# set protocols dhcp6 guard policy p2 device-role server
admin@SwitchC# set protocols dhcp6 guard policy p3 device-role client
```

Step 4 Configure multiple filtering policies on the port connected to switch B.

```
admin@SwitchC# set protocols dhcp6 guard policy p2 match server source-address 2001::0/64
admin@SwitchC# set protocols dhcp6 guard policy p2 match reply ia-prefix 2001::0/64
admin@SwitchC# set protocols dhcp6 guard policy p2 preference-max 200
admin@SwitchC# set protocols dhcp6 guard policy p2 preference-min 100
```

Step 5 Commit the configuration.

```
admin@SwitchC# commit
```

Verifying the Configuration

The command **run show dhcp6 guard** can be used to check the configuration information of the DHCPv6 Guard.

```
admin@SwitchC# run show dhcp6 guard
dhcp6 guard policy: p1
  trust Port
  interface: ge-1/1/5
dhcp6 guard policy: p2
  match: server
    source-address: 2001::1/128
      reply ia-prefix: 3001::0/64
  preference-max: 200
  preference-min: 100
  device role: server
  interface: ge-1/1/6
dhcp6 guard policy: p3
  device role: client
  interface: ge-1/1/7
```

As shown in the command output:

- policy p1 is set as a trusted port and applied to port ge-1/1/5.
- Policy p2 checks the packets from the server and allows the packets whose source address is 2001::0/64 to pass and the IA reply packets whose prefix is 2001::0/64 to pass.
- The maximum value of the priority is 200 and the minimum value is 100.
- The role of the port is “server”, which is applicable to port ge-1/1/6.
- Policy p3 defines the port role as client and applies it to port ge-1/1/7.

RFC Lists

The following table lists the RFC documents related to DHCP snooping and DHCP relay.

RFC	Description
RFC 3046	DHCP Relay Agent Information Option
RFC2131	Dynamic Host Configuration Protocol
RFC2132	DHCP Options and BOOTP Vendor Extensions
RFC1534	Interoperation Between DHCP and BOOTP

Default Administrative Distance Values

Select the Best Path

A PicOS system can run multiple routing protocols simultaneously. For example, RIP may be used to distribute routes within our network and BGP to learn external routes. In some situations this can lead to a router learning the same route from more than one routing protocol.

For example, these two routes might be learned:
• Subnet: 128.16.64.0/24, nexthop: 192.150.187.1, learned from BGP via an external peering. AS Path: 123 567 987.
• Subnet: 128.16.64.0/24, nexthop: 10.0.0.2, learned from RIP with metric 13

The longest prefix match rule doesn't help us because the prefix lengths are the same, and the metric used for RIP is not directly comparable against the AS path length or any other attribute attached to a BGP route. So, how do we decide which route to take? A PicOS system uses the concept of administrative distance to determine which route wins. Basically, each routing protocol has a configured "distance," and if a route is heard from two protocols, then the version with the smallest distance wins.

Default Distance Value Table

This table lists the administrative distance default values of the protocols that PicOS supports:

Route Protocol	Default Distance Values
Directly connected	0
Static route	1
External BGP	20
OSPF	110
RIP	120
Internal BGP	200

Hence, in the example above, the route learned from BGP will be preferred.

> ⚠ The administrative distance is fixed in the PicOS system, and cannot be modified.

OSPF (Open Shortest Path First)

OSPF (Open Shortest Path First) is a link-state routing protocol that is not proprietary to any vendor or organization. OSPF was developed by IETF (Internet Engineering Task Force), and it is the IGP (Interior Gateway Protocol) recommended by Pica8.

OSPF has evolved through several RFCs. OSPF version 2, which is the current version for IPv4, is defined in RFC 2328. PicOS supports version 2 of the OSPF protocol in L2/L3 mode.

Pica8 PicOS Version 2.6 supports the following OSPF area types:

1. Normal Area
2. Stub Area
3. NSSA (Not-So-Stubby Area)

> **NOTE:**
> Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.

- OSPF GR

OSPF Overview

> **NOTE:**
> Both OSPFv2 and OSPFv3 protocol support VRF.

The high-level operation of OSPF is explained below:

1. OSPF routers send Hello packets out of all OSPF-enabled interfaces. Two routers sharing a common data link become *neighbors.* If they agree on certain parameters in Hello packets.
2. Some neighbors move on and form *adjacencies*, which can be thought of as virtual point-to-point links over which routing information is exchanged.
3. Each OSPF router sends LSAs (link-state advertisements) over all its adjacencies. The LSAs describe the router's neighbors, links, and the state of the links. OSPF defines multiple LSA types to communicate different types of link-state information.
4. When an OSPF router receives an LSA from a neighbor, it adds the LSA to its link-state database. The router also sends a copy of the LSA over all of its adjacencies. The flooding of LSAs throughout an OSPF area enables all routers to have identical link-state databases.
5. When the link-state databases are built, every router runs the Dijkstra's SPF (Shortest Path First) algorithm to calculate the shortest loop-free path to every known subnet. The collection of all paths calculated by the router, with itself as the root, is known as the SPF tree.
6. Each router populates its routing table from its SPF tree.

Basic OSPF Configuration Tasks

To configure OSPF on a PicOS device, complete the tasks described in the following sections.

Configuring OSPF Router ID

The OSPF router ID is a 32-bit value similar to an IP address by which the OSPF router or switch is uniquely identified within the OSPF domain.

Use the following command to configure OSPF router ID:

set protocols ospf router-id *<router-id>*

The following example configures 1.1.1.1 as the OSPF router ID:

```
admin@XorPlus# set protocols ospf router-id 1.1.1.1
admin@XorPlus# commit
Commit OK.
Save done.
```

Do not change the router ID after completing the configuration.

Configuring OSPF Areas

Divide an OSPF domain into areas, which contains the flow of most routing protocol traffic within a single area and reduces the impact of protocol on CPU and memory.

Use the following command to configure OSPF areas:

set protocols ospf area *<area-id>* **area-type** *<type>*

Area ID 0.0.0.0 is reserved for the backbone and each OSPF domain must have the backbone area. All traffic between two non-backbone areas must pass through the backbone area. OSPF area types supported by PicOS are: normal, stub, and NSSA. A normal or standard area in OSPF is one that is configured neither as Stub nor NSSA.

The example that follows demonstrates configuration of three different areas:

Area ID	Area Type
0.0.0.0	Normal
1.1.1.1	Stub
2.2.2.2	NSSA

```
admin@XorPlus# set protocols ospf area 0.0.0.0
admin@XorPlus# set protocols ospf area 1.1.1.1 area-type stub
admin@XorPlus# set protocols ospf area 2.2.2.2 area-type nssa
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring OSPF Interfaces

After configuring OSPF areas, assign a switch interface to the area. Once an interface is assigned to an OSPF area, it will start sending OSPF hello messages.

Use the following command to assign a Layer 3 interface to an OSPF area, where the Layer 3 interface can be the VLAN interface, loopback interface, routed interface or sub-interface:

set protocol ospf interface *<interface-name>* **area {***<ipv4>|<0-4294967295>***}**

The following commands create Layer 3 VLAN interfaces vlan20 and vlan30. The interfaces are given IP addresses and switch ports are assigned to them. Finally, both interfaces are configured to be in the OSPF backbone area according to the table shown below.

VLAN Interface	IP Address / Mask Length	Assigned Switch Interface(s)	OSPF Area
vlan20	10.10.70.10 / 24	ge-1/1/1	0.0.0.0
vlan30	10.10.71.10 / 24	ge-1/1/2	0.0.0.0

```
admin@XorPlus# set vlans vlan-id 20 l3-interface vlan20
admin@XorPlus# set vlans vlan-id 30 l3-interface vlan30
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 30
admin@XorPlus# set l3-interface vlan-interface vlan20 address 10.10.70.10 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan30 address 10.10.71.10 prefix-length 24
admin@XorPlus# set protocols ospf interface vlan20 area 0.0.0.0
```

```
admin@XorPlus# set protocols ospf interface vlan30 area 0.0.0.0
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Additional OSPF Parameters

Fine-tune OSPF operation by configuring additional OSPF interface parameters including hello interval, interface cost, passive interface, BFD, router dead interval, MD5 authentication and MD5 key.

The following example demonstrates how to configure some of the OSPF interface parameters:

```
admin@XorPlus# set protocols ospf interface vlan20 hello-interval 5
admin@XorPlus# set protocols ospf interface vlan20 cost 8
admin@XorPlus# set protocols ospf interface vlan20 dead-interval 120
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring OSPF Route Summarization

In large scale OSPF networks, configuring route summarization can effectively reduce the size of routing table and free up system resources while maintaining system performance. In addition, if a link within the aggregated IP address range frequently goes up and down, the change will not be notified to the upstream devices. OSPF is a CPU intensive protocol especially in large deployments. Constant route flapping can impact the performance of a router significantly. Route summarization will shield all the upstream routers from constantly processing and updating routing information caused by route flapping.

Configuring ABR Route Summarization

The following commands can be used to configure OSPF route summarization.

set protocols ospf [instance-id <*instance-id***> | vrf** <*vrf-name*>**] area {**<*ipv4*>|<*area-id*>**} range** <*prefix/mask*> [**advertise** <**true | false**> **| cost** <*cost*> **| substitute** <*prefix/mask*>]

set protocols ospf6 [vrf <*vrf-name*>**] area {**<*ipv4*>|<*area-id*>**} range** <*prefix/mask*> [**advertise** <**true | false**> **| cost** <*cost*>]

Route summarization is configured on ABRs. Since ABRs share routing LSAs with other regions, if there are large number of destinations in an area, flooding all this information individually using separate LSA for each destination can easily overwhelm routers processing these LSAs. Instead, we can specify a range of routing subnets to be summarized or grouped into a single segment and shared with other regions. This can save both router processing cycles and also minimize the size of the routing table on routers receiving the summary LSAs.

The following commands configure route summarization in OSPF area 1.

```
admin@Xorplus# set protocols ospf area 1 range 10.42.0.0/16
admin@Xorplus# commit
```

Configuring ASBR Route Summarization

When the imported routes have the same routing prefix, you can aggregate these introduced routes and publish them as one aggregated route by using the ASBR route summarization. By configuring route summarization, you can reduce the routing information and the size of the routing table to improve the performance of the device.

The following commands can be used to configure ASBR route summarization.

set protocols ospf [vrf <*vrf-name*>] **summary-address** <*prefix/mask*> **[no-advertise | tag** <*tag-value*>**]**

set protocols ospf [vrf <*vrf-name*>**] aggregation timer** <*aggregation-timer*>

The following commands configure OSPF route summarization for ASBR.

```
admin@Xorplus# set protocols ospf summary-address 10.2.0.0/16 tag 2
admin@Xorplus# set protocols ospf aggregation timer 100
admin@Xorplus# commit
```

You can use the command **run show ospf summary-address** to show the configuration for display all configured summary routes with matching external LSA information.

```
admin@Xorplus# run show ospf summary-address
Summary-address     Metric-type     Metric     Tag       External_Rt_count
aggregation delay interval :100(in seconds)
10.2.0.0/16           E2              20        2        0
```

Basic OSPF Configuration Example

Open Shortest Path First (OSPF) is a widely used routing protocol based on the Dijkstra's Shortest Path First algorithm that determines the shortest path for packets to reach a destination. This is opposed to the older Routing Information Protocol (RIP) in which best path is based on the fewest number of “hops” to the destination, meaning that a path in which the packet would have to traverse the fewest number of routers is considered the best one. OSPF is an interior gateway protocol (IGP) intended for use in a single routing domain, or autonomous system (AS). It is a dynamic routing protocol that, like RIP, changes routing tables whenever the network topology changes. It determines the shortest path through a network based on the “cost” of the route, meaning it considers the amount of available bandwidth, delay and load on different network segments. This document describes an example of basic OSPF configuration for PICOS-based switches.

Fig.5-3 presents an example topology for configuring OSPF routing. There are two areas configured in this network, Router 1 has two interfaces both in area 1 whereas Router 2 and 3 have two interfaces each, with one interface each in area 0 and area1.

After OSPF is configured on the four routers, the routers will send LSAs to each and hence will have routes to all the subnets in the network. Router1 will have routes to all the connected subnets of Router2, Router3 and Router4. Similarly, all the other routers will have access to all the other subnets configured for OSPF. The detailed configuration of each router is shown below.

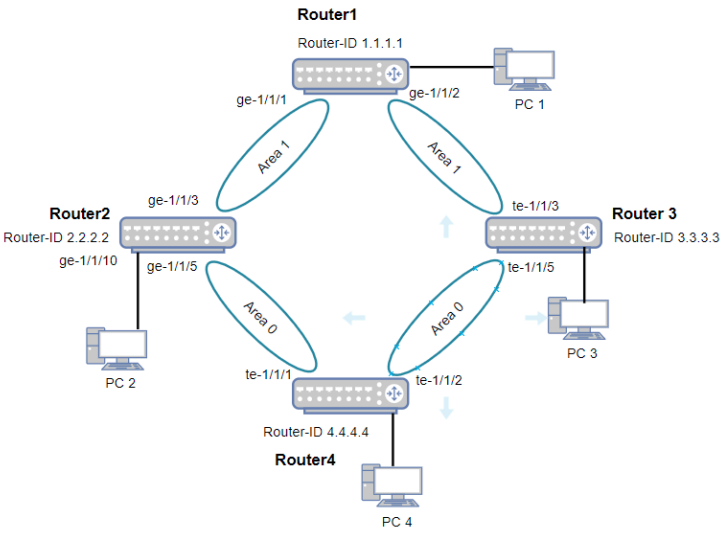

Figure 5-3 Basic OSPF Configuration

Configuring Router 1

Configure 2 VLAN interfaces for networks 10.1.1.0/24 and 20.1.1.0/24. There is only one area configured on Router 1, area 1 which include networks 10.1.1.0/24 and 20.1.1.0/24.

```
admin@router1# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@router1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@router1# set protocols ospf router-id 1.1.1.1
admin@router1# set protocols ospf network 10.1.1.0/24 area 1
admin@router1# set protocols ospf network 20.1.1.0/24 area 1
admin@router1# set protocols ospf network 1.1.1.1/32 area 1
admin@router1# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
admin@router1# set l3-interface vlan-interface vlan10 address 10.1.1.1 prefix-length 24
admin@router1# set l3-interface vlan-interface vlan20 address 20.1.1.1 prefix-length 24
admin@router1# set vlans vlan-id 10 l3-interface "vlan10"
admin@router1# set vlans vlan-id 20 l3-interface "vlan20"
```

Configuring Route 2

On Router 2, we will configure the router ID as 1.1.1.1 and configure two VLAN interfaces. For 10.1.1.1.0/24 we will configure interface vlan10 in area 1 and for network 30.1.1.0/24 we will configure interface vlan30 in area 0.

```
admin@router2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 10
admin@router2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching native-vlan-id 30
admin@router2# set protocols ospf router-id 2.2.2.2
admin@router2# set protocols ospf network 10.1.1.0/24 area 1
admin@router2# set protocols ospf network 30.1.1.0/24 area 0
admin@router2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@router2# set l3-interface vlan-interface vlan10 address 10.1.1.2 prefix-length 24
```

```
admin@router2# set l3-interface vlan-interface vlan30 address 30.1.1.1 prefix-length 24
admin@router2# set vlans vlan-id 10 l3-interface "vlan10"
admin@router2# set vlans vlan-id 30 l3-interface "vlan30"
```

Configuring Router 3

On Router 3 we will configure the router ID as 3.3.3.3 and two VLAN interfaces. Interface vlan10 for network 10.1.1.0/24 is added to area 1 and VLAN interface vlan30 for network 30.1.1.0/24 is added to area 0.

```
admin@router3# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 20
admin@router3# set interface gigabit-ethernet te-1/1/3 auto-speeds 1000
admin@router3# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 40
admin@router3# set interface gigabit-ethernet te-1/1/5 auto-speeds 1000
admin@router3# set protocols spanning-tree enable false
admin@router3# set protocols ospf router-id 3.3.3.3
admin@router3# set protocols ospf network 20.1.1.0/24 area 1
admin@router3# set protocols ospf network 40.1.1.0/24 area 0
admin@router3# set l3-interface vlan-interface vlan20 address 20.1.1.2 prefix-length 24
admin@router3# set l3-interface vlan-interface vlan40 address 40.1.1.1 prefix-length 24
admin@router3# set vlans vlan-id 20 l3-interface "vlan20"
admin@router3# set vlans vlan-id 40 l3-interface "vlan40"
admin@router3# commit
Commit OK.
Save done.
```

Configuring Router 4

The router ID on Router 4 is configured as 4.4.4.4 and two VLAN interfaces both of which are in area 0. VLAN interface vlan30 for network 30.1.1.0/24 is in area 0 and VLAN interface vlan40 for network 40.1.1.0/24 also belonging to area 0.

```
admin@router4# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 30
admin@router4# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 40
admin@router4# set protocols ospf router-id 4.4.4.4
admin@router4# set protocols ospf network 30.1.1.0/24 area 0
admin@router4# set protocols ospf network 40.1.1.0/24 area 0
admin@router4# set protocols ospf network 4.4.4.4/32 area 0
admin@router4# set protocols ospf redistribute static
admin@router4# set l3-interface loopback lo address 4.4.4.4 prefix-length 32
admin@router4# set l3-interface vlan-interface vlan30 address 30.1.1.2 prefix-length 24
admin@router4# set l3-interface vlan-interface vlan40 address 40.1.1.2 prefix-length 24
admin@router4# set vlans vlan-id 40 l3-interface vlan40
admin@router4# set vlans vlan-id 30 l3-interface vlan30
Commit OK.
Save done.
```

Verifying the OSPF configuration

We can verify the OSPF configuration of a switch by checking its OSPF neighbors by running the command **run show ospf neighbor.**
Below is the command output on Router 1. As we can see Router 1 has established neighbor relationship with Router 2 (router ID 2.2.2.2) and Router 3 (router ID 3.3.3.3).

```
admin@router1# run show ospf neighbor
Neighbor ID     Pri State           Dead Time Address         Interface                       RXmtL RqstL DBsmL
2.2.2.2           1 Full/DR           35.852s 10.1.1.2        vlan.2:10.1.1.1                     0     0     0
3.3.3.3           1 Full/DR           31.187s 20.1.1.2        vlan.3:20.1.1.1                     0     0     0
```

Now check the OSPF database on Router 1 by running the command **run show ospf database.**

```
admin@router1# run show ospf database
OSPF Router with ID (1.1.1.1)

```

OSPF Area Type Configuration Example: NSSA, Stub and Standard Areas

In OSPF terminology, a stub is an area in which external routes are not advertised. To reach external networks, a default summary route 0.0.0.0 is installed in the stub area to achieve connectivity with other areas. In the OSPF not-so-stubby-area (NSSA), the restriction on advertising external routes in the NSSA area is removed but in a limited fashion.

Configuration Example

Figure 5-4 depicts a sample OSPF topology with three different types of areas, the Standard, NSSA and the stub areas.

The configuration of OSPF NSSA and stub areas is shown in Fig. 5-4. Router 2 connects to the backbone area (area 0) through Router 4. This area between Switch 4 and Switch 3 is configured as the not-so-stubby-area (NSSA). Similarly, Router 1 connects with the backbone area through Router 2. Both Router 4 and Router 2 have one interface each in area 0. Router 3 will receive routes for network 10.10.4.0/24, 10.10.3.0/24, 10.10.2.0/24 and 10.10.1.0/24. Similarly, Router 1 will receive routes from network 10.10.3.0/24, 10.10.4.0/24, 10.10.5.0/24 and 10.10.6.0/24.

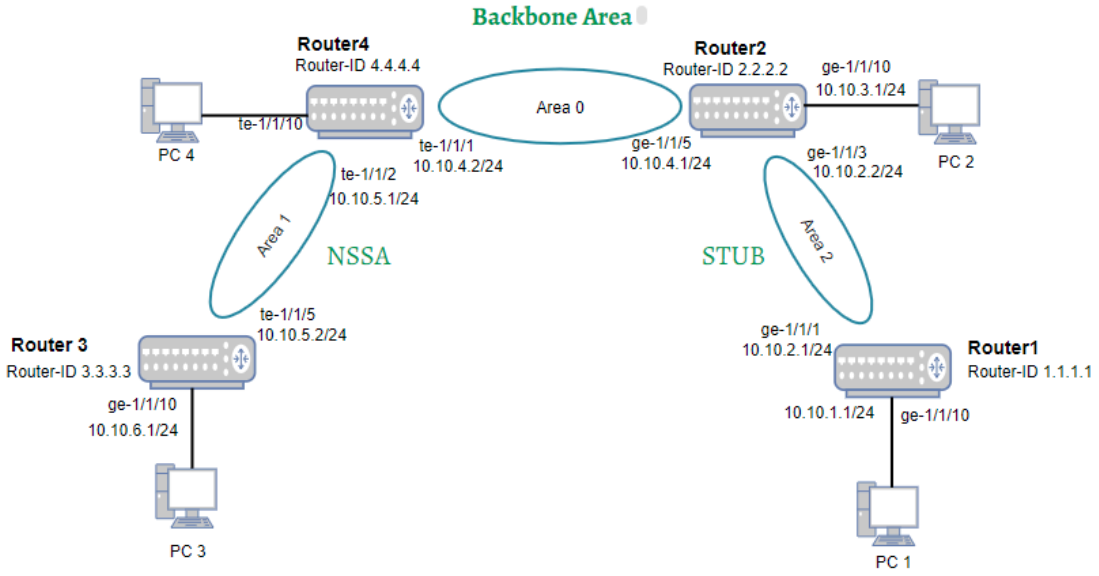

Figure 5-4. OSPF NSSA and Stub area configurations.

Configuring Router 1

On Router 1, we will configure one VLAN interface for network 10.10.2.1/24. Also we will configure OSPF area 0.0.0.2 and include network 10.10.2.1/24 in area 2.

```
admin@router1# set vlans vlan-id 10 l3-interface vlan10
admin@router1# set vlans vlan-id 20 l3-interface vlan20
admin@router1# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@router1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@router1# set protocols ospf router-id 1.1.1.1
admin@router1# set protocols ospf network 10.10.2.0/24 area 0.0.0.2
admin@router1# set protocols ospf network 1.1.1.1/32 area 0.0.0.2
admin@router1# set protocols ospf area 2 area-type stub
admin@router1# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
admin@router1# set l3-interface vlan-interface vlan10 address 10.10.2.1 prefix-length 24
admin@router1# set l3-interface vlan-interface vlan20 address 10.10.1.1 prefix-length 24
Commit OK.
Save done.
admin@router1#
```

Configuring Router 2

Router 2 has to VLAN interfaces, one in area 0.0.0.2 and another in area 0.0.0.0. We will configure these interfaces for network 10.10.2.0/24 and 10.10.4.0/24 in the configuration shown below.

```
admin@router2# set vlans vlan-id 30 l3-interface "vlan30"
admin@router2# set vlans vlan-id 40 l3-interface "vlan40"
admin@router2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@router2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching native-vlan-id 40
admin@router2# set protocols ospf router-id 2.2.2.2
```

```
admin@router2# set protocols ospf network 10.10.2.0/24 area 0.0.0.2
admin@router2# set protocols ospf network 10.10.4.0/24 area 0.0.0.0
admin@router2# set protocols ospf area 0.0.0.2 area-type stub
admin@router2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@router2# set l3-interface vlan-interface vlan30 address 10.10.2.2 prefix-length 24
admin@router2# set l3-interface vlan-interface vlan40 address 10.10.4.1 prefix-length 24
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Router 3

On Router 3 we will configure one OSPF interface in area 0.0.0.1.

```
admin@router3# set vlans vlan-id 50 l3-interface vlan50
admin@router3# set l3-interface vlan-interface vlan50 address 10.10.5.2 prefix-length 24
admin@router3# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 50
admin@router3# set interface gigabit-ethernet te-1/1/5 auto-speeds 1000
admin@router3# set protocols spanning-tree enable false
admin@router3# set protocols ospf router-id 3.3.3.3
admin@router3# set protocols ospf network 10.10.5.0/24 area 0.0.0.1
admin@router3# set protocols ospf area 0.0.0.1 area-type nssa
admin@router3# commit
Commit OK.
Save done.
```

Configuring Router 4

On Router 4 we will configure two network interfaces one each in area 0.0.0.0 and 0.0.0.1. Router 4 connects with Router 3 in area 0.0.0.1 and Router 2 in area 0.0.0.0.

```
admin@router4# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 40
admin@router4# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 50
admin@router4# set protocols ospf router-id 4.4.4.4
admin@router4# set protocols ospf network 10.10.4.0/24 area 0.0.0.0
admin@router4# set protocols ospf network 10.10.5.0/24 area 0.0.0.1
admin@router4# set protocols ospf area 0.0.0.1 area-type nssa
admin@router4# set protocols ospf network 4.4.4.4/32 area 0
admin@router4# set protocols ospf redistribute static
admin@router4# set l3-interface loopback lo address 4.4.4.4 prefix-length 32
admin@router4# set l3-interface vlan-interface vlan40 address 10.10.4.2 prefix-length 24
admin@router4# set l3-interface vlan-interface vlan50 address 10.10.5.1 prefix-length 24
admin@router4# set vlans vlan-id 40 l3-interface "vlan40"
admin@router4# set vlans vlan-id 50 l3-interface "vlan50"
Commit OK.
Save done.
```

Verify Routing Table

The routing table on Router 1 is displayed below.

```
admin@router1> show route ipv4
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

O   0.0.0.0/0 [110/11] via 10.10.2.2, vlan10, weight 1, 00:08:11
K>* 0.0.0.0/0 [0/0] via 10.10.51.1, eth0, 02:35:35
O   1.1.1.1/32 [110/0] is directly connected, lo, weight 1, 02:16:35
C>* 1.1.1.1/32 is directly connected, lo, 02:16:35
O>* 4.4.4.4/32 [110/20] via 10.10.2.2, vlan10, weight 1, 00:06:55
O   10.10.2.0/24 [110/10] is directly connected, vlan10, weight 1, 00:46:21
C>* 10.10.2.0/24 is directly connected, vlan10, 00:47:01
O>* 10.10.4.0/24 [110/20] via 10.10.2.2, vlan10, weight 1, 00:07:05
O>* 10.10.5.0/24 [110/30] via 10.10.2.2, vlan10, weight 1, 00:02:25
```

The routing table on Router 3 is displayed below.

```
admin@router3> show route ipv4
Codes: K - kernel route, C - connected, S - static, R - RIP,
```

```
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

O   0.0.0.0/0 [110/11] via 10.10.5.1, vlan50, weight 1, 00:16:09
O>* 1.1.1.1/32 [110/30] via 10.10.5.1, vlan50, weight 1, 00:16:09
O>* 4.4.4.4/32 [110/10] via 10.10.5.1, vlan50, weight 1, 00:16:09
O>* 10.10.2.0/24 [110/30] via 10.10.5.1, vlan50, weight 1, 00:16:09
O>* 10.10.4.0/24 [110/20] via 10.10.5.1, vlan50, weight 1, 00:16:09
O   10.10.5.0/24 [110/10] is directly connected, vlan50, weight 1, 00:21:59
C>* 10.10.5.0/24 is directly connected, vlan50, 00:21:59
```

OSPF Stub and NSSA Areas with no-summary

By default, external routes and inter-area routes will be injected into stub or NSSAs areas in the same OSPF domain in the absence of effective route summarization. This can overwhelm a node particularly in large OSPF routing domains. Changing an area from stub to a *totally-stubby* area solves this issue. To change an area from stub to a totally-stubby-area, user can apply the command **set protocols ospf area 0.0.0.1 no-summary** from the PiCOS configuration mode.

In Figure 5-5 below, Router 2 is an ABR, to reduce the number of routes on Router 1 in area 0.0.0.2, we will configure area 0.0.0.2 on Router 2 as a totally stubby area.

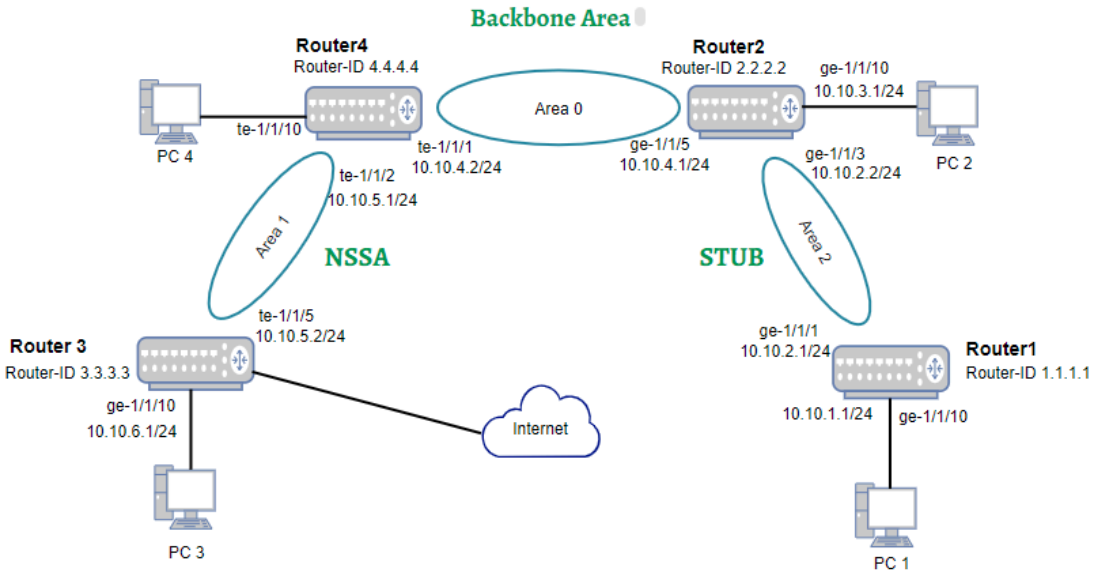

Figure 5-5. OSPF Stub area/NSSA summary: area 1.1.1.1 should be a stub area or an NSSA

Configuring Router 2

```
admin@router2# set vlans vlan-id 30 l3-interface "vlan30"
admin@router2# set vlans vlan-id 40 l3-interface "vlan40"
admin@router2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@router2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching native-vlan-id 40
admin@router2# set l3-interface vlan-interface vlan30 address 10.10.2.2 prefix-length 24
admin@router2# set l3-interface vlan-interface vlan40 address 10.10.4.1 prefix-length 24
admin@router2# set protocols ospf router-id 2.2.2.2
admin@router2# set protocols ospf area 0.0.0.2 area-type "stub"
admin@router2# set protocols ospf area 0.0.0.2 no-summary
admin@router2# set protocols ospf network 10.10.2.0/24 area 0.0.0.2
admin@router2# set protocols ospf network 10.10.4.0/24 area 0.0.0.0
admin@router2# set l3-interface loopback lo address 2.2.2.2 32 prefix-length 32
Commit OK.
Save Done.
admin@router2#
```

Similarly, on Router4, we will run the same command to stop injecting summaries in NSSA area 0.0.0.1.

Configuring Router 4

```
admin@router4# set vlans vlan-id 40 l3-interface "vlan40"
admin@router4# set vlans vlan-id 50 l3-interface "vlan50"
admin@router4# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 40
admin@router4# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 50
admin@router4# set l3-interface vlan-interface vlan40 address 10.10.4.2 prefix-length 24
admin@router4# set l3-interface vlan-interface vlan50 address 10.10.5.1 prefix-length 24
admin@router4# set protocols ospf router-id 4.4.4.4
admin@router4# set protocols ospf network 10.10.4.0/24 area 0.0.0.0
admin@router4# set protocols ospf network 10.10.5.0/24 area 0.0.0.1
admin@router4# set protocols ospf area 0.0.0.1 area-type nssa
admin@router4# set protocols ospf area 0.0.0.1 no-summary
admin@router4# set protocols ospf network 4.4.4.4/32 area 0
admin@router4# set protocols ospf redistribute static
admin@router4# set l3-interface loopback lo address 4.4.4.4 prefix-length 32
Commit OK.
Save done.
```

OSPF Area Range Configuration Guide

OSPF should aggregate route entries from the backbone area into a non-backbone area or from a non-backbone area into the backbone area. Route aggregation works only on the ABR.

To disable injecting routes into an area from an ABR manually, the user can apply the prefix lists in *inbound* or *outbound* directions to control the dissemination of routes into and out of OSPF areas. The command used to control route dissemination is **set protocols ospf area in filter-list prefix**. The keyword **in** indicated routes advertised into an area. Whereas **out** indicates routes going out of the area. Its important to note that the user must configure the prefix list before applying it through the **set protocols ospf area in filter-list prefix** command. The command to create the prefix list is **set routing prefix-list.**

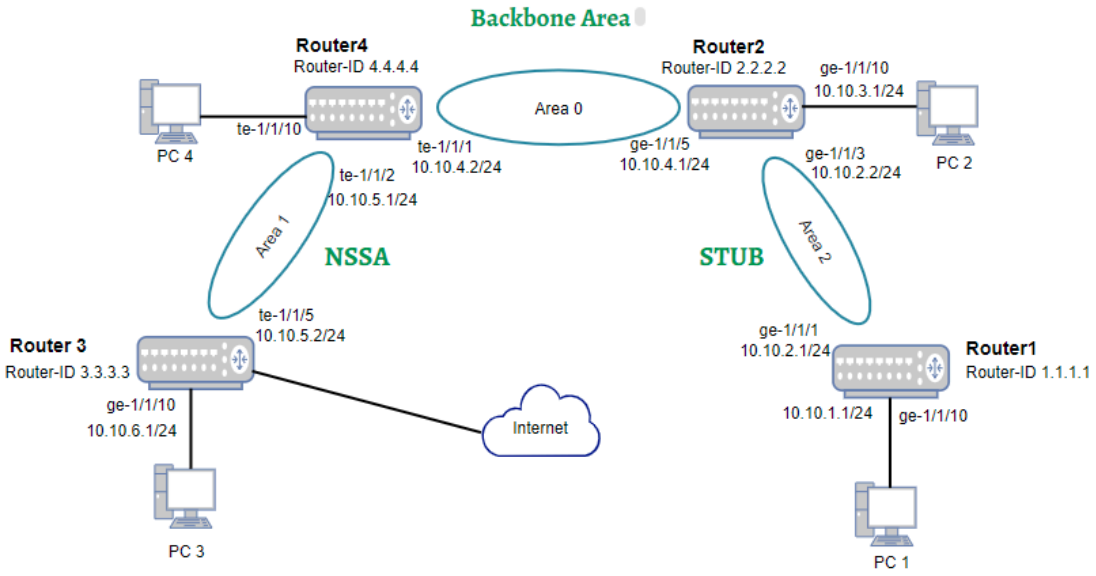

Figure 5-6. OSPF area range configuration.

Figure 5-6 shows a sample OSPF topology with three different areas configured. In this example we will focus on the configuration on Router 2 to see how it affects the routing table on Router 1 which is in area 0.0.0.2. First we will see the configuration on Router 2.

Configuring Router 2

```
admin@router2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@router2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching native-vlan-id 40
admin@router2# set protocols lldp enable true
admin@router2# set protocols ospf router-id 2.2.2.2
admin@router2# set protocols ospf area 0.0.0.2 area-type "stub"
admin@router2# set protocols ospf area 0.0.0.1 in filter-list
admin@router2# set protocols ospf network 10.10.2.0/24 area 0.0.0.2
admin@router2# set protocols ospf network 10.10.4.0/24 area 0.0.0.0
admin@router2# set system hostname "router2"
admin@router2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@router2# set l3-interface vlan-interface vlan30 address 10.10.2.2 prefix-length 24
admin@router2# set l3-interface vlan-interface vlan40 address 10.10.4.1 prefix-length 24
admin@router2# set vlans vlan-id 30 l3-interface "vlan30"
admin@router2# set vlans vlan-id 40 l3-interface "vlan40"
```

Check the Routing Table on Router 1

If we check the routing table on Router 1, we can see prefix 10.10.5.0 is in the routing table advertised through OSPF.

```
admin@router1> show route ipv4
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

O   0.0.0.0/0 [110/11] via 10.10.2.2, vlan10, weight 1, 04:01:47
O   1.1.1.1/32 [110/0] is directly connected, lo, weight 1, 04:03:37
C>* 1.1.1.1/32 is directly connected, lo, 04:03:37
```

```
O>* 4.4.4.4/32 [110/20] via 10.10.2.2, vlan10, weight 1, 00:00:02
O   10.10.2.0/24 [110/10] is directly connected, vlan10, weight 1, 04:02:37
C>* 10.10.2.0/24 is directly connected, vlan10, 04:02:37
O>* 10.10.4.0/24 [110/20] via 10.10.2.2, vlan10, weight 1, 00:00:02
O>* 10.10.5.0/24 [110/30] via 10.10.2.2, vlan10, weight 1, 00:00:02
```

Now we will add the commands **set protocols ospf area 0.0.0.2 in filter-list prefix list1** and **set routing prefix-list IPv4 list1 deny prefix 10.10.5.0/24** to Router 2.

```
admin@router2# set routing prefix-list IPv4 list1 deny prefix 10.10.5.0/24
admin@router2# set protocols ospf area 0.0.0.2 in filter-list prefix "list1"
Commit OK.
Save Done.
admin@router2#
```

Now if we check the routing table on Router 1 again, we see the prefix 10.10.5.0/24 has disappeared from the routing table.

```
admin@router1> show route ipv4
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

O   0.0.0.0/0 [110/11] via 10.10.2.2, vlan10, weight 1, 04:54:16
K>* 0.0.0.0/0 [0/0] via 10.10.51.1, eth0, 04:56:35
O   1.1.1.1/32 [110/0] is directly connected, lo, weight 1, 04:56:06
C>* 1.1.1.1/32 is directly connected, lo, 04:56:06
O   10.10.2.0/24 [110/10] is directly connected, vlan10, weight 1, 04:55:06
C>* 10.10.2.0/24 is directly connected, vlan10, 04:55:06
```

OSPF Route Redistribution and Route Maps

OSPF has the ability to redistribute routes of other routing protocols in the routing table into OSPF. In OSPF terminology, routes from other routing protocols are known as external routes and they can be redistributed into OSPF as Type-5 LSAs.

When redistributing external routes, we can specify filters to control which type of routes are redistributed into OSPF otherwise it has the potential to overwhelm the OSPF process especially in large networks. It also gives the administrator the ability to stop advertising unnecessary routes through OSPF. Filtering of routes for redistribution is achieved by route maps. To create a route map, we can run the command **set routing route-map <***map-name***>**.

In the following section we will demonstrate route redistribution and the use of route map in a sample topology shown in Figure 1.

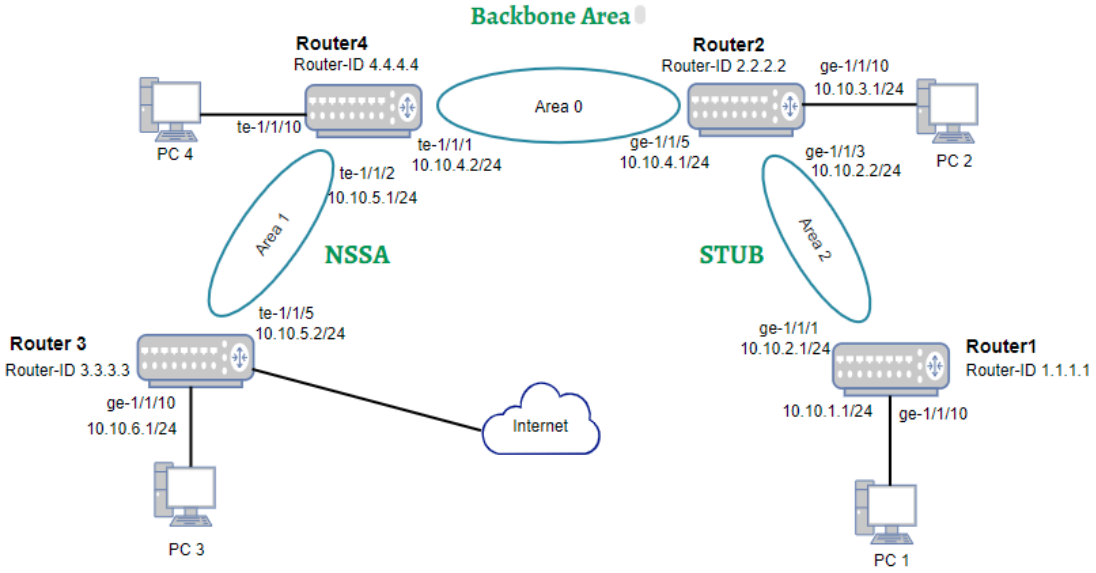

Figure 1 OSPF Route Redistribution and Route Maps

Configuration on Router 2

On Router 2, we have the following basic OSPF configuration.

```
admin@router2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@router2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching native-vlan-id 40
admin@router2# set protocols ospf router-id 2.2.2.2
admin@router2# set protocols ospf area 0.0.0.2 area-type stub
admin@router2# set protocols ospf network 10.10.2.0/24 area 0.0.0.2
admin@router2# set protocols ospf network 10.10.4.0/24 area 0.0.0.0
admin@router2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@router2# set l3-interface vlan-interface vlan30 address 10.10.2.2 prefix-length 24
admin@router2# set l3-interface vlan-interface vlan40 address 10.10.4.1 prefix-length 24
admin@router2# set vlans vlan-id 30 l3-interface vlan30
admin@router2# set vlans vlan-id 40 l3-interface vlan40
Commit OK.
Save done.
admin@router2#
```

If we wish to redistribute external routes through OSPF, we can configure the **set protocols ospf redistribute** command. And then configure a route map to control which type or specific prefixes are allowed to be redistributed through OSPF. The configuration shown below permits the redistribution of prefix 2.2.2.3/32 through OSPF.

```
admin@router2# set routing prefix-list IPv4 list2 permit prefix 2.2.2.3/32
admin@router2# set routing route-map map2 order 1 matching-policy "permit"
admin@router2# set routing route-map map2 order 1 match ip address prefix-list "list2"
admin@router2# set protocols ospf redistribute connected route-map "map2"
```

The configuration above first creates a prefix list *list2,* which permits prefix 2.2.2.3/32. Then create a route map *map2* with matching policy of permit. The match IP for map2 is set to *list2.* Finally, the command **set protocols ospf redistribute connected route-map map2** applies the configuration to Router 2. We can confirm that the prefix is advertised to Router 4 by checking the routing table on Router 4.

```
admin@router4> show route ipv4
Possible completions:
  <ip-address>                   An IPv4/IPv6 address or prefix length
  ipv4                           IPv4
admin@router4> show route ipv4
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

K>* 0.0.0.0/0 [0/0] via 10.10.51.1, eth0, 04:05:50
O>* 2.2.2.3/32 [110/20] via 10.10.4.1, vlan40, weight 1, 04:03:30        <-----OSPF Redistributed Prefix
O   4.4.4.4/32 [110/0] is directly connected, lo, weight 1, 04:05:23
C>* 4.4.4.4/32 is directly connected, lo, 04:05:23
O>* 10.10.2.0/24 [110/20] via 10.10.4.1, vlan40, weight 1, 01:55:32
O   10.10.4.0/24 [110/10] is directly connected, vlan40, weight 1, 04:04:21
C>* 10.10.4.0/24 is directly connected, vlan40, 04:04:21
O   10.10.5.0/24 [110/10] is directly connected, vlan50, weight 1, 04:04:02
C>* 10.10.5.0/24 is directly connected, vlan50, 04:04:21
```

The OSPF redistribute command can redistribute the following types of external routes.

- **BGP Routes**
- **Connected Routes**
- **Kernel Routes**
- **Static Routes**
- **Table**

We can also specify the OSPF metric for these routes, for example run the command **set protocols ospf redistribute static metric** to specify the metric for the redistributed static routes.

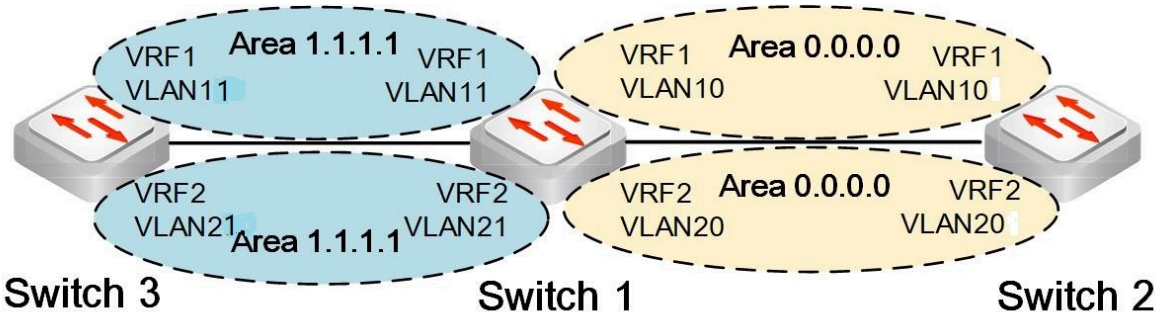
Example for Configuring OSPF with Different VRFs

- Networking Requirements
  - Basic Deployment
  - Networking Address Planning
- Procedure
  - Switch1
  - Switch2
  - Switch3
- Verify the Configuration

Networking Requirements

As shown in **Figure 1**, by configuring OSPF routing protocol on switch 1, switch 2 and switch 3, the three devices can exchange routing information with each other. We will implement the VRF function on Switch 1, Switch 2 and Switch 3 to segregate the users' routing spaces of different Tenants. We will create two VRFs on each device and run OSPF in these VRFs.

Figure1. User Configuration Topology of OSPF with Different VRFs



Basic Deployment

Figure 1 shows the user configuration topology of OSPF with different VRFs. Follow the configuration roadmap below to complete the configuration.

- Configure IP addresses and VLANs for the VLAN interfaces on switches to establish communication within the network segments.
- Configure basic OSPF functions on each switch. Configure Switch 1 as the ABR to divide the OSPF network into two areas (Area: 0.0.0.0 and Area: 1.1.1.1), so that the entire OSPF network can be extended using the area where Switch 1 and Switch 2 are located as the backbone area.
- In order to make different tenants have different routing space, configure two VRFs on each of the three switches.

Networking Address Planning

The networking IP address planning is shown in the following table.

Switch	Physical Interface	VRF and VLAN Interface	OSPF Configurations
Switch1	Te-1/1/1	vrf1 VLANIF11: 11.251.201.2	Area: 1.1.1.1 Router ID: 1.1.1.1
		vrf2 VLANIF 21: 21.251.201.2	Area: 1.1.1.1 Router ID: 1.1.1.1
	Te-1/1/2	vrf1 VLANIF 10: 10.251.201.2	Area: 0.0.0.0 Router ID: 1.1.1.1
		vrf2 VLANIF 20: 20.251.201.2	Area: 0.0.0.0 Router ID: 1.1.1.1
Switch2	Te-1/1/5	vrf1 VLANIF 10: 101.251.201.3	Area: 0.0.0.0 Router ID: 2.2.2.2
		vrf2 VLANIF 20: 201.251.201.3	Area: 0.0.0.0 Router ID: 2.2.2.2
Switch3	Te-1/1/5	vrf1 VLANIF 11: 100.251.201.3	Area: 1.1.1.1 Router ID: 3.3.3.3
		vrf2 VLANIF 21: 200.251.201.3	Area: 1.1.1.1 Router ID: 3.3.3.3

Procedure

Configure Switch 1, Switch 2 and Switch 3 according to the networking requirements described above.

Switch1

Step1 Configure the VLANs and VLAN interfaces.

```
admin@switch1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@switch1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 11
admin@switch1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 21
admin@switch1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 10
admin@switch1# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@switch1# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 10
admin@switch1# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 20
admin@switch1# set l3-interface loopback vrf1 address 1.1.1.1 prefix-length 32
admin@switch1# set l3-interface vlan-interface vlan10 address 10.251.201.2 prefix-length 24
admin@switch1# set l3-interface vlan-interface vlan20 address 20.251.201.2 prefix-length 24
admin@switch1# set l3-interface vlan-interface vlan11 address 11.251.201.2 prefix-length 24
admin@switch1# set l3-interface vlan-interface vlan21 address 21.251.201.2 prefix-length 24
admin@switch1# set vlans vlan-id 10 l3-interface vlan10
admin@switch1# set vlans vlan-id 11 l3-interface vlan11
admin@switch1# set vlans vlan-id 20 l3-interface vlan20
admin@switch1# set vlans vlan-id 21 l3-interface vlan21
```

Step2 Configure VRF.

a. Enable IP routing function before using VRF function and configure the system hostname.

```
admin@switch1# set ip routing enable true
admin@switch1# set system hostname switch1
```

b. Create VRFs.

```
admin@switch1# set ip vrf vrf1 description orange
admin@switch1# set ip vrf vrf2 description purple
```

c. Bind the Layer 3 VLAN interface to the VRF.

```
admin@switch1# set l3-interface vlan-interface vlan10 vrf vrf1
admin@switch1# set l3-interface vlan-interface vlan20 vrf vrf2
admin@switch1# set l3-interface vlan-interface vlan11 vrf vrf1
admin@switch1# set l3-interface vlan-interface vlan21 vrf vrf2
```

Step3 Configure basic OSPF functions.

```
admin@switch1# set protocols ospf vrf vrf1 router-id 1.1.1.1
admin@switch1# set protocols ospf vrf vrf1 network 10.251.201.0/24 area 0.0.0.0
admin@switch1# set protocols ospf vrf vrf1 network 11.251.201.0/24 area 1.1.1.1
admin@switch1# set protocols ospf vrf vrf2 router-id 1.1.1.1
admin@switch1# set protocols ospf vrf vrf2 network 20.251.201.0/24 area 0.0.0.0
admin@switch1# set protocols ospf vrf vrf2 network 21.251.201.0/24 area 1.1.1.1
```

Step4 Commit the configuration.

```
admin@Switch1# commit
```

Switch2

Step1 Configure the VLANs and VLAN interfaces.

```
admin@switch2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching port-mode "trunk"
admin@switch2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 10
admin@switch2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 20
admin@switch2# set vlans vlan-id 10 l3-interface "vlan10"
admin@switch2# set vlans vlan-id 20 l3-interface "vlan20"
admin@switch2# set l3-interface vlan-interface vlan20 address 20.251.201.3 prefix-length 24
admin@switch2# set l3-interface vlan-interface vlan10 address 10.251.201.3 prefix-length 24
```

Step2 Configure VRF.

a. Enable IP routing function before using VRF function and set the system hostname.

```
admin@switch2# set ip routing enable true
admin@switch2# set system hostname "switch2"
```

b. Create VRFs.

```
admin@switch2# set ip vrf vrf1 description orange
admin@switch2# set ip vrf vrf2 description purple
```

c. Bind the Layer 3 VLAN interface to the VRF.

```
admin@switch2# set l3-interface vlan-interface vlan10 vrf "vrf1"
admin@switch2# set l3-interface vlan-interface vlan20 vrf "vrf2"
```

Step3 Configure basic OSPF functions.

```
admin@switch2# set protocols ospf vrf vrf1 router-id 2.2.2.2
admin@switch2# set protocols ospf vrf vrf1 network 10.251.201.0/24 area 0.0.0.0
admin@switch2# set protocols ospf vrf vrf2 router-id 2.2.2.2
admin@switch2# set protocols ospf vrf vrf2 network 20.251.201.0/24 area 0.0.0.0
```

Step4 Commit the configuration.

```
admin@switch2# commit
```

Switch3

Step1 Configure the VLANs and VLAN interfaces.

```
admin@switch3# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching port-mode "trunk"
admin@switch3# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 11
admin@switch3# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 21
admin@switch3# set vlans vlan-id 11 l3-interface "vlan11"
admin@switch3# set vlans vlan-id 21 l3-interface "vlan21"
admin@switch3# set l3-interface vlan-interface vlan11 address 11.251.201.4 prefix-length 24
admin@switch3# set l3-interface vlan-interface vlan21 address 21.251.201.4 prefix-length 24
```

Step2 Configure VRF.

a. Enable IP routing function before using VRF function.

```
admin@switch3# set ip routing enable true
admin@switch3# set system hostname "switch3"
```

b. Create VRFs.

```
admin@Switch3# set ip vrf vrf1 description orange
admin@Switch3# set ip vrf vrf2 description purple
```

c. Bind the Layer 3 VLAN interface to the VRF.

```
admin@switch3# set l3-interface vlan-interface vlan11 vrf "vrf1"
admin@switch3# set l3-interface vlan-interface vlan21 vrf "vrf2"
```

Step3 Configure basic OSPF functions.

```
admin@switch3# set protocols ospf vrf vrf1 router-id 3.3.3.3
admin@switch3# set protocols ospf vrf vrf1 network 11.251.201.0/24 area 1.1.1.1
admin@switch3# set protocols ospf vrf vrf2 router-id 3.3.3.3
admin@switch3# set protocols ospf vrf vrf2 network 21.251.201.0/24 area 1.1.1.1
```

Step4 Commit the configuration.

```
admin@switch3# commit
```

Verify the Configuration

- You can use the run show vrf command to view the binding information between VRFs and the Layer 3 VLAN interfaces.

```
admin@switch1# run show vrf
Vrf          Description       Interfaces
----------   ---------------   ------------------------
vrf1         orange            vlan10,vlan11
vrf2         purple            vlan20,vlan21

admin@switch2# run show vrf
Vrf          Description       Interfaces
----------   ---------------   ------------------------
vrf1         orange            vlan10
vrf2         purple            vlan20
```

- You can use the **run show route vrf** command to check the routing table information of the specific VRF.

```
admin@switch3# run show route vrf vrf1
show ip route vrf vrf1
=======================
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,

```

OSPFv3 Configuration Guide

We will demonstrate a sample OSPFv3 configuration in this guide. The topology consists of two switches, Switch1 and Switch2.

Both OSPF version 2 and 3 can be configured primarily using two different methods. Either we directly specify the interfaces and enable OSPFv3 on them or we enable OSPFv3 on a network prefix. If we use a network prefix to enable OSPF then all the interfaces who share the same network prefix become part of the OSPF network and OSPFv3 tries to create adjacencies with peers on these interfaces. These interfaces are advertised to peers using Type-1 Router LSAs. In this example we will use interface names to enable OSPFv3.

Figure 1. below depicts our basic OSPFv3 sample topology.

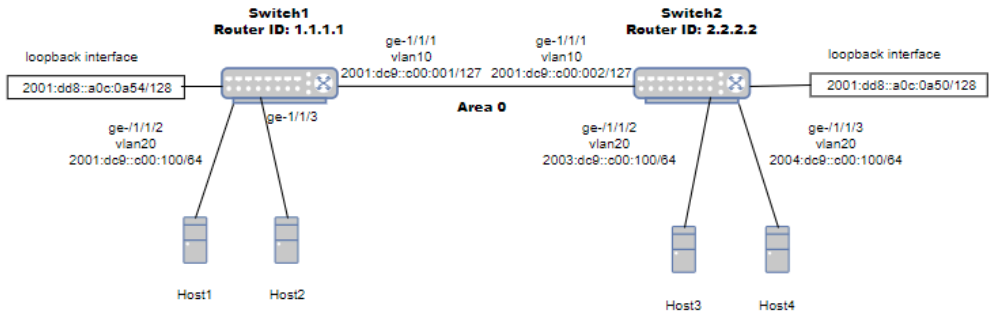

Figure 1. OSPFv3 Sample Configuration

Switch Configuration

Below is the switch configuration for the two switches, Switch1 and Switch2.

Switch1 Configuration

Interface ge-1/1/1 connects with Switch1. Interface ge-1/1/2 and ge-1/1/3 connects with hosts. The host-connecting interfaces will be put in passive mode. Which means that these interfaces will be advertised to Switch2 but OSPFv3 will not attempt to form any adjacencies on these two interfaces.

```
admin@Switch1# set vlans vlan-id 10
admin@Switch1# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@Switch1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@Switch1# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@Switch1# set vlans vlan-id 10 l3-interface vlan10
admin@Switch1# set l3-interface loopback lo address 2001:dd8::a0c:0a54 prefix-length 128
admin@Switch1# set l3-interface vlan-interface vlan10 address 2001:dc9::c00:001 prefix-length 127
admin@Switch1# set l3-interface vlan-interface vlan20 address 2001:dc9::c00:100 prefix-length 64
admin@Switch1# set l3-interface vlan-interface vlan30 address 2002:dc9::c00:100 prefix-length 64
admin@Switch1# set protocols ospf6 router-id 1.1.1.1
admin@Switch1# set protocols ospf6 interface lo area 0.0.0.0
admin@Switch1# set protocols ospf6 interface vlan10 area 0.0.0.0
admin@Switch1# set protocols ospf6 interface vlan20 area 0.0.0.0
admin@Switch1# set protocols ospf6 interface vlan30 area 0.0.0.0
admin@Switch1# set protocols ospf6 interface vlan20 passive
admin@Switch1# set protocols ospf6 interface vlan30 passive
admin@Switch1# set protocols ospf6 interface vlan10 network point-to-point
admin@Switch1# commit
```

Switch2 Configuration

The Switch2 configuration is almost identical to Switch1, the host-connecting interfaces are put in passive mode.

```
admin@Switch2# set vlans vlan-id 10
admin@Switch2# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@Switch2# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@Switch2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 30
admin@Switch2# set vlans vlan-id 10 l3-interface vlan10
```

```
admin@Switch2# set l3-interface loopback lo address 2001:dd8::a0c:0a50 prefix-length 128
admin@Switch2# set l3-interface vlan-interface vlan10 address 2001:dc9::c00:002 prefix-length 127
admin@Switch2# set l3-interface vlan-interface vlan20 address 2003:dc9::c00:100 prefix-length 64
admin@Switch2# set l3-interface vlan-interface vlan30 address 2004:dc9::c00:100 prefix-length 64
admin@Switch2# set protocols ospf6 router-id 2.2.2.2
admin@Switch2# set protocols ospf6 interface lo area 0.0.0.0
admin@Switch2# set protocols ospf6 interface vlan10 area 0.0.0.0
admin@Switch2# set protocols ospf6 interface vlan20 area 0.0.0.0
admin@Switch2# set protocols ospf6 interface vlan30 area 0.0.0.0
admin@Switch2# set protocols ospf6 interface vlan20 passive
admin@Switch2# set protocols ospf6 interface vlan30 passive
admin@Switch2# set protocols ospf6 interface vlan10 network point-to-point
admin@Switch2# commit
```

Optional OSPFv3 Parameters

Hello Interval

To set the OSPFv3 interface hello interval to 5 seconds, run the following set command.

```
admin@Switch1# set protocols ospf6 interface vlan10 hello-interval 5
admin@Switch1# commit
```

Dead Interval

To set the OSPFv3 interface dead interval to 10 seconds, run the following set command.

```
admin@Switch1# set protocols ospf6 interface vlan10 dead-interval 10
admin@Switch1# commit
```

Priority

To set the OSPFv3 interface priority value to 5, run the below set command.

```
admin@Switch1# set protocols ospf6 interface vlan10 priority 5
admin@Switch1# commit
```

SPF Timers

To set the SPF initial delay to 1000ms, run the command below.

```
admin@Switch1# set protocols ospf6 timers throttle spf delay 1000
admin@Switch1# commit
```

To set the SPF initial hold-time to 2000ms, run the command below.

```
admin@Switch1# set protocols ospf6 timers throttle spf initial-holdtime 2000
admin@Switch1# commit
```

To set the SPF maximum hold-time to 10000ms, run the command below.

```
admin@Switch1# set protocols ospf6 timers throttle spf maximum-holdtime 10000
admin@Switch1# commit
```

OSPF Multi-Instance Support

> **NOTEs**:
>
> OSPF multi-instance is not supported in PICOS version 4.4.5.

OSPFv2 supports multiple instances of OSPF to run simultaneously on the device. Each instance is identified by an Instance ID which is a non-zero positive integer and must be provided when creating an instance.

Limitations of Multi-Instance OSPF

Multi-Instance OSPF can not coexist with single instance OSPF. If the user wants to configure multi-instance OSPF on a device which already has the single instance version of OSPF running then the user must first remove all the configuration related to single instance OSPF before configuring multi-instance OSPF.

Multiple instances of OSPFv2 can only be created in the default VRF. Multiple instances of OSPFv2 in the user defined (non-default) VRFs are not supported.

There are a maximum of 8 instances of OSPF allowed on a device.

The OSPF feature of enabling OSPF using the network command is not allowed under the multi-instance OSPF. Only by specifying a specific interface can the user enable OSPF on network interfaces.

Basic OSPF Multi-Instance Configuration

First of all we need to enable multi-instance OSPF on the device, run the command below to achieve this.

```
admin@Xorplus# set protocols ospf multi-instance disable false
admin@Xorplus# commit
```

To create an OSPF instance and configure the router ID, run the command below.

```
admin@Xorplus# set protocols ospf instance-id 5 router-id 1.1.1.1
admin@Xorplus# commit
```

Specify the backbone area for this instance and choose area-type as stub.

```
admin@Xorplus# set protocols ospf instance-id 5 area 0.0.0.0 area-type stub
admin@Xorplus# commit
```

Add a VLAN interface *vlan200* to the backbone area for instance ID 5. This command enables OSPF on the interface.

```
admin@Xorplus# set protocols ospf instance-id 5 interface vlan200 area 0.0.0.0
admin@Xorplus# commit
```

Usually, OSPF will try to form adjacencies with other routers on all interfaces that match the network prefix of an OSPF enabled interface. It is desirable to stop OSPF from forming adjacencies on interfaces facing the end users. To stop OSPF from forming adjacency on interface *vlan10*, run the command below.

```
admin@Xorplus# set protocols ospf instance-id 5 passive-interface vlan10
admin@Xorplus# commit
```

To redistribute BGP routes through an OSPF instance, run the command below.

```
admin@Xorplus# set protocols ospf instance-id 5 redistribute bgp
admin@Xorplus# commit
```

To configure OSPF SPF timers, run the commands shown below. This example configures the initial delay to 20ms, initial hold time to 100ms and the maximum hold time to 1000ms.

```
admin@Xorplus# set protocols ospf instance-id 5 timers throttle spf delay 20
admin@Xorplus# set protocols ospf instance-id 5 timers throttle spf initial-holdtime 100
admin@Xorplus# set protocols ospf instance-id 5 timers throttle spf maximum-holdtime 1000
admin@Xorplus# commit
```

And finally, to enable debugging information, run the below commands. These three commands enable debugging for Interface State Machine (ISM) events, the Link State Advertisement (LSA) flooding and the zebra module. For a full list of debugging options, please refer to the OSPFv2 command reference.

```
admin@Xorplus# set protocols ospf instance-id 5 traceoption ism events
admin@Xorplus# set protocols ospf instance-id 5 traceoption lsa flooding
admin@Xorplus# set protocols ospf instance-id 5 traceoption zebra
admin@Xorplus# commit
```

OSPF GR

- Overview
  - Device as a restarting device
  - Device as a Graceful Restart Helper
- Configuring OSPFv2 GR
  - Procedure
- Configuring OSPFv3 GR
  - Procedure
- Configuration Example
  - Networking Requirements
  - Procedure
    - Switch A
    - Switch B
    - Switch C
  - Verify the Configuration

NOTEs:

- PICOS supports Graceful Restart (GR) for both OSPFv2 and OSPFv3.
- Before configuring OSPF GR, you must enable OSPF's Opaque LSA capability by using the following command.

  For OSPFv2, using command **set protocols ospf [instance-id <***instance-id***>] [vrf**<*vrf-name*>**] capability opaque**.

  For OSPFv3, using command **set protocols ospf6 [instance-id <***instance-id***>] [vrf**<*vrf-name*>**] capability opaque**.
- Be cautious: After executing the **run graceful-restart prepare ospf** or **run graceful-restart prepare ospf6** command, the system will be in a waiting state for the OSPF protocol to restart. Users are not allowed to perform any OSPF configuration until the OSPF protocol restart is completed, or unpredictable results can occur.
- Before restarting the OSPF process, the device needs to use the command **run graceful-restart prepare ospf** (for OSPFv2) or **run graceful-restart prepare ospf6** (for OSPFv3) to send Type 9 LSAs for GR capability negotiation. After the negotiation, the OSPF process must be restarted within the negotiated **grace-period**; otherwise, it will timeout and exit the GR state.

Overview

OSPF GR (Graceful Restart) is a feature that allows a router to temporarily suspend OSPF routing operations without impacting the forwarding of data traffic. During a graceful restart, the router remains operational and continues forwarding packets using the routing information it had before OSPF protocol restarting process began.

In essence, OSPF GR allows a OSPF process to gracefully restart by preserving its OSPF neighbor relationships and forwarding state during the restart process.

Graceful restart is disabled by default. You can either globally enable graceful restart for all OSPF instances, or you can enable graceful restart for specific OSPF instance.

For a PICOS device, OSPF Graceful Restart involves the following operations:

Device as a restarting device

- In OSPF Graceful Restart (GR), a router that undergoes a restart process is referred to as the restarting router or restarting device. Here's a detailed description of its role and behavior during the GR process:
- **Restarting Process Initiation**: When a router undergoes a restart, it enters a restarting state. This can occur due to a planned restart (where the router voluntarily initiates the restart process) or an unplanned restart (such as a software upgrade or hardware failure).

a. **Neighbor State Maintenance**: During the restarting process, the router continues to maintain its OSPF neighbor adjacencies. It sends hello packets to its OSPF neighbors, indicating its restarting capability. These hello packets contain the Restart State (RS) bit, indicating that the router is in the process of restarting.
b. **Graceful Restart LSAs**: The restarting router advertises Graceful Restart (GR) LSAs into the OSPF domain, informing its neighbors about its restarting process and the estimated time for the restart to complete. These LSAs are Type 9 LSAs and are flooded throughout the OSPF domain.
c. **State Retention**: Despite undergoing a restart, the restarting router retains its OSPF link-state database (LSDB) and continues forwarding traffic based on the pre-restart OSPF topology. This helps prevent service disruptions and maintains network stability during the restart process.
d. **Neighbor Acknowledgment**: OSPF neighbors of the restarting router acknowledge the reception of GR LSAs and adjust their behavior accordingly. They continue forwarding traffic through the restarting router, considering it as a transit router, until it completes the restart process and reestablishes full adjacency.
e. **Restart Completion**: Once the restarting router completes its restart process and is ready to resume normal operation, it sends OSPF hello packets without the RS bit set, indicating that it has completed the restart. It then reestablishes OSPF adjacencies with its neighbors and begins exchanging OSPF routing information.

- The restarting router in OSPF GR ensures seamless network operation during the restart process by maintaining adjacency with OSPF neighbors, advertising its restarting capability, and retaining its OSPF LSDB to continue forwarding traffic without disruption.

Device as a Graceful Restart Helper

- In OSPF Graceful Restart (GR), a router that assists a restarting router during its restart process is known as a Graceful Restart Helper. Here's a detailed description of its role and behavior:
- **Neighbor Detection**: When a router undergoing restart sends OSPF hello packets with the Restart State (RS) bit set, indicating its restarting status, neighboring routers detect this and voluntarily become Graceful Restart Helpers. They recognize the need to assist the restarting router to maintain network stability during the restart process.
  a. **LSDB Synchronization**: Graceful Restart Helpers maintain a synchronized copy of the restarting router's Link-State Database (LSDB). They ensure that they have the same set of OSPF LSAs as the restarting router before the restart process began.
  b. **Forwarding Continuity**: During the restart process, Graceful Restart Helpers continue to forward traffic through the restarting router as if it were still operational. They do this based on the pre-restart OSPF topology information stored in their LSDB. This ensures that network traffic flows smoothly without interruptions.
  c. **Designated Router Election**: In OSPF broadcast and non-broadcast networks, Graceful Restart Helpers participate in the election of Designated Routers (DR) and Backup Designated Routers (BDR). They help maintain the integrity of the OSPF network topology by ensuring that DR and BDR elections are conducted correctly even during the restarting router's downtime.
  d. **Monitoring Restart Progress**: Graceful Restart Helpers continuously monitor the progress of the restarting router's restart process. They keep track of the receipt of Graceful Restart (GR) Link-State Advertisements (LSAs) from the restarting router and maintain synchronization with its restart state.
  e. **Adjacency Retention**: Helpers maintain OSPF adjacencies with the restarting router throughout the restart process. They acknowledge the receipt of GR LSAs from the restarting router and adjust their behavior to accommodate its restarting status, ensuring seamless traffic forwarding.
  f. **Restart Completion Acknowledgment**: Once the restarting router completes its restart process and resumes normal operation, it sends OSPF hello packets without the RS bit set. Graceful Restart Helpers recognize this and acknowledge the completion of the restart. They then transition back to normal OSPF operation mode.

Graceful Restart Helpers play a critical role in assisting a restarting router to maintain network stability and continuity during the restart process. They synchronize LSDBs, ensure traffic forwarding, participate in DR/BDR elections, monitor restart progress, retain adjacencies, and acknowledge restart completion, contributing to the overall resilience and reliability of the OSPF network.

Configuring OSPFv2 GR

Procedure

Step 1 Enable the capability to generate Opaque LSAs in the OSPF process to support OSPF GR through Type9 LSA.

set protocols ospf [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] capability opaque**

Step 2 Enable OSPFv2 GR on the Restarting Router. By default, OSPFv2 GR is disabled.

set protocols ospf [**instance-id <***instance-id***>**] [**vrf**<*vrf-name*>] **graceful-restart enable** <**true** | **false**>

Step 3 (Optional) Specify the GR restart interval on the Restarting Router. This determines the duration for which the restarting router remains in the Graceful Restart state. The default grace period is 120 seconds.

set protocols ospf [**instance-id** <*instance-id*>] [**vrf**<*vrf-name*>] **grace-period <***grace-period***>**

Step 4 Configure GR Helper Mode on Neighboring Routers.

set protocols ospf [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper** [**router-id** <*ipv4*>] **enable <true | false>**

Step 5 (Optional) Configure Graceful Restart Helper parameters.

set protocols ospf [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper planned-only**

set protocols ospf [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper strict-lsa-checking enable <true | false>**

set protocols ospf [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper supported-grace-time <***supported-grace-time***>**

Step 6 Configure to let the restarting router advertises Graceful Restart (GR) LSAs into the OSPF domain.

- Be cautious: After executing the **run graceful-restart prepare ospf** or **run graceful-restart prepare ospf6** command, the system will be in a waiting state for the OSPF protocol to restart. Users are not allowed to perform any OSPF configuration until the OSPF protocol restart is completed, or unpredictable results can occur.
- Before restarting the OSPF process, the device needs to use the command **run graceful-restart prepare ospf** (for OSPFv2) or **run graceful-restart prepare ospf6** (for OSPFv3) to send Type 9 LSAs for GR capability negotiation. After the negotiation, the OSPF process must be restarted within the negotiated **grace-period**; otherwise, it will timeout and exit the GR state.

run graceful-restart prepare ospf

Step 7 Commit the configuration.

commit

Step 8 Verify the configuration.

After the configuration is complete, run **run show ospf** [**instance-id <***instance-id***>**][**vrf**<*vrf-name***>**] **graceful-restart helper [detail]** command to display the Graceful Restart Helper details including helper config changes.

By following these steps, you can configure OSPFv2 Graceful Restart to enhance network resilience and minimize service disruptions during router restarts.

Configuring OSPFv3 GR

Procedure

Step 1 Enable the capability to generate Opaque LSAs in the OSPF process to support OSPF GR through Type9 LSA.

set protocols ospf6 [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] capability opaque**

Step 2 Enable OSPFv3 GR on the Restarting Router. By default, OSPFv3 GR is disabled.

set protocols ospf6 [**instance-id <***instance-id***>**] [**vrf**<*vrf-name*>] **graceful-restart enable** <**true** | **false**>

Step 3 (Optional) Specify the GR restart interval on the Restarting Router. This determines the duration for which the restarting router remains in the Graceful Restart state. The default grace period is 120 seconds.

set protocols ospf6 [**instance-id** <*instance-id*>] [**vrf**<*vrf-name*>] **grace-period <***grace-period***>**

Step 4 Configure GR Helper Mode on Neighboring Routers.

set protocols ospf6 [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper** [**router-id** <*ipv4*>] **enable <true | false>**

Step 5 (Optional) Configure Graceful Restart Helper parameters.

set protocols ospf6 [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper planned-only**

set protocols ospf6 [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper lsa-checking-disable**

set protocols ospf6 [instance-id <*instance-id***>] [vrf**<*vrf-name*>**] graceful-restart helper supported-grace-time <***supported-grace-time***>**

Step 6 Configure to let the restarting router advertises Graceful Restart (GR) LSAs into the OSPFv3 domain.

- Be cautious: After executing the **run graceful-restart prepare ospf** or **run graceful-restart prepare ospf6** command, the system will be in a waiting state for the OSPF protocol to restart. Users are not allowed to perform any OSPF configuration until the OSPF protocol restart is completed, or unpredictable results can occur.
- Before restarting the OSPF process, the device needs to use the command **run graceful-restart prepare ospf** (for OSPFv2) or **run graceful-restart prepare ospf6** (for OSPFv3) to send Type 9 LSAs for GR capability negotiation. After the negotiation, the OSPF process must be restarted within the negotiated **grace-period**; otherwise, it will timeout and exit the GR state.

run graceful-restart prepare ospf6

Step 7 Commit the configuration.

commit

Step 8 Verify the configuration.

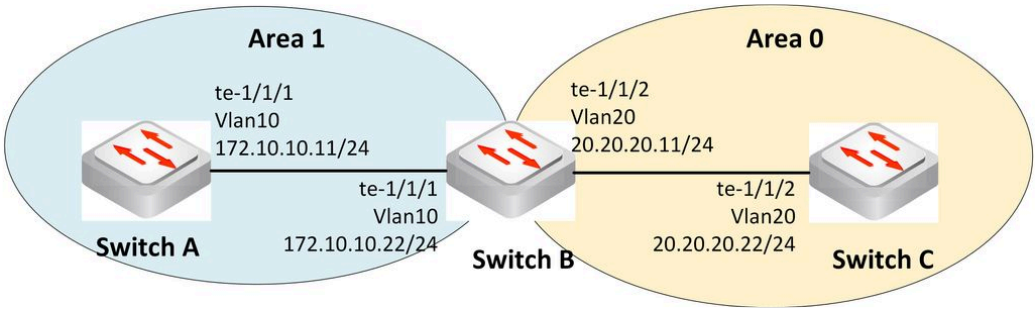
After the configuration is complete, run **run show ospf6** [**instance-id <***instance-id***>**][**vrf**<*vrf-name***>**] **graceful-restart helper [detail]** command to display the Graceful Restart Helper details including helper config changes.

By following these steps, you can configure OSPFv3 Graceful Restart to enhance network resilience and minimize service disruptions during router restarts.

Configuration Example

Networking Requirements

Figure 1. Network of Configuring OSPFv2 GR



As shown in **Figure 1**, the OSPF network is divided into two areas, Area 0 and Area 1, among the three devices running the OSPF protocol: Switch A, Switch B, and Switch C. It is now required that restarting the OSPF protocol on Switch A should not affect the normal data forwarding during the restart process.

The configuration approach is as follows:

1. Configure basic OSPF functions on each switch to achieve basic interoperability of OSPF networks.
2. Enable Opaque LSA function on Switch A and Switch B to enable OSPF to support OSPF GR through Type9 LSA.
3. Configure GR function on Switch A and Switch B to ensure normal data forwarding when OSPF protocol restarts.

Procedure

Switch A

Step 1 Configure the VLAN.

```
admin@SwitchA# set vlans vlan-id 10
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
admin@SwitchA# set l3-interface vlan-interface vlan10 address 172.10.10.11 prefix-length 24
admin@SwitchA# set vlans vlan-id 10 l3-interface vlan10
```

Step 2 Configure the OSPF protocol to advertise the network segments connected to each node.

```
admin@SwitchA# set protocols ospf router-id 1.1.1.1
admin@SwitchA# set protocols ospf network 172.10.10.0/24 area 1
```

Step 3 Enable the capability to generate Opaque LSAs in the OSPF process to support OSPF GR through Type9 LSA.

```
admin@SwitchA# set protocols ospf capability opaque
```

Step 4 Enable OSPF GR on Switch A. By default, OSPF GR is disabled.

- Be cautious: After executing the **run graceful-restart prepare ospf** or **run graceful-restart prepare ospf6** command, the system will be in a waiting state for the OSPF protocol to restart. Users are not allowed to perform any OSPF configuration until the OSPF protocol restart is completed, or unpredictable results can occur.
- Before restarting the OSPF process, the device needs to use the command **run graceful-restart prepare ospf** (for OSPFv2) or **run graceful-restart prepare ospf6** (for OSPFv3) to send Type 9 LSAs for GR capability negotiation. After the negotiation, the OSPF process must be restarted within the negotiated **grace-period**; otherwise, it will timeout and exit the GR state.

```
admin@SwitchA# set protocols ospf graceful-restart enable true
```

Step 5 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step 1 Configure VLAN.

```
admin@SwitchB# set vlans vlan-id 10
admin@SwitchB# set vlans vlan-id 20
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
admin@SwitchB# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchB# set l3-interface vlan-interface vlan10 address 172.10.10.22 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan20 address 20.20.20.11 prefix-length 24
admin@SwitchB# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchB# set vlans vlan-id 20 l3-interface vlan20
```

Step 2 Configure the OSPF protocol to advertise the network segments connected to each node.

```
admin@SwitchB# set protocols ospf router-id 2.2.2.2
admin@SwitchB# set protocols ospf network 172.10.10.0/24 area 1
admin@SwitchB# set protocols ospf network 20.20.20.0/24 area 0
```

Step 3 Enable the capability to generate Opaque LSAs in the OSPF process to support OSPF GR through Type9 LSA.

```
admin@SwitchA# set protocols ospf capability opaque
```

Step 4 Configure GR Helper Mode on Switch B.

```
admin@SwitchB# set protocols ospf graceful-restart helper enable true
```

Step 5 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step 1 Configure VLAN.

```
admin@SwitchC# set vlans vlan-id 20
admin@SwitchC# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchC# set l3-interface vlan-interface vlan20 address 20.20.20.22 prefix-length 24
admin@SwitchC# set vlans vlan-id 20 l3-interface vlan20
```

Step 2 Configure the OSPF protocol to advertise the network segments connected to each node.

```
admin@SwitchC# set protocols ospf router-id 3.3.3.3
admin@SwitchC# set protocols ospf network 20.20.20.0/24 area 0
```

Step 3 Commit the configuration.

```
admin@SwitchC# commit
```

Verify the Configuration

- After the configuration is complete, use command **run show ospf neighbor** to check the OSPF neighbor information. From the result, we can see that the neighbor state of Switch A and Switch B is **Full**.

```
admin@SwitchA# run show ospf neighbor
Neighbor ID     Pri State           Up Time         Dead Time Address         Interface
RXmtL RqstL DBsmL
2.2.2.2           1 Full/DR         7m46s             35.806s 172.10.10.22    vlan10:172.10.10.11
0     0     0
admin@SwitchB# run show ospf neighbor
```

```
Neighbor ID     Pri State           Up Time         Dead Time Address         Interface
RXmtL RqstL DBsmL
1.1.1.1           1 Full/Backup     7m53s             36.400s 172.10.10.11    vlan10:172.10.10.22
0     0     0
3.3.3.3           1 Full/Backup     17m16s            33.592s 20.20.20.22     vlan20:20.20.20.11
0     0     0
```

- On Switch B, use command **run show ospf graceful-restart helper detail** to check the information of OSPF graceful restart helper. From the result, we can see that the negotiated OSPF GR information, including `Grace period`, `Remaining GraceTime`, etc.

```
admin@SwitchB# run show ospf graceful-restart helper detail
OSPF Router with ID (2.2.2.2)

 Graceful restart helper support enabled.
 Strict LSA check is enabled.
 Helper supported for Planned and Unplanned Restarts.
 Supported Graceful restart interval: 1800(in seconds).
 Last Helper exit Reason :Successful graceful restart
 Number of Active neighbours in graceful restart: 1
 Neighbour 1 :
   Address  : 172.10.10.11
   Routerid : 1.1.1.1
   Received Grace period : 120(in seconds).
   Actual Grace period : 120(in seconds)
   Remaining GraceTime:101(in seconds).
   Graceful Restart reason: Software restart.
```

- On Switch A, use the following Linux command to terminate the OSPF process. Then, the system will automatically restart the OSPF process.

```
root@SwitchA:/home/admin# pkill ospfd
```

- On Switch B, check the GR status. From the result, we can see that during the restart of `ospfd` on Switch A, the neighbor relationship between B and A remains in the **FULL** state, unaffected by the graceful restart of Switch A's OSPF process.

```
admin@SwitchB# run show ospf graceful-restart helper detail
OSPF Router with ID (2.2.2.2)

 Graceful restart helper support enabled.
 Strict LSA check is enabled.
 Helper supported for Planned and Unplanned Restarts.
 Supported Graceful restart interval: 1800(in seconds).
 Last Helper exit Reason :Successful graceful restart
 Number of Active neighbours in graceful restart: 1
 Neighbour 1 :
   Address  : 172.10.10.11
   Routerid : 1.1.1.1
   Received Grace period : 120(in seconds).
   Actual Grace period : 120(in seconds)
   Remaining GraceTime:86(in seconds).
   Graceful Restart reason: Software restart.

admin@SwitchB# run show ospf neighbor

ECMP (Equal-Cost Multipath Routing) Configuration

NOTE:

- Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.
- IPv6 static ECMP routing is not supported.

In L2/L3, ECMP is supported. The maximum ECMP outgoing port group is 4*128. If each ECMP route is configured to have up to 4 equal-cost paths, for example, the maximum ECMP outgoing port group support is 128. If each ECMP route is configured to have up to 16 equal-cost paths, the maximum ECMP outgoing port group support is 32. Several different ECMP routes can share the same outgoing port group. After configuring the ECMP equal-cost path maximum, reboot the switch to make it available.

Configuring the Equal-Cost Path Maximum

```
admin@XorPlus# set interface ecmp path_max 8
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
ECMP max path changes, please reset the box!
admin@XorPlus# run request system reboot
The system is going down NOW!
Sending SIGTERM to all processes
Sending SIGKILL to all processes
Requesting system reboot
Restarting system.
rstcr compatible register does not exist!
uses the mpc8541's gpio to do a reset.

```

Configuring Static ECMP Routing

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set vlans vlan-id 3
admin@XorPlus# set vlans vlan-id 4
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching native-vlan-id 3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching native-vlan-id 4
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set vlans vlan-id 4 l3-interface vlan-4
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.60.10 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.61.10 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-4 address 10.10.62.10 prefix-length 24
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# set protocols static route 10.10.51.0/24 next-hop 10.10.61.20
admin@XorPlus# set protocols static route 10.10.51.0/24 next-hop 10.10.62.20
admin@XorPlus# commit
Waiting for merging configuration.
```

```
Commit OK.
Save done.
```

Check the static ECMP route for 10.10.51.0/24 in the RIB with command **run show route ipv4**.

Configuring ECMP Hash Fields

In the default setting, all fields are hashed by IP-source, port-destination, port-source, and VLAN. Additional fields can be enabled, as shown below:

```
admin@XorPlus# set interface ecmp hash-mapping field ingress-interface disable false
admin@XorPlus# set interface ecmp hash-mapping field ip-destination disable false
admin@XorPlus# set interface ecmp hash-mapping field ip-protocol disable false
admin@XorPlus# set interface ecmp hash-mapping field ip-source disable false
admin@XorPlus# set interface ecmp hash-mapping field port-destination disable false
admin@XorPlus# set interface ecmp hash-mapping field port-source disable false
admin@XorPlus# set interface ecmp hash-mapping field vlan disable false
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring ECMP Hash Mode

When you configure ECMP hash mode, follow these restrictions and guidelines:

- **round-robin-load-balancing**, **randomized-load-balancing**, **symmetric, dlb-normal**, **dlb-optimal** and **dlb-assigned** for ECMP are only supported on **Trident3** and **Tomahawk3** platforms.
- **resilient-load-balancing** for ECMP is only supported on **Tomahawk2, Trident3-X7, Tomahawk3**, **Tomahawk4**, **Tomahawk5** and **Trident4** platforms.
- When the ECMP hash-mapping mode configuration (set/delete) changes, a system restart is required for the configuration to take effect.
- ECMP hash-mapping modes (**round-robin-load-balancing**, **randomized-load-balancing**, **symmetric, resilient-load-balancing, dlb-normal**, **dlb-optimal** and **dlb-assigned**) are mutually exclusive. To switch between modes, you must first delete the configured mode before setting up the new one. Then, restart the system for the configuration to take effect.

- Enable Randomized Load Balancing for ECMP.

```
admin@PICOS# set interface ecmp hash-mapping randomized-load-balancing
admin@PICOS# commit
admin@PICOS# exit
admin@PICOS> request system reboot
```

- Enable round robin mode of ECMP load balancing.

```
admin@PICOS# set interface ecmp hash-mapping round-robin-load-balancing
admin@PICOS# commit
admin@PICOS# exit
admin@PICOS> request system reboot
```

- Enable normal mode of Dynamic Load Balancing for ECMP.

```
admin@PICOS# set interface ecmp hash-mapping dlb-normal
admin@PICOS# commit
admin@PICOS# exit
admin@PICOS> request system reboot
```

- Enable Symmetric Hash for ECMP.

```
admin@PICOS# set interface ecmp hash-mapping symmetric true
admin@PICOS# commit
admin@PICOS# exit
admin@PICOS> request system reboot
```

- Enable Resilient Load Balancing for ECMP.

```
admin@PICOS# set interface ecmp hash-mapping resilient-load-balancing
admin@PICOS# commit
admin@PICOS# exit
```

```
admin@PICOS> request system reboot
```

Symmetric Hash for ECMP Configuration Example

Symmetric Hash support for ECMP. Symmetric hash need the hashing field must be symmetric. For example, packet 1 and packet 2 are symmetric in table 1 and table 2 as below, and then packet 1 and packet2 will go out from the same physical port. Now Our symmetric Hash use IP layer and L4 field to hash when packets are transmitted on ECMP. Only matching symmetric condition, two packets can be transmitted on the same member port of ECMP.

IP Packet	Source IP Address	Destination IP Address
Packet1	10.1.1.1	20.1.1.1
Packet2	20.1.1.1	10.1.1.1

Table 1.

Layer 4 Packet	Source IP Address	Destination IP Address	Source Port Number	Destination Port Number
Packet1	10.1.1.1	20.1.1.1	100	200
Packet2	20.1.1.1	10.1.1.1	200	100

Table 2.

Symmetric Hash field as below:

1. ip-source
2. ip-destination
3. port-source
4. port-destination

By default, Enable hash field on ECMP:

1. ip-source
2. ip-destination
3. port-source
4. port-destination

> Symmetric hashing is supported on Helix4 **,** Trident2, Trident2+, Trident3 and Tomahawk platform switches.

ECMP Configuration

```
set interface ecmp hash-mapping symmetric true
```

ECMP Examples:

configure three ECMP route:

```
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 199
set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 299
set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 300
set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 301
set protocols static route 100.100.100.0/24 next-hop 182.168.1.100
set protocols static route 100.100.100.0/24 next-hop 183.168.1.100
set protocols static route 100.100.100.0/24 next-hop 184.168.1.100
set protocols static route 172.168.1.0/24 next-hop 182.168.1.100
set protocols static route 172.168.1.0/24 next-hop 183.168.1.100
set protocols static route 172.168.1.0/24 next-hop 184.168.1.100
set l3-interface vlan-interface vlan199 address 172.168.1.1 prefix-length 24
set l3-interface vlan-interface vlan299 address 182.168.1.1 prefix-length 24
set l3-interface vlan-interface vlan300 address 183.168.1.1 prefix-length 24
set l3-interface vlan-interface vlan301 address 184.168.1.1 prefix-length 24
set l3-interface vlan-interface vlan399 address 100.100.100.1 prefix-length 24
set vlans vlan-id 199 l3-interface "vlan199"
set vlans vlan-id 299 l3-interface "vlan299"
set vlans vlan-id 300 l3-interface "vlan300"
set vlans vlan-id 301 l3-interface "vlan301"
set vlans vlan-id 399 l3-interface "vlan399"
```

Configure the symmetric hash true

```
set interface ecmp hash-mapping symmetric true
```

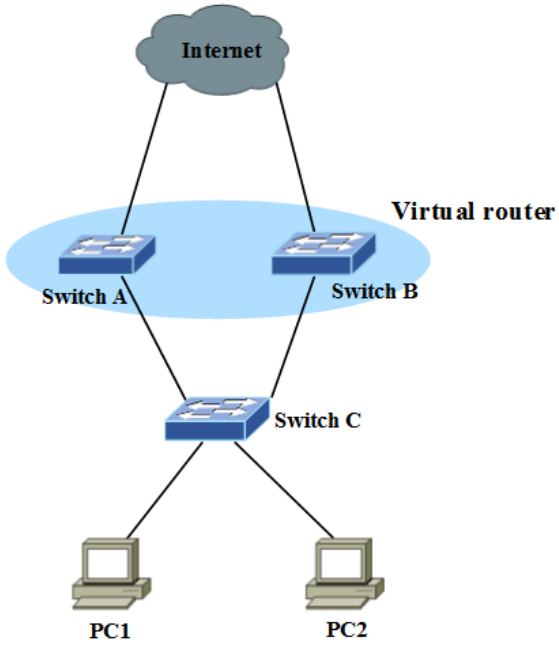
Introduction

Virtual Router Redundancy Protocol (VRRP) is a redundancy and backup function of network devices. VRRP group combines several routing devices into one virtual routing device and uses the IP address of the virtual routing device as the default gateway to establish communication with external networks. When a gateway device in a VRRP group fails, the VRRP mechanism can elect a new gateway device as Master to transmit the data traffic to ensure reliable network communication.

Figure 1. VRRP Networking Diagram



As shown in Figure 1, Switch A and Switch B form a virtual router. This virtual router has its own IP (could be IPv4 or IPv6) address. The hosts in the LAN use the virtual router IP as their default gateway IP. The switch with the highest priority between Switch A and Switch B functions as the master and the gateway device. The other switch functions as the backup router. For IPv4, the VRRP packets will use multicast MAC 01:00:5E:00:00:12 as destination MAC. For IPv6, the VRRP packets will use multicast MAC 33:33:00:00:00:12 as destination MAC. Switch C should support layer 2 switching function.

Besides the Standard VRRP protocol mode, PICOS also supports Active-Active VRRP mode. In the Standard VRRP protocol mode, only the Virtual Master Router can forward packets whereas the Virtual Backup Routers cannot forward packets. By adding a new working mechanism based on the VRRP standard protocol mode, Active-Active VRRP mode provides load balancing between the master and backup switches in the VRRP group, both of which are active, thus avoid the situation where the backup switches are always idle in the Standard VRRP protocol mode. This greatly improves usage efficiency of network resources.

In the version before PICOS 2.11.10, PICA8 switch supports only VRRPv2. From PICOS 2.11.10, PICA8 switch supports both VRRPv2 and VRRPv3. The differences between VRRPv2 and VRRPv3 are as follows:

- Apply to different networks. VRRPv3 supports IPv4 and IPv6 address families while VRRPv2 only supports IPv4 addresses.
- Packet format is different between VRRPv2 and VRRPv3, for details please refer to VRRP Packet Format.
- VRRPv3 supports accept mode while VRRPv2 does NOT support this mode. Accept mode controls whether a virtual router in master state will accept packets addressed to the virtual IPvX address of the VRRP group if it is not the IP address owner. However, in VRRPv2, the master switch always accepts packets addressed to the virtual IPvX address. For details about accept mode, please refer to Accept Mode.

NOTE:

- VRRPv2 and VRRPv3 interoperation is not supported, VRRP version configured on all devices in a VRRPv3 group must be the same.
- Standard VRRP mode supports one Master and several Backup switches in a VRRP group, while Active-Active VRRP mode supports only one Master and one Backup switch in a VRRP group.
- The same VRID must be configured on all devices for the same VRRP group.

- The IP address of the virtual router can be either an unassigned IP address in the network segment where the VRRP group resides or the IP address of an interface on a router in the VRRP group. A router whose interface IP address is same as the virtual IP address is called an "IP address owner". When the router is an IP address owner, its priority is always 255.
- Only one IP address owner can be configured in the same VRRP group.

The VRRP principle included in this document describes only the working mechanism of Active-Active VRRP mode for IPvX (In this document, the term "IPvX" (where X is 4 or 6) is introduced to mean either "IPv4" or "IPv6"). For details about standard VRRPv2 protocol mode, please refer to the RFC3768. For details about Standard VRRPv3 protocol mode, please refer to RFC5798.

Active-Active VRRP Mode

The basic principle in Active-Active VRRP is that one virtual IPvX address corresponds to two virtual MAC addresses, and each switch in the VRRP group corresponds to one virtual MAC address to support load balancing between the master and backup switches. This helps in avoiding the backup switch from being in idle state as is the case in Standard VRRP mode.

VRRP Working Mechanism

Active-Active VRRP mode working process is as follows:

1. Devices in a VRRP group elect the Master and Backup based on their priorities and VLAN interface/routed interface IPvX addresses by exchanging VRRP advertisement packets.

2. The master and backup devices periodically send VRRP Advertisement packets to each other to advertise its configuration (such as priority) and running status. This can also notify the downstream devices to refresh the MAC entries.

3. All the ARP requests / Neighbor Solicitation (NS) packets from the downstream devices or hosts are responded to by the master. ARP reply / Neighbor Advertisement (NA) packets carry one of the virtual MAC addresses of the VRRP group. For details about virtual MAC address allocation, please see Virtual MAC Address Allocation.

4. To notify the downstream devices of the virtual MAC, the master and backup devices periodically send virtual MAC update messages. For details, please refer to Virtual MAC Updating.

5. For IPv6, master sends Router Advertisements for the link-local addresses of virtual router IP address on the local area network to announce its availability for routing.

6. The VRRP device uses its real MAC address as source MAC for traffic forwarding.

VRRP Packet Format

VRRP packets are sent encapsulated in IPvX packets. For IPv4, in Layer 3 IP header of VRRP packets, source IP is the real IP (same segment with Virtual IP) of the VLAN interface/routed interface, destination IP is IPv4 multicast address 224.0.0.18 that is assigned to VRRP. In Ethernet header, source MAC is virtual MAC, and destination MAC is multicast MAC 01:00:5E:00:00:12. For IPv6, destination IP is IPv6 multicast address FF02::12 and destination MAC is multicast MAC 33:33:00:00:00:12.

VRRPv2 and VRRPv3 packet formats are shown below.

Figure 2. VRRPv2 Packet

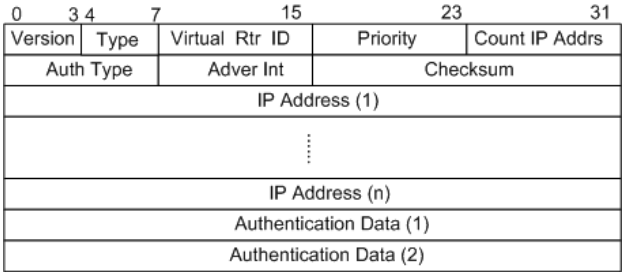


Figure 3. VRRPv3 Packet

VRRP Field	Descriptions
Version	The version field specifies the VRRP protocol mode. • VRRP_VERSION = 2, Standard VRRPv2 mode. • VRRP_VERSION = 3, Standard VRRPv3 mode. • VRRP_LOAD_BALANCE_VERSION = 4, Active-Active VRRPv2 mode. • VRRP_LOAD_BALANCE_VERSION = 5, Active-Active VRRPv3 mode.

Type	The type field specifies the type of VRRP packet. • VRRP_TYPE_ADVERTISEMENT = 1, advertisement packet sent by the master. • VRRP_BACKUP_ADVERTISEMENT = 2, advertisement packet sent by the backup device. • VRRP_UPDATE_ADVERTISEMENT = 3, MAC address update packet, sent periodically both by the master and backup devices. • VRRP_SYNC_ARP_ADVERTISEMENT / VRRP_SYNC_ NEIGHBOR_ADVERTISEMENT = 4, ARP synchronization /IPv6 Neighbor synchronization packet.
Virtual Rtr ID	Virtual router ID, range from 1 to 254.
Priority	Device priority in the VRRP group, range from 1 to 254. The default value is 100.
Count IP Addrs / Count IPvX Addr	The number of virtual IPvX addresses in the VRRP group.
Auth Type	Used only for VRRPv2 packets. The authentication type field identifies the authentication method being utilized. There are three types: • 0: Non Authentication. • 1: Simple Text Password. • 2: IP Authentication Header, which indicates the MD5 authentication mode. By default, there's no authentication.
rsvd	Reserved field for VRRPv3 packets.
Adver Int / Max Adver Int	VRRP advertisement interval, in second for IPv4 network and centisecond for IPv6 network. The default value is 4 seconds for both IPv4 and IPv6.
Checksum	The checksum field is used to detect data corruption in the VRRP packet.
IP Address / IPvX Addresses	IPvX address list that is associated with the virtual router. The number of addresses included is specified in the "Count IPvX Addr" field.
Authentication Data	Authentication key.

VRRP Packet Types

There are four types of VRRP packets in Active-Active VRRP mode: master advertisement, backup advertisement, virtual MAC update packet, and ARP synchronization / IPv6 neighbor synchronization packet.

1) Master advertisement where type = 1

The master device periodically sends VRRP advertisement packets to the backup device to advertise its configuration information (such as priority) and working status. The backup device determines whether the master is working properly by receiving VRRP advertisement packets.

When the master device fails to send advertisement packets due to some network fault, the backup device can not immediately get the working status of the master. It will wait until the Master_Down_Interval timer expires before it considers that the master device has failed, then switches its own state to Master. The value of the Master_Down_Interval timer is 3 × Advertisement_Interval + Skew_time, Skew_Time = (256 - Priority)/256, in seconds.

2) Backup advertisement message where type = 2

Backup device periodically sends VRRP advertisements to advertise its configuration information (such as priority) and working status in the VRRP group. The master device determines whether the backup device is working properly by receiving Backup advertisement packets. The interval for sending advertisement messages is the same as that of the Master advertisement message.

3) Virtual MAC update message where type = 3

To notify the downstream devices of the virtual MAC, the master and backup devices periodically send virtual MAC update messages. The virtual MAC address in Active-Active VRRP mode is used in the Ethernet header of virtual MAC update packet as the source MAC address. The connected network devices of the VRRP group refresh the MAC entries in time to perform packet forwarding. The default interval is 120s.

4) ARP synchronization message or IPv6 neighbor synchronization where type = 4

The VRRP device learns ARP entries / IPv6 Neighbor entries from the receiving traffic.

In order to ensure that both devices in the VRRP group can forward downstream data rapidly, ARP **/** IPv6 Neighbor synchronization packets are sent between the Master and Backup device when the ARP **/** IPv6 Neighbor table on the VRRP group device is updated.

For IPv4, the IPv4 addresses in the ARP table that are in the same network segment with virtual IPv4 address are synchronized to the peer VRRP device.

For IPv6, two types of IPv6 address in the Neighbor table are synchronized to the peer VRRP device,

- The global IPv6 addresses in the IPv6 Neighbor table that are in the same network segment with virtual IPv6 address.
- The link-local addresses that are in the same VLAN with the VRRP group.

Upon receiving the ARP synchronization **/** IPv6 Neighbor synchronization packet, the peer device initiates ARP **/** IPv6 Neighbor learning process. The ARP **/** IPv6 Neighbor entries on both VRRP devices will eventually reach a consistent state and both devices in the VRRP group can forward downstream data rapidly.

VRRP States

VRRP protocol defines three state machines: Initialize, Master and Backup.

Initialize

- VRRP is unavailable. The device in Initialize state cannot process VRRP advertisement packets.
- When the VRRP process starts it goes into initialize state. When the device is in master or backup states and it detects a fault, it enters the Initialize state.

- After receiving an interface Up message, the VRRP-enabled device first switches to the Backup state and then switches to the Master state after the Master_Down_Interval timer expires.

Master

The VRRP device in Master state performs the following operations:

- Sends VRRP advertisement packets periodically.
- Receives VRRP advertisement packets from the backup and determines whether the backup is working properly.
- Uses the virtual MAC address to respond to ARP request destined for the virtual IPv4 address.
- Uses the virtual MAC address to respond to ND Neighbor Solicitation messages destined for the virtual IPv6 address.
- Forwards IPvX packets destined for the virtual MAC address.
- Becomes the backup if the device receives a VRRP advertisement packet with a higher priority than its VRRP priority.
- Becomes the backup if the device receives a VRRP advertisement packet with the same priority as its VRRP priority and the local VLAN interface/routed interface address is smaller than the connected interface address on the peer VRRP device.
- For VRRPv3, accepts packets addressed to the IPvX address(es) associated with the virtual router if it is the IPvX address owner or if Accept Mode is True. For details about Accept Mode, please see Accept Mode.
- Sends Router Advertisement for the link-local addresses in virtual IP address list, as the source IP address of the RA packet, on the local area network to announce its virtual IP address as available for routing. In the prefix information field of the RA packet, it carries the global addresses in virtual IP address list for applying IPv6 stateless address auto-configuration protocol (refer to RFC2462 IPv6 Stateless Address Autoconfiguration).

Backup

The VRRP device in Backup state performs the following operations:

- Sends VRRP advertisement packets periodically.
- Receives VRRP advertisement packets from the master and determines whether the master is working properly.
- Does NOT respond to ARP request / ND Neighbor Solicitation messages destined for the virtual IPv4 / IPv6 address.
- Forwards IPvX packets destined for the virtual MAC address in Active-Active mode for load balancing.
- When it receives a packet of lower priority, it immediately switches to the Master state by default. If non-preemptive is configured, the device remains in the backup state.
- Master_Down_Interval timer: If the backup receives no advertisement packet after the timer expires, the backup takes the role of the master. The calculation formula is as follows:

  Master_Down_Interval = 3*Advertisement_Interval + Skew_time (offset time)

  Skew_Time = (256 - Priority) / 256
- For VRRPv3, does NOT accept packets addressed to the IPvX address(es) associated with the virtual router.
- Does NOT send Router Advertisement messages for the virtual router.

Virtual MAC Address Allocation

In Active-Active VRRP mode, the master switch no longer sends gratuitous ARP request or unsolicited ND Neighbor Advertisement packets as Standard VRRP protocol mode does. Instead, the master switch receives the ARP request / ND Neighbor Solicitation message sent by the connected hosts or devices and responds with ARP reply / ND Neighbor Solicitation message using the virtual MAC address instead of the real MAC address of the interface.

The virtual MAC address is allocated according to the hash value calculated from the source MAC address in the ARP request packet / ND Neighbor Solicitation message. This results in half of the hosts end up learning the virtual MAC address of Master and the other half of the hosts learn the virtual MAC address of the Backup. In this way, traffic from the hosts is shared between two VRRP devices to achieve load balancing.

The virtual router generates the virtual MAC address based on the virtual router ID, the format is 00: 00: 5E: 00: 0X: VRID. For IPv4, X is 1 in master device and 2 in backup device; For IPv6, X is 2 in master device and 1 in backup device.

For example, assuming that VRID 5 enables Active-Active VRRP mode for IPv4 and VRID 6 enables Active-Active VRRP mode for IPv6, then the virtual MAC addresses of VRID 5 will be 00-00-5E-00-01-05 and 00-00-5E-00-02-05, and that of VRID 6 will be 00-00-5E-00-02-06 and 00-00-5E-00-01-06.

Role Elect of Master and Backup

VRRP determines the device role in the VRRP group based on device priority and VLAN interface/routed interface by exchanging VRRP advertisement packets. The device with a higher priority is more likely to become the master. If two devices have the same priority, the device with a larger VLAN interface/routed interface IP address becomes the master.

The VRRP-enabled device in a VRRP group initially works in Initialize state. After receiving an interface Up message, if the priority of the device is 255, it will become the master directly; if the priority of the device is less than 255, the VRRP-enabled device first switches to the Backup state and then switches to the Master state when the Master_Down_Interval timer expires.

The device that first switches to the Master state obtains the priorities of other devices in the group by exchanging VRRP advertisement packet and then elect the master router.

- If the master priority in VRRP advertisement packets is higher than or equal to the priority of the device, the backup remains in Backup state.
- If the backup device has a higher priority than the master, the working mode of the backup (preemptive or non-preemptive) determines whether the master is re-elected.
  - Preemptive mode: If the priority of the backup router is higher than the priority of the current master router, the backup router automatically becomes the master router.
  - Non-preemptive mode: As long as the master router is working properly, the backup router with a higher priority cannot become the master router.
- The IP address owner's running priority is always 255; the IP address owner always works in preemptive mode, regardless of whether the preemption function is enabled. If the VRRP device is the IP address owner, it will switch to the master state immediately after receiving the interface Up message.

Virtual MAC Updating

To notify the downstream devices of the virtual MAC, the master and backup devices periodically send virtual MAC update messages. The virtual MAC address in Active-Active VRRP mode is used in the Ethernet header of virtual MAC update packet as the source MAC address. The connected network devices of the VRRP group refresh the MAC entries in time to perform packet forwarding. The default interval is 120s.

ARP / IPv6 Neighbor synchronization

The VRRP devices learn ARP entries / IPv6 Neighbor entries when receiving downstream traffic.

In order to ensure that both devices in the VRRP group can forward downstream data rapidly, ARP **/** IPv6 Neighbor synchronization packets are sent between the Master and Backup device when the ARP **/** IPv6 Neighbor table on the VRRP group device is updated.

For IPv4, the IPv4 addresses in the ARP table that are in the same network segment with virtual IPv4 address are synchronized to the peer VRRP device.

For IPv6, two IP addresses in the Neighbor table are synchronized to the peer VRRP device,

- The global IPv6 addresses in the IPv6 Neighbor table that are in the same network segment with virtual IPv6 address.
- The link-local addresses that are in the same VLAN with the VRRP group.

Upon receiving the ARP synchronization **/** IPv6 Neighbor synchronization packet, the peer device initiates ARP **/** IPv6 Neighbor learning process. The ARP **/** IPv6 Neighbor entries on both VRRP devices will eventually reach a consistent state and both devices in the VRRP group can forward downstream data rapidly.

Accept Mode

VRRPv3 supports Accept Mode which controls whether a virtual router in Master state will accept packets addressed to the virtual IPvX address of a VRRP group if it is not the IP address owner (the IP address owner is the router that has the interface whose actual IP address is used as the virtual router's IP address).

By default, the Accept Mode is disabled, if the master is not the IP address owner, it only accepts the ARP requests/ARP replies or NS/NA messages addressed to the virtual IP, any other messages whose destination IP is the virtual IP are not accepted. But when accept mode is enabled, it can accept all packets whose destination IP is a virtual IP.

Deployments that rely on, for example, pinging the address owner's IPvX address may choose to configure Accept Mode to True.

NOTE:

- Accept Mode is only supported in VRRPv3 while VRRPv2 does NOT support. In VRRPv2, the master switch always accepts packets addressed to the virtual IPvX address.
- When Accept Mode is disabled, PICOS can still accept and process IPv6 Neighbor Solicitations / Neighbor Advertisements packets and ARP Request / ARP Reply packets.
- If the master is the IP address owner, it accepts all the packets addressed to the IPvX address(es) associated with the virtual router even though Accept Mode is disabled.

Configuration Notes of VRRP

When configuring VRRP on a device, pay attention to the following points:

- Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.
- VRRPv3 supports IPv4 and IPv6 address families while VRRPv2 only supports IPv4 addresses.
- As VRRPv2 and VRRPv3 interoperation is not supported, VRRP version must be the same on both devices in a VRRP group. If the VRRP versions on the switches in the same VRRP group are different, it may cause VRRP communication to fail.
- When upgrading, we recommend that PICOS versions of the VRRP group devices be upgraded to PICOS 2.11.10 or later versions at the same time, as PICOS supports VRRPv3 from PICOS 2.11.10.
- VRRP supports VRF function by binding the Layer 3 interface to a specified VRF.
- The following configurations must be identical on both devices in the same VRRP group,
  - VRRP version.
  - Interval of sending VRRP advertisement packets.
  - Virtual IPvX lists.
  - Active-Active VRRP mode. You should either enable or disable Active-Active VRRP mode on both VRRP devices.
  - Authentication mode and authentication key.
- Active-Active VRRP mode supports only one Master and one Backup switch in a VRRP group. Standard VRRP mode supports one Master and several Backup switches in a VRRP group.
- One chassis switch supports a maximum of 128 VRRP groups. Please set the number of VRRP group based on device performance.
- One VRRP group supports a maximum of 254 virtual IPv4 addresses, and 64 virtual IPv6 addresses.
- Follow the rules below when configuring the virtual IPv4 / IPv6 address:
  - For IPv4, the virtual IPv4 of the VRRP group and the IPv4 address of the interface should be configured in the same network segment to ensure that the VRRP group can work normally.
  - The IP address of the virtual router can be either an unassigned IP address in the network segment where the VRRP group resides or the IP address of an interface on a router in the VRRP group. A router whose interface IP address is the same as the virtual IP address is called an "IP address owner".
  - The virtual IPv4 address of the VRRP group cannot be all zeros, broadcast address (255.255.255.255), network address or network broadcast address of the segment where the virtual IP address resides, loopback address, non-A / B / C address or any other illegal IP Address (e.g., 0.0.0.1).
  - For IPv6, the global virtual IPv6 address of the VRRPv3 group and the global IPv6 address of the interface should be configured in the same network segment to ensure that the VRRPv3 group can work normally.
  - In one VRRP group, IPv4 and IPv6 networks cannot be mixed. That is, the configured virtual IP addresses in the same VRRP group could either be IPv4 addresses or IPv6 addresses.
  - For IPv6, configure at least one link-local IPv6 address in a VRRPv3 group which will be used as the gateway address for the hosts, the format is FE80::/10.
  - Virtual IP address list on both devices of VRRP group must be the same.
  - Configure one or more global virtual IPv6 addresses, for the purpose of configuring global addresses via stateless address autoconfiguration of the downstream host (refer to RFC2462 IPv6 Stateless Address Autoconfiguration).
- The gateway address of the downstream host should be configured as the virtual IPvX address of the VRRP virtual router device. For IPv6, the gateway address should be the virtual link-local address.
- IPv4 address of Layer 3 interfaces in a VRRP group should be configured within the same network segment.
- Two devices in a VRRP group must be configured with the same VRID.
- It is recommended that VRRP groups on different L3 interfaces of a device should be configured with a different VRIDs.
- VRRPv3 protocol and the function of sending Router Advertisement message cannot be configured at the same time, as VRRPv3 master device could send Router Advertisements for the link-local addresses in virtual IP address list. Before you enable VRRPv3, disable sending RA message by using the command **set l3-interface vlan-interface** <*interface-name*> **ipv6-nd suppress-ra true** or **set l3-interface routed-interface** <*interface-name*> **ipv6-nd suppress-ra true**.
- When Accept Mode is disabled, PICOS can still accept and process IPv6 Neighbor Solicitations / Neighbor Advertisements packets and ARP Request / ARP Reply packets.

Configuring Standard VRRP

Procedure

Step1 Configure Layer 3 interface. VRRP can be enabled on a VLAN interface or a routed interface.

- Configure a VLAN interface.

  a) Configure VLAN ID.

  set vlans vlan-id <*vlan-id*>

  b) Configure the interface to VLAN.

  set interface gigabit-ethernet <*port*> **family ethernet-switching native-vlan-id** <*vlan-id*>

  c) Configure the IP address of the VLAN.

  set l3-interface vlan-interface <*interface-name*> **address** <*address*> **prefix-length** <*number*>

  d) Associate a Layer 3 interface with a VLAN.

  set vlans vlan-id <vlan-id> **l3-interface** <*interface-name*>

- Configure a routed interface.

  a) Enable routed interface.

  set interface gigabit-ethernet <*interface-name*> **routed-interface enable** <**true | false**>

  set interface gigabit-ethernet <*interface-name*> **routed-interface name** <*string*>

  b) Configure reserved-vlan for the routed interface.

  set vlans reserved-vlan <*reserved-vlan*>

  c) (Optional) Create the sub-interface and add it into a VLAN.

  set interface aggregate-ethernet <*interface-name*> **routed-interface sub-interface** <*sub-interface-name*> **vlan-id** <*vlan-id*>

  d) Configure the IP address of the routed interface.

  set l3-interface routed-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*prefix-number*>

Step2 Create a VRRP group.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*>

NOTE:

- Two devices in a VRRP group must be configured with the same VRID.
- One chassis switch supports a maximum of 128 VRRP groups. Please set the number of VRRP group based on device performance.
- It is recommended that VRRP groups on different L3 interfaces of a device should be configured with different VRIDs.

Step3 Enable the VRRP function.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **disable** <**true | false**>

By default, the VRRP function is enabled. Currently, VRRP can be configured on the VLAN interfaces or routed interfaces.

Step4 Configure the VRRP version number.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **version** <**2** | **3**>

By default, the system uses VRRPv2.

Step5 Configure a virtual IP address for the VRRP group.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **ip** <*ipv4-address*>

NOTE:

- One VRRP group supports a maximum of 254 virtual IPv4 addresses, and 64 virtual IPv6 addresses.
- For IPv4, the virtual IPv4 address of the VRRP group and the IPv4 address of the interface should be configured in the same network segment to ensure that the VRRP group can work normally.
- The IP address of the virtual router can be either an unassigned IP address in the network segment where the VRRP group resides or the IP address of an interface on a router in the VRRP group. A router whose interface IP address is the same as the virtual IP address is called an "IP address owner".
- The virtual IPv4 address of the VRRP group cannot be all zeros, broadcast address (255.255.255.255), network address or network broadcast address of the segment where the virtual IP address resides, loopback address, non-A / B / C address or any other illegal IP Address (e.g., 0.0.0.1).
- For IPv6, the global virtual IPv6 address of the VRRPv3 group and the global IPv6 address of the interface should be configured in the same network segment to ensure that the VRRPv3 group can work normally.
- In one VRRP group, IPv4 and IPv6 networks cannot be mixed. That is, the configured virtual IP addresses in the same VRRP group could either be IPv4 addresses or IPv6 addresses.
- For IPv6, configure at least one link-local IPv6 address in a VRRPv3 group which will be used as the gateway address for the hosts, the format is FE80::/10.
- Virtual IP address list on both devices of VRRP group must be the same.

- Configure one or more global virtual IPv6 addresses, for the purpose of configuring global addresses via stateless address autoconfiguration of the downstream host refer to RFC2462 IPv6 Stateless Address Autoconfiguration.

Step6 (Optional) Configure the interval of sending VRRP advertisement packets.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **interval** <*interval-value*>

NOTE:

- By default, the value is 4 seconds.
- The configurations of the interval of sending VRRP advertisement packets on both devices of VRRP group must be the same.

Step7 (Optional) Configure VRRP preemptive mode.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **preempt enable** <**true | false**>

By default, preemptive mode is enabled.

Step8 (Optional) Configure the priority of the device in a VRRP group.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **priority** <*priority-value*>

By default, the priority of the device in a VRRP group is 100.

Step9 (Optional) Configure an authentication mode and authentication key for a VRRP group. Note that VRRP authentication is only supported by VRRPv2, which is not supported by VRRPv3.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **authentication type** <**none** | **md5** | **simple**>

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **authentication simple-key** <*simple-key*>

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **authentication md5-key** <*md5-key*>

Step10 (Optional) Enable accept mode.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **accept disable** <**true** | **false**>

NOTE:

- Accept mode is only supported in VRRPv3.
- By default, accept mode is disabled.

Step10 (Optional) Configure the paremeters for sending router advertisement messages.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **ipv6-nd** *xx*

Configuring Active-Active VRRP

Procedure

Step1 Configure Layer 3 interface. VRRP can be enabled on a VLAN interface or a routed interface.

- Configure a VLAN interface.

  a) Configure VLAN ID.

  set vlans vlan-id <*vlan-id*>

  b) Configure the interface to VLAN.

  set interface gigabit-ethernet <*port*> **family ethernet-switching native-vlan-id** <*vlan-id*>

  c) Configure the IP address of the VLAN.

  set l3-interface vlan-interface <*interface-name*> **address** <*address*> **prefix-length** <*number*>

  d) Associate a Layer 3 interface with a VLAN.

  set vlans vlan-id <vlan-id> **l3-interface** <*interface-name*>

- Configure a routed interface.

  a) Enable routed interface.

  set interface gigabit-ethernet <*interface-name*> **routed-interface enable** <**true | false**>

  set interface gigabit-ethernet <*interface-name*> **routed-interface name** <*string*>

  b) Configure reserved-vlan for the routed interface.

  set vlans reserved-vlan <*reserved-vlan*>

  c) (Optional) Create the sub-interface and add it into a VLAN.

  set interface aggregate-ethernet <*interface-name*> **routed-interface sub-interface** <*sub-interface-name*> **vlan-id** <*vlan-id*>

  d) Configure the IP address of the routed interface.

  set l3-interface routed-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*prefix-number*>

Step2 Create a VRRP group.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*>

NOTE:

- Two devices in a VRRP group must be configured with the same VRID.
- One chassis switch supports a maximum of 128 VRRP groups. Please set the number of VRRP group based on device performance.
- It is recommended that VRRP groups on different L3 interfaces of a device should be configured with different VRIDs.

Step3 Configure the VRRP version number.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **version** <**2** | **3**>

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **disable** <**true | false**>

By default, the VRRP function is enabled. Currently, VRRP can be configured on the VLAN interfaces or routed interfaces.

Step5 Enable the Active-Active VRRP function.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **load-balance disable** <**true | false**>

NOTE:

- By default, the Active-Active VRRP function is disabled.
- The setting of enabling Active-Active VRRP must be the same on both devices of VRRP group.

Step6 Configure a virtual IP address for the VRRP group.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **ip** <*ipv4-address*>

NOTE:

- One VRRP group supports a maximum of 254 virtual IPv4 addresses, and 64 virtual IPv6 addresses.
- For IPv4, the virtual IPv4 address of the VRRP group and the IPv4 address of the interface should be configured in the same network segment to ensure that the VRRP group can work normally.
- The IP address of the virtual router can be either an unassigned IP address in the network segment where the VRRP group resides or the IP address of an interface on a router in the VRRP group. A router whose interface IP address is the same as the virtual IP address is called an "IP address owner".
- The virtual IPv4 address of the VRRP group cannot be all zeros, broadcast address (255.255.255.255), network address or network broadcast address of the segment where the virtual IP address resides, loopback address, non-A / B / C address or any other illegal IP Address (e.g., 0.0.0.1).

- For IPv6, the global virtual IPv6 address of the VRRPv3 group and the global IPv6 address of the interface should be configured in the same network segment to ensure that the VRRPv3 group can work normally.
- In one VRRP group, IPv4 and IPv6 networks cannot be mixed. That is, the configured virtual IP addresses in the same VRRP group could either be IPv4 addresses or IPv6 addresses.
- For IPv6, configure at least one link-local IPv6 address in a VRRPv3 group which will be used as the gateway address for the hosts, the format is FE80::/10.
- Virtual IP address list on both devices of VRRP group must be the same.
- Configure one or more global virtual IPv6 addresses, for the purpose of configuring global addresses via stateless address autoconfiguration of the downstream host refer to RFC2462 IPv6 Stateless Address Autoconfiguration.

Step7 (Optional) Configure the interval of sending VRRP advertisement packets.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **interval** <*interval-value*>

NOTE:

- By default, the value is 4 seconds.
- The configurations of the interval of sending VRRP advertisement packets on both devices of VRRP group must be the same.

Step8 (Optional) Configure VRRP preemptive mode.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **preempt enable** <**true | false**>

By default, preemptive mode is enabled.

Step9 (Optional) Configure the interval of updating the virtual MAC.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **load-balance virtual-MAC time-interval** <*interval-value*>

Step10 (Optional) Configure the priority of the device in a VRRP group.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **priority** <*priority-value*>

By default, the priority of the device in a VRRP group is 100.

Step11 (Optional) Configure an authentication mode and authentication key for a VRRP group. Note that VRRP authentication is only supported by VRRPv2, which is not supported by VRRPv3.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **authentication type** <**none** | **md5** | **simple**>

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **authentication simple-key** <*simple-key*>

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **authentication md5-key** <*md5-key*>

Step12 (Optional) Enable accept mode.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **accept disable** <**true** | **false**>

NOTE:

- Accept mode is only supported in VRRPv3.
- By default, accept mode is disabled.

Step13 (Optional) Configure the paremeters for sending router advertisement messages.

set protocols vrrp interface <*interface-name*> **vrid** <*virtual-router-id*> **ipv6-nd** *xx*

VRRP Configuration Example

- Example for Configuring Standard VRRPv3 for IPv4
- Example for Configuring Active-Active VRRPv3 for IPv4
- Example for Configuring Active-Active VRRPv3 for IPv6

Example for Configuring Standard VRRPv3 for IPv4

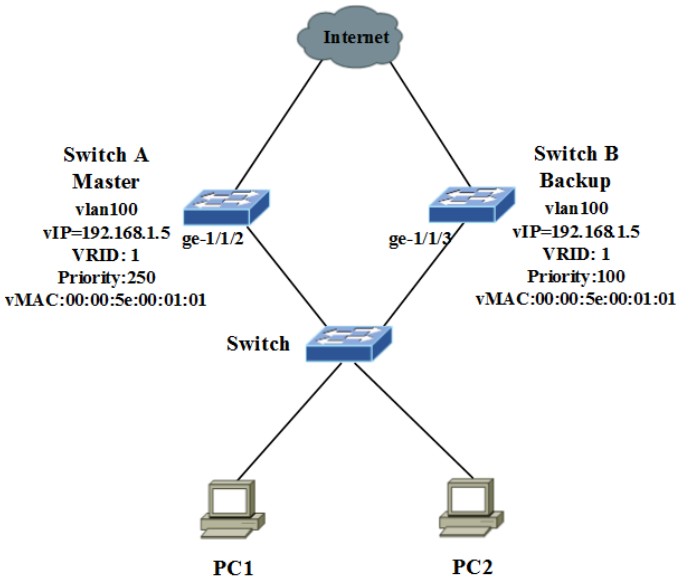
- Networking Requirements
- Procedure
  - Switch A
  - Switch B
- Verify the Configuration

Networking Requirements

In figure 1, Switch connects to the internet through gateway switches Switch A and Switch B. To ensure nonstop service availability, a VRRP group in standard mode needs to be configured on SwitchA and SwitchB.

- Configure the VRRP router ID as 1, Switch A is the Master and Switch B is the Backup switch of VRRP group.
- The virtual IP of VRRP router is 192.168.1.5, virtual MAC is 00:00:5e:00:01:01.
- The gateway address of the downstream host PC1 and PC2 needs to be configured as the IP address of the VRRP virtual router device.

Figure 1. Networking of Standard VRRP



Procedure

Switch A

Step1 Configure VLAN.

admin@SwitchA# set vlans vlan-id 100

admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 100

admin@SwitchA# set l3-interface vlan-interface vlan100 address 192.168.1.1 prefix-length 24

admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100

Step2 Create a VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1

Step3 Configure the VRRP version number to v3.

admin@SwitchA#set protocols vrrp interface vlan100 vrid 1 version 3

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 disable false

By default, the VRRP function is enabled.

Step5 Configure a virtual IP address for the VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 ip 192.168.1.5

Step6 Configure the priority of a device in a VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 priority 250

Step7 Commit the configuration.

admin@SwitchA# commit

Switch B

Step1 Configure VLAN.

admin@SwitchB# set vlans vlan-id 100

admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 100

admin@SwitchB# set l3-interface vlan-interface vlan100 address 192.168.1.2 prefix-length 24

admin@SwitchB# set vlans vlan-id 100 l3-interface vlan100

Step2 Create a VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1

Step3 Configure the VRRP version number to v3.

admin@SwitchB#set protocols vrrp interface vlan100 vrid 1 version 3

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 disable false

By default, the VRRP function is enabled.

Step5 Configure a virtual IP address for the VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 ip 192.168.1.5

Step6 Configure the priority of the device in a VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 priority 100

Step7 Commit the configuration.

admin@SwitchB# commit

Verify the Configuration

- After the configuration is complete, run **run show vrrp** command to view the configuration information of VRRP group. The result of show command on the master is as follows.

```
admin@SwitchA# run show vrrp
Interface:                    vlan100
VRID:                         1
Version:                      3
Load-balance:                 disable
State:                        Master
Master IP:                    192.168.1.1
Virtual MAC:                  00:00:5e:00:01:01
Preempt:                      enable
Adver Interval:               4
Priority:                     250
Virtual IP:                   192.168.1.5
Auth-type:                    none
Auth-key:
```

- When showing MAC address table on the downstream switch to check the MAC address of the device, you can see the virtual MAC entries corresponding to the virtual IP address of the VRRP group.
- On PC1 and PC2, ping the virtual IP address 192.168.1.5 to check the connectivity with the devices in VRRP group.

Example for Configuring Active-Active VRRPv3 for IPv4

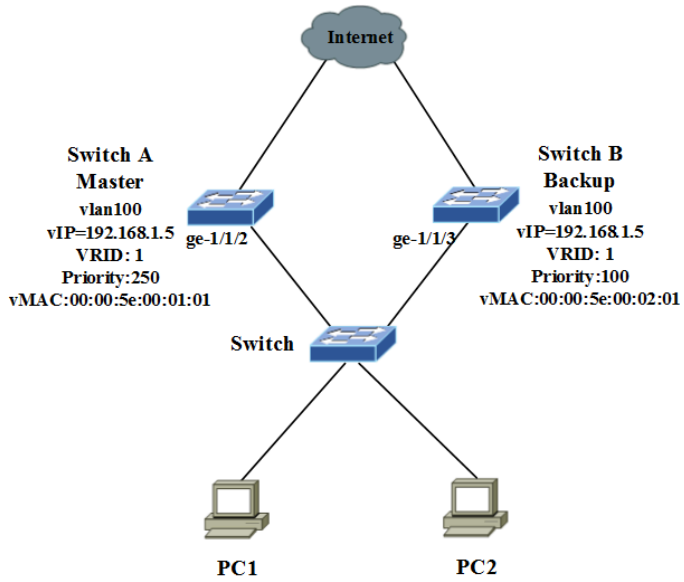
- Networking Requirements
- Procedure
  - Switch A
  - Switch B
- Verify the Configuration

Networking Requirements

In figure 1, Switch connects to the internet through gateway switches Switch A and Switch B. To ensure nonstop service availability, a VRRP group in Active-Active mode needs to be configured on SwitchA and SwitchB.

- Configure the VRRP router ID as 1, Switch A is the master and Switch B is the backup switch of VRRP group.
- The virtual IP of VRRP virtual router is 192.168.1.5, virtual MAC on master switch is 00:00:5e:00:01:01 and 00:00:5e:00:02:01 on the backup switch.
- The gateway address of the downstream host PC1 and PC2 needs to be configured as the IP address of the VRRP virtual router device.

Figure 1. Networking of Active-Active VRRP



Procedure

Switch A

Step1 Configure VLAN.

admin@SwitchA# set vlans vlan-id 100

admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 100

admin@SwitchA# set l3-interface vlan-interface vlan100 address 192.168.1.1 prefix-length 24

admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100

Step2 Create a VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1

Step3 Configure the VRRP version number to v3.

admin@SwitchA#set protocols vrrp interface vlan100 vrid 1 version 3

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 disable false

By default, the VRRP function is enabled.

Step5 Enable the Active-Active VRRP function.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 load-balance disable false

By default, the Active-Active VRRP function is enabled.

Step6 (Optional) Configure the interval for sending VRRP Advertisement packets.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 interval 1

By default, the value is one second.

Step7 Configure a virtual IP address for the VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 ip 192.168.1.5

Step8 (Optional) Configure VRRP preemptive mode.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 preempt enable true

By default, the device uses the preemptive mode.

Step9 (Optional) Configure the interval of updating the virtual MAC.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 load-balance virtual-MAC time-interval 120

By default, the value is 120s.

Step10 (Optional) Configure the priority of the device in a VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 priority 250

Step11 Commit the configuration.

admin@SwitchA# commit

Switch B

Step1 Configure VLAN.

admin@SwitchB# set vlans vlan-id 100

admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 100

admin@SwitchB# set l3-interface vlan-interface vlan100 address 192.168.1.2 prefix-length 24

admin@SwitchB# set vlans vlan-id 100 l3-interface vlan100

Step2 Create a VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1

Step3 Configure the VRRP version number to v3.

admin@SwitchB#set protocols vrrp interface vlan100 vrid 1 version 3

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 disable false

By default, the VRRP function is enabled.

Step5 Enable the Active-Active VRRP function.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 load-balance disable false

By default, the Active-Active VRRP function is enabled.

Step6 (Optional) Configure the interval of sending VRRP Advertisement packets.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 interval 1

By default, the value is one second.

Step7 Configure a virtual IP address for the VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 ip 192.168.1.5

Step8 (Optional) Configure VRRP preemptive mode.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 preempt enable true

By default, the device uses the preemptive mode.

Step9 (Optional) Configure the interval of updating the virtual MAC.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 load-balance virtual-MAC time-interval 120

By default, the value is 120s.

Step10 (Optional) Configure the priority of the device in a VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 priority 100

Step11 Commit the configuration.

Example for Configuring Active-Active VRRPv3 for IPv6

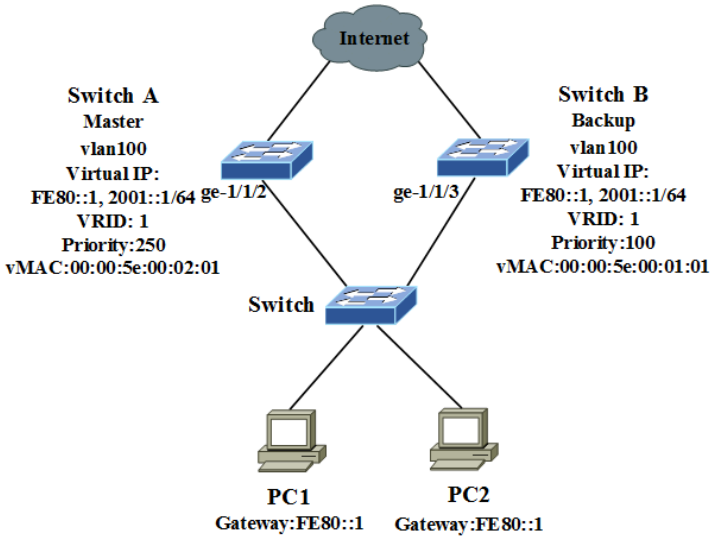
- Networking Requirements
- Procedure
  - Switch A
  - Switch B
- Verify the Configuration

Networking Requirements

Figure 1 below depicts an IPv6 network. Switch connects to the internet through gateway switches Switch A and Switch B. To ensure nonstop service availability, a VRRP group in Active-Active mode needs to be configured on Switch A and Switch B.

- Configure the VRRP router ID as 1, Switch A is the master and Switch B is the backup switch of VRRP group.
- Configure the virtual IPv6 address as 2001::1/64 and link-local address FE80::1, virtual MAC on master switch is 00:00:5e:00:02:01 and 00:00:5e:00:01:01 on the backup switch.

Figure 1. Networking of Active-Active VRRPv3 for IPv6



Procedure

Switch A

Step1 Configure VLAN.

admin@SwitchA# set vlans vlan-id 100

admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 100

admin@SwitchA# set l3-interface vlan-interface vlan100 address 2001::2 prefix-length 64

admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100

Step2 Create a VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1

Step3 Configure the VRRP version number to v3.

admin@SwitchA#set protocols vrrp interface vlan100 vrid 1 version 3

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 disable false

By default, the VRRP function is enabled.

Step5 Enable the Active-Active VRRP function.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 load-balance disable false

By default, the Active-Active VRRP function is enabled.

Step6 (Optional) Configure the interval for sending VRRPv3 advertisement packets.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 interval 1

By default, the value is one second.

Step7 Configure virtual IPv6 addresses for the VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 ip 2001::1

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 ip FE80::1

Step8 (Optional) Configure VRRP preemptive mode.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 preempt enable true

By default, the preemptive mode is enabled.

Step9 (Optional) Configure the interval of updating the virtual MAC.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 load-balance virtual-MAC time-interval 120

By default, the value is 120s.

Step10 Configure the priority of the device in a VRRP group.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 priority 250

Step11 (Optional) Enable accept mode.

admin@SwitchA# set protocols vrrp interface vlan100 vrid 1 accept disable false

Step12 Commit the configuration.

admin@SwitchA# commit

Switch B

Step1 Configure VLAN.

admin@SwitchB# set vlans vlan-id 100

admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 100

admin@SwitchB# set l3-interface vlan-interface vlan100 address 2001::3 prefix-length 64

admin@SwitchB# set vlans vlan-id 100 l3-interface vlan100

Step2 Create a VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1

Step3 Configure the VRRP version number to v3.

admin@SwitchB#set protocols vrrp interface vlan100 vrid 1 version 3

By default, the system uses VRRPv2.

Step4 Enable the VRRP function.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 disable false

By default, the VRRP function is enabled.

Step5 Enable the Active-Active VRRP function.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 load-balance disable false

By default, the Active-Active VRRP function is enabled.

Step6 (Optional) Configure the interval of sending VRRPv3 advertisement packets.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 interval 1

By default, the value is one second.

Step7 Configure virtual IPv6 addresses for the VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 ip 2001::1

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 ip FE80::1

Step8 (Optional) Configure VRRP preemptive mode.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 preempt enable true

By default, the preemptive mode is enabled.

Step9 (Optional) Configure the interval of updating the virtual MAC.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 load-balance virtual-MAC time-interval 120

By default, the value is 120s.

Step10 Configure the priority of the device in a VRRP group.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 priority 100

Step11 (Optional) Enable accept mode.

admin@SwitchB# set protocols vrrp interface vlan100 vrid 1 accept disable false

Step12 Commit the configuration.

admin@SwitchB# commit

Verify the Configuration

- After the configuration is completed, run **run show vrrp** command to view the configuration information of VRRP group. The result of show command on master is as follows.

```
admin@SwitchA# run show vrrp
Interface:                    vlan100
VRID:                         1
Version:                      2
Load-balance:                 enable
State:                        Master
Master IP:                    2001::2
Virtual MAC:                  00:00:5e:00:02:01
Preempt:                      enable
Adver Interval:               4
Priority:                     250
Virtual IP:                   2001::1, FE80::1
Auth-type:                    none
Auth-key:
```

- When showing MAC address table on the downstream switch to check the MAC address of the device, you will see the virtual MAC entries corresponding to the virtual IP address of the VRRP group.
- On PC1 and PC2, ping the virtual IP address FE80::1 to check the connectivity with the devices of VRRP group.

IPv4/IPv6 BGP Configuration

This section describes how to use Border Gateway Protocol (BGP) protocol.

NOTE:
- Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.
- BGP protocol supports VRF.

BGP Introduction

BGP is a path vector protocol used to carry routing information between autonomous systems.The term path vector comes from the fact that BGP routing information carries a sequence of AS numbers that identifies the path of AS's that a network prefix has traversed. The path information associated with the prefix is used to enable loop prevention.

BGP uses TCP as its transport protocol (port 179). This ensures that all the transport reliability (such as retransmission) is taken care of by TCP and does not need to be implemented in BGP, thereby simplifying the complexity associated with designing reliability into the protocol itself.

> **NOTE:**
> BGP protocol supports VRF.

BGP Speaker and BGP Peers

Routers that run a BGP routing process are often referred to as BGP speakers.Two BGP speakers that form a TCP connection between one another for the purpose of exchanging routing information, are referred to as neighbors or peers. Peer routers exchange open messages to determine the connection parameters.These messages are used to communicate values such as the BGP speaker's version number.

Gracefully Shutdown

BGP also provides a mechanism to gracefully close a connection with a peer. In other words, in the event of a disagreement between the peers, be it resultant of configuration, incompatibility, operator intervention, or other circumstances, a NOTIFICATION error message is sent, and the peer connection does not get established or is torn down if it's already established. The benefit of this mechanism is that both peers understand that the connection could not be established or maintained and do not waste resources that would otherwise be required to maintain or blindly reattempt to establish the connection. The graceful close mechanism simply ensures that all outstanding messages, primarily NOTIFICATION error messages, are delivered before the TCP session is closed.

BGP Session Establishment

Initially, when a BGP session is established between a set of BGP speakers, all candidate BGP routes are exchanged. After the session has been established and the initial route exchange has occurred, only incremental updates are sent as network information changes.

Routes are advertised between a pair of BGP routers in UPDATE messages. The UPDATE message contains, among other things, a list of <length, prefix> tuples that indicate the list of destinations that can be reached via a BGP speaker. The UPDATE message also contains the path attributes, which include such information as the degree of preference for a particular route and the list of AS's that the route has traversed.

In the event that a route becomes unreachable, a BGP speaker informs its neighbors by withdrawing the invalid route. Withdrawn routes are part of the UPDATE message. These routes are no longer available for use. If information associated with a route has changed or a new path for the same prefix has been selected, a withdrawal is not required; it is enough to just advertise a replacement route.

KEEPALIVE Message

If no routing changes occur, the routers exchange only KEEPALIVE packets.

KEEPALIVE messages are sent periodically between BGP neighbors to ensure that the connection is kept alive. KEEPALIVE packets (19 bytes each) should not cause any strain on the router CPU or link bandwidth because they consume a minimal amount of bandwidth.

BGP Attributes

BGP attributes of the routes can be used in route selection and load balancing. The following describes common BGP route attributes:

- **Origin**

  The Origin attribute defines the origin of a route and marks the path of a BGP route. The Origin attribute is classified into three types:

  - IGP

    A route with IGP as the Origin attribute is of the highest priority. The Origin attribute of the routes imported into a BGP routing table using the **set protocols bgp** [**vrf** <*vrf-name*>] **{ipv4-unicast|ipv6-unicast} network <***ipv4/prefixlen***> [label-index**<*label-index*>|**route-map** <*ROUTE-MAP-NAME*>**]** command is IGP.

  - EGP

    A route with EGP as the Origin attribute is of the secondary highest priority. The Origin attribute of the routes obtained through EGP is EGP.

- Incomplete

  A route with Incomplete as the Origin attribute is of the lowest priority. The Origin attribute of the routes learned by other means is Incomplete. For example, the Origin attribute of the routes imported by BGP using the **set protocols bgp** [**vrf** <*vrf-name*>] **{ipv4-unicast|ipv6-unicast} redistribute** {**connected|kernel|ospf|static|table <***table-number***>**} [**metric** <*metric-number*>|**route-map** <*route-map*>] command is Incomplete.

- **AS_Path**

  The AS_Path attribute records all the ASs that a route passes through from the source to the destination in the vector order. To prevent inter-AS routing loops, a BGP device does not receive the routes of which the AS_Path list contains the local AS number.

  When a BGP speaker advertises an imported route:

  - If the route is advertised to EBGP peers, the BGP speaker creates an AS_Path list containing the local AS number in an Update message.
  - If the route is advertised to IBGP peers, the BGP speaker creates an empty AS_Path list in an Update message.

  When a BGP speaker advertises a route learned in the Update message sent by another BGP speaker:

  - If the route is advertised to EBGP peers, the BGP speaker adds the local AS number to the leftmost of the AS_Path list. According to the AS_Path list, the BGP speaker that receives the route can learn about the ASs through which the route passes to reach the destination. The number of the AS that is nearest to the local AS is placed on the top of the AS_Path list. The other AS numbers are listed according to the sequence in which the route passes through ASs.
  - If the route is advertised to IBGP peers, the BGP speaker does not change the AS_Path attribute of the route.

- **Next_Hop**

  The Next_Hop attribute records the next hop that a route passes through. The Next_Hop attribute of BGP is different from that of an IGP because it may not be the neighbor IP address. A BGP speaker processes the Next_Hop attribute based on the following rules:

  - When advertising a route to an EBGP peer, a BGP speaker sets the Next_Hop attribute of the route to the address of the local interface through which the BGP peer relationship is established with the peer.
  - When advertising a locally originated route to an IBGP peer, the BGP speaker sets the Next_Hop attribute of the route to the address of the local interface through which the BGP peer relationship is established with the peer.
  - When advertising a route learned from an EBGP peer to an IBGP peer, the BGP speaker does not change the Next_Hop attribute of the route.

- **Local_Pref**

  The Local_Pref attribute indicates the BGP preference of a device and helps determine the optimal route when traffic leaves an AS. When a BGP device obtains multiple routes to the same destination address but with different next hops from different IBGP peers, the BGP device prefers the route with the highest Local_Pref. The Local_Pref attribute is exchanged only between IBGP peers and is not advertised to other ASs. The Local_Pref attribute can be manually configured. If no Local_Pref attribute is configured for a route, the Local_Pref attribute of the route uses the default value 100.

- **MED**

  The multi-exit discriminator (MED) attribute helps determine the optimal route when traffic enters an AS. When a BGP device obtains multiple routes to the same destination address but with different next hops from EBGP peers, the BGP device selects the route with the smallest MED value as the optimal route.

  The MED attribute is exchanged only between two neighboring ASs. The AS that receives the MED attribute does not advertise it to any other ASs. The MED attribute can be manually configured. If no MED attribute is configured for a route, the MED attribute of the route uses the default value 0.

- **Community**

  The Community attribute identifies the BGP routes with the same characteristics, simplifies the applications of routing policies, and facilitates route maintenance and management.

  The Community attribute includes self-defined community attributes and well-known community attributes. **Table 1** lists well-known community attributes.

  Table 1 Well-known community attributes

Community Attribute	Value	Description
Internet	0 (0x00000000)	A BGP device can advertise the received route with the Internet attribute to all peers.
No_Advertise	4294967042 (0xFFFFFF02)	A BGP device does not advertise the received route with the No_Advertise attribute to any peer.
No_Export	4294967041 (0xFFFFFF01)	A BGP device does not advertise the received route with the No_Export attribute to devices outside the local AS.
No_Export_Subconfed	4294967043 (0xFFFFFF03)	A BGP device does not advertise the received route with the No_Export_Subconfed attribute to devices outside the local AS or to devices outside the local sub-AS.

- **Originator_ID and Cluster_List**

  The Originator_ID attribute and Cluster_List attribute help eliminate loops in route reflector scenarios.

BGP Regular Expressions

A regular expression is a mode matching tool. You can create a matching mode based on specified rules and then match target objects based on the matching mode. A regular expression consists of 1 to 256 common characters and special characters.

- Common characters

  Common characters are used to match themselves in a string, including all upper-case and lower-case letters, digits, punctuations, underline, and special symbols. For example, a matches the letter "a" in "abc", 10 matches the digit "10" in "10.113.25.155", and @ matches the symbol "@" in "xxx@xxx.com".

- Special characters

  Special characters are a set of symbols with special meanings which are provided to flexibly create matching modes. The following special characters are supported by PICOS:

  .* Matches any single character.
  * Matches 0 or more occurrences of pattern.
  + Matches 1 or more occurrences of pattern.
  ? Match 0 or 1 occurrences of pattern.
  ^ Matches the beginning of the line.
  $ Matches the end of the line.
  _ The _ character has special meanings in BGP regular expressions. It matches to space and comma , and AS set delimiter { and } and AS confederation delimiter (and). And it also matches to the beginning of the line and the end of the line. So _ can be used for AS value boundaries match. This character technically evaluates to (^|[,{}()]|$).

> **NOTE:**
> Note that space is not supported, even if in a double quotation marks "".

Basic BGP Configuration

- Configuring a BGP Router ID
- Configuring BGP Local-AS
- Configuring External BGP Peering
- Configuring Internal BGP Peering
- Configuring a BGP Peer Group
- Configuring BGP to Import Routes
  - Redistribute Mode
  - Network Mode

For IPv6 BGP configuration, the following command must be configured to enable the IPv6 address family capability and exchange of information specific to an IPv6 address family with a BGP neighbor.
set protocols bgp [**vrf** *<vrf-name>*] **{neighbor** *<ip>***| peer-group** *<peer-group>* |**interface** *<interface>***}** {**ipv6-unicast|ipv6-labeled-unicast**} **activate true**

Configuring a BGP Router ID

The router ID should be configured first when you configure BGP. The router ID is a string similar to the IP address, and is the identifier of a BGP router in an AS. You should not change the router ID after completing the configuration. By default, the BGP router ID is not configured.

```
admin@XorPlus# set protocols bgp router-id 1.1.1.1
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring BGP Local-AS

The local ASN (Autonomous System Number) should be configured when you configure BGP. An Autonomous System (AS) is a group of IP networks that are controlled by one entity, typically an Internet service provider (ISP), and that have the same routing policy. Each AS is assigned a unique AS number, which identifies an AS on a BGP network.

The AS_Path attribute records all the AS numbers that a route passes through, from the source to the destination, following the order of vectors.

```
admin@XorPlus# set protocols bgp local-as 100
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring External BGP Peering

If the AS number of the specified peer is different from the local AS number during the configuration of BGP peers, an EBGP peer is configured. To establish point-to-point connections between peer autonomous systems, configure a BGP session on each interface of a point-to-point link. Generally, such sessions are made at network exit points with neighboring hosts outside the AS.

```
admin@XorPlus# set protocols bgp local-as 100
admin@XorPlus# set protocols bgp neighbor 192.168.49.1 remote-as 200
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Internal BGP Peering

If the AS number of the specified peer is the same as the local AS number during the configuration of BGP peers, an IBGP peer is configured.

```
admin@XorPlus# set protocols bgp local-as 100
admin@XorPlus# set protocols bgp neighbor 192.168.49.1 remote-as 100
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring a BGP Peer Group

A large BGP network has a large number of peers. It is difficult to configure and maintain these peers. You can add the BGP peers with the same configurations to a BGP peer group and then configure the BGP peers in batches. This simplifies peer management and improves route advertisement efficiency.

> **NOTE:**
>
> - If a BGP configuration exists on a peer and its peer group, the BGP configuration on the peer takes precedence over the configuration on the peer group.
> - If the peer you want to add to a group already exists in the BGP configuration, delete it first, than add it to the peer group.

The following example commands create a peer group called Leaf1 that includes two external peers.

```
admin@XorPlus# set protocols bgp peer-group Leaf1
admin@XorPlus# set protocols bgp peer-group Leaf1 remote-as external
admin@XorPlus# set protocols bgp neighbor 10.10.0.1 peer-group Leaf1
admin@XorPlus# set protocols bgp neighbor 10.10.0.12 peer-group Leaf1
admin@XorPlus# commit
```

Configuring BGP to Import Routes

BGP cannot discover routes and needs to import routes such as IGP routes into BGP routing tables so that the imported routes can be transmitted within an AS or between ASs. BGP imports routes in either redistribute or network mode.

> **NOTE:**
> If you do not want to control the route exchanging via use BGP policies, you need to disable feature *ebgp-requires-policy* manually, or the route cannot be correctly exchanged. For details about *ebgp-requires-policy*, see page Configuring ebgp-requires-policy.

Redistribute Mode

In redistribute mode, BGP imports IGP routes, including RIP, OSPF, and IS-IS routes, into BGP routing tables based on protocol type. To ensure the validity of imported IGP routes, BGP can also import static routes and direct routes in redistribute mode.

Use the following command to configure to import BGP route:

set protocols bgp [**vrf** <*vrf-name*>] **{ipv4-unicast|ipv6-unicast} redistribute** {**connected|kernel|ospf|static|table <***table-number***>**} [**metric** <*metric-number*>|**route-map** <*route-map*>]

Network Mode

In network mode, BGP imports the routes in the IP routing table one by one to BGP routing tables. The network mode is more accurate than the redistribute mode. The ORIGIN attribute of BGP routes advertised in this way is IGP.

Use the following commands to configure BGP to statically add routes in the IP routing table to the BGP routing table and advertise these routes to peers.

Apply the specified route policy or a route label to control network advertisements with the following command:

set protocols bgp [**vrf** <*vrf-name*>] **{ipv4-unicast|ipv6-unicast} network <***ipv4/prefixlen***> [label-index**<*label-index*>|**route-map** <*ROUTE-MAP-NAME*>**]**

The network mode command is used to import exactly-matching routes. The mask length as configured in the network statement must match the mask length of prefixes in the routing table. This means that the specified network must be available and active in the local IP routing table.

Configuring BGP Security

- Configuring MD5 Authentication
- Configuring TTL Security Hop Count

Configuring MD5 Authentication

BGP uses TCP as the transmission protocol, and considers a packet valid as long as the source address, destination address, source port, destination port, and TCP sequence number of the packet are correct. However, most parameters in a packet may be easily obtained by attackers. To protect BGP from attacks, MD5 authentication can be used between BGP peers to reduce the possibility of attacks. The MD5 algorithm is easy to configure, generates a single password that needs to be manually changed.

```
admin@XorPlus# set protocols bgp neighbor 192.10.10.2 password picos12345
admin@XorPlus# commit
```

Configuring TTL Security Hop Count

This feature enables BGP to establish connection with external peers residing on networks that are not directly connected. By enabling this feature, the received TTL from a BGP peer is compared with the difference "255 - hop-count". BGP messages coming with a TTL less than this value are not accepted. BGP peering will not be established if the TTL in the session establishment is received with a lower value. Also, by enabling this feature the router will send BGP packets with TTL value of 255 to the neighbor. For a neighbor, either TTL security or ebgp-multihop can be configured, not both together. If there are multiple paths to reach the node, then the hop count should be configured considering the longest route.

```
admin@XorPlus# set protocols bgp neighbor 192.10.10.2 ttl-security hops 200
admin@XorPlus# commit
```

Configuring a BGP Route Reflector

To ensure the connectivity between IBGP peers within an AS, you need to establish full-mesh connections between the IBGP peers. When there are many IBGP peers, it is costly to establish a fully-meshed network. A route reflector (RR) can solve this problem.

A cluster ID can help prevent routing loops between multiple RRs within a cluster and between clusters. When a cluster has multiple RRs, the same cluster ID must be configured for all the RRs within the cluster.

Enabling Route Reflector

The following example configures the local device Switch1 as the route reflector and the peer Switch2 as the client of the route reflector. No configuration is required on the client.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast route-reflector-client
admin@XorPlus# commit
```

Configuring Cluster ID

The following example configures a cluster ID for the RR. By default, each RR uses its router ID as the cluster ID.

```
admin@XorPlus# set protocols bgp cluster-id 100.100.100.100
admin@XorPlus# commit
```

Configuring BGP Timers

When deploying BGP, there are several timers can be configured.

- Configuring BGP Keepalive and Hold Timers
- Configuring a BGP Reconnect Timer
- Configuring a Advertisement Interval
- Configuring the Global BGP Timers

Configuring BGP Keepalive and Hold Timers

Keepalive messages are used by BGP to maintain peer relationships.

- If short Keepalive time and holdtime are set, BGP can detect a link fault quickly. This speeds up BGP network convergence, but increases the number of Keepalive messages on the network and loads of devices, and consumes more network bandwidth resources.
- If long Keepalive time and holdtime are set, the number of Keepalive messages on the network is reduced, loads of devices are reduced, and fewer network bandwidth are consumed. If the Keepalive time is too long, BGP is unable to detect link status changes in a timely manner. This is unhelpful for implementing rapid BGP network convergence and may cause many packets to be lost.

Keepalive and hold timers can be configured either for a specific peer or peer group, and the configurations for a specific peer take precedence over those for the peer group of this peer.

The following example commands set the keepalive interval to 10 seconds and the hold time to 30 seconds.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 timers keepalive 10
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 timers holdtime 30
admin@XorPlus# commit
```

Configuring a BGP Reconnect Timer

After BGP initiates a TCP connection, the Reconnect timer will be stopped if the TCP connection is established successfully. If the first attempt to establish a TCP connection fails, BGP tries again to establish the TCP connection after the Reconnect timer expires.

- Setting a short Reconnect interval reduces the period BGP waits between attempts to establish a TCP connection. This speeds up the establishment of the TCP connection.
- Setting a long Reconnect interval suppresses routing flapping caused by peer relationship flapping.

A Reconnect timer can be configured either for a specific peer or peer group, and the configurations for a specific peer take precedence over those for the peer group of this peer.

This example sets the Re-connection value to 30 seconds.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 timers connect 30
admin@XorPlus# commit
```

Configuring a Advertisement Interval

BGP does not periodically update a routing table. When BGP routes change, BGP updates the changed BGP routes in the BGP routing table by sending Update messages.

- If a short Update message interval is set, BGP can fast detect route changes. This speeds up BGP network convergence, but increases the number of Update messages on the network and loads of devices, and consumes more network bandwidth resources.
- If a long Update message interval is set, the number of Update messages on the network is reduced, loads of devices are reduced, and fewer network bandwidth are consumed. This avoids network flapping. If the Update message interval is too long, BGP is unable to detect route changes in a timely manner. This is unhelpful for implementing rapid BGP network convergence and may cause many packets to be lost.

When routes change, the switch sends routing updates to notify its peers. If a route changes frequently, the **set protocols bgp** [**vrf** <*vrf-name*>] {**neighbor** <*ip*>| **peer-group** <*peer-group*> | **interface** <*interface*>**} advertisement-interval** <*advert-interval*> command can be used to adjust the interval at which Update packets are sent for changes of this route. This frees the switch from sending Update packets for every route change.

The following example commands set the advertisement interval to 5 seconds:

```
admin@XorPlus# set protocols bgp neighbor 1.1.1.1 advertisement-interval 5
admin@XorPlus# commit
```

Configuring the Global BGP Timers

In addition to the timers configured for a specific neighbor or a peer goup described above, BGP also supports to configure global timers for all the BGP neighbors.

The following example commands set the keepalive interval to 10 seconds and the hold time to 30 seconds globally for all the BGP neighbors.

```
admin@XorPlus# set protocols bgp timers keepalive 10
admin@XorPlus# set protocols bgp timers holdtime 30
```

```
admin@XorPlus# commit
```

Configuring BGP Route Aggregation

Route aggregation is a mechanism that combines multiple routes into one route. This mechanism allows a BGP device to advertise only the summarized route but not all the specific routes to peers, therefore reducing the size of the BGP routing table. If the aggregated route flaps, the network is not affected, so network stability is improved.

To prevent routing loops caused by route summarization, BGP uses the AS_Set attribute. The AS_Set attribute is an unordered set of all ASs that a route passes through. When the summarized route enters an AS in the AS_Set attribute again, BGP finds that the local AS number has been recorded in the AS_Set attribute of the route and discards this route to prevent a routing loop.

The following example command aggregates a range of addresses, such as 10.10.1.0/24, 10.10.2.0/24, 10.10.3.0/24 into the single prefix 10.10.0.0/16.

```
admin@Xorplus# set protocols bgp ipv4-unicast aggregate-address 10.10.0.0/16
admin@Xorplus# commit
```

Configuring BGP Dynamic Neighbors

BGP dynamic neighbors are established by creating a listen range and accepting incoming connections from neighbors in that address range.

The BGP command **set protocols bgp** [**vrf** <*vrf-name*>] **listen range {**<*ipv4/prefixlen*>|<*ipv6/prefixlen*>**} peer-group** <*peer-group*> specifies a range of IPv4 addresses from which the switch will accept incoming dynamic BGP peering requests, and creates the named dynamic peer group to which those peers belong. Dynamic BGP neighbors are peers which have not been manually established, but are accepted into a dynamic peer group when the switch receives a peering request from them.

Dynamic peers cannot be configured individually, but inherit any configuration that is applied to the peer group to which they belong. In larger BGP networks, implementing BGP dynamic neighbors can reduce the amount and complexity of CLI configuration and save CPU and memory usage. Only IPv4 peering is supported. Peering relationships with dynamic peers are terminated if the peer group is deleted.

The following example commands create the peer group Leaf1 and configure BGP peering to remote neighbors within the address range 10.10.10.0/31. The **set protocols bgp listen limit** command limits the number of dynamic peers. The default value is 100.

```
admin@XorPlus# set protocols bgp peer-group Leaf1
admin@XorPlus# set protocols bgp peer-group Leaf1 remote-as external
admin@XorPlus# set protocols bgp listen range 10.10.10.0/31 peer-group Leaf1
admin@XorPlus# set protocols bgp listen limit 10
admin@XorPlus# commit
```

Configuring eBGP Multihop

External BGP peering sessions are configured to allow BGP peers from different autonomous systems to exchange routing updates. By design, a BGP routing process expects eBGP peers to be directly connected. When the neighbor is not directly connected, then we can enable eBGP Multihop function to allow the session to be established.

In this example, BGP is configured to allow connections to or from neighbor 192.168.1.1, which resides on a network that is not directly connected.

```
admin@XorPlus# set protocols bgp neighbor 192.168.1.1 remote-as external
admin@XorPlus# set protocols bgp neighbor 192.168.1.1 ebgp-multihop maximum-hop 5
admin@XorPlus# commit
```

Configuring Removing and Replacing Private ASNs from the AS Path

External BGP requires that globally unique AS numbers be used when routing to the global Internet. Using private AS numbers (64512 to 65535) would prevent access to the global Internet. This feature allows routers that belong to a private AS to access the global Internet. A network administrator configures the routers to remove private AS numbers from the AS path contained in outgoing update messages and optionally, to replace those numbers with the ASN of the local router, so that the AS Path length remains unchanged.

The **replace-as** keyword is available to replace the private AS numbers being removed from the path with the local AS number, thereby retaining the same AS path length.

This example removes all the private AS numbers from the AS path in outgoing eBGP updates and replaces them with the public AS number of the local router.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast remove-private-as all replace-as
admin@XorPlus# commit
```

Configuring BGP Multipath

On a large network, there may be multiple valid BGP routes to the same destination. A switch will select and add the optimal BGP route to its routing table for traffic forwarding and advertises this route to its peers. This, however, will result in uneven load balancing of many traffic. Configuring BGP load balancing can enable the switch to add these multiple equal-cost BGP routes to its routing table, implementing traffic load balancing and reducing network congestion. After BGP load balancing is configured, the switch will still select the optimal route among the multiple routes and advertise only this route to its peers.

In PICOS system, the BGP multipath option is enabled so that the switch can install multiple equal-cost BGP paths to the forwarding table and load balance traffic across multiple links. You can change the number of paths allowed, according to your needs.

The example commands change the maximum number of paths to 12. You can set a value between 1 and 32. 1 disables the BGP multipath option.

```
admin@XorPlus# set protocols bgp ipv4-unicast multipath ibgp maximum-paths 12
admin@XorPlus# commit
```

For paths to be consider equal, they must have the same routes attributes, such as weight, local preference, origin and AS_Path attributes are the same. If any of these attribues are different, BGP multipath will NOT take effect.

But in a special case, we can use the **set protocols bgp**[***vrf***<*vrf-name*>]**bestpath as-path multipath-relax [as-set|no-as-set]** command to configure Border Gateway Protocol (BGP) to treat two BGP routes as equal cost even if their AS-paths differ, as long as their AS-path lengths and other relevant attributes are the same. This allows routes with different AS-paths to be programmed into the forwarding table as equal cost multipath routes. Any changes in BGP configuration are applied by restarting the current BGP sessions on the VRFs.

```
admin@XorPlus# set protocols bgp bestpath as-path multipath-relax
admin@XorPlus# commit
```

Configuring ebgp-requires-policy

Users can use the command **set protocols bgp** [**vrf** <*vrf-name*>] **ebgp-requires-policy** <**true | false**> to determine whether or not EBGP will exchange routes with peers based on a policy. Choosing **true** requires filters (filter-list, prefix-list or route-map defined) for every eBGP session.

Consider creating appropriate route maps and using them rather than disabling the policy check. As a best practice, using policies is a more secure behavior and can prevent unintended routes from being exchanged. Function **ebgp-requires-policy** is introduced and enabled by default.

With this command enabled, EBGP will not exchange routes with a neighbor unless there is a route map configured on the address family neighbor entry which matches and permits the routes inbound and outbound. That is, without an incoming filter, no routes will be accepted. Similarly, without an outgoing filter, no routes will be announced.

The following commands configure a BGP route policy “rm1” and enables ebgp-requires-policy to filter the incoming routes based on this policy.

```
admin@Xorplus# set routing prefix-list ipv4-family plist1 permit prefix 13.13.13.0/24
admin@Xorplus# set routing route-map rm1 order 1 matching-policy permit
admin@Xorplus# set routing route-map rm1 order 1 match ipv4-addr address prefix-list plist1
admin@Xorplus# set protocols bgp neighbor 192.168.170.1 ipv4-unicast in route-map rm1
admin@Xorplus# set protocols bgp ebgp-requires-policy true
admin@Xorplus# commit
```

NOTE:
If you do not want to control the route exchange via the use of BGP policies, you need to disable this feature manually otherwise the routes will not be exchanged properly.

When **ebgp-requires-policy** is enabled but the incoming or outgoing filter is missing, then the incoming route would be discarded and the outgoing route would not be allowed to advertise.

Additionally, a **run show bgp neighbor** command output would indicate in the *For address family:* section that *updates discarded due to missing policy* as shown below:

```
admin@Xorplus# run show bgp neighbor
...
For address family: IPv4 Unicast
  Update group 1, subgroup 1
  Packet Queue length 0
  Community attribute sent to this neighbor(all)
  Inbound updates discarded due to missing policy
  Outbound updates discarded due to missing policy
  0 accepted prefixes
...
For address family: IPv6 Unicast
  Update group 2, subgroup 2
  Packet Queue length 0
  Community attribute sent to this neighbor(all)
  Inbound updates discarded due to missing policy
  Outbound updates discarded due to missing policy
  0 accepted prefixes
```

Enable BGP Read-only Mode

When the router starts to receive the prefix at the time of initialization, the path selection process has been run in advance, which will cause the best path to keep changing, so that multiple updates of the same prefix will be sent, which is inefficient.

Enable read-only mode to reduce CPU and network usage when restarting the BGP process. When applicable, read-only mode would begin as soon as the first peer reaches Established status and a timer for maximum delay seconds is started. During this mode BGP doesn't run any best-path or generate any updates to its peers. This mode continues until either of the following two conditions are met:
1. All the configured peers, except the shutdown peers, have sent explicit EOR (End-Of-RIB) or an implicit- EOR. The first keep-alive after BGP has reached Established is considered an implicit-EOR. If the establish-wait optional value is given, then BGP will wait for peers to reach established from the beginning of the update-delay till the establish-wait period is over, i.e. the minimum set of established peers for which EOR is expected would be peers established during the establish-wait window, not necessarily all the configured neighbors.
2. maximum delay period is over.
On hitting any of the above two conditions, BGP resumes the decision process and generates updates to its peers.
Default maximum delay is 0, i.e. the read-only mode is disabled by default.

Note that the establish-wait setting is optional; however, if specified, it must be shorter than the maximum delay timer.

The following example commands enable read-only mode by setting the maximum delay timer to 500 seconds and the establish-wait timer to 90 seconds.

```
admin@XorPlus# set protocols bgp update-delay delay 500
admin@XorPlus# set protocols bgp update-delay establish-wait 90
admin@XorPlus# commit
```

Configuring Route Maps for Route Updates

You can apply **route maps** in BGP in one of two ways:

- Filter routes from BGP into Zebra
- Filter routes from Zebra into the Linux kernel

Filter Routes from BGP into Zebra

You can apply a route map on route updates from BGP to Zebra. All the applicable match operations are allowed, such as match on prefix, next hop, communities, and so on. Set operations are limited to metric and next hop only. Applying a route map on route updates from BGP to Zebra does not affect the BGP internal RIB.
Both IPv4 and IPv6 address families are supported. Route maps work on multi-paths; however, the metric setting is based on the best path only.

The following example command applies a route map called routemap1 to filter route updates from BGP into Zebra:

```
admin@XorPlus# set protocols bgp ipv4-unicast table-map routemap1
admin@XorPlus# commit
```

Filter Routes from Zebra into the Linux Kernel

The following example commands apply a route map called routemap1 to filter route updates from Zebra into the Linux kernel:

```
admin@XorPlus# set routing protocol bgp route-map routemap1
admin@XorPlus# commit
```

BGP Unnumbered

- Overview of BGP Unnumbered
- Example for Configuring Basic BGP Unnumbered
- Example for Configuring BGP Unnumbered EVPN Fabric

Overview of BGP Unnumbered

In a traditional Layer 3 network, an IP address should be assigned to each interface to provide connectivity from one link endpoint to another. But in the data center network, with a large number of spine and leaf devices and the number of interfaces interconnecting them could be very large. This leads to a sharp increase in the number of IP addresses required. Such large networks can consume a lot of IP addresses, where each peer requires a separate IP address.

BGP unnumbered is very useful in this kind of scenarios. BGP unnumbered interface is a BGP interface that does not need to specify a unique IP address, it uses the IPv6 link-local address, which is assigned automatically to each interface. BGP unnumbered works by using the Extended Next Hop Encoding (ENHE) as defined in RFC 5549, which provides a way to advertise an IPv4 route with an IPv6 next-hop. The IPv6 next-hop is resolved by using the IPv6 Neighbor Discovery (ND) process. Prior to RFC 5549, an IPv4 route could only be advertised with an IPv4 next-hop.

For BGP unnumbered, the next-hop address for each prefix is an IPv6 link-local address, which is assigned automatically to each interface. Using the IPv6 link-local address as a next-hop instead of an IPv4 unicast address, BGP unnumbered saves you from having to configure IPv4 addresses on each interface.

NOTEs:

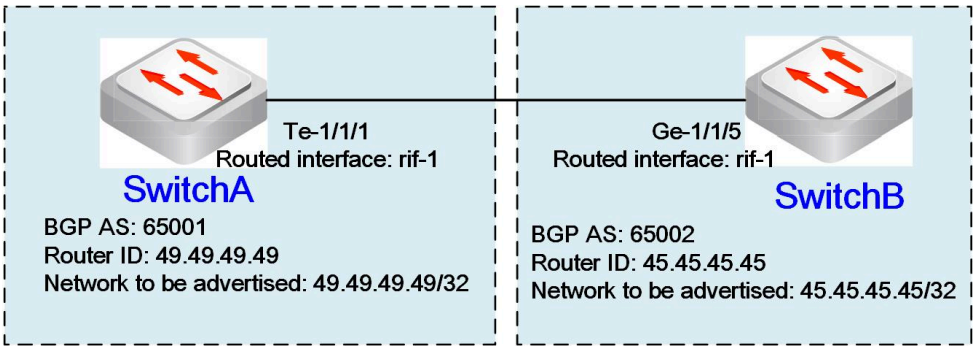
BGP unnumbered can only be used on two switches with point-to-point connection.

Example for Configuring Basic BGP Unnumbered

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
- Verify the Configuration

Networking Requirements

Figure 1. BGP Unnumbered Configuration Example



As shown in **Figure 1**, Switch A and Switch B are BGP peers. An EBGP connection is established between Switch A and Switch B. To save IP addresses, BGP unnumbered can be configured between Switch A and Switch B. In this example, routed interfaces are configured for the use of BGP unnumbered interface.

The only difference between a BGP unnumbered configuration and the BGP numbered configuration is that the BGP neighbor is specified as an interface instead of an IP address. The interface between the two peers does not need to have an IP address configured on each side.

> **NOTE:**
>
> The ebgp-requires-policy function needs to be disabled in EBGP, no need in IBGP.

Procedure

Switch A

Step 1 Enable te-1/1/1 as a routed interface and configure the interface name as rif-1.

```
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 routed-interface enable true
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 routed-interface name rif-1
admin@SwitchA# set vlans reserved-vlan 80-90
admin@SwitchA# set l3-interface routed-interface rif-1
```

Step 2 Configure EBGP and disable ebgp-requires-policy policy.

```
admin@SwitchA# set protocols bgp local-as 65001
admin@SwitchA# set protocols bgp router-id 49.49.49.49
admin@SwitchA# set protocols bgp interface rif-1 remote-as 65002
admin@SwitchA# set protocols bgp interface rif-1 ipv6-unicast activate true
admin@SwitchA# set protocols bgp interface rif-1 capability extended-nexthop
admin@SwitchA# set protocols bgp ebgp-requires-policy false
```

Step 3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step 4 Advertise the host subnets through BGP.

```
admin@SwitchA# set protocols bgp ipv4-unicast network 49.49.49.49/32
```

Step 5 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step 1 Enable ge-1/1/5 as a routed interface and configure interface name as rif-1.

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/5 routed-interface enable true
admin@SwitchB# set interface gigabit-ethernet ge-1/1/5 routed-interface name rif-1
admin@SwitchB# set vlans reserved-vlan 80-90
admin@SwitchB# set l3-interface routed-interface rif-1
```

Step 2 Configure EBGP and disable ebgp-requires-policy policy.

```
admin@SwitchB# set protocols bgp local-as 65002
admin@SwitchB# set protocols bgp router-id 45.45.45.45
admin@SwitchB# set protocols bgp interface rif-1 remote-as 65001
admin@SwitchB# set protocols bgp interface rif-1 ipv6-unicast activate true
admin@SwitchB# set protocols bgp interface rif-1 capability extended-nexthop
admin@SwitchB# set protocols bgp ebgp-requires-policy false
```

Step 3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step 4 Advertise the host subnets through BGP.

```
admin@SwitchB# set protocols bgp ipv4-unicast network 45.45.45.45/32
```

Step 5 Commit the configuration.

```
admin@SwitchB# commit
```

Verify the Configuration

- Check the BGP neighbor by running the following command.

```
admin@SwitchA# run show bgp neighbor

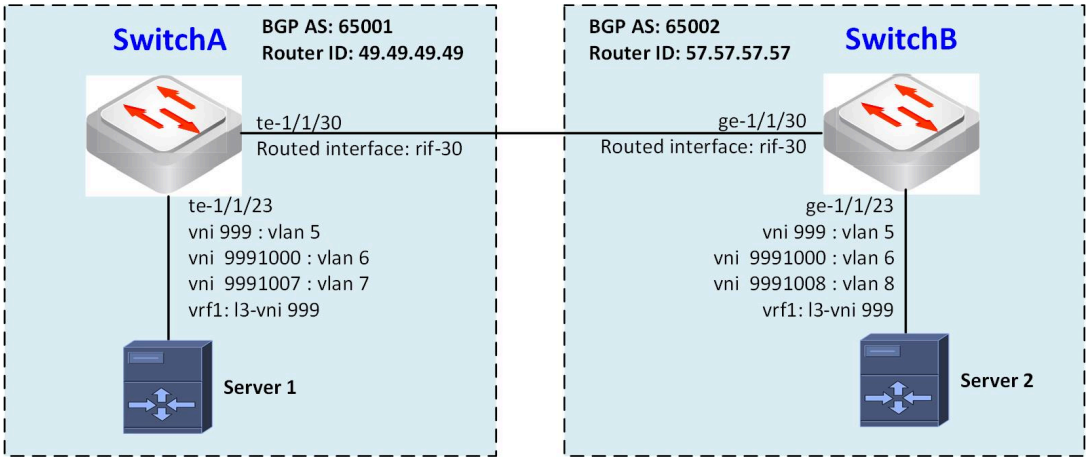
Example for Configuring BGP Unnumbered EVPN Fabric

- Networking Requirements
  - Figure 1. BGP Unnumbered EVPN Fabric Configuration Example
- Procedure
  - Switch A
  - Switch B
- Verify the Configuration

Networking Requirements

Figure 1. BGP Unnumbered EVPN Fabric Configuration Example



As shown in **Figure 1**, this example configures BGP unnumbered on EVPN VTEP devices Switch A and Switch B. An eBGP connection is established between Switch A and Switch B.

In this example, routed interfaces are configured f to be used as BGP unnumbered interfaces for EVPN underlay fabric.

The only difference between a BGP unnumbered configuration and the BGP numbered configuration is that the BGP neighbor is specified as an interface instead of an IP address. The interfaces connecting the two peers do not need to have IP addresses configured on each side.

> **NOTE:**
>
> The ebgp-requires-policy function needs to be disabled in EBGP, no need in IBGP.

Procedure

Switch A

Step 1 Configure physical interfaces, VLAN interfaces and VRF.

```
admin@SwitchA# set vlans vlan-id 5 l3-interface vlan-5
admin@SwitchA# set vlans vlan-id 6 l3-interface vlan-6
admin@SwitchA# set vlans vlan-id 7 l3-interface vlan-7
admin@SwitchA# set interface gigabit-ethernet te-1/1/30 routed-interface enable true
admin@SwitchA# set interface gigabit-ethernet te-1/1/30 routed-interface name rif-30
admin@SwitchA# set interface gigabit-ethernet te-1/1/23 family ethernet-switching native-vlan-id 6
admin@SwitchA# set interface gigabit-ethernet te-1/1/23 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet te-1/1/23 family ethernet-switching vlan members 5
admin@SwitchA# set interface gigabit-ethernet te-1/1/23 family ethernet-switching vlan members 7
admin@SwitchA# set vlans reserved-vlan 3000-3100
admin@SwitchA# set l3-interface routed-interface rif-30
admin@SwitchA# set ip vrf vrf1
admin@SwitchA# set l3-interface vlan-interface vlan-5 vrf vrf1
admin@SwitchA# set l3-interface vlan-interface vlan-6 vrf vrf1
admin@SwitchA# set l3-interface vlan-interface vlan-6 address 192.168.60.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan-7 vrf vrf1
admin@SwitchA# set l3-interface vlan-interface vlan-7 address 192.168.70.1 prefix-length 24
```

Step 2 Configure EBGP and BGP related configuration.

```
admin@SwitchA# set protocols bgp local-as 65001
```

```
admin@SwitchA# set protocols bgp router-id 49.49.49.49
admin@SwitchA# set protocols bgp interface rif-30 remote-as 65002
admin@SwitchA# set protocols bgp interface rif-30 ipv6-unicast activate true
admin@SwitchA# set protocols bgp interface rif-30 capability extended-nexthop
admin@SwitchA# set protocols bgp ebgp-requires-policy false
admin@SwitchA# set protocols bgp ipv4-unicast network 49.49.49.49/32
admin@SwitchA# set protocols bgp evpn advertise-all-vni
admin@SwitchA# set protocols bgp evpn advertise ipv4-unicast
admin@SwitchA# set protocols bgp evpn advertise ipv6-unicast
admin@SwitchA# set protocols bgp evpn advertise-svi-ip
admin@SwitchA# set protocols bgp vrf vrf1 local-as 65001
admin@SwitchA# set protocols bgp vrf vrf1 router-id 49.49.49.49
admin@SwitchA# set protocols bgp vrf vrf1 ipv4-unicast network 192.168.60.0/24
admin@SwitchA# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
admin@SwitchA# set protocols bgp vrf vrf1 evpn advertise ipv6-unicast
```

Step 3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step 4 Configure VXLAN source interface, VXLAN VNI and map VNI IDs to VLAN IDs. Also create an L3 VNI in vrf1.

```
admin@SwitchA# set vxlans source-interface lo address 49.49.49.49
admin@SwitchA# set vxlans vni 999 vlan 5
admin@SwitchA# set vxlans vni 9991000 vlan 6
admin@SwitchA# set vxlans vni 9991007 vlan 7
admin@SwitchA# set vxlans vrf vrf1 l3-vni 999
```

Step 5 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step 1 Configure physical interfaces, VLAN interfaces and VRF.

```
admin@SwitchB# set vlans vlan-id 5 l3-interface vlan-5
admin@SwitchB# set vlans vlan-id 6 l3-interface vlan-6
admin@SwitchB# set vlans vlan-id 8 l3-interface vlan-8
admin@SwitchB# set interface gigabit-ethernet ge-1/1/30 routed-interface enable true
admin@SwitchB# set interface gigabit-ethernet ge-1/1/30 routed-interface name rif-30
admin@SwitchB# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching native-vlan-id 6
admin@SwitchB# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching vlan members 5
admin@SwitchB# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching vlan members 8
admin@SwitchB# set vlans reserved-vlan 3000-3100
admin@SwitchB# set l3-interface routed-interface rif-30
admin@SwitchB# set ip vrf vrf1
admin@SwitchB# set l3-interface vlan-interface vlan-5 vrf vrf1
admin@SwitchB# set l3-interface vlan-interface vlan-6 vrf vrf1
admin@SwitchB# set l3-interface vlan-interface vlan-6 address 192.168.60.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan-8 vrf vrf1
admin@SwitchB# set l3-interface vlan-interface vlan-8 address 192.168.80.1 prefix-length 24
```

Step 2 Configure EBGP and BGP related configuration.

```
admin@SwitchB# set protocols bgp local-as 65002
admin@SwitchB# set protocols bgp router-id 57.57.57.57
admin@SwitchB# set protocols bgp interface rif-30 remote-as 65001
admin@SwitchB# set protocols bgp interface rif-30 ipv6-unicast activate true
admin@SwitchB# set protocols bgp interface rif-30 capability extended-nexthop
admin@SwitchB# set protocols bgp ebgp-requires-policy false
admin@SwitchB# set protocols bgp ipv4-unicast network 57.57.57.57/32
admin@SwitchB# set protocols bgp evpn advertise-all-vni
admin@SwitchB# set protocols bgp evpn advertise ipv4-unicast
admin@SwitchB# set protocols bgp evpn advertise ipv6-unicast
admin@SwitchB# set protocols bgp evpn advertise-svi-ip
admin@SwitchB# set protocols bgp vrf vrf1 local-as 65002
```

```
admin@SwitchB# set protocols bgp vrf vrf1 router-id 57.57.57.57
admin@SwitchB# set protocols bgp vrf vrf1 ipv4-unicast network 192.168.80.0/24
admin@SwitchB# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
admin@SwitchB# set protocols bgp vrf vrf1 evpn advertise ipv6-unicast
```

Step 3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step 4 Configure VXLAN source interface, VXLAN VNI and map VNI IDs to VLAN IDs. Also create an L3 VNI in vrf1.

```
admin@SwitchB# set vxlans source-interface lo address 57.57.57.57
admin@SwitchB# set vxlans vni 999 vlan 5
admin@SwitchB# set vxlans vni 9991000 vlan 6
admin@SwitchB# set vxlans vni 9991008 vlan 8
admin@SwitchB# set vxlans vrf vrf1 l3-vni 999
```

Step 5 Commit the configuration.

```
admin@SwitchB# commit
```

Verify the Configuration

- Run the **run l3-interface routed-interface** *<interface-name>* command to check the information of the unnumbered BGP interface.

```
admin@SwitchB# run show l3-interface routed-interface rif-30
rif-30         Hwaddr 18:5A:58:03:35:81, Vlan:3000, MTU: 1500, State:UP

Configuring BGP Attribute

- Configuring the AS_Path Attribute
- Configuring the BGP Community Attribute
- Configuring the MED Attribute
- Configuring the Next_Hop Attribute

Configuring the AS_Path Attribute

The AS_Path attribute records all the ASs that a route passes through from the source to the destination in the vector order. To prevent inter-AS routing loops, a BGP device does not receive the routes of which the AS_Path list contains the local AS number.

When a BGP speaker advertises an imported route:

- If the route is advertised to EBGP peers, the BGP speaker creates an AS_Path list containing the local AS number in an Update message.
- If the route is advertised to IBGP peers, the BGP speaker creates an empty AS_Path list in an Update message.

When a BGP speaker advertises a route learned in the Update message sent by another BGP speaker:

- If the route is advertised to EBGP peers, the BGP speaker adds the local AS number to the leftmost of the AS_Path list. According to the AS_Path list, the BGP speaker that receives the route can learn about the ASs through which the route passes to reach the destination. The number of the AS that is nearest to the local AS is placed on the top of the AS_Path list. The other AS numbers are listed according to the sequence in which the route passes through ASs.
- If the route is advertised to IBGP peers, the BGP speaker does not change the AS_Path attribute of the route.

You can configure the AS_Path attribute to implement flexible route selection.

Apply a Routing Policy to Routes Advertised

The **set protocols bgp neighbor route-map** command applies a route map to incoming or outgoing routes. It can be used to configure the route map for modifying the AS_Path attribute of the route.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast in route-map map1
admin@XorPlus# commit
```

Configure an AS Path List to Advertise or Receive Routes from Peers

The **set protocols bgp neighbor filter-list** command configures an AS Path list to advertise or receive routes from peers.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast in filter-list List1
admin@XorPlus# commit
```

Configure BGP to Treat two BGP Routes as Equal Cost ven if AS-paths Differ

he **set protocols bgp bestpath as-path multipath-relax** command configures Border Gateway Protocol (BGP) to treat two BGP routes as equal cost even if their AS-paths differ, as long as their AS-path lengths and other relevant attributes are the same. This allows routes with different AS-paths to be programmed into the forwarding table as equal cost multipath routes. Any changes in BGP configuration are applied by restarting the current BGP sessions on the VRFs.

```
admin@XorPlus# set protocols bgp bestpath as-path multipath-relax
admin@XorPlus# commit
```

Configuring the BGP Community Attribute

The Community attribute is a private BGP route attribute. It is transmitted between BGP peers and is not restricted within an AS. The Community attribute allows a group of BGP devices in multiple ASs to share the same routing policies, which simplifies routing policy applications and facilitates routing policy management and maintenance. A BGP device can add or change the community attributes of routes to be advertised.

Enable Community Exchange with Peer

The **set protocols bgp neighbor send-community** command enables community and/or extended community exchange with the specified neighbor. When this command is configured for the peer-group, then all the neighbors that are part of peer-group will send the community values to the peers.

The following example allows community values to be sent to a specific neighbor.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast send-community both
admin@XorPlus# commit
```

Apply a Routing Policy to Routes Advertised

The **set protocols bgp neighbor route-map** command applies a route map to incoming or outgoing routes. It can be used to configure the route map for modifying the community attribute of the route.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast in route-map map1
admin@XorPlus# commit
```

BGP Community Lists

You can use community lists to define a BGP community to tag one or more routes. You can then use the communities to apply a route policy on either egress or ingress.
The BGP community list can be either standard or expanded. The standard BGP community list is a pair of values (such as 100:100) that can be tagged on a specific prefix and advertised to other neighbors or applied on route ingress. Or, it can be one of four BGP default communities:

- **internet**: a BGP community that matches all routes
- **local-AS**: a BGP community that restricts routes to your confederation's sub-AS
- **no-advertise**: a BGP community that is not advertised to anyone
- **no-export**: a BGP community that is not advertised to the eBGP peer

An expanded BGP community list takes a regular expression (BGP Regular Expressions) of communities and matches the listed communities.
When the neighbor receives the prefix, it examines the community value and takes action accordingly, such as permitting or denying the community member in the routing policy.
Here is an example of a standard community list filter:

```
admin@Xorplus# set routing community-list standard COMMUNITY1 permit community 100:100
admin@Xorplus# commit
```

You can apply the community list to a route map to define the routing policy:

```
admin@Xorplus# set routing route-map GlobalMap order 10 match community COMMUNITY1
admin@Xorplus# set routing route-map GlobalMap order 10 matching-policy permit
admin@Xorplus# commit
```

Configuring the MED Attribute

The multi-exit discriminator (MED) helps determine the optimal route for incoming traffic of an AS. It is similar to the metric used in IGP. When a BGP device obtains multiple routes to the same destination address but with different next hops from EBGP peers, the BGP device selects the route with the smallest MED value as the optimal route.

- Run the following command to enable comparison of the Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems.

  set protocols bgp [***vrf*** <*vrf-name*>] **always-compare-med**

  MED is one of the parameters that is considered when selecting the best path among many alternative paths. The path with a lower MED is preferred over a path with a higher MED.

  During the best-path selection process, MED comparison is done only among paths from the same autonomous system. Use the command bgp always-compare-med to change this behavior by enforcing MED comparison between all paths, regardless of the autonomous system from which the paths are received.

- Run the following command to configure a BGP routing process to assign a value of infinity (max possible) to routes that are missing the Multi Exit Discriminator (MED) attribute.

  set protocols bgp [***vrf*** <*vrf-name*>] **bestpath med missing-as-worst**

Configuring the Next_Hop Attribute

The Next_Hop attribute records the next hop that a route passes through. The Next_Hop attribute of BGP is different from that of an IGP because it may not be the neighbor IP address. A BGP speaker processes the Next_Hop attribute based on the following rules:

- When advertising a route to an EBGP peer, a BGP speaker sets the Next_Hop attribute of the route to the address of the local interface through which the BGP peer relationship is established with the peer.
- When advertising a locally originated route to an IBGP peer, the BGP speaker sets the Next_Hop attribute of the route to the address of the local interface through which the BGP peer relationship is established with the peer.
- When advertising a route learned from an EBGP peer to an IBGP peer, the BGP speaker does not change the Next_Hop attribute of the route.

Configure the Router as the Next Hop for Routes Sent

When an Autonomous System Boundary Router (ASBR) forwards the route learned from an EBGP peer to an IBGP peer, the ASBR does not change the next hop of the route by default. When the IBGP peer receives this route, it finds the next hop unreachable, sets the route to inactive, and does not use this route to guide traffic forwarding. To enable the IBGP peer to use this route to guide traffic forwarding, configure the ASBR to set its IP address as the next hop of the route when the ASBR forwards this route to the IBGP peer. After the IBGP peer receives the route from the ASBR, it finds the next hop of the route reachable, sets the route to active, and uses this route to guide traffic forwarding.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast next-hop-self
admin@XorPlus# commit
```

Apply a Routing Policy to Routes Advertised

The **set protocols bgp neighbor route-map** command applies a route map to incoming or outgoing routes. It can be used to configure the route map for modifying the Next_Hop attribute of the route.

```
admin@XorPlus# set protocols bgp neighbor 2.2.2.2 ipv4-unicast in route-map map1
admin@XorPlus# commit
```

Configuration Examples

- Example for Configuring Basic BGP Functions
- Example for Configuring a BGP Route Reflector
- Example for Configuring BGP Load Balancing

Example for Configuring Basic BGP Functions

- Network Requirement
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
  - Viewing BGP Peer Status on Switch B
  - Configuring Switch A to Advertise Route 192.168.10.0/24
  - Configuring Switch B to Advertise a Connected Route

Network Requirement

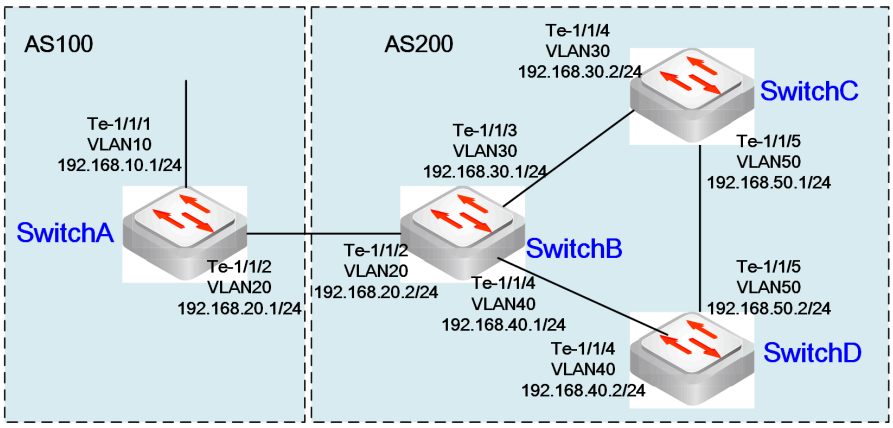
As shown in Figure. 1, BGP runs on all the switches.

An EBGP connection is established between Switch A and Switch B, and IBGP fullmesh connections are established between Switch B, Switch C, and Switch D.

Configure IBGP connections between Switch B, Switch C, and Switch D.

Configure an EBGP connection between Switch A and Switch B.

Figure 1. BGP configuration



Procedure

This section describes the steps of how to configure basic BGP functions on SwitchA, SwitchB, SwitchC and SwitchD.

Switch A

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchA# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchA# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
admin@SwitchA# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchA# set l3-interface vlan-interface vlan10 address 192.168.10.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan20 address 192.168.20.1 prefix-length 24
```

Step2 Configure an EBGP connection.

```
admin@SwitchA# set protocols bgp router-id 1.1.1.1
admin@SwitchA# set protocols bgp local-as 100
admin@SwitchA# set protocols bgp neighbor 192.168.20.2 remote-as 200
admin@SwitchA# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchB# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchB# set vlans vlan-id 30 l3-interface vlan30
admin@SwitchB# set vlans vlan-id 40 l3-interface vlan40
admin@SwitchB# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchB# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 30
admin@SwitchB# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 40
admin@SwitchB# set l3-interface vlan-interface vlan20 address 192.168.20.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan30 address 192.168.30.1 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan40 address 192.168.40.1 prefix-length 24
```

Step2 Configure EBGP and IBGP connections.

```
admin@SwitchB# set protocols bgp router-id 2.2.2.2
admin@SwitchB# set protocols bgp local-as 200
admin@SwitchB# set protocols bgp neighbor 192.168.20.1 remote-as 100
admin@SwitchB# set protocols bgp neighbor 192.168.30.2 remote-as 200
admin@SwitchB# set protocols bgp neighbor 192.168.40.2 remote-as 200
admin@SwitchB# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchC# set vlans vlan-id 30 l3-interface vlan30
admin@SwitchC# set vlans vlan-id 50 l3-interface vlan50
admin@SwitchC# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 30
admin@SwitchC# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 50
admin@SwitchC# set l3-interface vlan-interface vlan30 address 192.168.30.2 prefix-length 24
admin@SwitchC# set l3-interface vlan-interface vlan50 address 192.168.50.1 prefix-length 24
```

Step2 Configure the IBGP connection.

```
admin@SwitchC# set protocols bgp router-id 3.3.3.3
admin@SwitchC# set protocols bgp local-as 200
admin@SwitchC# set protocols bgp neighbor 192.168.30.1 remote-as 200
admin@SwitchC# set protocols bgp neighbor 192.168.50.2 remote-as 200
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchC# commit
```

Switch D

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchD# set vlans vlan-id 40 l3-interface vlan40
```

```
admin@SwitchD# set vlans vlan-id 50 l3-interface vlan50
admin@SwitchD# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 40
admin@SwitchD# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 50
admin@SwitchD# set l3-interface vlan-interface vlan40 address 192.168.40.2 prefix-length 24
admin@SwitchD# set l3-interface vlan-interface vlan50 address 192.168.50.2 prefix-length 24
```

Step2 Configure the IBGP connection.

```
admin@SwitchD# set protocols bgp router-id 4.4.4.4
admin@SwitchD# set protocols bgp local-as 200
admin@SwitchD# set protocols bgp neighbor 192.168.40.1 remote-as 200
admin@SwitchD# set protocols bgp neighbor 192.168.50.1 remote-as 200
```

Step3 Enable IP routing.

```
admin@SwitchD# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchD# commit
```

Viewing BGP Peer Status on Switch B

```
admin@SwitchB# run show bgp neighbor

Example for Configuring a BGP Route Reflector

- Network Requirement
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
  - Configuring Switch A to Advertise Route 192.168.10.0/24
- Verify the Configurations

Network Requirement

As shown in **Figure. 1**, BGP runs on all the switches.

An EBGP connection is established between Switch A and Switch B, and IBGP fullmesh connections are established between Switch B, Switch C, and Switch D.

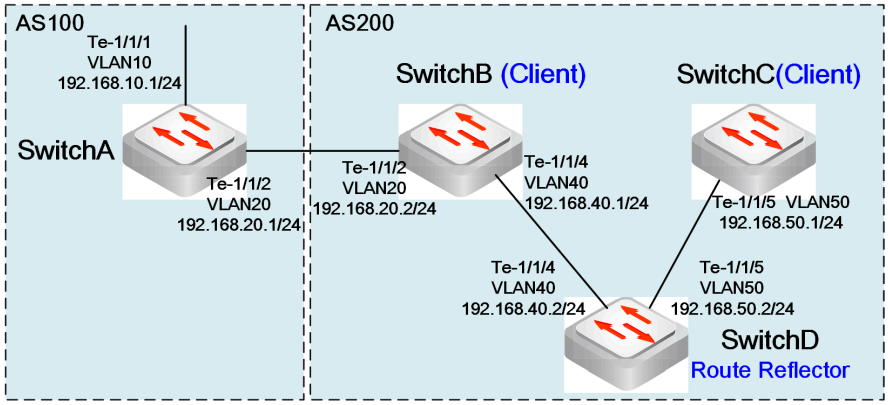
Configure IBGP connections between Switch B, Switch C, and Switch D.

Configure an EBGP connection between Switch A and Switch B.

Configure Switch D as the route reflector for Switch B and Switch C, which is the clients of Switch D, to simplify device configuration and management.

You have to finish configurations on Switch D to be a route reflector. No configuration is required on the client.

Figure 1. BGP Route Reflector Configuration



Procedure

This section describes the steps to configure basic BGP functions on SwitchA, SwitchB, SwitchC and SwitchD, configure Switch D as the route reflector for Switch B and Switch C.

Switch A

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchA# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchA# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
admin@SwitchA# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchA# set l3-interface vlan-interface vlan10 address 192.168.10.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan20 address 192.168.20.1 prefix-length 24
```

Step2 Configure an EBGP connection.

```
admin@SwitchA# set protocols bgp router-id 1.1.1.1
admin@SwitchA# set protocols bgp local-as 100
admin@SwitchA# set protocols bgp neighbor 192.168.20.2 remote-as 200
admin@SwitchA# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchB# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchB# set vlans vlan-id 40 l3-interface vlan40
admin@SwitchB# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchB# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 40
admin@SwitchB# set l3-interface vlan-interface vlan20 address 192.168.20.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan40 address 192.168.40.1 prefix-length 24
```

Step2 Configure EBGP and IBGP connections.

```
admin@SwitchB# set protocols bgp router-id 2.2.2.2
admin@SwitchB# set protocols bgp local-as 200
admin@SwitchB# set protocols bgp neighbor 192.168.20.1 remote-as 100
admin@SwitchB# set protocols bgp neighbor 192.168.40.2 remote-as 200
admin@SwitchB# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchC# set vlans vlan-id 50 l3-interface vlan50
admin@SwitchC# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 50
admin@SwitchC# set l3-interface vlan-interface vlan50 address 192.168.50.1 prefix-length 24
```

Step2 Configure the IBGP connection.

```
admin@SwitchC# set protocols bgp router-id 3.3.3.3
admin@SwitchC# set protocols bgp local-as 200
admin@SwitchC# set protocols bgp neighbor 192.168.50.2 remote-as 200
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchC# commit
```

Switch D

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchD# set vlans vlan-id 40 l3-interface vlan40
admin@SwitchD# set vlans vlan-id 50 l3-interface vlan50
admin@SwitchD# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 40
admin@SwitchD# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 50
admin@SwitchD# set l3-interface vlan-interface vlan40 address 192.168.40.2 prefix-length 24
admin@SwitchD# set l3-interface vlan-interface vlan50 address 192.168.50.2 prefix-length 24
```

Step2 Configure the IBGP connection.

```
admin@SwitchD# set protocols bgp router-id 4.4.4.4
admin@SwitchD# set protocols bgp local-as 200
admin@SwitchD# set protocols bgp neighbor 192.168.40.1 remote-as 200
admin@SwitchD# set protocols bgp neighbor 192.168.50.1 remote-as 200
```

Step3 Configure Switch D to be a route reflector for Switch B and Switch C.

```
admin@SwitchD# set protocols bgp neighbor 192.168.40.1 ipv4-unicast route-reflector-client
admin@SwitchD# set protocols bgp neighbor 192.168.50.1 ipv4-unicast route-reflector-client
```

Step4 Enable IP routing.

```
admin@SwitchD# set ip routing enable true
```

Step5 Commit the configurations.

```
admin@SwitchD# commit
```

Configuring Switch A to Advertise Route 192.168.10.0/24

```
admin@SwitchA# set protocols bgp ipv4-unicast network 192.168.10.0/24
admin@SwitchA# commit
```

Verify the Configurations

- View the BGP routing table of Switch D.

```
admin@SwitchD# run show bgp route 192.168.10.0/24
BGP routing table entry for 192.168.10.0/24
Paths: (1 available, best #1, table default)
  Advertised to non peer-group peers:
  192.168.50.2
  200
    192.168.10.0 from 192.168.20.1 (2.2.2.2)
      Origin IGP, metric 0, valid, external, best (First path received)
      Last update: Wed Apr  7 16:13:35 2021
```

Example for Configuring BGP Load Balancing

- Network Requirement
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
  - Viewing BGP Peer Status on Switch B
  - Configuring Switch D to Advertise Route 192.168.10.0/24
  - Configure Switch A to Enable BGP Load Balancing

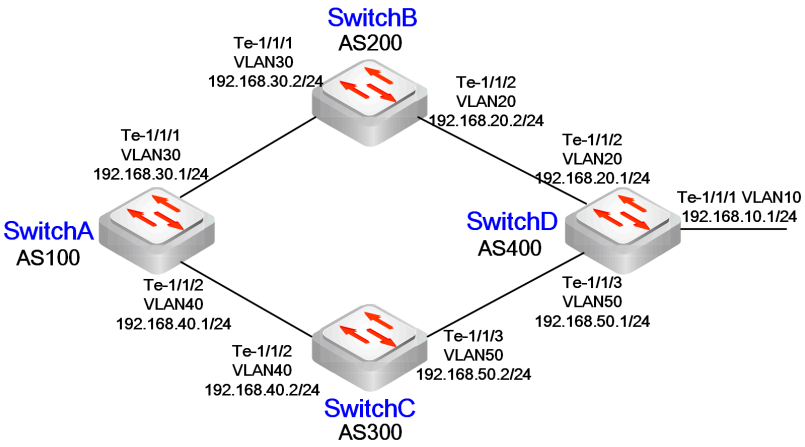
Network Requirement

Configure load balancing on Switch A.

Configure EBGP connections between Switch B and Switch A and between Switch B and Switch D.

Configure EBGP connections between Switch C and Switch A and between Switch C and Switch D.

Figure 1. BGP Load Balancing



Procedure

Switch A

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchA# set vlans vlan-id 30 l3-interface vlan30
admin@SwitchA# set vlans vlan-id 40 l3-interface vlan40
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 30
admin@SwitchA# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 40
admin@SwitchA# set l3-interface vlan-interface vlan30 address 192.168.30.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan40 address 192.168.40.1 prefix-length 24
```

Step2 Configure an EBGP connection.

```
admin@SwitchA# set protocols bgp router-id 1.1.1.1
admin@SwitchA# set protocols bgp local-as 100
admin@SwitchA# set protocols bgp neighbor 192.168.30.2 remote-as 200
admin@SwitchA# set protocols bgp neighbor 192.168.40.2 remote-as 300
admin@SwitchA# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchB# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchB# set vlans vlan-id 30 l3-interface vlan30
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 30
admin@SwitchB# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchB# set l3-interface vlan-interface vlan20 address 192.168.20.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan30 address 192.168.30.2 prefix-length 24
```

Step2 Configure EBGP connections.

```
admin@SwitchB# set protocols bgp router-id 2.2.2.2
admin@SwitchB# set protocols bgp local-as 200
admin@SwitchB# set protocols bgp neighbor 192.168.30.1 remote-as 100
admin@SwitchB# set protocols bgp neighbor 192.168.20.1 remote-as 400
admin@SwitchB# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchC# set vlans vlan-id 40 l3-interface vlan40
admin@SwitchC# set vlans vlan-id 50 l3-interface vlan50
admin@SwitchC# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 40
admin@SwitchC# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 50
admin@SwitchC# set l3-interface vlan-interface vlan40 address 192.168.40.2 prefix-length 24
admin@SwitchC# set l3-interface vlan-interface vlan50 address 192.168.50.2 prefix-length 24
```

Step2 Configure the EBGP connection.

```
admin@SwitchC# set protocols bgp router-id 3.3.3.3
admin@SwitchC# set protocols bgp local-as 300
admin@SwitchC# set protocols bgp neighbor 192.168.40.1 remote-as 100
admin@SwitchC# set protocols bgp neighbor 192.168.50.1 remote-as 400
admin@SwitchC# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchC# commit
```

Switch D

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchD# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchD# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchD# set vlans vlan-id 50 l3-interface vlan50
admin@SwitchD# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
```

```
admin@SwitchD# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@SwitchD# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 50
admin@SwitchD# set l3-interface vlan-interface vlan10 address 192.168.10.1 prefix-length 24
admin@SwitchD# set l3-interface vlan-interface vlan20 address 192.168.20.1 prefix-length 24
admin@SwitchD# set l3-interface vlan-interface vlan50 address 192.168.50.1 prefix-length 24
```

Step2 Configure the EBGP connection.

```
admin@SwitchD# set protocols bgp router-id 4.4.4.4
admin@SwitchD# set protocols bgp local-as 400
admin@SwitchD# set protocols bgp neighbor 192.168.20.2 remote-as 200
admin@SwitchD# set protocols bgp neighbor 192.168.50.2 remote-as 300
admin@SwitchD# set protocols bgp ebgp-requires-policy false
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@SwitchD# commit
```

Viewing BGP Peer Status on Switch B

```
admin@SwitchB# run show bgp neighbor

Configuring Switch D to Advertise Route 192.168.10.0/24

```
admin@SwitchD# set protocols bgp ipv4-unicast network 192.168.10.0/24
admin@SwitchD# commit
```

Configure Switch A to Enable BGP **Load Balancing**

Because Switch A has two routes to reach AS 400, configuring load balancing over the two BGP routes on Switch A can improve link usage.

```
admin@SwitchA# set protocols bgp ipv4-unicast multipath ebgp maximum-paths 2
admin@SwitchA# commit
```

Then you can view the BGP routing table to 192.168.10.0/24 on Switch A, you can find that:

- The route 192.168.10.0/24 has two next hops, 192.168.30.2 and 192.168.40.2, both of which are marked with a greater-than sign (>), indicating that they are the optimal routes.
- By using the **run show bgp route 192.168.10.0/24** command, you can find two routes to 192.168.10.0/24. One has next hop 192.168.30.2 and output interface VLAN interface vlan30, and the other has next hop 192.168.40.2 and output interface VLAN interface vlan40.

Routing Map Configuration

This section describes how to use routing map to filter routes and change route attributes.

- Routing Map Introduction
- Configuring Filters
  - Configuring a Community Filter
  - Configuring a Large Community Filter
  - Configuring an AS_Path Filter
  - Configuring an Extended Community Filter
  - Configuring an IP Prefix List
- Configuring a Routing Map
- Example for Filtering the Routes to Be Advertised and Receiving

Routing Map Introduction

A routing policy uses different matching rules and modes to select routes and change route attributes. There are different filters in the routing policy that can be used independently to filter routes in specific scenarios.

Matching Rule

A routing map is a routing policy consists of *N* nodes of match and set statements (*N* ≥ 1). Each node has its own set of **match** clauses that must be matched in order to accept a policy. The **match** clauses define matching rules related to route attributes and filters. The system checks routes in the orders of a routing map in ascending order of order IDs.

When a route matches all **match** clauses in a order, the route enters the matching modes defined in **matching-policy** and **set-action** clauses and stops checking **match** clauses in other nodes. The two supported matching modes are:

- **permit**: A route is permitted, and actions defined by **set-action** clauses are performed on the route to set its attributes.
- **deny**: A route is denied.

If a route does not match any **match** clause in a node, the route is passed to the next node. If the route does not match any node, the route is filtered out.

Note that, in all configurations, **matching-policy** is a required clause to enable a route map. Other clauses are optional.

The default action of a route-map, if no entries match, is to deny. I.e. a route-map essentially has as its last entry an empty deny entry, which matches all routes. To change this behaviour, one must specify an empty permit entry as the last entry in the route-map.

Filters

There are different filters specified in **match** clauses in a routing policy which including IP prefix list, AS_Path filter, community filter, extended community filter, and large community filter. These filters have their own matching rules and modes and can be used independently to filter routes in specific situations. The following offers a brief explanation to each of these filters.

IP Prefix List

IP prefix lists filter routes based on the IP prefixes of the source IP address, destination IP address, and next-hop IP address of packets. They can be used independently when routing protocols advertise and receive routes.

Each IP prefix list consists of multiple indexes, and each index matches a node. An IP prefix list checks routes in the nodes of a routing policy in ascending order of sequence numbers. If a route matches one node, the route is not checked by additional nodes. If a route does not match any one of the nodes, the route is filtered out.

The IP prefix list supports exact matching or matching within a specified mask length.

> **NOTE:**
> - When an IP address is 0.0.0.0 (a wildcard address), all routes in the mask length range are permitted or denied.
> - When configuring IP prefix list, it is strongly recommended to configure sequence number for each IP prefix list node. Otherwise, the precedence of this IP prefix list will be uncertain, and thus the desired IP filtering effect will not be achieved.

AS_Path Filter

The AS_Path filter uses the AS_Path attribute of BGP to filter routes. It can be used independently when BGP advertises and receives routes.

The AS_Path attribute records all ASs that a route passes through. For details about the AS_Path attribute, see Configuring the AS_Path Attribute.

Community Filter

The community filter uses the community attribute of BGP to filter routes. It can be used independently when BGP advertises and receives routes.

The community attribute identifies a group of routes with the same properties. For details about the community attribute, see Configuring the BGP Community Attribute.

Extended Community Filter

The extended community filter uses the extended community attribute of BGP to filter routes. It can be used independently when VPN targets are used to identify routes in a VPN.

Large Community Filter

The large community filter uses the large community attribute of BGP to filter routes. The commands **set routing large-community-list {standard <***large-community-list-name***>| seq-standard***<integer>***} {deny|permit}** [**large-community** *<large-community-number>*] and **set routing large-community-list {expanded** *<large-community-list-name>*| **seq-expanded** *<integer>*} **{deny|permit} regex** *<line>* can be used to define the large community list.

Configuring Filters

- Configuring a Community Filter
- Configuring a Large Community Filter
- Configuring an AS_Path Filter
- Configuring an Extended Community Filter
- Configuring an IP Prefix List

Configuring a Community Filter

The community attribute identifies routes with the same characteristics without considering IP prefixes and AS numbers. Configuring community filters and community attributes simplifies route management when it is inconvenient to use the IP prefix list or AS_Path filter. For example, a company branch needs to receive routes only from its headquarters and from branches in adjacent countries. In this case, you can configure different community attributes for each of the branches. Routes in the original branch can then be managed based on community attributes, without considering IP prefixes and AS numbers of routes in different countries.

Community filters are classified into standard and expanded community filters. An expanded community filter supports regular expressions (BGP Regular Expressions) and is more flexible than a standard community filter.

- To configure a standard community filter, run the following command:

set routing community-list standard <*community-list-name*> **{deny|permit} [local-as|no-advertise|no-export|internet|community** <*community*>**]**

- To configure an expanded community filter, run the following command:

set routing community-list expanded <*community-list-name*> **{deny|permit} regex** <*regular-expression*>

The following example configures a standard community list filter:

```
admin@Xorplus# set routing community-list standard COMMUNITY1 permit community 100:100
admin@Xorplus# commit
```

Configuring a Large Community Filter

The BGP Large Communities attribute was introduced in Feb 2017 with RFC 8092.
The BGP Large Communities Attribute is similar to the BGP Communities Attribute except that it has 3 components instead of two and each of which are 4 octets in length. Large Communities bring additional functionality and convenience over traditional communities, specifically the fact that the GLOBAL part below is now 4 octets wide allowing seamless use in networks using 4-byte ASNs.
GLOBAL:LOCAL1:LOCAL2 This is the format to define Large Community values.

- To configure a standard large community filter, run the following command:

set routing large-community-list {standard <*large-community-list-name***>| seq-standard**<*integer*>} **{deny|permit}** [**large-community** <*large-community-number*>]

- To configure an expanded large community filter, run the following command:

set routing large-community-list {expanded <*large-community-list-name*>| **seq-expanded** <*integer*>} **{deny|permit} regex** <*line*>

The following example configures a standard large community filter:

```
admin@Xorplus# set routing large-community-list standard LargeCom deny large-community 6215:22:33
admin@Xorplus# commit
```

Configuring an AS_Path Filter

An AS_Path filter is used to filter routes based on the AS_Path attributes of BGP routes. If you do not want to receive routes of a specified AS number, configure an AS_Path filter based on the specified AS number. On a complex network, multiple ACLs or IP prefix lists must be configured to filter BGP routes. This can be a complicated process; configuring an AS_Path filter can simplify the configuration.

You can use the following command to configure the AS_Path filter.

set routing as-path-list <*as-path-list-name*> **{deny|permit} regex** <*txt*>

The following example configures an AS Path list, permit routes that contain 20 in the AS_Path to pass through.

```
admin@Xorplus# set routing as-path-list Aslist permit regex _20_
admin@Xorplus# commit
```

Configuring an Extended Community Filter

You can use an extended community filter when using the route target (RT) attribute to filter routes.

- To configure a standard extended community filter, run the following command:

set routing extcommunity-list standard <*community-list-name*> **{deny|permit} {rt|soo} extcommunity** <*extcommunity*>

- To configure an expanded extended community filter, run the following command:

set routing extcommunity-list expanded <*community-list-name*> **{deny|permit} regex** <*regular-expression*>

The following example configures a standard extended community filter:

```
admin@Xorplus# set routing extcommunity-list standard EXTcom1 permit rt extcommunity 20
admin@Xorplus# commit
```

Configuring an IP Prefix List

Configuring an IP prefix list controls the advertising and receiving of routes based on the destination address.

You can use the following command to configure the IPv4 prefix list.

set routing prefix-list {ipv4-family <*ipv4-prefix-name*> | **ipv6-family** <*ipv6-prefix-name*>} [**seq** <*sequence-number*>] {**deny|permit} {prefix** <*ipv4/prefixlen*> **[ge <***greater-equal-value***>] [le <***less-equal-value***>]** | **prefix-any**}

> **NOTE:**
> - If an IP prefix list is not used together with the **match** clauses in a routing map, you must set at least one node to the **permit** mode in the IP prefix list. If no node is set to the **permit** mode, all routes are filtered out.
> - When configuring IP prefix list, it is strongly recommended to configure sequence number for each IP prefix list node. Otherwise, the precedence of this IP prefix list will be uncertain, and thus the desired IP filtering effect will not be achieved.

The following example configures the IP prefix list named **p1** to permit only the routes with the mask length ranging from 8 to 16 on the network segment 35.0.0.0/8.

```
admin@Xorplus# set routing prefix-list ipv4-family p1 seq 1 permit prefix 35.0.0.0/8 ge 16
admin@Xorplus# commit
```

Configuring a Routing Map

- Creating a matching-policy Clause
- (Optional) Configuring a match Clause
- (Optional) Configuring a set-action Clause
- Checking the Configuration

A routing map can consist of multiple matching policies, multiple match rules and set-action actions.

Creating a matching-policy Clause

> **NOTE:**
> You should set at least one node to the **permit** mode in a routing policy; otherwise, all routes are filtered out.

The following example create a route map matching policy.

```
admin@Xorplus# set routing route-map GlobalMap order 1 matching-policy permit
admin@Xorplus# commit
```

(Optional) Configuring a match Clause

A **match** clause defines matching rules related to route filters and attributes in a routing policy.

If no **match** clause is configured for a node in a routing policy, routes match the routing policy in this node. If one or more **match** clauses are configured in a node, the relationship between the clauses is "AND". This means that a route matches this node only when they match all the **match** clauses in this node.

> **NOTE:**
> If a **match** clause defines a filter that is not configured, all routes match this **match** clause by default.

The command **set routing route-map <***route-map-name***> order <***NUMBER***> match xx** can be used for configure routing map match clause. PICOS supports most of the route filter parameters, for details about each match clause, see Route Map Commands.

The following commands configure a match clause in the route map to match the community list:

```
admin@Xorplus# set routing community-list standard COMMUNITY1 permit community 100:100
admin@Xorplus# set routing route-map GlobalMap order 10 match community COMMUNITY1
admin@Xorplus# set routing route-map GlobalMap order 10 matching-policy permit
admin@Xorplus# commit
```

(Optional) Configuring a set-action Clause

A **set-action** clause specifies the action of setting attributes for routes that have matched a routing policy node. If a node does not have a **set-action** clause configured, the node will only filter routes. If one or more **set-action** clauses are configured in a node, all the **set-action** clauses are applied to routes that have matched the node.

The command **set routing route-map <***route-map-name***> order <***NUMBER***> set-action xx** can be used for configure routing map **set-action** clause. PICOS supports to set most of the several route parameters, for details about each set-action clause, see Route Map Commands.

The following commands configure a match clause in the route map to match the community list and change the community value to 11:101:

```
admin@Xorplus# set routing community-list standard COMMUNITY1 permit community 100:100
admin@Xorplus# set routing route-map GlobalMap order 10 match community COMMUNITY1
admin@Xorplus# set routing route-map GlobalMap order 10 matching-policy permit
admin@Xorplus# set routing route-map GlobalMap order 10 set-action community 11:101
admin@Xorplus# commit
```

Checking the Configuration

Run the **run show routing route-map** command to check information about the route-policy.

```
admin@Xorplus# run show routing route-map
ZEBRA:
route-map: GlobalMap Invoked: 0 Optimization: disabled Processed Change: false
 permit, sequence 10 Invoked 0
  Match clauses:
  Set clauses:
  Call clause:
```

```
  Action:
    Exit routemap
OSPF:
route-map: GlobalMap Invoked: 0 Optimization: disabled Processed Change: false
 permit, sequence 10 Invoked 0
  Match clauses:
  Set clauses:
  Call clause:
  Action:
    Exit routemap
BGP:
route-map: GlobalMap Invoked: 0 Optimization: disabled Processed Change: false
 permit, sequence 10 Invoked 0
  Match clauses:
    community COMMUNITY1
  Set clauses:
    community 11:101
  Call clause:
  Action:
    Exit routemap
```

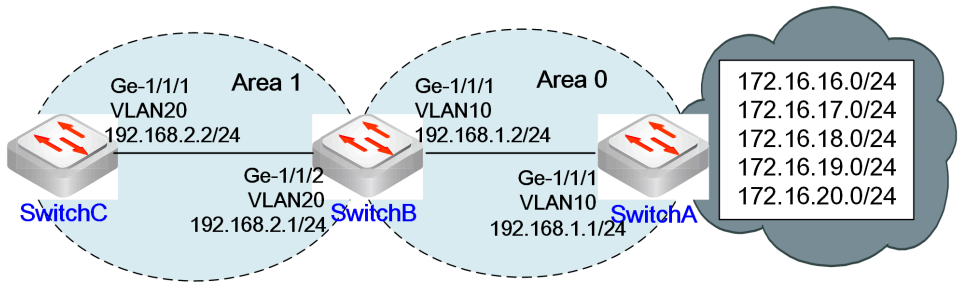
Example for Filtering the Routes to Be Advertised and Receiving

- Network Requirement
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Configure Static Routes on SwitchA
  - Configure a Policy for Advertising Routes on SwitchA
  - Configure a Policy for Receiving Routes on SwitchB

Network Requirement

Figure 1 shows on an OSPF network, how SwitchA receives routes from the Internet and provides these routes for the OSPF network. By configuring the routing map, users on the OSPF network are only allowed to access only the network segments 172.16.17.0/24, 172.16.18.0/24, and 172.16.19.0/24, and do not allow Area 1 to access the IP 1.1.1.1/32 of the loopback address of SwitchA.

Figure 1. Networking diagram for filtering the advertised routes



To implement the route filtering function as above, follow the configuration described below:

1. Configure a routing policy on SwitchA and apply the routing policy during route advertisement. When routes are advertised, the routing policy allows SwitchA to provide routes from network segments 172.16.17.0/24, 172.16.18.0/24, and 172.16.19.0/24 for SwitchB, and allows devices on the OSPF network to access the three network segments.
2. To implement that not allow Area 1 to access the IP 1.1.1.1/32 of the loopback address of SwitchA. Configure a prefix list of "**deny 1.1.1.1/32**" and a "**prefix-any**", and apply to OSPF filter in policy on SwitchB.

Procedure

Switch A

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchA# set vlans vlan-id 10 l3-interface 10
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@SwitchA# set l3-interface vlan-interface 10 address 192.168.1.1 prefix-length 24
admin@SwitchA# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
```

Step2 Configure basic OSPF functions.

```
admin@SwitchA# set protocols ospf router-id 1.1.1.1
admin@SwitchA# set protocols ospf area 0
admin@SwitchA# set protocols ospf network 192.168.1.0/24 area 0
admin@SwitchA# set protocols ospf network 1.1.1.1/32 area 0
```

Step3 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchB# set vlans vlan-id 10 l3-interface 10
admin@SwitchB# set vlans vlan-id 20 l3-interface 20
admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
```

```
admin@SwitchB# set l3-interface vlan-interface 10 address 192.168.1.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface 20 address 192.168.2.1 prefix-length 24
```

Step2 Configure basic OSPF functions.

```
admin@SwitchB# set protocols ospf router-id 2.2.2.2
admin@SwitchB# set protocols ospf area 0
admin@SwitchB# set protocols ospf area 1
admin@SwitchB# set protocols ospf network 192.168.1.0/24 area 0
admin@SwitchB# set protocols ospf network 192.168.2.0/24 area 1
```

Step3 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure the VLANs and VLAN interfaces.

```
admin@SwitchC# set vlans vlan-id 20 l3-interface 20
admin@SwitchC# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@SwitchC# set l3-interface vlan-interface 20 address 192.168.2.1 prefix-length 24
```

Step2 Configure basic OSPF functions.

```
admin@SwitchC# set protocols ospf router-id 3.3.3.3
admin@SwitchC# set protocols ospf area 1
admin@SwitchC# set protocols ospf network 192.168.2.0/24 area 1
```

Step3 Commit the configurations.

```
admin@SwitchC# commit
```

Configure Static Routes on SwitchA

Configure five static routes on SwitchA and import these routes into OSPF.

```
admin@SwitchA# set protocols static route 172.16.16.0/24 null0
admin@SwitchA# set protocols static route 172.16.17.0/24 null0
admin@SwitchA# set protocols static route 172.16.18.0/24 null0
admin@SwitchA# set protocols static route 172.16.19.0/24 null0
admin@SwitchA# set protocols static route 172.16.20.0/24 null0
admin@SwitchA# set protocols ospf redistribute static
admin@SwitchA# commit
```

Check the IP routing table on SwitchB. You can see that the five static routes are imported into OSPF.

```
admin@SwitchA# run show route ospf
RIB entry for ospf
==================
Codes: K - kernel route, C - connected, S - static, R - RIP,

O   192.168.2.0/24 [110/10] is directly connected, 20, weight 1, 00:34:56
```

Configure a Policy for Advertising Routes on SwitchA

Configure an IP prefix list named **a2b** on SwitchA.

```
admin@SwitchA# set routing prefix-list ipv4-family a2b seq 10 permit prefix 172.16.17.0/24
admin@SwitchA# set routing prefix-list ipv4-family a2b seq 20 permit prefix 172.16.18.0/24
admin@SwitchA# set routing prefix-list ipv4-family a2b seq 30 permit prefix 172.16.19.0/24
```

Configure a policy for advertising routes on SwitchA, and use the IP prefix list **a2b** to filter routes.

```
admin@SwitchA# set routing route-map a2b order 1 match ipv4-addr address prefix-list a2b
admin@SwitchA# set routing route-map a2b order 1 matching-policy permit
admin@SwitchA# commit
```

Add route-map **a2b** when redistribute static route to OSPF route table.

```
admin@SwitchA# set protocols ospf redistribute static route-map a2b
admin@SwitchA# commit
```

Check the IP routing table on SwitchB. You can see that SwitchB receives only three routes defined in **a2b**.

```
admin@SwitchB# run show route ospf
RIB entry for ospf
==================
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

O>* 172.16.18.0/24 [110/20] via 192.168.1.1, 10, weight 1, 00:02:01
O>* 172.16.19.0/24 [110/20] via 192.168.1.1, 10, weight 1, 00:02:01
O   192.168.1.0/24 [110/10] is directly connected, 10, weight 1, 00:36:27
O   192.168.2.0/24 [110/10] is directly connected, 20, weight 1, 00:34:56
```

Configure a Policy for Receiving Routes on SwitchB

Configure an IP prefix list named **filter_in** on SwitchB to deny route with prefix 1.1.1.1/32. Note that as there is a "**deny all**" command implicitly configured at the end of all prefix list, do not forget to configure a "**permit prefix-any**" command to allow other routes.

```
admin@SwitchB# set routing prefix-list ipv4-family filter_in seq 10 deny prefix 1.1.1.1/32
admin@SwitchB# set routing prefix-list ipv4-family filter_in seq 20 permit prefix-any
```

Configure a OSPF filter policy for receiving routes on SwitchB, and use the IP prefix list **filter_in** to filter routes.

```
admin@SwitchB# set protocols ospf area 1 in filter-list prefix filter_in
admin@SwitchB# commit
```

Check the IP routing table on SwitchC. You can see that SwitchC does not receive the route 1.1.1.1/32.

```
admin@SwitchC# run show route ospf
RIB entry for ospf

IPv6 Support

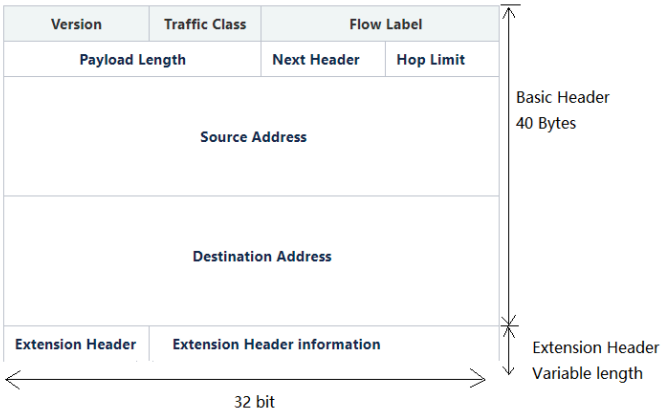
Please note that the N22XX series switches do not support IPv6.

IPv6 Basics

Due to an increased demand for IP addresses across the globe with the introduction of technologies like Internet of Things (IOT), the number of available IP addresses in the IPv4 pool is quickly running out. IPv6 was developed as a replacement for IPv4. An IPv4 address is a 32 bit number where as IPv6 is 128 bits in length and hence has far larger capacity to generate enough IPv6 addresses to cater to the needs of modern IP based networking. In this section we'll discuss some basics of IPv6 addressing including its packet format.

IPv6 Header Format

The IPv6 header format is shown in Figure 1 below.



IPv6 Packet Header

Version is a 4-bit IP protocol version number and is equal to 6.

Traffic Class is an 8-bit field which specifies the traffic class of the IPv6 packet. It is an equivalent of TOS field in IPv4 packet and used in QoS.

Flow Label is 20-bit long and used to differentiate IPv6 traffic. A data flow cab be identified with a source IP and flow label. This field is used by intermediate network devices to differentiate flows.

Payload Length is a 16-bit long field that specifies the length of IPv6 payload following the header including any extension headers in bytes.

Next Header is an 8-bit field and identifies the type of the first extension header that follows the IPv6 basic header or the protocol type of the upper layer PDU.

Hop Limit is 8-bit long and specifies the number of hops the packets can pass. This value is decremented each time the packet passes through a hop and is discarded when the value becomes zero.

Source Address is 128-bit long and defines the source IPv6 address.

Destination Address is also 128-bit long and specifies the destination IPv6 address.

IPv6 uses extension headers between the IPv6 basic header and the upper layer PDU to enhance flexibility in processing IPv6 packets. These extension headers are similar to the Options field in IPv4 packets but unlike IPv4 Options, the header extensions are of variable length to facilitate packet processing. For more information on IPv6 extension headers click here to see IPv6 RFC.

Since version 4.1.0, PICOS fully supports IPv6.

IPv6 Neighbor Discovery Protocol

Neighbor Discovery Protocol (NDP) is part of the Internet Protocol Suite and is used for gathering various network related information. It operates at the link layer in the IP model of layered communication. NDP defines five ICMPv6 packet types for **Router Solicitation**, **Router Advertisement**, **Neighbor Solicitation**, **Neighbor Advertisement** and **Redirect**. NDP is similar in functionality to Address Resolution Protocol (ARP) but the major difference is that ARP is designed to work with IPv4 whereas NDP is designed for IPv6. These ICMPv6 packet types are further explained below.

1. **Router Solicitation--Type-133 (RS):** Router solicitation messages are used by IPv6 capable devices to try to acquire routers on the link. Routers on the link receiving these messages immediately reply with **Router Advertisement** messages. Normally routers periodically advertise themselves on the link but in the case of receiving an RS message the routers respond immediately with Router Advertisement message.
2. **Router Advertisement--Type-134 (RA):** Router advertisements are issued by routers on the link to periodically advertise their presence or these messages can be issued in response to a RS message.
3. **Neighbor Solicitation--Type-135 (NS):** Neighbor solicitation messages are issued by devices on the link to acquire the link layer address of a device or to verify that a neighbor is still alive on the link via cached link layer address.
4. **Neighbor Advertisement--Type-136 (NA):** Neighbor advertisement messages are issued in response to Neighbor Solicitation messages.
5. **Redirect--Type-137:** These messages are used by routers to inform hosts of a better first host router for a destination.

These messages provide the combined functionality listed below.

- **Router Discovery**
- **Prefix Discovery**
- **Parameter Discovery**
- **Address Autoconfiguration**
- **Address Resolution**
- **Next Hop Determination**
- **Neighbor Unreachability Detection**
- **Duplicate Address Detection**
- **DNS and Recursive DNS Search List Via RA Options**
- **Packet Redirection for better next hop**

- IPv6 Neighbor Discovery Configuration
- PICOS L2/L3 Support for IPv6
- Enable Path MTU Discovery

IPv6 Neighbor Discovery Configuration

In this section we will demonstrate briefly the commands used to configure some of the most common IPv6 Neighbor Discovery (ND) features. All these commands apply to layer 3 VLAN interfaces or routed interfaces. For more detailed command references of all the IPv6 ND features, visit the IPv6 Command Reference Page by clicking here.

Router Advertisement (RA)

IPv6 Routers periodically advertise their presence to other nodes by sending RA packets. Run the command below to enable RA on a layer 3 interface.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd suppress-ra false
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd suppress-ra false
admin@Xorplus# commit
```

Router Advertisement Interval

To set the RA interval, run the command below. RA interval can be set in milliseconds or in seconds. The example below sets the RA interval to 1000 seconds.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd ra-interval sec 1000
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd ra-interval sec 1000
admin@Xorplus# commit
```

RA Fast Retransmit

According to RFC4861 consecutive RA packets should be sent with at least 3 seconds delay. PICOS by default bypasses this restriction by fast transmission of RA to achieve better convergence. Run the command below enable or disable this feature. Default is enabled.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd ra-fast-retrans false
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd ra-fast-retrans false
admin@Xorplus# commit
```

Default Router Preference

Routers may include the default router preference in RA packets to signal to nodes the router preference in *low, medium* or *high.* Router preference is send using the unused bits in the RA packet. The hosts that do not implement the default router preference will ignore these bits. The command below sets the default router preference to low.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd router-preference low
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd router-preference low
admin@Xorplus# commit
```

Advertisement Interval Option

The Advertisement Interval Option indicates to host the maximum time in milliseconds between successive unsolicited Router Advertisements. Run the command below to set this option.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd adv-interval-option
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd adv-interval-option
admin@Xorplus# commit
```

Home Agent Option

The Home Agent Option flag can be set or unset in IPv6 RA packets and is used to indicate to hosts that the router acts as Home Agent and includes a Home Agent Option. This option is not set by default. Run the command below to set this option.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd home-agent-config-flag
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd home-agent-config-flag
admin@Xorplus# commit
```

Home Agent Lifetime

This parameter specifies the value to be place in Home Agent Option when its set. The default value is 0 which means the current Router Lifetime value. The command below sets the Home Agent Lifetime to 5 seconds.

```
admin@XorPlus# set l3-interface vlan-interface vlan4001 ipv6-nd home-agent-lifetime 5
admin@Xorplus# commit
```

or

```
admin@XorPlus# set l3-interface routed-interface rif-ge3 ipv6-nd home-agent-lifetime 5
admin@Xorplus# commit
```

PICOS L2/L3 Support for IPv6

Please note that the N22XX series switches do not support IPv6.

Since PICOS version 4.1.0, the following protocols are protocol components supports IPv6.

- VRRPv3
- BGPv3
- OSPFv3
- DHCP Relay
- RIPng

The following System related features offer support for IPv6.

- Syslog
- NTP
- TACACS

Enable Path MTU Discovery

Overview

The Path MTU (PMTU) discovery protocol dynamically discovers the MTU value of each hop along a given transmission path, which saves IPv6 device processing resources and helps IPv6 networks run more efficiently.

The PMTU protocol is accomplished through the Packet Too Big message of ICMPv6. The basic idea is that a source node initially assumes that the PMTU of a path is the MTU of its outgoing interface. If any of the IPv6 packets sent on that path are too large to be forwarded by some node along the path, that node will discard them and return ICMPv6 Packet Too Big messages to the source node with its own MTU value.

Upon receipt of such a message, the source node reduces its assumed PMTU for the path based on the MTU of the constricting hop as reported in the Packet Too Big message. The decreased PMTU causes the source to send smaller packets. This process is repeated until the message reaches the destination, then the source node knows the minimum MTU in the path of two communicating hosts which is called the Path MTU value.

The PMTU of a path may change over time, due to changes in the routing topology. Reductions of the PMTU are detected by Packet Too Big messages. To detect increases in a path's PMTU, a node periodically restores its assumed PMTU to the originally configured MTU value of the system (configured by using command **set l3-interface vlan-interface** <*interface-name*> **mtu** <*mtu-value*> or **set l3-interface routed-interface** <*interface-name*> **mtu** <*mtu-value*>).

NOTE:

- Although the PMTU value is triggered by the IPv6 packets, once generated, it controls the size of both the IPv4 and IPv6 packets forwarded.
- The PMTU value takes effect only to the packets in the outgoing direction of the interface.

Enabling Path MTU Discovery

The following commands can be used to enable or disable PMTU function on a VLAN interface or a routed interface.

set l3-interface vlan-interface <*vlan-interface*> **pmtu-discovery disable** <**true | false**>

set l3-interface routed-interface <*routed-interface*> **pmtu-discovery disable** <**true | false**>

Enable PMTU function on all the nodes in the path where you want to apply the PMTU function.

- The following example enables PMTU function on VLAN interface *vlan100*.

```
admin@PICOS# set l3-interface vlan-interface vlan100 pmtu-discovery disable falseadmin@PICOS# commit
```

- The following example enables PMTU function on routed interface *rif-te19*.

```
admin@PICOS# set l3-interface routed-interface rif-te19 pmtu-discovery disable false
admin@PICOS# commit
```

IPv6 Neighbor Discovery Inspection

- Overview of ND Inspection

- Example for ND Inspection

Overview of ND Inspection

- Terminology
  - Neighbor Solicitation (NS)
  - Neighbor Advertisement (NA)
  - Router Solicitation (RS)
  - Router Advertisement (RA)
  - Redirect (RR)
  - DHCPv6 Snooping
  - Duplicate Address Detection (DAD)
  - ND Inspection Trusted port
  - ND Inspection Untrusted port
- ND Inspection Operation Mechanism
  - Binding Entry Check
  - Source MAC Address Validation

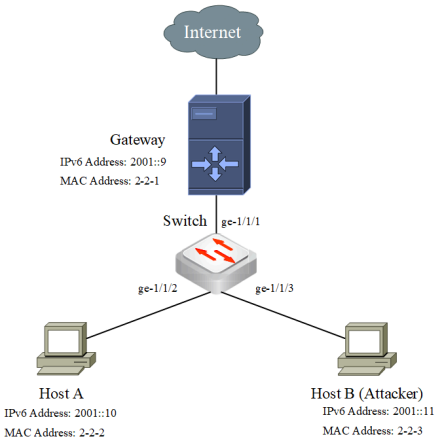
IPv6 Neighbor Discovery (ND) Inspection mitigates NDP security vulnerability by checking detailed information of message and verifying them against DHCPv6 snooping binding table or neighbor discovery snooping binding table.

The detailed information referred to the following points:

The HostB (Attacker) spoofs the IPv6 address of the victim's (Host A) by sending NS/NA/RS messages. As a result, the gateway and other hosts update the neighbor incorrect address information. All messages intended for the victim are sent to the attacking terminal.

The HostB (Attacker) spoofs the gateway by sending NA messages. As a result, all hosts attached to the victim gateway maintain an incorrect IPv6 configuration.

Figure 1. ND Attack Diagram



Terminology

Neighbor Solicitation (NS)

IPv6 nodes (a host or network device using IPv6 protocol) send NS messages primarily to get the link-layer addresses of their neighbors and detect neighbor reachability and duplicate addresses.

Neighbor Advertisement (NA)

IPv6 hosts respond to NS messages by sending. Additionally, IPv6 nodes, including hosts and network devices, send NA messages when the link-layer topology changes.

Router Solicitation (RS)

When an IPv6 node starts, it sends an RS packet to a router to request prefixes and other essential configuration details. It then waits for RA packet from the router in response.

Router Advertisement (RA)

A router periodically advertises RA messages, including network configurations such as network prefix to IPv6 nodes. The router also returns RA messages as the responses to RS messages.

Redirect (RR)

When detecting that the inbound interface and outbound interface of a packet are the same, a router sends a Redirect message to request the IPv6 node to select a better next hop address.

DHCPv6 Snooping

DHCPv6 snooping is a security feature that establishes DHCPv6 snooping binding table to record client information by capturing messages between server and client. DHCP snooping creates a binding table, which includes the client IP address, MAC address, VLAN ID, physical port and the lease time.

Duplicate Address Detection (DAD)

In an IPv6 network, when an interface attempts to configure a unicast IPv6 address, it first performs DAD to ensure that the address is unique on the link.

The purpose of DAD is to prevent address conflicts and ensure smooth network communication.

ND Inspection Trusted port

This type of port is used to connect to trusted IPv6 nodes. After the user configures the port as a trusted port, the device will no longer check NS/NA/RS/RA messages in the table entries.

ND Inspection Untrusted port

All ports are untrusted by default without modifying port properties.

ND Inspection Operation Mechanism

ND inspection is mainly for filtering illegal messages, the forged ND message has the following characteristics:

The source MAC address and the MAC address in the source link layer address in the forged ND message do not match.

The mapping relationship between the source IPv6 address and the source MAC address in the forged ND message is not real for the legal user.

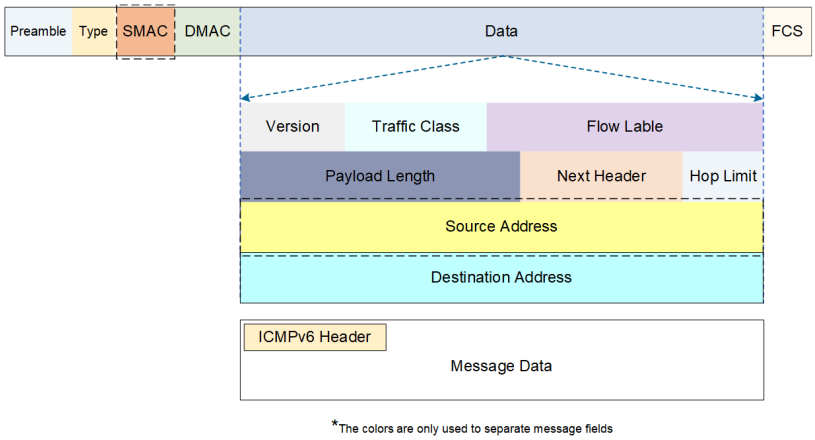
According to the characteristics of the attack messages, the device can check ND messages to effectively prevent ND attacks.

Binding Entry Check

With ND inspection enabled, after a device receives an ND message, the device will verify the NS/NA/RS/RA message with the DHCPv6 snooping table entry already generated.

Verify if the source MAC address and source IP address exists in ND message, if the ND message fields match with the source IPv6 address and source MAC address in the table, the device will consider ND message is legal and forward the message. Otherwise, the device discards the message.

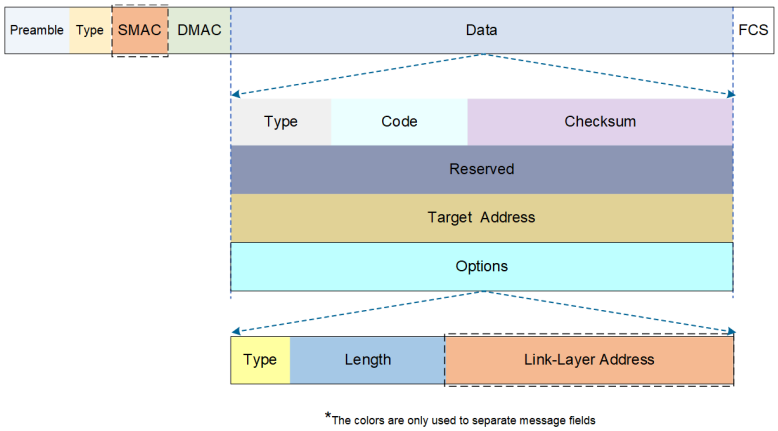
Figure 2. IPv6 Message Diagram



Source MAC Address Validation

After configuring source MAC address validation, the device will check if the source MAC address in the ND message is consistent with the Link-Layer Address (for example: 22:22:22: 22:22:21), if they are not the same, the device will discard the message. The diagram is shown below.

Figure 3. ND Message Diagram



If the user specifies a trusted port, the system will no longer check the ND message and directly forward the message, but still check source MAC consistency.

Configuring ND Inspection

Step 1 Enable DHCPv6 snooping.

set protocols dhcp snooping vlan <*vlan-id*> **disable** <**true** | **false**>

NOTE:

ND inspection does not generate table entries by itself and needs to rely on the table entries formed by DHCPv6 snooping, thus, user needs to enable DHCPv6 snooping first.

Step 2 Enable ND inspection for a VLAN.

set protocols neighbour inspection vlan <*vlan-id*> **disable** <**true** | **false**>

NOTE:

DAD message does not carry a source MAC address; therefore, this type of message will be skipped in ND inspection.

Step 3 (Optional) Configure the device to check source MAC address against the link-layer source address.

set protocols neighbour inspection validate source-mac

Step 4 (Optional) Configure the trust-port for a device.

set protocols neighbour inspection trust-port <*port*>

Step 5 Commit the configurations.

commit

Step 6 View DHCPv6 snooping dynamic binding table entries used by ND inspection.

run show nd inspection dhcp6-snooping binding

Example for ND Inspection

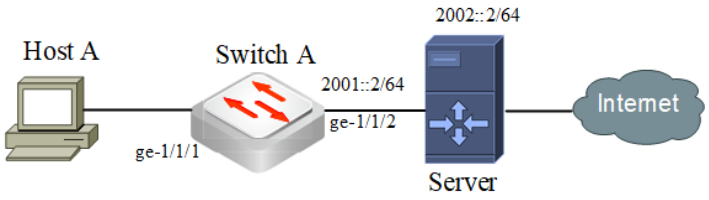
- Networking Requirements
- Procedure
  - Switch A
  - Verifying the Configuration

Networking Requirements

Building the corresponding network according to the topology diagram, and do the basic network connectivity configuration, configure the ND snooping inspection feature on Switch A, and after the correct configuration is completed, check the effective configuration on Switch A.

Host A accesses the DHCPv6 Server through Switch A and Switch A forwards the IPv6 address assigned by the DHCPv6 Server to Host A.

Figure 1. ND Inspection Configuration Example



Procedure

Switch A

Step 1 Add VLAN members to trunk ports.

```
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 20
```

Step 2 Enable DHCPv6 snooping.

```
admin@SwitchA# set protocols dhcp6 snooping trust-port ge-1/1/2
admin@SwitchA# set protocols dhcp6 snooping vlan 20 disable false
admin@SwitchA# set protocols dhcp6 traceoptions flag all disable false
```

Step 3 Enable ND inspection and verify source MAC address.

```
admin@SwitchA# set protocols neighbour inspection vlan 20 disable false
admin@SwitchA# set protocols neighbour inspection trust-port ge-1/1/2
admin@SwitchA# set protocols neighbour inspection validate source-mac
```

Step 4 Commit the configurations.

```
admin@ SwitchA # commit
```

Verifying the Configuration

The show command can be used to show table entry about configuration on Switch A.

The **run show dhcp6 snooping binding** command is used to view DHCPv6 snooping binding table.

The **run show nd inspection dhcp6-snooping binding** command is used to view DHCPv6 snooping dynamic binding table entries used by ND inspection..

- View DHCPv6 snooping binding table.

```
admin@ Switch A# run show dhcp6 snooping binding
Total Snooping host count:     1
MAC Address        IPv6 Address     Port   VLAN ID   Lease(sec)
-------------------------------------------------------------------

  - RA Attack

The IPv6 ND (Neighbor Discovery) protocol is a key protocol in IPv6 networks that combines and enhances the ARP (Address Resolution Protocol), ICMP (Internet Control Message Protocol) route discovery, and ICMP redirection protocols of IPv4. The ND protocol plays a critical role in IPv6 networks, providing several important functions to ensure that devices in the network can communicate with each other and maintain network stability.

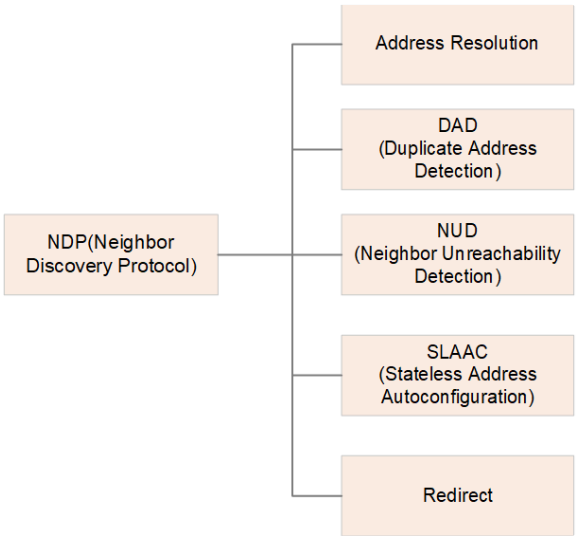
The IPv6 ND protocol is powerful but does not have a relevant security mechanism. ND snooping is a security feature for IPv6 ND, which allows users to configure the port type. The port will capture messages from the corresponding ports and generate prefix management or dynamic binding tables to defend against ND attacks from bogus hosts or gateways.

Terminology

IPv6 ND

The ND protocol is a key protocol for IPv6, which combines the protocols of ARP, ICMP route discovery, and ICMP redirection from IPv4 and improves them. As a fundamental protocol for IPv6, ND provides multiple functions as show in the following figure.

Figure 1. Neighbor Discovery Protocol Function Diagram



Neighbor Solicitation (NS)

IPv6 nodes (hosts or network devices using the IPv6 protocol) can get the link-layer addresses of their neighbors through NS messages to check whether the neighbors are reachable or not, and they can also perform DAD (Duplicate Address Detect).

Neighbor Advertisement (NA)

IPv6 hosts respond to NS message by sending NA packets. Additionally, IPv6 nodes, including hosts and network devices, send NA message when the link-layer topology changes.

Router Solicitation (RS)

Upon starting, an IPv6 node sends an RS message to a router to request prefixes and other essential configuration details. It waits for a RA message from the router in response.

Router Advertisement (RA)

A router periodically advertises RA message, including network configurations such as network prefix to IPv6 nodes. The router also returns RA message as the responses to RS message.

Duplicate Address Detection (DAD)

In an IPv6 network, when an interface attempts to configure a unicast IPv6 address, it first performs DAD to ensure that the address is unique on the link.

The purpose of DAD is to prevent address conflicts and ensure smooth network communication.

Redirect (RR)

When detecting that the inbound interface and outbound interface of a packet are the same, a router sends a redirect packet to request the IPv6 node to select a better next hop address.

ND Snooping Trusted Port

This type of port is used to connect to trusted IPv6 nodes, for ND messages received from this type of port, the device forwards them normally, and at the same time, the device will build a prefix management table based on the received RA messages.

Users can execute `set protocols neighbour snooping trust-port` command to specify ports connected to IPv6 nodes into trusted ports. By default, all ports of the device are untrusted

ND Snooping Untrusted port

This type of port is used to connect untrusted IPv6 nodes, and the device considers RA messages received from this type of port as illegal messages and directly discards them.

ND protocol provides powerful functions, but it is easier to be utilized by the attacker for its weaker security mechanism, ND protocol attacks include the following types.

ND Attacks

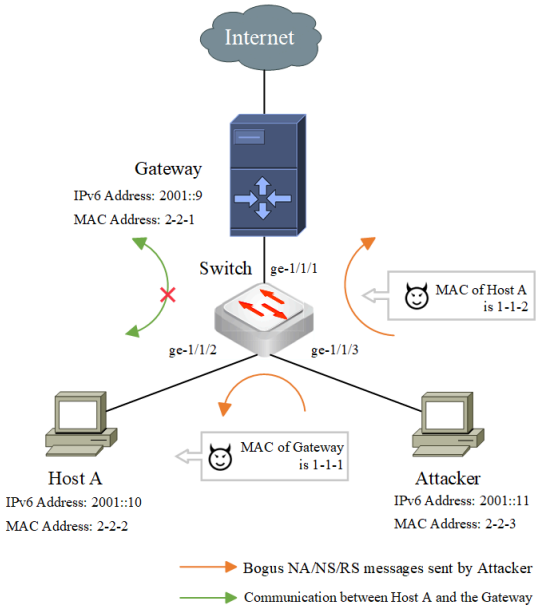
ND protocol provides powerful functions, but it is easier to be utilized by the attacker for its weaker security mechanism, ND protocol attacks include the following types.

Address Spoofing Attack

Attacker uses the IP of Host A and sends NA/NS/RS message to the gateway, which modifies the ND entries of the gateway and records the incorrect entries of Host A. The attacker easily gets the data that the gateway communicates with Host A.

Attacker uses the IP of gateway and sends forged NA/NS/RS message to Host A, Host A records wrong entry. As a result, Host A cannot receive message from the gateway, Host A and the gateway cannot communicate with each other, and the attacker can easily get the data that intended to be sent to the gateway.

Figure 2. Address Spoofing Attack

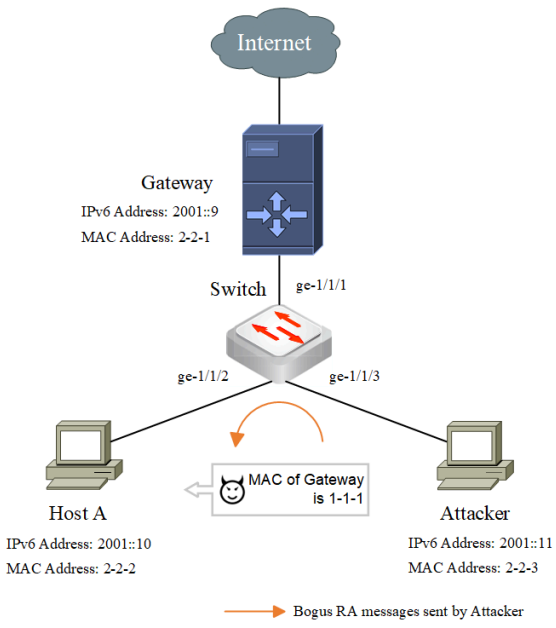


RA Attack

Attacker sends forged RA messages.

- Forges non-existent prefixes, modifies Host A's routing table.
- Forges the gateway's MAC and router lifetime, modifies the host's default gateway.
- Forges the DHCP server, and at the same time, forges the flag bit in the RA message, which made Host A being assigned a false address using the DHCP server.

Figure 3. RA Attack



In summary, getting the real IPv6 address-MAC of the device and filtering out the illegal ND messages are the keys to solve the anti-attack of the ND protocol. ND snooping is proposed at this point. This feature enables the filtering of illegal messages by checking the fields of

the established table entries. For a detailed description, please refer to Operation Mechanism of ND Snooping

Operation Mechanism of ND Snooping

- Prefix Management Table
  - Entry Creation and Update Mechanism of Prefix Management Table
  - Aging Mechanism of Prefix Management Table Entries
- ND Snooping Dynamic Binding Table
  - Entry Creation and Update Mechanism of Dynamic Binding Table
    - Receiving DAD Messages
    - Receiving NS or RS Messages
    - Receiving NA Messages
  - Aging Mechanism of Dynamic Binding Table Entries

Prefix Management Table

After enabled the ND snooping, the device captures RA messages sent from the trusted port and generates a prefix management table. An entry includes information about prefix, prefix length, port, VLAN ID, valid- time, prefix-type.

Entry Creation and Update Mechanism of Prefix Management Table

After ND snooping is enabled, a trusted port receives an RA message and checks whether the prefix of the message exists.

- If the prefix does not exist, the system creates a new prefix management table entry.
- If the prefix exists, the device updates the entries according to the RA message and forwards.

When the untrusted port receives a RA message, it will discard the message. If the port receives the NS/NA/RS message, it will process the entries then decide forward or not.

Aging Mechanism of Prefix Management Table Entries

When the valid time in the prefix table expires, the entry will be deleted.

ND Snooping Dynamic Binding Table

After ND snooping enabled, the device establishes the ND snooping dynamic binding table, and the device can filter spoofed messages by checking NA, NS, and RS messages against dynamic binding table entry. An entry includes information about IPv6 address, MAC address, input port, VLAN ID, lease.

Entry Creation and Update Mechanism of Dynamic Binding Table

After ND snooping enabled, the device receives a DAD NS message, it will check whether there is a corresponding prefix management table entry based on the Target Address.

The creation and update mechanism of the dynamic binding table in ND snooping is as follows:

Receiving DAD Messages

If entry does not exist, the message will be discarded.

If the entry exists, it then checks whether there is a ND snooping dynamic binding table entry based on Target Address.

> **NOTE:**
>
> The Target Address cannot be a multicast address.

- If no such entry exists, the device creates a new ND snooping dynamic binding table entry and forwards the message.

- If the entry exists, the device checks whether the source MAC address, input port, and VLAN of the DAD NS message are the same with the entry.
  - If they are consistent, it updates the address lease of the corresponding entry.
  - If the MAC addresses are consistent but other information is not, it updates other fields in the entry and forwards the message.
  - If the MAC addresses are different, the device retains the entry and forwards the message.

Receiving NS or RS Messages

When the device receives a common NS or RS message, it checks if there is a corresponding dynamic binding entry based on source IP address. If no such entry exists, the message will be discarded. If an entry exists, the device checks if the MAC address, input port, and VLAN of the NS/RS message are the same with the entry.

- If all the information is consistent, the device updates lease.
- If the information is different, the device discards the message.

Receiving NA Messages

When the device receives a NA message, it checks if there is a corresponding dynamic binding entry based on source IP address. If no such entry exists, the NA message will be discarded. If an entry exists, the device then checks if the MAC address, port, and VLAN in the NA message are the same.

- If all the information is same, the device will update lease.
- If the MAC address is the same but other information are not, the device will update data and forward the message.
- If the MAC address is different, the device discards the message.

Aging Mechanism of Dynamic Binding Table Entries

If the lease time of a user address expires, the table entry ages automatically.

When the device receives a new or updated entry from NS message, the detailed description is as follows.

If it receives a response NA message notifying that the user's address has been used from other users within a certain period, the device will delete the entry.

If the device receives a response NA message notifying that the user's address has been used from other users beyond this period, the device does not delete the entry.

Configuring ND Snooping

Step 1 Enable ND snooping protocol in corresponding VLAN.

set protocols neighbour snooping vlan <*vlan-id*> **enable true**

Step 2 ND snooping classifies ports connected to IPv6 nodes into trusted and untrusted ports. By default, all ports of the device are untrusted.

set protocols neighbour snooping trust-port <*port*>

> **NOTE:**
>
> `<port>` can be a valid physical port or a LAG (Link Aggregation Group) port. The members of the LAG port don't support configuration as a trust port.

Step 3 (Optional) Configure the maximum number of ND snooping dynamic binding table entries a device is allowed to learn.

set protocols neighbour snooping max-user-number <*max-user-num*>

Step 4 (Optional) If the device does not send RA messages, the prefix management table entries cannot automatically generate, in this scenario, user can configure static prefix.

set protocols neighbour snooping static-prefix <*IPv6Net*> **vlan** <*vlan-id*>

> **NOTES:**
>
> - `<IPv6Net>` cannot be ::/0, multicast address.
> - `<vlan-id>` must be configured when add or delete.

Step 5 Commit the configuration.

commit

Step 6 View the configuration information and table entries about ND snooping.

run show neighbor snooping

run show neighbor snooping prefix [static | dynamic]

run show neighbor snooping binding

Step 7 (Optional) If needed, users can clear the entries of ND snooping.

run clear neighbor snooping prefix

run clear neighbor snooping binding

Example for ND Snooping

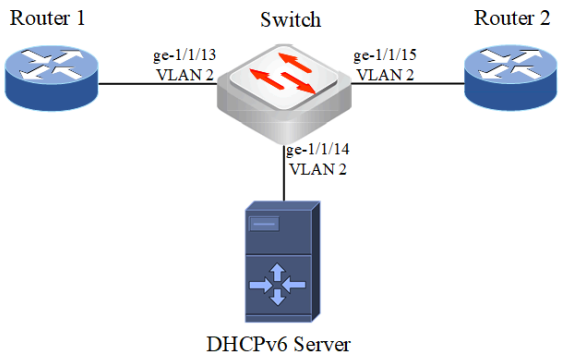
  - Switch A
  - Verifying the Configuration

Networking Requirements

Building the corresponding network according to the topology diagram, and do the basic network connectivity configuration, configure the ND snooping function on Switch A, and after the correct configuration is completed, check the effective ND snooping binding table on Switch A.

- Router1 gets an IP address through SLAAC (Stateless Address Autoconfiguration).
- Router2 gets an IP through DHCP (Dynamic Host Configuration Protocol).

Figure 1. ND Snooping Configuration Example



Procedure

Switch A

Step 1 Add VLANs members to trunk ports.

```
admin@SwitchA# set interface gigabit-ethernet ge-1/1/13 family ethernet-switching native-vlan-id 2
admin@SwitchA# set interface gigabit-ethernet ge-1/1/13 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/13 family ethernet-switching vlan members 2
admin@SwitchA#set interface gigabit-ethernet ge-1/1/14 family ethernet-switching native-vlan-id 2
admin@SwitchA# set interface gigabit-ethernet ge-1/1/14 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/14 family ethernet-switching vlan members 2
admin@SwitchA# set interface gigabit-ethernet ge-1/1/15 family ethernet-switching native-vlan-id 2
admin@SwitchA# set interface gigabit-ethernet ge-1/1/15 family ethernet-switching port-mode trunk
admin@SwitchA# set interface gigabit-ethernet ge-1/1/15 family ethernet-switching vlan members 2
admin@SwitchA# set vlans vlan-id 2
```

Step 2 Configure ge-1/1/14 as trust port and enable ND snooping on VLAN 2.

```
admin@SwitchA# set protocols neighbour snooping vlan 2 enable true
admin@SwitchA# set protocols neighbour snooping trust-port ge-1/1/14
admin@SwitchA# set protocols neighbour traceoptions disable false
admin@SwitchA# set system log-level trace
```

Step 3 Commit the configurations.

```
admin@ SwitchA # commit
```

Verifying the Configuration

The **run show neighbor snooping binding** command is used to view ND snooping dynamic management table entries on Switch A.

The **run show neighbor snooping prefix** command is used to view ND snooping prefix management table entries on Switch A.

The **run show neighbor snooping** command is used to view ND snooping configuration on Switch A.

- View ND snooping dynamic management table entries.

```
admin@SwitchA # run show neighbor snooping binding
Total Snooping binding count:     2
MAC Address     IPv6 Address       Port     VLAN ID   Status     Lease(sec)
-------------------------------------------------------------------------------
dc:b:9:65:6f:f7  3000::de0b:9ff:fe65:6ff7  ge-1/1/13   2      Valid      48/120
dc:b:9:65:6f:f7  fe80::de0b:9ff:fe65:6ff7  ge-1/1/13   2      Valid      27/120
```

- View ND snooping prefix management table entries.

```
admin@ SwitchA # run show neighbor snooping prefix
Total Snooping table prefix count:    1
Total Snooping table dynamic count:  1
Total Snooping table static count:     0
Prefix          Length     Port       VLAN ID   Valid-Time    Prefix-Type
-------------------------------------------------------------------------------
3000::          64       ge-1/1/14      2        48/120       Dynamic
```

- View ND snooping configuration.

```
admin SwitchA # run show neighbor snooping
ND Snooping enabled vlans: 1
ND Snooping trust-ports: ge-1/1/14
ND Snooping max-user-number: 9216
```

VRF Route Leaking Configuration

Generally speaking, multiple VRFs maintain separate routing tables that are independent of each other. But there are scenarios where a specific destination is only reachable from a specific VRF. For example, a DHCP server in one VRF can only be accessible to hosts in that VRF. If clients in other VRFs want to access this DHCP server, we need to have a mechanism where we can have a route in one VRF for which the destination next-hop address is located in a different VRF.

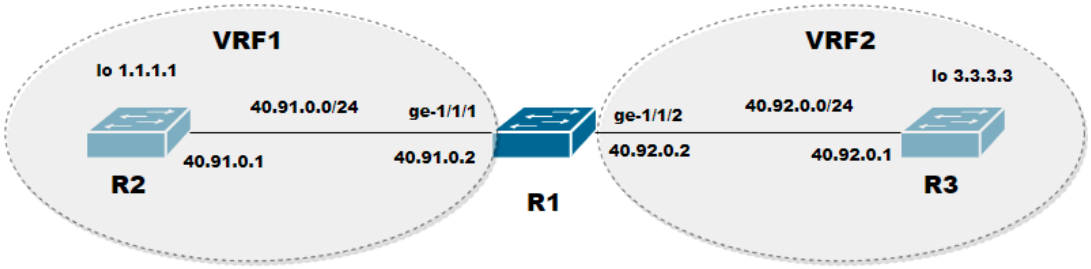


Figure 1. VRF Route Leaking Example

As shown in Figure 1, if hosts attached to R1 in VRF1 wants to access resources located in VRF2 and accessible through R3, we will need to enable route leaking between VRF1 and VRF2. From the topology above, R1 has two interfaces, one each in VRF1 and VRF2. For resources in VRF2 to be accessible to hosts in VRF1, routes in VRF2 needs to be leaked into VRF1.

Leaked routes once configured on a device can be distributed to neighboring devices through either BGP or OSPF. If a leaked route is a BGP route then it will be dynamically replicated from source to destination VRF by BGP. If the route to be leaked is a non-BGP route, then that route first needs to be redistributed into BGP before it can be leaked to the destination VRF.

Route leaking can be used to reach directly connected hosts in the source VRF as well as reach remote destinations accessible through the source VRF. In Figure 1, the leak will be configured on R1. For the loopback interface 1.1.1.1 on R2 in VRF1, to ping loopback interface 3.3.3.3 on R3 in VRF2, R1 device will need two routes in both VRF1 and VRF2. On R1, the route to reach 3.3.3.3 in VRF2 is **3.3.3.3/32 next-hop 40.92.0.1**. Similarly, to reach 1.1.1.1 the route in VRF2 will be **1.1.1.1 next-hop 40.91.0.2 next-hop vrf vrf1.** VRF2 does not have a route for loopback 1.1.1.1 in VRF2 hence apart from specifying the next-hop address of 40.91.0.1, the route must also specify the next-hop VRF which in this case is VRF1. Similarly, there are also two routes in VRF1. The two routes in VRF1 on R1 are, **1.1.1.1/32 next-hop 40.91.0.1** and **3.3.3.3/32 next-hop 40.92.0.1 next-hop vrf vrf2.**

In PICOS, there is no restriction on leaking routes to and from the default VRF. Routes can be leaked from the default VRF into any user defined VRF and vice versa.

Route Leaking Limitation

1. Directly connected subnets or hosts are not allowed to be leaked from one VRF into another. In Figure 1, for example, subnet 40.92.0.0/24 in VRF 2 cannot be leaked into VRF 1 on R1.
2. On R3 switch, all routes in VRF2 can be leaked into VRF1 by configuring route leaking on R1 except the subnets directly connected with R1, for example in this case, subnet 40.92.0.0/24 cannot be leaked into VRF1.
3. Overlapping addresses in two VRFs are not allowed when enabling route leaking between these two VRFs. It is thus strongly recommended to use non-overlapping addresses in different VRFs before implementing route leaking.
4. VRF route leaking doesn't work in case of VXLAN routing. The routes cannot be leaked to a VRF corresponding to an VXLAN instance.
5. The configuration of route leaking by importing BGP IPv4 routes from one user-defined VRF into another user-defined VRF, for example:

   set protocols bgp vrf vrf1 local-as 1
   set protocols bgp vrf vrf1 ipv4-unicast import vrf vrf2
   set protocols bgp vrf vrf2 local-as 2
   This will cause configuration from PICOS CLI is not consistent with FRR configuration. Specifically, FRR will add "set protocols bgp local-as 1" (local as number is same as the value in vrf1) to its configuration automatically, which is not in PICOS CLI. From version 4.4.0, if "set protocols bgp local-as 1" is not configured, the above configurations are not allowed.

BGP Route Leaking Configuration Example

This document illustrates dynamic route leaking between different VRFs. There are three switches in our example topology as shown in Figure 1.

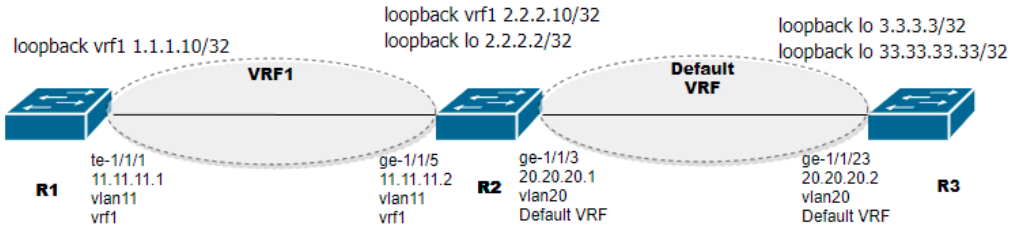

Figure 1. Dynamic Route Leaking Example Topology

Topology Introduction

- OSPFv2 is configured between devices R1 and R2. The interfaces connecting these two devices both belong to VRF1.
- BGP is configured between devices R2 and R3. The interfaces connecting these two devices both belong to the default VRF.
- Dynamic route leaking using BGP is configured on R2.
- On R2, BGP routes in the default VRF are leaked into VRF1. The BGP routes are then redistributed into OSPF in VRF1.
- Similarly, on R2, BGP routes in VRF1 are leaked into the default VRF.
- On R2, OSPF routes in VRF1 are redistributed into BGP.
- Route map is used on R2 to demonstrate route filtering when leaking routes between the two VRFs.

Router Configuration

This section describes the configuration used on the three devices.

R1 Configuration

Step 1. Configure physical interfaces, L3 VLAN interfaces and IP addressing.

```
root@R1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode "trunk"
root@R1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 11
root@R1# set interface gigabit-ethernet te-1/1/10 family ethernet-switching port-mode "trunk"
root@R1# set interface gigabit-ethernet te-1/1/10 family ethernet-switching vlan members 101
root@R1# set l3-interface vlan-interface vlan101 address 101.101.101.1 prefix-length 24
root@R1# set l3-interface vlan-interface vlan11 address 11.11.11.1 prefix-length 24
root@R1# set vlans vlan-id 11 l3-interface "vlan11"
root@R1# set vlans vlan-id 101 l3-interface "vlan101"
```

Step 2. Create vrf1 and assign vlan11 and vlan101 to vrf1 and enable IP routing on the device.

```
root@R1# set ip vrf vrf1
root@R1# set l3-interface vlan-interface vlan11 vrf "vrf1"
root@R1# set l3-interface vlan-interface vlan101 vrf "vrf1"
root@R1# set ip routing enable true
```

Step 3. Create a loopback interface in vrf1 and set system hostname.

```
root@R1# set l3-interface loopback vrf1 address 1.1.1.10 prefix-length 32
root@R1# set system hostname R1
```

Step 4. Configure OSPFv2 by setting router ID and enable OSPF for different network prefixes.

```
root@R1# set protocols ospf vrf vrf1 router-id 1.1.1.10
root@R1# set protocols ospf vrf vrf1 network 101.101.101.0/24 area "0"
root@R1# set protocols ospf vrf vrf1 network 11.11.11.0/24 area "0"
```

```
root@R1# set protocols ospf vrf vrf1 network 1.1.1.10/32 area "0.0.0.0"
```

R2 Configuration

Step 1. Configure physical interfaces, L3 VLAN interfaces and IP addressing.

```
root@R2# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 20
root@R2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching port-mode "trunk"
root@R2# set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 11
root@R2# set l3-interface vlan-interface vlan11 address 11.11.11.2 prefix-length 24
root@R2# set l3-interface vlan-interface vlan20 address 20.20.20.1 prefix-length 24
root@R2# set vlans vlan-id 11 l3-interface "vlan11"
root@R2# set vlans vlan-id 20 l3-interface "vlan20"
```

Step 2. Create vrf1 and assign vlan11 to vrf1 and enable IP routing on the device.

```
root@R2# set ip routing enable true
root@R2# set ip vrf vrf1
root@R2# set l3-interface vlan-interface vlan11 vrf "vrf1"
```

Step 3. Create loopback interfaces in the default VRF and vrf1 and set the system hostname.

```
root@R2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
root@R2# set l3-interface loopback vrf1 address 2.2.2.10 prefix-length 32
root@R2# set system hostname R2
```

Step 4. Configure OSPFv2 by setting router ID and enable OSPF for different network prefixes. Also enable redistribution of BGP routes into OSPFv2.

```
root@R2# set protocols ospf vrf vrf1 router-id 2.2.2.10
root@R2# set protocols ospf vrf vrf1 network 11.11.11.0/24 area "0"
root@R2# set protocols ospf vrf vrf1 network 21.21.21.0/24 area "0"
root@R2# set protocols ospf vrf vrf1 redistribute bgp
```

Step 5. Configure BGP by setting router ID, specify BGP neighbor, AS number and enable route leaking by importing routes into VRF1 from the default VRF.

```
root@R2# set protocols bgp local-as 200
root@R2# set protocols bgp router-id 2.2.2.2
root@R2# set protocols bgp neighbor 20.20.20.2 remote-as "300"
root@R2# set protocols bgp ipv4-unicast network 2.2.2.2/32
root@R2# set protocols bgp ipv4-unicast import vrf vrf1
root@R2# set protocols bgp vrf vrf1 local-as 201
root@R2# set protocols bgp vrf vrf1 router-id 2.2.2.2
root@R2# set protocols bgp vrf vrf1 ipv4-unicast redistribute ospf
root@R2# set protocols bgp vrf vrf1 ipv4-unicast import vrf default
```

Step 6. Configure route map *map1* to filter route 33.33.33.33/32 and only leak 3.3.3.3/32 into VRF1.

```
root@R2# set routing prefix-list ipv4-family pre1 seq 1 permit prefix 3.3.3.3/32
root@R2# set routing route-map map1 order 1 matching-policy "permit"
root@R2# set routing route-map map1 order 1 match ipv4-addr address prefix-list "pre1"
root@R2# set protocols bgp vrf vrf1 ipv4-unicast import vrf-route-map "map1"
```

R3 Configuration

Step 1. Configure physical interfaces, L3 VLAN interfaces and IP addressing.

```
admin@R3# set interface gigabit-ethernet ge-1/1/10 family ethernet-switching native-vlan-id 200
admin@R3# set interface gigabit-ethernet ge-1/1/10 family ethernet-switching port-mode trunk
admin@R3#set interface gigabit-ethernet ge-1/1/10 family ethernet-switching vlan members 201
admin@R3# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching native-vlan-id 20
admin@R3# set l3-interface vlan-interface vlan20 address 20.20.20.2 prefix-length 24
admin@R3# set l3-interface vlan-interface vlan200 address 200.200.200.1 prefix-length 24
admin@R3# set vlans vlan-id 20 l3-interface vlan20
admin@R3# set vlans vlan-id 200 l3-interface vlan200
admin@R3# set vlans vlan-id 201 l3-interface vlan201
```

Step 2. Enable IP routing on the device and create vrf1.

```
admin@R3# set ip routing enable true
admin@R3# set ip vrf vrf1
```

Step 3. Create loopback interfaces and set system hostname.

```
admin@R3# set l3-interface loopback lo address 3.3.3.3 prefix-length 32
admin@R3# set l3-interface loopback lo address 33.33.33.33 prefix-length 32
admin@R3# set system hostname R3
```

Step 4. Configure BGP AS number, router ID and add network prefixes.

```
admin@R3# set protocols bgp local-as 300
admin@R3# set protocols bgp router-id 3.3.3.3
admin@R3# set protocols bgp neighbor 20.20.20.1 remote-as "200"
admin@R3# set protocols bgp ipv4-unicast network 33.33.33.33/32
admin@R3# set protocols bgp ipv4-unicast network 3.3.3.3/32
```

Verify Configuration

R1 Routing Table

The command below shows the routing table of vrf1. As you can notice, route 33.33.33.33/32 is not leaked and redistributed into VRF1 because this prefix was filtered out by route map.

```
root@R1# run show route vrf vrf1
show ip route vrf vrf1
=======================
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

VRF vrf1:
K>* 0.0.0.0/0 [255/8192] unreachable (blackhole), 01:08:45
O   1.1.1.10/32 [110/0] is directly connected, vrf1, weight 1, 01:08:44
C>* 1.1.1.10/32 is directly connected, vrf1, 01:08:45
O>* 3.3.3.3/32 [110/20] via 11.11.11.2, vlan11, weight 1, 00:33:58

C>* 101.101.101.0/24 is directly connected, vlan101, 01:07:44
```

R2 Routing Table

The following show command displays the routing table of vrf1 on R2. Again, route 33.33.33.33/32 is not present in this routing table since it is filtered using route map.

```
root@R2# run show route vrf vrf1
show ip route vrf vrf1
=======================
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

VRF vrf1:
K>* 0.0.0.0/0 [255/8192] unreachable (blackhole), 01:09:36
O>* 1.1.1.10/32 [110/10] via 11.11.11.1, vlan11, weight 1, 01:08:20
C>* 2.2.2.10/32 is directly connected, vrf1, 01:09:36

```

Static Route Leaking Example

This document explains PICOS static route leaking. As shown in Figure 1, three devices, R1, R2 and R3 participate in this static route leaking example. The goal is to allow hosts connected to R2 in the default VRF, access to hosts connected to R3 in vrf2. To achieve this, static leaks will be configured on R1, which has two interfaces in two different VRFs, vrf2 and the default VRF. The interface connecting R2 belongs to the default VRF and the interface connecting R3 belongs to vrf2.

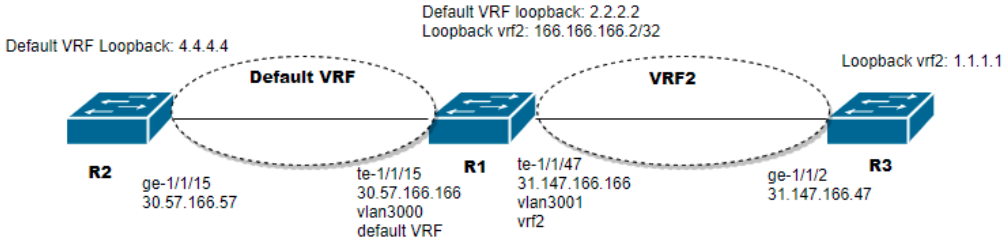

Figure1. Static Routing Leaking Topology

Static route leaks will be configured on R1. Additionally, a static route will be configured on R2 to reach 1.1.1.1 with a next-hop router address of R1 L3 VLAN interface. Similarly another static route will be configured on R3 to reach 4.4.4.4 with the next-hop router address of the R1 L3 VLAN interface. The sections below explains the device configuration of the three devices.

R1 Configuration

Step 1. Configure interface te-1/1/15 and te-1/1/47. Assign VLAN ID and configure the L3 VLAN interface IP address.

```
admin@R1# set interface gigabit-ethernet te-1/1/15 family ethernet-switching native-vlan-id 3000
admin@R1# set interface gigabit-ethernet te-1/1/47 family ethernet-switching native-vlan-id 3001
admin@R1# set l3-interface vlan-interface vlan3000 address 30.57.166.166 prefix-length 24
admin@R1# set l3-interface vlan-interface vlan3001 address 31.147.166.166 prefix-length 24
admin@R1# set vlans vlan-id 3001 l3-interface "vlan3001"
admin@R1# set vlans vlan-id 3000 l3-interface "vlan3000"
admin@R1# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@R1# set l3-interface loopback vrf2 address 166.166.166.2
```

Step 2. Create VRF vrf2 and assign vlan3001 to vrf2. Also enable IP routing on the device.

```
admin@R1# set ip vrf vrf2
admin@R1# set l3-interface vlan-interface vlan3001 vrf "vrf2"
admin@R1# set ip routing enable true
```

Step 3. Create static leak routes on R1. Route 1.1.1.1/32 in created in the default VRF whereas route 4.4.4.4/32 is created in vrf2.

```
admin@R1# set protocols static route 1.1.1.1/32 nexthop-vrf vrf2 next-hop 31.147.166.47
admin@R1# set protocols static vrf vrf2 route 4.4.4.4/32 nexthop-vrf default next-hop 30.57.166.57
```

R2 Configuration

Step1. Configure interface ge-1/1/15, VLAN ID and L3 VLAN interface and IP address.

```
admin@R2# set interface gigabit-ethernet ge-1/1/15 family ethernet-switching native-vlan-id 3000
admin@R2# set l3-interface vlan-interface vlan3000 address 30.57.166.57 prefix-length 24
admin@R2# set vlans vlan-id 3000 l3-interface "vlan3000"
```

Step 2. Configure a static route to destination 1.1.1.1 and enable IP routing on the device. Also create the loopback interface and assign IP address.

```
admin@R2# set l3-interface loopback lo address 4.4.4.4 prefix-length 32
admin@R2# set protocols static route 1.1.1.1/32 next-hop 30.57.166.166
admin@R2# set ip routing enable true
```

R3 Configuration

Step1. Configure interface ge-1/1/2, L3 VLAN interface and IP address.

```
admin@R3# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3001
admin@R3# set l3-interface vlan-interface vlan3001 address 31.147.166.47 prefix-length 24
admin@R3# set vlans vlan-id 3001 l3-interface "vlan3001"
admin@R3# set l3-interface vlan-interface vlan3001 vrf vrf2
```

Step 2. Create vrf2, create loopback and configure a static route to destination 4.4.4.4/32 and also enable IP routing on the device.

```
admin@R3# set ip vrf vrf2
admin@R3# set l3-interface loopback vrf2 address 1.1.1.1 prefix-length 32
admin@R3# set protocols static vrf vrf2 route 4.4.4.4/32 next-hop 31.147.166.166
admin@R3# set ip routing enable true
```

Verify configuration

Ping 1.1.1.1 from R2 to test connectivity.

```
admin@R2# run ping 1.1.1.1
PING 1.1.1.1 (1.1.1.1) 56(84) bytes of data.
64 bytes from 1.1.1.1: icmp_seq=1 ttl=63 time=2.15 ms
64 bytes from 1.1.1.1: icmp_seq=2 ttl=63 time=1.61 ms
64 bytes from 1.1.1.1: icmp_seq=3 ttl=63 time=2.43 ms
64 bytes from 1.1.1.1: icmp_seq=4 ttl=63 time=2.22 ms
64 bytes from 1.1.1.1: icmp_seq=5 ttl=63 time=1.97 ms
```

Verify Routing Table on R1

```
admin@R1# run show route vrf vrf2

Introduction of BFD

- Overview
- Single-Hop and Multi-Hop BFD
- BFD Working Process
- BFD Session Establishment
- Echo Function

Overview

Bidirectional Forwarding Detection (BFD) is a two-way forwarding detection mechanism, which can provide millisecond detection and realize the rapid detection of link faults.

Traditionally, the Hello message mechanism of routing protocols such as Open Shortest Path First (OSPF) and BGP has been used for link fault detection. The time required for this mechanism to detect a fault is in seconds. However, for high-speed data transmission, such as gigabit rate level, more than 1 second detection time will lead to a large amount of data loss; for delay-sensitive services, such as voice services, more than 1 second delay is unacceptable. BFD will help solve this problem and improve the speed of fault detection.

PICOS implementation of BFD supports OSPF, BGP, and PIM protocols.

Single-Hop and Multi-Hop BFD

You can create a single-hop or multi-hop BFD session on an IP link to detect faults quickly:

- **Single-hop BFD** is the IP connectivity detection of two directly connected systems, with only one hop.
- **Multi-hop BFD** detects IP connectivity of paths between two indirectly connected systems, which may span multiple hops.

BFD Working Process

The main working process of BFD is as follows:

1. BFD first establishes a BFD session on a link between two endpoints (established by relying on the upper-layer protocol, e.g., when OSPF neighbors are established, the neighbor information is synced to BFD to establish BFD neighbors based on this information).

2. After two systems establish a BFD session, they will periodically send BFD control packets along the path between them. If a link failure is detected, the BFD neighbor is removed and the upper-layer protocol is immediately notified to handle the path loss issue.

BFD Session Establishment

BFD session can be established in two ways: static establishment and dynamic establishment:

- **Static Establishment**

BFD session parameters, including the local address and peer address, are manually specified. The neighbor adjacency will be established after all the configurations are manually committed.

- **Dynamic Establishment**

BFD sessions are established based on the neighbor adjacencies established by other routing protocols such as OSPF, BGP, and PIM, we refer to this as Dynamic Establishment of BFD.

Echo Function

Once the BFD session is Up, a system can choose to start the Echo function. When the Echo function is active, a stream of BFD Echo packets is transmitted in such a way as to have the other system loop them back through its forwarding path. If a number of packets of the echoed data stream are not received, the session is declared to be down. For more details, please refer to RFC 5880.

This may reduce round-trip jitter and thus allow more aggressive Detection Times, as well as potentially detecting some classes of failure that might not otherwise be detected.

The Echo function can be run independently in each direction between a pair of systems.

When the Echo function is active, a system SHOULD set the minimum receive interval (the command is **set protocols bfd** [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer**<*peer-ip*> **receive-interval <***receive-interval***>**) to a value of not less than one second (1,000,000 microseconds). This is intended to keep received BFD Control traffic at a negligible level, since the actual detection function is being performed using BFD Echo packets.

Users can use the command **set protocols bfd** [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] ***peer***<*peer-ip*> **echo-mode** to enable echo function.

NOTEs:
- Echo function is only supported in single-hop BFD case.
- BFD echo mode is incompatible with that on other vendors, that is, echo mode can work only between PICOS switches.

Configuring BFD

Users can configure static BFD or dynamic BFD (BFD for OSPF, BFD for BGP or BFD for PIM protocols). Please refer to the following sections for configuration.

- Configuring Static BFD
- Configuring Dynamic BFD

Configuring Static BFD

To statically establish a BFD session, users need to manually set the BFD session parameters, such as the local address and peer address. The neighbor adjacency will be established after all the configurations are manually committed.

The following two sections list the configuration steps and commands for how to establish a single-hop session and a multi-hop BFD session.

Configuring Single-Hop BFD

Step 1 Enable single-hop BFD.

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> [**local-address** <*local-ip*>]

Step 2 (Optional) Configure single-hop BFD session parameters.

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **minimum-ttl <***minimum-ttl***>**

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **receive-interval <***receive-interval***>**

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **transmit-interval <***transmit-interval***>**

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **detect-multiplier <***MULTIPLIER***>**

Step 3 (Optional) Enable BFD echo function.

> **NOTEs:**
> - Echo function is only supported in single-hop BFD case.
> - BFD echo mode is incompatible with that on other vendors, that is, echo mode can work only between PICOS switches.

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **echo-mode**

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **echo receive-interval** [**<***receive-interval***> | disabled**]

set protocols bfd [**vrf** <*vrf-name*>] [**interface**<*interface-name*>] **peer** <*peer-ip*> **echo transmit-interval <***transmit-interval***>**

Step 4 Commit the configurations.

commit

Configuring Multi-Hop BFD

Step 1 Enable multi-hop BFD.

set protocols bfd multihop [**vrf** <*vrf-name*>] **peer** <*peer-ip*> [**local-address** <*local-ip*>]

Step 2 (Optional) Configure multi-hop BFD session parameters.

set protocols bfd multihop [**vrf** <*vrf-name*>] **peer** <*peer-ip*> **local-address** <*local-ip*> **minimum-ttl <***minimum-ttl***>**

set protocols bfd multihop [**vrf** <*vrf-name*>] **peer** <*peer-ip*> **local-address** <*local-ip*> **receive-interval <***receive-interval***>**

set protocols bfd multihop [**vrf** <*vrf-name*>] **peer** <*peer-ip*> **local-address** <*local-ip*> **transmit-interval <***transmit-interval***>**

set protocols bfd multihop [**vrf** <*vrf-name*>] **peer** <*peer-ip*> **local-address** <*local-ip*> **detect-multiplier <***MULTIPLIER***>**

Step 3 **Commit the configurations.**

commit

Configuring Dynamic BFD

In Dynamic BFD sessions are established based on the neighbor adjacencies established by the routing protocols such as OSPF, BGP, and PIM.

Link failures or topology changes on the network can lead to route recalculation. It is important to shorten the convergence time of routing protocols to improve the availability of the network. Users can enable the association between BFD and the routing protocols to quickly detect faults on links between network devices and achieve fast route convergence.

The following sections list the configuration steps and commands for how to establish BFD sessions for OSPFv2, OSPFv3, BGP and PIM.

Note that echo function is only supported in the single-hop BFD case.

Configuring BFD for OSPFv2

Step 1 (Optional) Create a profile to modify BFD session parameters.

set protocols bfd profile <*profile-name*> **detect-multiplier <***MULTIPLIER***>**

set protocols bfd profile <*profile-name*> **minimum-ttl <***minimum-ttl***>**

set protocols bfd profile <*profile-name*> **receive-interval <***receive-interval***>**

set protocols bfd profile <*profile-name*> **transmit-interval <***transmit-interval***>**

Step 2 (Optional) Create a profile to enable BFD echo function.

set protocols bfd profile <*profile-name*> **echo-mode**

set protocols bfd profile <*profile-name*> **echo receive-interval** [**<***receive-interval***> | disabled**]

set protocols bfd profile <*profile-name*> **echo transmit-interval <***transmit-interval***>**

Step 3 Enable BFD for OSPFv2.

set protocols ospf interface <*vlan-interface*> **bfd** [**profile** <*profile-name*>]

Step 4 Commit the configurations.

commit

Configuring BFD for OSPFv3

Step 1 (Optional) Create a profile to modify BFD session parameters.

set protocols bfd profile <*profile-name*> **detect-multiplier <***MULTIPLIER***>**

set protocols bfd profile <*profile-name*> **minimum-ttl <***minimum-ttl***>**

set protocols bfd profile <*profile-name*> **receive-interval <***receive-interval***>**

set protocols bfd profile <*profile-name*> **transmit-interval <***transmit-interval***>**

Step 2 (Optional) Create a profile to enable BFD echo function.

set protocols bfd profile <*profile-name*> **echo-mode**

set protocols bfd profile <*profile-name*> **echo receive-interval** [**<***receive-interval***> | disabled**]

set protocols bfd profile <*profile-name*> **echo transmit-interval <***transmit-interval***>**

Step 3 Enable BFD for OSPFv3.

set protocols ospf6 interface <*vlan-interface*> **bfd** [**profile** <*profile-name*>]

Step 4 Commit the configurations.

commit

Configuring BFD for BGP

Step 1 (Optional) Create a profile to modify BFD session parameters.

set protocols bfd profile <*profile-name*> **detect-multiplier <***MULTIPLIER***>**

set protocols bfd profile <*profile-name*> **minimum-ttl <***minimum-ttl***>**

set protocols bfd profile <*profile-name*> **receive-interval <***receive-interval***>**

set protocols bfd profile <*profile-name*> **transmit-interval <***transmit-interval***>**

Step 2 (Optional) Create a profile to enable BFD echo function.

set protocols bfd profile <*profile-name*> **echo-mode**

set protocols bfd profile <*profile-name*> **echo receive-interval** [**<***receive-interval***> | disabled**]

set protocols bfd profile <*profile-name*> **echo transmit-interval <***transmit-interval***>**

Step 3 Enable BFD for BGP.

set protocols bgp [**vrf** <*vrf-name*>] **{neighbor** <*ip*>**| peer-group** <*peer-group*> |**interface** <*interface*>**}** **bfd** [**profile** <*profile-name*>]

Step 4 Commit the configurations.

commit

Configuring BFD for PIM

Step 1 (Optional) Create a profile to modify BFD session parameters.

set protocols bfd profile <*profile-name*> **detect-multiplier <***MULTIPLIER***>**

set protocols bfd profile <*profile-name*> **minimum-ttl <***minimum-ttl***>**

set protocols bfd profile <*profile-name*> **receive-interval <***receive-interval***>**

set protocols bfd profile <*profile-name*> **transmit-interval <***transmit-interval***>**

Step 2 (Optional) Create a profile to enable BFD echo function.

set protocols bfd profile <*profile-name*> **echo-mode**

set protocols bfd profile <*profile-name*> **echo receive-interval** [**<***receive-interval***> | disabled**]

set protocols bfd profile <*profile-name*> **echo transmit-interval <***transmit-interval***>**

Step 3 Enable BFD for PIM.

set protocols pim interface <*vlan-interface*> **bfd** [**profile** <*profile-name*>]

Step 4 Commit the configurations.

commit

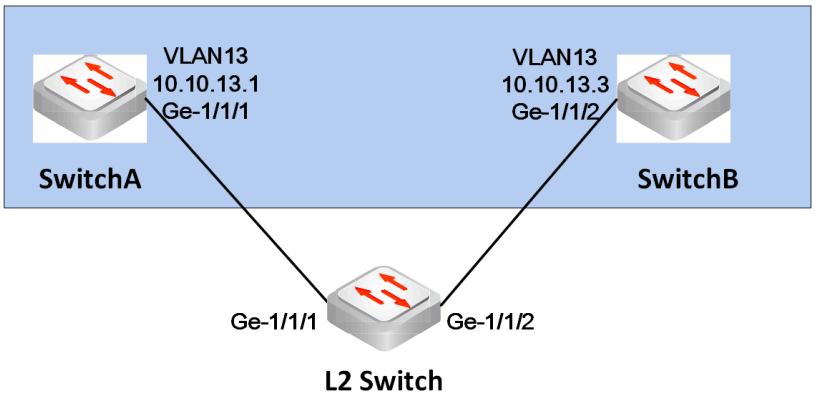
Example for Configuring Single-Hop BFD

- Networking Requirements
  - Figure 1 Single-hop BFD for detecting faults
- Procedure
  - Switch A
  - L2 Switch
  - Switch B
- Verify the Configuration

Networking Requirements

As shown in Figure 1, SwitchA and SwitchB are connected through the Layer 2 switch. Users can configure BFD sessions on SwitchA and SwitchB so that faults on the link between SwitchA and SwitchB can to be detected rapidly.

Figure 1 Single-hop BFD for detecting faults



Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 13
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 13
admin@SwitchA# set l3-interface vlan-interface vlan13 address 10.10.13.1 prefix-length 24
admin@SwitchA# set vlans vlan-id 13 l3-interface vlan13
```

Step2 Enable BFD and create a single-hop BFD session on SwitchA.

```
admin@SwitchA# set protocols bfd interface vlan13 peer 10.10.13.3
```

Step3 Commit the configurations.

```
admin@SwitchA# commit
```

L2 Switch

Step1 Configure the VLAN.

```
admin@L2Switch# set vlans vlan-id 13
admin@L2Switch# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 13
admin@L2Switch# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
```

Step2 Commit the configurations.

```
admin@L2Switch# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 13
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
admin@SwitchB# set l3-interface vlan-interface vlan13 address 10.10.13.3 prefix-length 24
admin@SwitchB# set vlans vlan-id 13 l3-interface vlan13
```

Step2 Enable BFD and create a BFD session on SwitchB.

```
admin@SwitchB# set protocols bfd interface vlan13 peer 10.10.13.1
```

Step3 Commit the configurations.

```
admin@SwitchB# commit
```

Verify the Configuration

- After the configuration is complete, run the command **run show bfd peers brief** on SwitchA and SwitchB. You can see that a single-hop BFD session is set up and its status is up.

```
admin@SwitchA# run show bfd peers brief
Session count: 1
SessionId  LocalAddress                          PeerAddress                          Status
=========  ============                         ===========                          ======
2107973506 10.10.13.1                            10.10.13.3                           up

admin@SwitchB# run show bfd peers brief
Session count: 1
SessionId  LocalAddress                          PeerAddress                          Status
=========  ============                         ===========                          ======
1620807635 10.10.13.3                            10.10.13.1                           up
```

- Run the **set interface gigabit-ethernet ge-1/1/2 disable true** command on the GE-1/1/2 interface of SwitchB to simulate a link fault.

```
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 disable true
admin@SwitchB# commit
```

- After the configuration is complete, run the command **run show bfd peers brief** on SwitchA and SwitchB. You can see that a single-hop BFD session is set up and its status is down.

```
admin@SwitchA# run show bfd peers brief
Session count: 1
SessionId  LocalAddress                          PeerAddress                          Status
=========  ============                         ===========                          ======

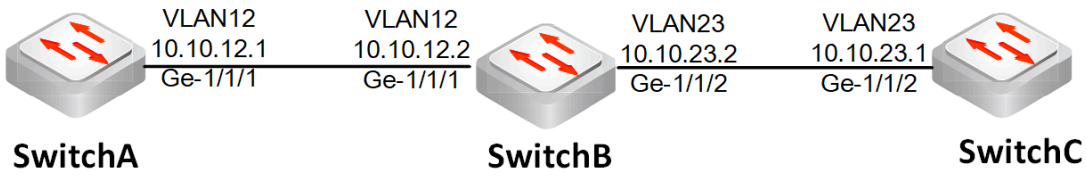
Example for Configuring Multi-Hop BFD

- Networking Requirements
  - Figure 1 Multi-hop BFD for detecting faults
- Procedure
  - Switch A
  - Switch B
  - Switch C
- Verify the Configuration

Networking Requirements

As shown in Figure 1, SwitchA and SwitchC are connected through the Layer 3 switch SwitchB. Users can configure multi-hop BFD session on SwitchA and SwitchC so that faults on the multi-hop link between SwitchA and SwitchC can be detected rapidly.

Figure 1 Multi-hop BFD for detecting faults



Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 12
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 12
admin@SwitchA# set l3-interface vlan-interface vlan12 address 10.10.12.1 prefix-length 24
admin@SwitchA# set vlans vlan-id 12 l3-interface vlan12
```

Step2 Configure a static route for connection between SwitchA and SwitchC.

```
admin@SwitchA# set protocols static route 10.10.23.0/24 next-hop 10.10.12.2
```

Step3 Enable BFD and create a multi-hop BFD session on SwitchA.

```
admin@SwitchA# set protocols bfd multihop peer 10.10.23.1 local-address 10.10.12.1
```

Step4 Commit the configurations.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 12
admin@SwitchB# set vlans vlan-id 23
admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 12
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 23
admin@SwitchB# set l3-interface vlan-interface vlan12 address 10.10.12.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan23 address 10.10.23.2 prefix-length 24
admin@SwitchB# set vlans vlan-id 12 l3-interface vlan12
admin@SwitchB# set vlans vlan-id 23 l3-interface vlan23
```

Step2 Commit the configurations.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN interface.

```
admin@SwitchC# set vlans vlan-id 23
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 23
admin@SwitchC# set l3-interface vlan-interface vlan23 address 10.10.23.1 prefix-length 24
admin@SwitchC# set vlans vlan-id 23 l3-interface vlan23
```

Step2 Configure a static route for connection between SwitchA and SwitchC.

```
admin@SwitchC# set protocols static route 10.10.12.0/24 next-hop 10.10.23.2
```

Step3 Enable BFD and create a multi-hop BFD session on SwitchC.

```
admin@SwitchC# set protocols bfd multihop peer 10.10.12.1 local-address 10.10.23.1
```

Step4 Commit the configurations.

```
admin@SwitchC# commit
```

Verify the Configuration

- After the configuration is complete, run the command **run show bfd peers brief** on SwitchA and SwitchC. You can see that a multi-hop BFD session is set up and its status is up.

```
admin@SwitchA# run show bfd peers brief
Session count: 1
SessionId  LocalAddress                          PeerAddress                          Status
=========  ============                         ===========                          ======

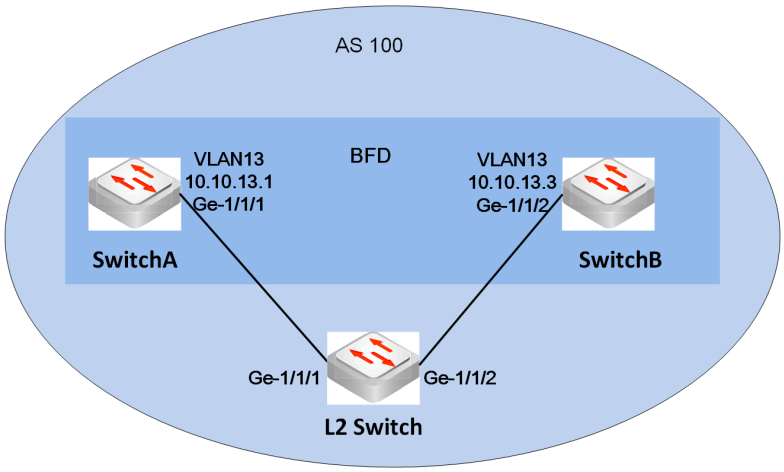
Example for Configuring BFD for BGP

- Networking Requirements
  - Figure 1 Configuring BFD for BGP
- Procedure
  - Switch A
  - L2 Switch
  - Switch B
- Verify the Configuration

Networking Requirements

As shown in Figure 1, BGP is established between SwitchA and SwitchB, and the L2 switch between SwitchA and SwitchB only provides the transparent transmission function. Users can configure BFD sessions on SwitchA and SwitchB so that faults on the link between SwitchA and SwitchB can be detected rapidly.

Figure 1 Configuring BFD for BGP



Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 13
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 13
admin@SwitchA# set l3-interface vlan-interface vlan13 address 10.10.13.1 prefix-length 24
admin@SwitchA# set vlans vlan-id 13 l3-interface vlan13
```

Step2 Configure basic BGP functions.

```
admin@SwitchA# set protocols bgp local-as 100
admin@SwitchA# set protocols bgp router-id 1.1.1.1
admin@SwitchA# set protocols bgp neighbor 10.10.13.3 remote-as 100
```

Step3 Enable BFD and create a BFD session for BGP on SwitchA.

```
admin@SwitchA# set protocols bgp neighbor 10.10.13.3 bfd
```

Step4 Commit the configuration.

```
admin@SwitchA# commit
```

L2 Switch

Step1 Configure the VLAN.

```
admin@L2Switch# set vlans vlan-id 13
admin@L2Switch# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 13
admin@L2Switch# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
```

Step2 Commit the configuration.

```
admin@L2Switch# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 13
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
admin@SwitchB# set l3-interface vlan-interface vlan13 address 10.10.13.3 prefix-length 24
admin@SwitchB# set vlans vlan-id 13 l3-interface vlan13
```

Step2 Configure basic BGP functions.

```
admin@SwitchB# set protocols bgp local-as 100
admin@SwitchB# set protocols bgp router-id 3.3.3.3
admin@SwitchB# set protocols bgp neighbor 10.10.13.1 remote-as 100
```

Step3 Enable BFD and create a BFD session for BGP on SwitchB.

```
admin@SwitchB# set protocols bgp neighbor 10.10.13.1 bfd
```

Step4 Commit the configuration.

```
admin@SwitchB# commit
```

Verify the Configuration

- After the configuration is complete, run the command **run show bfd peers brief** on SwitchA and SwitchB. You can see that a BFD session between SwitchA and SwitchB is set up and its status is up.

```
admin@SwitchA# run show bfd peers brief
Session count: 1
SessionId  LocalAddress                          PeerAddress                          Status

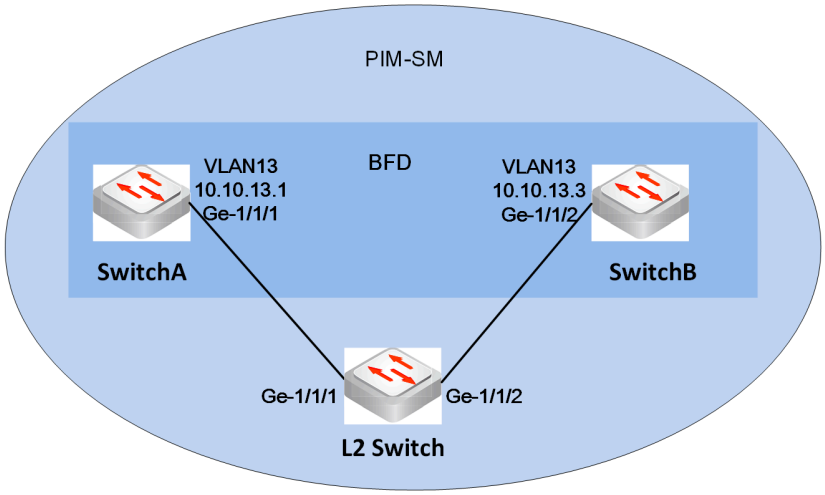
Example for Configuring BFD for PIM-SM

Networking Requirements

As shown in Figure 1, PIM-SM is configured between SwitchA and SwitchB, and the L2 switch between SwitchA and SwitchB only provides the transparent transmission function. Users can configure BFD sessions on SwitchA and SwitchB so that faults on the link between SwitchA and SwitchB can be detected rapidly.

Figure 1 Configuring BFD for PIM-SM



Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 13
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 13
admin@SwitchA# set l3-interface vlan-interface vlan13 address 10.10.13.1 prefix-length 24
admin@SwitchA# set vlans vlan-id 13 l3-interface vlan13
```

Step2 Configure basic PIM functions.

```
admin@SwitchA# set protocols pim interface vlan13 sm
```

Step3 Enable BFD and create a BFD session for PIM on SwitchA.

```
admin@SwitchA# set protocols pim interface vlan13 bfd
```

Step4 Commit the configuration.

```
admin@SwitchA# commit
```

L2 Switch

Step1 Configure the VLAN.

```
admin@L2Switch# set vlans vlan-id 13
admin@L2Switch# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 13
admin@L2Switch# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
```

Step2 Commit the configuration.

```
admin@L2Switch# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 13
admin@SwitchB# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
admin@SwitchB# set l3-interface vlan-interface vlan13 address 10.10.13.3 prefix-length 24
admin@SwitchB# set vlans vlan-id 13 l3-interface vlan13
```

Step2 Configure basic PIM functions.

```
admin@SwitchB# set protocols pim interface vlan13 sm
```

Step3 Enable BFD and create a BFD session for PIM on SwitchB.

```
admin@SwitchB# set protocols pim interface vlan13 bfd
```

Step4 Commit the configuration.

```
admin@SwitchB# commit
```

Verify the Configuration

- After the configuration is complete, run the command **run show bfd peers brief** on SwitchA and SwitchB. You can see that a BFD session between SwitchA and SwitchB is set up and its status is up.

```
admin@SwitchA# run show bfd peers brief
Session count: 1
SessionId  LocalAddress                          PeerAddress                          Status
=========  ============                         ===========                          ======
406990062  10.10.13.1                            10.10.13.3                           up

admin@SwitchB# run show bfd peers brief
Session count: 1

RFC Lists for BFD

The following table lists the RFC documents related to BFD function.

RFC	Description
RFC 5880	Bidirectional Forwarding Detection (BFD)
RFC 5881	Bidirectional Forwarding Detection (BFD) for IPv4 and IPv6 (Single Hop)
RFC 5882	Generic Application of Bidirectional Forwarding Detection (BFD)
RFC 5883	Bidirectional Forwarding Detection (BFD) for Multihop Paths

RIP/RIPng Configuration

- RIP/RIPng Overview
- Enabling RIP/RIPng
- Configuring RIP Version
- Configuring RIP Route Redistribute
- Configuring RIPv2 Authentication
- Configuring RIP to Advertise Default Routes
- Example for Configuring Basic RIP
- Example for Configuring Basic RIPng
- RFC Lists for RIP/RIPng

RIP/RIPng Overview

RIP is short for Routing Information Protocol, which is a simple Interior Gateway Protocol. RIP exchanges routing information through UDP packets using the port number 520.

RIP is a protocol based on the Distance-Vector algorithm, which uses the Hop Count as the metric to measure the distance to the destination network. The metric is equal to the number of devices between the local network and the destination network, the number of hops from a device to a network directly connected to it is 0. To limit the convergence time, RIP specifies that the metric value is an integer between 0 and 15, anything greater than 15 is considered infinite, i.e., the destination network or host is unreachable. This limitation makes it impossible for RIP to be used in large networks.

RIP protocol is applied in IPv4 networks, while in IPv6 networks, the corresponding RIPng routing protocol is used. RIPng refers to RIP next generation protocol, mainly used to provide routing functionality in IPv6 networks, which is an important component of routing technology in IPv6 networks.

Enabling RIP/RIPng

- Enabling RIP/RIPng on a Specified Network Segment
- Enabling RIP/RIPng on an L3 Interface

RIP/RIPng runs only on interfaces on specified network segments. For interfaces that are not on the specified network segment, RIP/RIPng neither receives and sends routes on it, nor forwards its interface routes out. Users can enable RIP/RIPng in the following two ways:

- Enabling RIP/RIPng on a Specified Network Segment
- Enabling RIP/RIPng on an L3 Interface

Enabling RIP/RIPng on a Specified Network Segment

The following command enables RIP routing on the specified network segments 10.0.0.0/24 and 192.168.10.0/24.

```
admin@PICOS# set protocols rip network 10.0.0.0/24
admin@PICOS# set protocols rip network 192.168.10.0/24
admin@PICOS# commit
```

The following command enables RIPng routing on the specified network segments FC00:0:0:1000::0/64.

```
admin@PICOS# set protocols ripng network FC00:0:0:1000::0/64
admin@PICOS# commit
```

Enabling RIP/RIPng on an L3 Interface

Users can enable RIP/RIPng on an L3 interface, which can be a VLAN interface, routed interface or loopback interface. All routes for all network segments on this interface will be advertised via RIP/RIPng messages.

> **NOTE:**
> Although it is supported to enable RIP on a loopback interface by using command **set protocols rip interface** <*looplack-interface-name*>, but it doesn't work for RIPng by using command **set protocols ripng interface** <*looplack-interface-name*>. Users can use command **set protocols ripng route** <*loopback-IPv6-net*> command to set RIPng static network routing announcement for loopback interface.

The following command enables RIP routing to send and receive routes on all network segments on VLAN interface *vlan100*.

```
admin@PICOS# set protocols rip interface vlan100
admin@PICOS# commit
```

The following command enables RIPng routing to send and receive routes on all network segments on VLAN interface *vlan1000*.

```
admin@PICOS# set protocols ripng interface vlan1000
admin@PICOS# commit
```

Configuring RIP Version

The versions of RIP include RIPv1 and RIPv2, which have different functions. RIPv1 is a Classful Routing Protocol, which only supports protocol messages in broadcast mode. RIPv2 is a Classless Routing Protocol that supports sending update messages in multicast mode. RIPv1 does not support either route aggregation or Discontiguous Subnet. But RIPv2 supports both features. Users can configure the version number of RIP on the device running RIP protocol as needed.

Figure 1 and **Figure 2** show the packet format of RIPv1 and RIPv2.

Figure 1. RIPv1 Packet Format

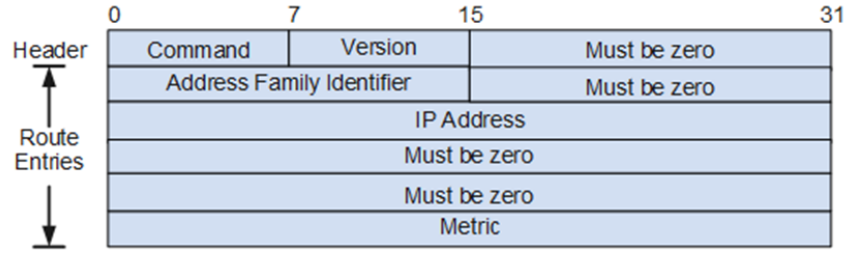

Figure 2. RIPv2 Packet Format

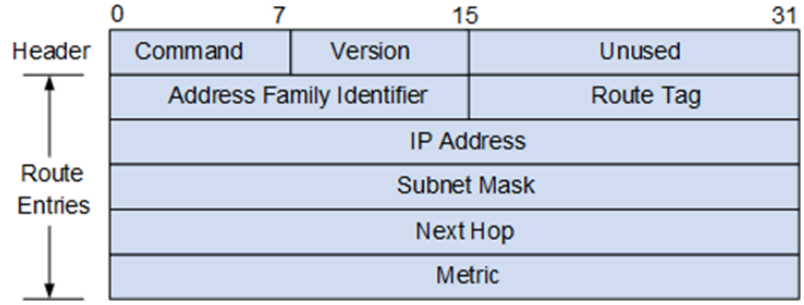


The **set protocols rip** [**vrf** <*vrf-name*>] **version** <**1**|**2**> command configures the RIP version to accept for receiving and sending RIP packets. RIP version can be either RIPv1 and RIPv2. By default, RIP version is RIPv2. The optional parameter **vrf** can be used to specify RIP for a particular VRF. If VRF is not defined then RIP takes effect for the default VRF.

This example configures RIP version to RIPv1.

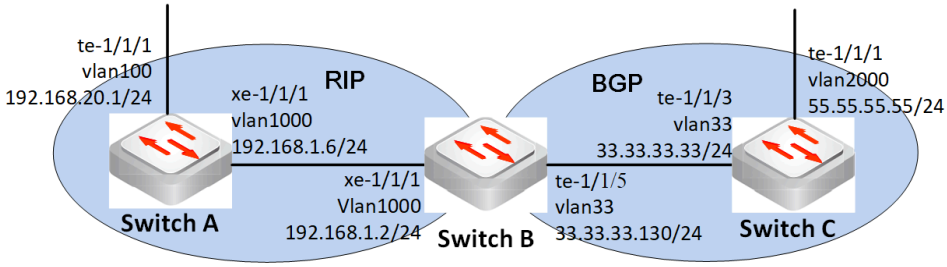
```
admin@PICOS# set protocols rip version 1
admin@PICOS# commit
```

Configuring RIP Route Redistribute

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - View RIP Route Table on Switch A
  - Configuring Switch B to Import Route between BGP and RIP
  - View RIP Route Table on Switch A

Networking Requirements

Figure 1. RIP Route Redistribute Example



As shown in **Figure 1**, there are three switches (Switch A, Switch B and Switch C) in this sample network. RIPv2 routing protocol runs between Switch A and Switch B, and BGP routing protocol runs between Switch B and Switch C. To enable communication between Switch A and Switch C, you need to configure to redistribute RIP routes to BGP routes, and BGP routes to RIP routes on Switch B.

Follow the configuration roadmap below to complete the configuration:

1. Configure VLAN interface and IP address for each interface to make the network reachable.
2. Enable RIP on Switch A and Switch B, and enable BGP on Switch B and Switch C.
3. On Switch B, configure route redistribution between route protocol RIP and BGP.

Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchA# set vlans vlan-id 1000 l3-interface vlan1000
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 100
admin@SwitchA# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching vlan members 1000
admin@SwitchA# set l3-interface vlan-interface vlan100 address 192.168.20.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan1000 address 192.168.1.6 prefix-length 24
```

Step2 Enable RIP for the network segment.

```
admin@SwitchA# set protocols rip network 192.168.20.0/24
admin@SwitchA# set protocols rip network 192.168.1.0/24
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 1000 l3-interface vlan1000
admin@SwitchB# set vlans vlan-id 33 l3-interface vlan33
admin@SwitchB# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching vlan members 1000
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching vlan members 33
admin@SwitchB# set l3-interface vlan-interface vlan1000 address 192.168.1.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan33 address 33.33.33.130 prefix-length 24
```

Step2 Enable RIP for the specified network segment.

```
admin@SwitchB# set protocols rip network 192.168.1.0/24
admin@SwitchB# set protocols rip network 33.33.33.0/24
```

Step3 Configure EBGP connection between Switch B and Switch C.

```
admin@SwitchB# set protocols bgp local-as 20000
admin@SwitchB# set protocols bgp router-id 2.2.2.2
admin@SwitchB# set protocols bgp ebgp-requires-policy false
admin@SwitchB# set protocols bgp ipv4-unicast network 192.168.1.0/24
admin@SwitchB# set protocols bgp neighbor 33.33.33.33 remote-as 30000
```

Step4 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step5 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN interface.

```
admin@SwitchC# set vlans vlan-id 33 l3-interface vlan33
admin@SwitchC# set vlans vlan-id 2000 l3-interface vlan2000
admin@SwitchC# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 33
admin@SwitchC# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 2000
admin@SwitchC# set l3-interface vlan-interface vlan33 address 33.33.33.33 prefix-length 24
admin@SwitchC# set l3-interface vlan-interface vlan2000 address 55.55.55.55 prefix-length 24
```

Step2 Configure EBGP connection between Switch B and Switch C.

```
admin@SwitchC# set protocols bgp local-as 30000
admin@SwitchC# set protocols bgp router-id 3.3.3.3
admin@SwitchC# set protocols bgp ebgp-requires-policy false
admin@SwitchC# set protocols bgp ipv4-unicast network 55.55.55.0/24
admin@SwitchC# set protocols bgp neighbor 33.33.33.130 remote-as 20000
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchC# commit
```

View RIP Route Table on Switch A

- On Switch A, use command **run show rip** to view RIP route table, 55.55.55.0/24 route is not existed.

```
admin@SwitchA# run show rip
Codes: R - RIP, C - connected, S - Static, O - OSPF, B - BGP
Sub-codes:
      (n) - normal, (s) - static, (d) - default, (r) - redistribute,
      (i) - interface
```

```
     Network            Next Hop         Metric From            Tag Time
R(n) 33.33.33.0/24      192.168.1.2           2 192.168.1.2       0 02:43
C(i) 192.168.1.0/24     0.0.0.0               1 self              0
C(i) 192.168.20.0/24    0.0.0.0               1 self              0
```

Configuring Switch B to Import Route between BGP and RIP

```
admin@SwitchB# set protocols rip redistribute bgp
admin@SwitchB# set protocols bgp ipv4-unicast redistribute rip
admin@SwitchB# commit
```

View RIP Route Table on Switch A

- On Switch A, use command **run show rip** to view RIP route table again, route 55.55.55.0/24 has been inserted to Switch A's routing table with metric value 2. Switch A and Switch C can communicate with each other now.

```
admin@SwitchA# run show rip
Codes: R - RIP, C - connected, S - Static, O - OSPF, B - BGP
Sub-codes:
      (n) - normal, (s) - static, (d) - default, (r) - redistribute,
      (i) - interface

     Network            Next Hop         Metric From            Tag Time
R(n) 33.33.33.0/24      192.168.1.2           2 192.168.1.2       0 02:43
R(n) 55.55.55.0/24      192.168.1.2           2 192.168.1.2       0 02:43
C(i) 192.168.1.0/24     0.0.0.0               1 self              0

```

Configuring RIPv2 Authentication

- Background
- Procedure
- Example

Background

RIPv2 allows packets to be authenticated via either an insecure plain text password, included with the packet, or via a more secure MD5 based HMAC (keyed-Hashing for Message AuthentiCation), RIPv1 can not be authenticated at all, thus when authentication is configured ripd will discard routing updates received via RIPv1 packets.

The MD5 Message-Digest Algorithm takes a message of arbitrary length as input and generates a 128 bit "fingerprint" or "message digest" as output. It is conjectured that it is computationally infeasible to produce two messages having the same message digest, or to produce any message having a given prespecified target message digest.

When authentication is enabled, PICOS will ignore updates from unauthenticated peers, including RIPv1 peers. Although updates from unauthenticated peers are ignored, but requests for routes from unauthenticated peers are still honored.

Procedure

NOTEs:

- Both the **authentication mode** and **authentication string** need to be configured, and the value should be identical at both ends of the link.
- When configuring the authentication mode of RIP-2 messages, if *text* mode is used, the password will be saved in plaintext in the configuration file, which is a security risk. It is recommended to use *md5* mode to encrypt the password and save it.

Step 1 Choose one of the following authentication modes to configure:

- **MD5:**

set l3-interface vlan-interface <*vlan-interface*> **ip-rip authentication mode md5 auth-length** [**old-ripd** | **rfc**]

- **text:**

set l3-interface vlan-interface <*vlan-interface*> **ip-rip authentication mode text**

Step 2 Configure authentication string.

set l3-interface vlan-interface <*vlan-interface*> **ip-rip authentication string** <*string*>

Step 3 Commit the configuration.

commit

Example

The following example commands configure RIPv2 authentication mode to MD5 and the authentication string is *PICOS*.

```
admin@PICOS# set l3-interface vlan-interface vlan100 ip-rip authentication mode md5 auth-length rfc
admin@PICOS# set l3-interface vlan-interface vlan100 ip-rip authentication string PICOS
admin@PICOS# commit
```

Configuring RIP to Advertise Default Routes

In the routing table, the default route is a route to network 0.0.0.0 (also with a mask of 0.0.0.0). When the destination address of a message cannot match with any destination address in the routing table, the device will select the default route to forward the message.

The **set protocols rip** [**vrf** <*vrf-name*>] **default-information originate** command can be used to configure the current device to generate a default route to advertise to its neighbors. The optional parameter **vrf** can be used to specify RIP for a particular VRF. If VRF is not defined then RIP takes effect for the default VRF.

The following example configures the current device to generate a default route to advertise to its neighbors.

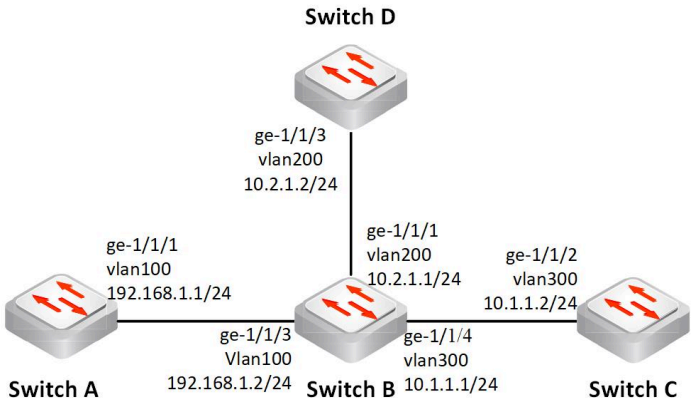
```
admin@PICOS# set protocols rip default-information originate
admin@PICOS# commit
```

Example for Configuring Basic RIP

- Networking Requirements
  - Figure 1. RIP Configuration Example
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
- Verifying the Configuration

Networking Requirements

Figure 1. RIP Configuration Example



As shown in **Figure 1**, there are four switches in a small network that require network interconnection on SwitchA, SwitchB, SwitchC, and SwitchD. Since it is a small network, it is recommended to configure RIPv2 routing protocol to achieve network interconnection of devices.

Follow the configuration roadmap below to complete the configuration:

1. Configure VLAN interface and IP address of each interface to make the network reachable.
2. Enable RIP on each switch to achieve basic network interconnection.
3. Run command **run show rip** to view RIP route information, **run show rip status** to view RIP general configuration information.

Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchA# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 100
admin@SwitchA# set l3-interface vlan-interface vlan100 address 192.168.1.1 prefix-length 24
```

Step2 Enable RIP for the specified network segment.

```
admin@SwitchA# set protocols rip network 192.168.1.0/24
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchB# set vlans vlan-id 200 l3-interface vlan200
admin@SwitchB# set vlans vlan-id 300 l3-interface vlan300
admin@SwitchB# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 200
admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 100
admin@SwitchB# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching vlan members 300
admin@SwitchB# set l3-interface vlan-interface vlan100 address 192.168.1.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan200 address 10.2.1.1 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan300 address 10.1.1.1 prefix-length 24
```

Step2 Enable RIP for the specified network segment.

```
admin@SwitchB# set protocols rip network 192.168.1.0/24
admin@SwitchB# set protocols rip network 10.2.1.0/24
admin@SwitchB# set protocols rip network 10.1.1.0/24
```

Step3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN interface.

```
admin@SwitchC# set vlans vlan-id 300 l3-interface vlan300
admin@SwitchC# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 300
admin@SwitchC# set l3-interface vlan-interface vlan300 address 10.1.1.2 prefix-length 24
```

Step2 Enable RIP for the specified network segment.

```
admin@SwitchC# set protocols rip network 10.1.1.0/24
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchC# commit
```

Switch D

Step1 Configure VLAN interface.

```
admin@SwitchD# set vlans vlan-id 200 l3-interface vlan200
admin@SwitchD# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 200
admin@SwitchD# set l3-interface vlan-interface vlan200 address 10.2.1.2 prefix-length 24
```

Step2 Enable RIP for the specified network segment.

```
admin@SwitchD# set protocols rip network 10.2.1.0/24
```

Step3 Enable IP routing.

```
admin@SwitchD# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchD# commit
```

Verifying the Configuration

- On Switch A, use command **run show rip** to view RIP route table.

```
admin@SwitchA# run show rip
Codes: R - RIP, C - connected, S - Static, O - OSPF, B - BGP
Sub-codes:
      (n) - normal, (s) - static, (d) - default, (r) - redistribute,
      (i) - interface

     Network            Next Hop         Metric From            Tag Time
R(n) 10.2.1.0/24        192.168.1.2           2 192.168.1.2       0 15:22
R(n) 10.1.1.0/24        192.168.1.2           2 192.168.1.2       0 15:22
C(i) 192.168.1.0/24     0.0.0.0               1 self              0
```

- On Switch A, use command **run show rip status** to view RIP general configuration information.

```
admin@SwitchA# run show rip status
Routing Protocol is "rip"
  Sending updates every 30 seconds with +/-50%, next due in 10 seconds
  Timeout after 180 seconds, garbage collect after 120 seconds

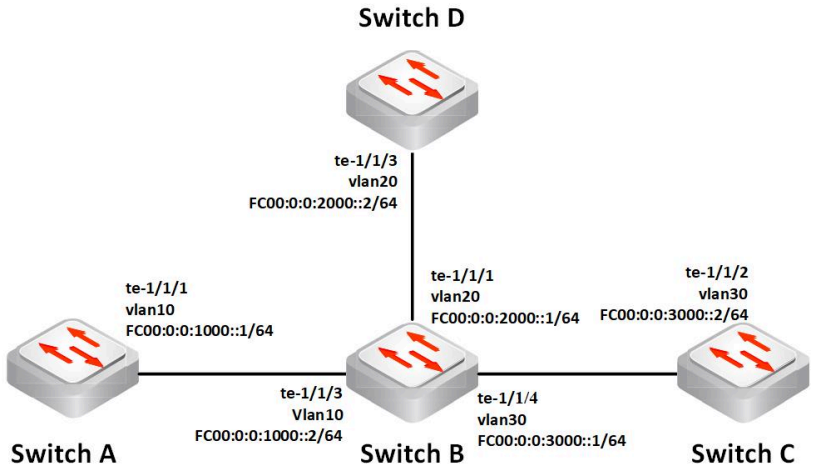
Example for Configuring Basic RIPng

- Networking Requirements
  - Figure 1. RIPng Configuration Example
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Switch D
- Verifying the Configuration

Networking Requirements

Figure 1. RIPng Configuration Example



As shown in **Figure 1**, there are four switches in a small network. It is required to enable RIPng on all interfaces of SwitchA, SwitchB, SwitchC, and SwitchD to interconnect the network through RIPng.

Follow the configuration roadmap below to complete the configuration:

1. Configure the VLAN and IP address of each interface to make the network reachable.
2. Enable RIPng on each switch to basically achieve network interconnection.

Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 100
admin@SwitchA# set l3-interface vlan-interface vlan10 address FC00:0:0:1000::1 prefix-length 64
```

Step2 Enable RIPng for the specified network segment.

```
admin@SwitchA# set protocols ripng network FC00:0:0:1000::0/64
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 10 l3-interface vlan10
admin@SwitchB# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchB# set vlans vlan-id 30 l3-interface vlan30
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 20
admin@SwitchB# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 10
admin@SwitchB# set interface gigabit-ethernet te-1/1/4 family ethernet-switching vlan members 30
admin@SwitchB# set l3-interface vlan-interface vlan10 address FC00:0:0:1000::2 prefix-length 64
admin@SwitchB# set l3-interface vlan-interface vlan20 address FC00:0:0:2000::1 prefix-length 64
admin@SwitchB# set l3-interface vlan-interface vlan30 address FC00:0:0:3000::1 prefix-length 64
```

Step2 Enable RIPng for the specified network segment.

```
admin@SwitchB# set protocols ripng network FC00:0:0:1000::0/64
admin@SwitchB# set protocols ripng network FC00:0:0:2000::0/64
admin@SwitchB# set protocols ripng network FC00:0:0:3000::0/64
```

Step3 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN interface.

```
admin@SwitchC# set vlans vlan-id 30 l3-interface vlan30
admin@SwitchC# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 30
admin@SwitchC# set l3-interface vlan-interface vlan30 address FC00:0:0:3000::2 prefix-length 64
```

Step2 Enable RIPng for the specified network segment.

```
admin@SwitchC# set protocols ripng network FC00:0:0:3000::0/64
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchC# commit
```

Switch D

Step1 Configure VLAN interface.

```
admin@SwitchD# set vlans vlan-id 20 l3-interface vlan20
admin@SwitchD# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 20
admin@SwitchD# set l3-interface vlan-interface vlan20 address FC00:0:0:2000::2 prefix-length 64
```

Step2 Enable RIPng for the specified network segment.

```
admin@SwitchD# set protocols ripng network FC00:0:0:3000::0/64
```

Step3 Enable IP routing.

```
admin@SwitchD# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchD# commit
```

Verifying the Configuration

- On Switch A, use command **run show ripng** to view RIPng route table.

```
admin@SwitchA# run show ripng
Codes: R - RIPng, C - connected, S - Static, O - OSPF, B - BGP
Sub-codes:
      (n) - normal, (s) - static, (d) - default, (r) - redistribute,
      (i) - interface, (a/S) - aggregated/Suppressed

   Network                    Next Hop                  Via       Metric Tag Time
C(i) FC00:0:0:1000::0/64
                              ::                        self       1      0
R(n) FC00:0:0:3000::0/64
                              FC00:0:0:1000::2          vlan10     2      0  02:58
R(n) FC00:0:0:2000::0/64
                              FC00:0:0:1000::2          vlan10     2      0  02:58
```

RFC Lists for RIP/RIPng

The following table lists the RFC documents related to RIP/RIPng function.

RFC	Description
RFC 1058	Routing Information Protocol. This document describes RIP protocol, describes the elements, characteristic, limitation of RIP version 1.
RFC 2453	RIP Version 2. This document specifies an extension of the Routing Information Protocol (RIP), to expand the amount of useful information carried in RIP messages and to add a measure of security.
RFC 2080	RIPng for IPv6. This document specifies a routing protocol for an IPv6 internet. It is based on protocols and algorithms currently in wide use in the IPv4 Internet.

Policy-Based Routing (PBR)

- Overview of PBR
- Configuring Policy-Based Routing
- Example for Configuring Policy-Based Routing

Overview of PBR

Policy-Based Routing (PBR) is a networking technique used to change the next hop IP address for traffic matching certain predefined policies or rule, rather than relying solely on traditional routing protocols and routing table entries. With PBR, administrators can direct traffic along specific paths according to various factors such as source/destination IP address, source/destination port.

After the device configures PBR, if the received messages match the rules of the PBR, they are forwarded according to the PBR route; if they fail to match, they are forwarded according to the destination address according to the traditional forwarding process.

The implementation and deployment of Policy-Based Routing consists of the following aspects:

1. **Policy Definition**: Administrators define policies that specify conditions under which certain types of traffic should be routed differently from the default routing behavior. A complete policy should be configured including **Match Rule**, **Action** and **Applying Interface**.

2. **Match Rule**: Policies in PBR include match rule, which are conditions that incoming packets must meet in order to be subjected to the policy. Match rule includes attributes such as source/destination IP address, source/destination port.

and is the logical operator between the matching fields with the same sequence number, that is, to be considered to match a PBR rule, the packets must match all the matching fields with the same sequence number.

3. **Action**: Once a packet matches the specified rule in a policy, an action is taken based on the policy configuration. This action involves routing the packet through a specific next-hop router/next-hop group routers or changing Quality of Service (QoS) policies such as DSCP value.

4. **Applying Interface**: Applying this policy to the VLAN interface where the traffic is coming in.

PBR provides flexibility and granular control over network traffic routing, allowing administrators to tailor routing decisions based on specific requirements or business needs, enhancing network performance, security, and flexibility.

Configuring Policy-Based Routing

Configuration Notes and Constraints
Configuring Policy-Based Routing
Procedure

Configuration Notes and Constraints

When configuring PBR, consider the following points:

- PBR processes only IP packets, L2 messages are not processed.
- PBR processes only unicast packets, multicast packets are not processed.
- PBR only handles forwarded packets, but does not handle locally originated packets (including local protocol and data packets).
- PBR policy applies to the VLAN interface where the traffic is coming in.
- Each PBR map can be applied to multiple Layer 3 interfaces, but each Layer 3 interface can have at most one PBR map configured.
- You cannot configure both IPv4 and IPv6 match conditions for the same PBR policy sequence.
- At least one match condition SHOULD be configured for a PBR policy.
- A PBR policy must contain an action configuration. However, if the action is configured with only DSCP, but no next-hop IP address, as shown in the following command line, this PBR policy only changes the DSCP value of the matched messages which will be forwarded based on the destination address according to the route table.

```
admin@PICOS# set routing pbr map PBR_map1 sequence 10 match destination-ipv4 1.1.1.0/24
admin@PICOS# set routing pbr map PBR_map1 sequence 10 action dscp 40
```

- The next-hop address must be directly connected and reachable without supporting recursion.
- The next-hop address in the action configuration does not support the tunnel IP address.
- If a message matches the Discard rule in the firewall filter ACL and also matches the PBR rule, the Discard rule in the firewall filter ACL has a higher priority than the PBR rule, then the message will be discarded.
- IPSG ACL takes precedence over PBR ACL. If a packet is discarded by the IPSG module, it will have no chance to be processed by the PBR module.

Configuring Policy-Based Routing

Follow the configuration roadmap below to complete the deployment of Policy-Based Routing:

1. Configure PBR match rule.

Policies in PBR include match rule, which are conditions that incoming packets must meet in order to be subjected to the policy. Match rules include attributes such as source/destination IP address, source/destination port.

2. Configure PBR action.

Once a packet matches the specified rule in a policy, an action is taken based on the policy configuration. This action could involve routing the packet through a specific next-hop router/next-hop group routers, changing Quality of Service (QoS) policies such as DSCP value.

3. Configure applying interface for the PBR policy.

Applying this policy to the VLAN interface where the traffic is coming in.

Procedure

Step 1 Enable IP routing for L3 forwarding.

set ip routing enable true

Step 2 Configure the match rule for PBR traffic classification.

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **match destination-ipv4** <*ipv4-address*/prefix-length>

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **match source-ipv4** <*ipv4-address/prefix-length*>

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **match destination-port** <*destination-port*>

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **match source-port** <*source-port*>

set routing pbr map <map-name> **sequence** <sequence-number> **match destination-ipv6** <ipv6-address/prefix-length>

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **match source-ipv6** <*ipv6-address/prefix-length*>

Step 3 Configure an action to redirect packets to a next-hop IPv4/IPv6 address for policy-based routing.

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **action nexthop** <*ip-address*> [**nexthop-vrf** <*vrf-name*>]

Step 4 (Optional) Configure an action to redirect packets to a next-hop group IPv4/IPv6 addresses for policy-based routing.

set routing nexthop-group <*group-name*> **nexthop-vrf** <*vrf-name*> **nexthop** <*ip-address*>

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **action nexthop-group** <*group-name*>

Step 5 Configure an action to modify the DSCP value in packets for policy-based routing.

set routing pbr map <*map-name*> **sequence** <*sequence-number*> **action dscp** <*dscp-value*>

Step 6 Apply the PBR policy to the VLAN interface where the traffic is coming in.

set routing pbr map <*map-name*> **vlan-interface** <*vlan-interface*>

Step 7 Commit the configuration.

commit

Step 8 View the configuration information of policy-based routing.

run show pbr map [<*map-name*>]

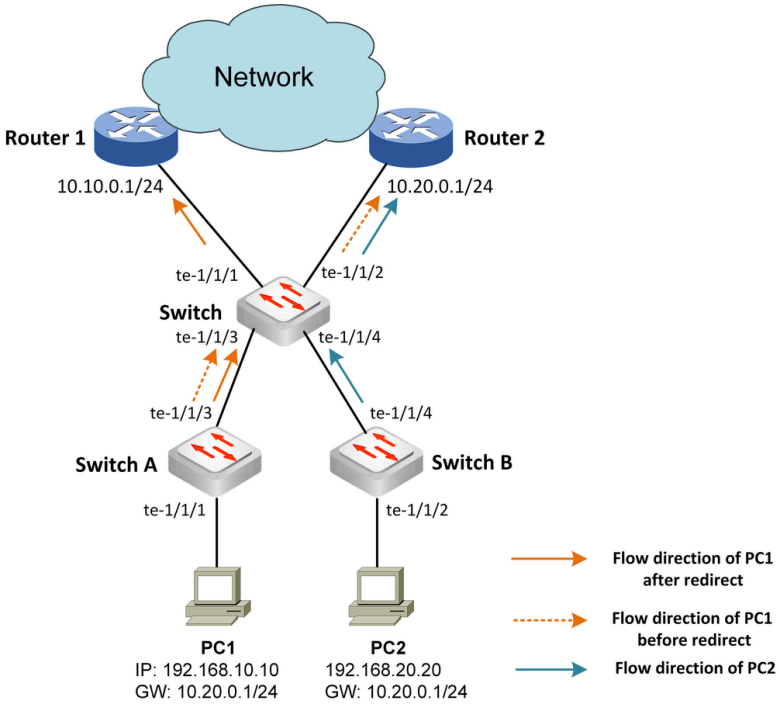
Example for Configuring Policy-Based Routing

Networking Requirements

Procedure on Switch

Networking Requirements

Figure 1. Policy-Based Routing Configuration Example



As shown in **Figure 1**, in the data center network, tenants PC1 and PC2 dually access to external network devices through the device Switch. The VLAN ID for PC1 is 100, and the IP address is 192.168.10.10. The VLAN ID for PC2 is 200, and the IP address is 192.168.20.20. The messages from both tenants are connected to external network devices through gateway Router 2 (10.20.0.1/24).

Now it is necessary to forward the packets from PC1 to external network devices through gateway Router 1 (10.10.0.1/24), and achieve routing redirection through policy-based routing to improve the tenant experience. The configuration parameters are shown in the table below.

Device	Port Name	VLAN Interface	IP Address
Switch	Te-1/1/1	VLAN100	10.10.0.2/24
Switch	Te-1/1/2	VLAN200	10.20.0.2/24
Switch	Te-1/1/3	VLAN300	192.168.10.2/24
Switch	Te-1/1/4	VLAN400	192.168.20.2/24

Follow the configuration roadmap below to complete the deployment of policy-based routing:

- Configure VLAN, VLAN interface and IP address on each switch to achieve network reachable. The configuration on the device Switch is provided in the following steps. Other devices have similar configurations and will therefore be ignored.
- On Switch, configure match rule based on the source IPv4 address 192.168.10.10/24 (IP address of PC1) for PBR traffic classification.

- On Switch, configure an action to redirect packets to a next-hop IP address 10.10.0.1/24 (IP address of Router 1) for policy-based routing.
- On Switch, apply the PBR policy to the VLAN interface VLAN300 where the traffic from PC1 is coming in.

Procedure on Switch

Step 1 Configure VLANs and VLAN interfaces.

```
admin@Switch# set vlans vlan-id 100
admin@Switch# set vlans vlan-id 200
admin@Switch# set vlans vlan-id 300
admin@Switch# set vlans vlan-id 400
admin@Switch# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@Switch# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 200
admin@Switch# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 300
admin@Switch# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 400
admin@Switch# set vlans vlan-id 100 l3-interface vlan100
admin@Switch# set vlans vlan-id 200 l3-interface vlan200
admin@Switch# set vlans vlan-id 300 l3-interface vlan300
admin@Switch# set vlans vlan-id 400 l3-interface vlan400
admin@Switch# set l3-interface vlan-interface vlan100 address 10.10.0.2 prefix-length 24
admin@Switch# set l3-interface vlan-interface vlan200 address 10.20.0.2 prefix-length 24
admin@Switch# set l3-interface vlan-interface vlan300 address 192.168.10.2 prefix-length 24
admin@Switch# set l3-interface vlan-interface vlan400 address 192.168.20.2 prefix-length 24
```

Step 2 Enable IP routing for L3 forwarding.

```
admin@Switch# set ip routing enable true
```

Step 3 Configure match rule based on the source IPv4 address 192.168.10.10/32 (IP address of PC1) for PBR traffic classification.

```
admin@Switch# set routing pbr map PBR_map1 sequence 100 match source-ipv4 192.168.10.10/32
```

Step 4 Configure an action to redirect packets to a next-hop IP address 10.10.0.1 (IP address of Router 1) for PBR.

```
admin@Switch# set routing pbr map PBR_map1 sequence 100 action nexthop 10.10.0.1
```

Step 5 Apply this policy PBR_map1 to the VLAN interface VLAN300 where the traffic from PC1 is coming in.

```
admin@Switch# set routing pbr map PBR_map1 vlan-interface vlan300
```

Step 6 Commit the configurations.

```
admin@Switch# commit
```

Step 7 View the configuration information of policy-based routing.

```
admin@Switch# run show pbr map PBR_map1
Sequence: 100
    match-condition:
        source-ipv4      192.168.10.10/32
action:
        nexthop     10.10.0.1 nexthop-vrf:
statistics:
        vlan300: 1864 pkts
```

IPv4 Source Guard (IPSG for IPv4)

- Overview
- Configuration Notes and Constraints
- Configuring IP Source Guard
  - Configure Static IP Source Guard Binding Entry
  - Configure Dynamic IP Source Guard Binding Entry
- Configuration Example
  - Networking Requirements
  - Procedure

Overview

IP Source Guard (IPSG) is a security feature implemented in network switches to mitigate IP address spoofing attacks. It generally works by ensuring that incoming packets on a network interface have a source IP address that matches an entry in the IP source guard binding table. Traffic from other IP addresses is dropped.

IP source guard binding table contains two types of entries: static entries and dynamic entries.

- **Static entries**: IP addresses that have been manually associated with a MAC address.
- **Dynamic entries**: IP addresses added through DHCP snooping binding table.

Dynamic table entry aging does not affect static table entries; that is to say, static table entries do not age.

IP source guard filtering items include either IP or IP+MAC based on specific interface and VLAN.

IP source guard permits traffic from the following sources, in addition to packets that match the entries in the IP source guard binding table:

- When DHCP snooping is enabled, IP source guard allows the reception of DHCP packets.
- IPv6 packets are not subjected to IP Source Guard checks.

By default, IP source guard is disabled. It must be enabled on each port where guarding is required.

Configuration Notes and Constraints

When configuring IP source guard, consider the following points:

- IP source guard be enabled on a physical interface or a Link Aggregation Group (LAG) interface but cannot be enabled on the member interfaces of a LAG.
- The interface that enables IPSG cannot be a DHCP snooping trust interface.
- IPSG has a higher priority than PBR (Policy-Based Routing) and 802.1X (downloadable ACL and dynamic ACL). When IPSG is enabled on the ingress interface and VLAN to which a packet belongs, the packet is subject to IPSG verification. As a result, it bypasses both PBR and 802.1X ACL matching processes.
- If a packet that matches the IP source guard entry also matches an ACL rule (such as a firewall filter ACL), and the action of the ACL rule is discard, then the packet will be discarded by the ACL regardless of other configurations.
- After configuring the IP source guard binding entry, it needs to be deployed to the hardware by the system. Therefore, the number of IP source guard binding entries supported by the switch depends on the current utilization of hardware resources. Of course, different switch platforms have different hardware performance, and thus support varying numbers of table entries.
- IPSG is not supported in MLAG scenarios.

Configuring IP Source Guard

Configuring IP Source Guard involves the following steps:

1. Configure IP Source Guard binding table entries in the following two ways:

- Static entries: Manually associate IP addresses with a MAC address.
- Enable DHCP snooping function to generate dynamic IP Source Guard entries. Dynamic entries are added through the DHCP Snooping binding table.

2. Enable IP source guard for a specific interface and VLAN.

> **NOTE**:
>
> - The command **set ip-source-guard interface** <*interface-name*> **vlan** <*vlan-id*> **enable** <**true | false**> is used for step 2.
> - The interface and VLAN configured in step 2 should be consistent with the values in the IP source guard binding table.
> - When IP source guard is enabled on a specific interface and VLAN, all IP packets from this interface and VLAN will be dropped except that match the entries in the IP source guard binding table.
> - Packets received from other interfaces or VLANs that do not have IP source guard enabled will not be inspected by the IP source guard module and will be processed normally.

3. (Optional) Configure IP source guard filtering item for a specific interface and VLAN.
4. Verify the IP source guard entries.

You can enable both static and dynamic entries for IP source guard, or you can choose to enable only one of them. For users with dynamically assigned IP addresses, enabling DHCP Snooping is necessary.

Configure Static IP Source Guard Binding Entry

Step 1 Configure static IP source guard entries.

set ip-source-guard binding ip <*ip_address*> **mac** <*mac-address*> **interface** <*interface-name*> **vlan** <*vlan-id*>

Step 2 Enable IP source guard based on specific interface and VLAN. Here, the interface and VLAN ID should be consistent with the values configured in the static IP source guard entries.

set ip-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **enable** <**true** | **false**>

Step 3 (Optional) Configure IP source guard filtering item based on specific interface and VLAN.

set ip-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **verify** <**ip** | **ip+mac**>

Step 4 Commit the configuration.

commit

Step 5 View the IP source guard binding entries.

run show ip-source-guard binding [**interface** <*interface-name*>]

Configure Dynamic IP Source Guard Binding Entry

Step 1 Enable DHCP snooping.

set protocols dhcp snooping vlan <*vlan-id*> **disable** <**true** | **false**>

set protocols dhcp snooping trust-port <*interface-name*>

Step 2 Enable IP source guard based on specific interface and VLAN. Here, the interface and VLAN ID is the one that enables DHCP snooping.

set ip-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **enable** <**true** | **false**>

Step 3 (Optional) Configure IP source guard filtering item based on specific interface and VLAN. Here, the VLAN is the one that enables DHCP snooping.

set ip-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **verify** <**ip** | **ip+mac**>

Step 4 Commit the configuration.

commit

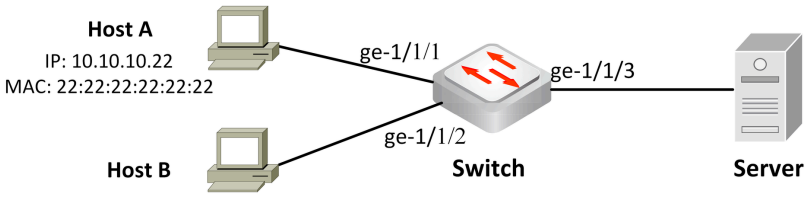
Step 5 View the IP source guard binding entries.

run show ip-source-guard binding [**interface** <*interface-name*>]

Configuration Example

Networking Requirements

Figure 1. IP Source Guard Configuration Example



As shown in **Figure 1**, on interfaces ge-1/1/1 and ge-1/1/2 of the device named Switch, enable IP Source Guard function to prevent IP address spoofing attacks. Enable both static IP source guard binding entry configuration and dynamic entry originating from the DHCP snooping binding table.

Follow the configuration roadmap below to complete the deployment on the Switch device:

1. Configure IP source guard binding table static entries for host A.
2. Enable DHCP Snooping for dynamically assigning IP to host B.
3. Enable IP source guard function for interfaces ge-1/1/1 and ge-1/1/2.
4. Configure IP source guard filtering item based on specific interface and VLAN.
5. Check the IP source guard entries.

Procedure

Step 1 Configure VLAN.

```
admin@PICOS# set vlans vlan-id 2
admin@PICOS# set vlans vlan-id 3
admin@PICOS# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@PICOS# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@PICOS#  set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 10,20
```

Step 2 Configure IP source guard static entry for host A.

```
admin@PICOS# set ip-source-guard binding ip 10.10.10.22 mac 3f:2c:99:51:48:01 interface ge-1/1/1 vlan 10
```

Step 3 For users with dynamically assigned IP addresses, DHCP snooping needs to be configured.

```
admin@PICOS# set protocols dhcp snooping vlan 20 disable false
admin@PICOS# set protocols dhcp snooping trust-port ge-1/1/3
```

Step 4 Enable IP source guard.

```
admin@PICOS# set ip-source-guard interface ge-1/1/1 vlan 10 enable true
admin@PICOS# set ip-source-guard interface ge-1/1/2 vlan 20 enable true
```

Step 5 Configure IP source guard filtering item based on specific interface and VLAN.

```
admin@PICOS# set ip-source-guard interface ge-1/1/1 vlan 10 verify ip+mac
admin@PICOS# set ip-source-guard interface ge-1/1/2 vlan 20 verify ip+mac
```

Step 6 Commit the configuration.

```
admin@PICOS# commit
```

Step 7 View the IP source guard binding entries.

```
admin@PICOS# run show ip-source-guard binding
Total ipsg host count:     2
Mac-Address         Ip-Address      Interface       VLAN      Type         Filter-Type         Status
-------------------------------------------------------------------------------------------------------------
--------
22:22:22:22:22:22   10.10.10.22     ge-1/1/1        10        static           ip+mac              effective
54:9c:99:d3:09:5c   20.1.1.10       ge-1/1/2        20        dhcp-snooping    ip+mac              effective

IPv6 Source Guard (IPSG for IPv6)

- Overview
- Configuration Notes and Constraints
- Configuring IPv6 Source Guard
  - Configure Static IPv6 Source Guard Binding Entry
  - Configure Dynamic IPv6 Source Guard Binding Entry
- Configuration Example
  - Networking Requirements
  - Procedure

Overview

IPv6 Source Guard, or IPSG for IPv6, is a security feature implemented in network switches to mitigate IPv6 address spoofing attacks. It generally works by ensuring that incoming packets on a network interface have a source IPv6 address that matches an entry in the IPv6 source guard binding table. Traffic from other IPv6 addresses is dropped.

IPv6 source guard binding table contains two types of entries: static entries and dynamic entries.

- **Static entries**: IPv6 addresses that have been manually associated with a MAC address.
- **Dynamic entries**: IPv6 addresses added through DHCPv6 snooping binding table.

Dynamic table entry aging does not affect static table entries; that is to say, static table entries do not age.

IPv6 source guard filtering items include either IP or IP+MAC based on specific interface and VLAN.

IPv6 source guard permits traffic from the following sources, in addition to packets that match the entries in the IPv6 source guard binding table:

- When DHCPv6 snooping is enabled, IPv6 source guard allows the reception of DHCPv6 packets.
- IPv4 packets are not subjected to IPv6 Source Guard checks.

By default, IPv6 source guard is disabled. It must be enabled on each port where guarding is required.

Configuration Notes and Constraints

When configuring IPSG for IPv6, consider the following points:

- The entries of IPv6 subnet address without mask length in the IPv6 source guard binding table are ineffective for IPSG.
- IPSG for IPv6 be enabled on a physical interface or a Link Aggregation Group (LAG) interface but cannot be enabled on the member interfaces of a LAG.
- The interface that enables IPSG for IPv6 cannot be a DHCPv6 snooping trust interface.
- IPSG for IPv6 has a higher priority than PBR (Policy-Based Routing) and 802.1X (downloadable ACL and dynamic ACL). When IPSG for IPv6 is enabled on the ingress interface and VLAN to which a packet belongs, the packet is subject to IPSG for IPv6 verification. As a result, it bypasses both PBR and 802.1X ACL matching processes.
- If a packet that matches the IPv6 source guard entry also matches an ACL rule (such as a firewall filter ACL), and the action of the ACL rule is discard, then the packet will be discarded by the ACL regardless of other configurations.
- After configuring the IPv6 source guard binding entry, it needs to be deployed to the hardware by the system. Therefore, the number of IPv6 source guard binding entries supported by the switch depends on the current utilization of hardware resources. Of course, different switch platforms have different hardware performance, and thus support varying numbers of table entries.
- IPSG for IPv6 is not supported in MLAG scenarios.

Configuring IPv6 Source Guard

Configuring IPv6 Source Guard involves the following steps:

1. Configure IPv6 Source Guard binding table entries in the following two ways:

- Static entries: Manually associate IPv6 addresses with a MAC address.
- Enable DHCPv6 snooping function to generate dynamic IPv6 Source Guard entries. Dynamic entries are added through the DHCPv6 Snooping binding table.

2. Enable IPv6 source guard for a specific interface and VLAN.

> **NOTE**:
>
> - The command **set ipv6-source-guard interface** <*interface-name*> **vlan** <*vlan-id*> **enable** <**true | false**> is used for step 2.
> - The interface and VLAN configured in step 2 should be consistent with the values in the IPv6 source guard binding table.
> - When IPv6 source guard is enabled on a specific interface and VLAN, all IPv6 packets from this interface and VLAN will be dropped except that match the entries in the IPv6 source guard binding table.
> - Packets received from other interfaces or VLANs that do not have IPv6 source guard enabled will not be inspected by the IPv6 source guard module and will be processed normally.

3. (Optional) Configure IPv6 source guard filtering item for a specific interface and VLAN.
4. Verify the IPv6 source guard entries.

You can enable both static and dynamic entries for IPv6 source guard, or you can choose to enable only one of them. For users with dynamically assigned IPv6 addresses, enabling DHCPv6 Snooping is necessary.

Configure Static IPv6 Source Guard Binding Entry

Step 1 Configure static IPv6 source guard entries.

set ipv6-source-guard binding ip <*ip_address*> **mac** <*mac-address*> **interface** <*interface-name*> **vlan** <*vlan-id*>

Step 2 Enable IPv6 source guard based on specific interface and VLAN. Here, the interface and VLAN ID should be consistent with the values configured in the static IPv6 source guard entries.

set ipv6-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **enable** <**true** | **false**>

Step 3 (Optional) Configure IPv6 source guard filtering item based on specific interface and VLAN.

set ipv6-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **verify** <**ip** | **ip+mac**>

Step 4 Commit the configuration.

commit

Step 5 View the IPv6 source guard binding entries.

run show ipv6-source-guard binding [**interface** <*interface-name*>]

Configure Dynamic IPv6 Source Guard Binding Entry

Step 1 Enable DHCPv6 snooping.

set protocols dhcpv6 snooping vlan <*vlan-id*> **disable** <**true** | **false**>

set protocols dhcpv6 snooping trust-port <*interface-name*>

Step 2 Enable IPv6 source guard based on specific interface and VLAN. Here, the interface and VLAN ID is the one that enables DHCPv6 snooping.

set ipv6-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **enable** <**true** | **false**>

Step 3 (Optional) Configure IPv6 source guard filtering item based on specific interface and VLAN. Here, the VLAN is the one that enables DHCPv6 snooping.

set ipv6-source-guard interface <*interface-name*> **vlan** <*vlan-id*> **verify** <**ip** | **ip+mac**>

Step 4 Commit the configuration.

commit

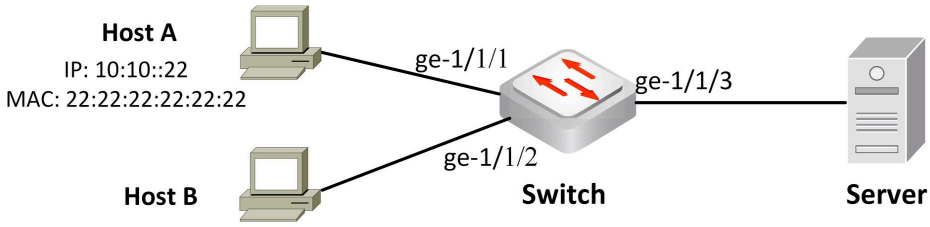
Step 5 View the IPv6 source guard binding entries.

run show ipv6-source-guard binding [**interface** <*interface-name*>]

Configuration Example

Networking Requirements

Figure 1. IPv6 Source Guard Configuration Example



As shown in **Figure 1**, on interfaces ge-1/1/1 and ge-1/1/2 of the device named Switch, enable IPv6 Source Guard function to prevent IPv6 address spoofing attacks. Enable both static IPv6 source guard binding entry configuration and dynamic entry originating from the DHCPv6 snooping binding table.

Follow the configuration roadmap below to complete the deployment on the Switch device:

1. Configure IPv6 source guard binding table static entries for host A.
2. Enable DHCPv6 Snooping for dynamically assigning IPv6 to host B.
3. Enable IPv6 source guard function for interfaces ge-1/1/1 and ge-1/1/2.
4. Configure IPv6 source guard filtering item based on specific interface and VLAN.
5. Check the IPv6 source guard entries.

Procedure

Step 1 Configure VLAN.

```
admin@PICOS# set vlans vlan-id 2
admin@PICOS# set vlans vlan-id 3
admin@PICOS# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 10
admin@PICOS# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 20
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@PICOS#  set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 10,20
```

Step 2 Configure IPv6 source guard static entry for host A.

```
admin@PICOS# set ipv6-source-guard binding ip 10:10::22 mac 22:22:22:22:22:22 interface ge-1/1/1 vlan 10
```

Step 3 For users with dynamically assigned IPv6 addresses, DHCPv6 snooping needs to be configured.

```
admin@PICOS# set protocols dhcpv6 snooping vlan 20 disable false
admin@PICOS# set protocols dhcpv6 snooping trust-port ge-1/1/3
```

Step 4 Enable IPv6 source guard.

```
admin@PICOS# set ipv6-source-guard interface ge-1/1/1 vlan 10 enable true
admin@PICOS# set ipv6-source-guard interface ge-1/1/2 vlan 20 enable true
```

Step 5 Configure IPv6 source guard filtering item based on specific interface and VLAN.

```
admin@PICOS# set ipv6-source-guard interface ge-1/1/1 vlan 10 verify ip+mac
admin@PICOS# set ipv6-source-guard interface ge-1/1/2 vlan 20 verify ip+mac
```

Step 6 Commit the configuration.

```
admin@PICOS# commit
```

Step 7 View the IPv6 source guard binding entries.

```
admin@PICOS# run show ipv6-source-guard binding
Total ipsg6 host count:     2
Mac-Address         Ip-Address      Interface       VLAN      Type         Filter-Type         Status
-------------------------------------------------------------------------------------------------------------------
--------
22:22:22:22:22:22   10:10::22       ge-1/1/1        10        static             ip+mac              effective
54:9c:99:d3:09:5c   20::10          ge-1/1/2        20        dhcp6-snooping    ip+mac              effective
```

IPv6 RA Guard Configuration

> **NOTE:**
> Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.

When the switch receives an ingress router advertisement (RA) message, it will attempt to match the message via the RA guard. If the ingress port has the RA guard applied but is not a trusted port, the applied VLAN ID will be matched first. If the RA tag is matched with the VLAN ID, the RA guard will continue matching conditions to determine whether to forward or drop the RA message. If the RA tag is *not* matched with the VLAN ID, the applied interface will be matched (followed by the subsequent conditions). RA guard policy can be configured using hop-limit, managed-config-flag, other-config-flag, prefix, source-ipv6-addr, and source-mac-addr options.

RA guard function can be configured on physical interfaces, LAG ports, or in VLANs, and only checks the router advertisement (RA) packets on the untrusted ports with RA guard enabled. By default, all interfaces are untrusted with respect to RA guard. Trusted interfaces are manually specified.

- If RA guard is enabled on an untrusted interface, the RA message received on the interface will be checked by the RA guard policy. The RA packets only matched the RA guard policy can be processed and forwarded.
- If RA guard is disabled on an untrusted interface, the RA message received on the interface will not be checked by the RA guard policy. All the RA packets received on this interface are processed and forwarded without inspection.
- If RA guard is enabled on a trusted interface, the RA message received on the interface will not be checked by the RA guard policy. All the RA packets received on this interface are processed and forwarded without inspection.

Configuring RA Guard Policy

```
admin@XorPlus# set protocols neighbour ra-guard term guard1 from hop-limit 1
admin@XorPlus# set protocols neighbour ra-guard term guard1 from managed-config-flag false
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# set protocols neighbour ra-guard term guard2 from prefix 2001:1:1:1::/64
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# set protocols neighbour ra-guard term guard3 from source-mac-addr 22:22:22:22:22:22
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Configuring Trusted-Port

No more than one RA guard can be applied to one interface. The RAs will be forwarded only if all conditions are matched. But if "trusted-port" has been configured for the RA guard, RAs will be forwarded on the trusted port regardless.

```
admin@XorPlus# set protocols neighbour ra-guard term 1 interface ge-1/1/1
admin@XorPlus# set protocols neighbour ra-guard term 1 interface ae1
admin@XorPlus# set protocols neighbour ra-guard term 1 vlan-id 2
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#set protocols neighbour ra-guard trusted-port ge-1/1/2
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus# set protocols neighbour ra-guard term 2 vlan-id 3
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
```

Displaying RA Guards

```
admin@XorPlus# run show ra-guard

- Application Scenarios

Overview

IS-IS (Intermediate System to Intermediate System) is a link-state routing protocol used to exchange routing information within an autonomous system (AS). It is commonly used in large service provider and enterprise networks. IS-IS operates at the OSI Layer 2 (data link layer) and Layer 3 (network layer) and is defined in the ISO/IEC 10589 standard.

IS-IS routers exchange information about the network topology by flooding Link State Protocol Data Unit (LSP) throughout the network. Each router builds a map of the network and calculates the best paths to destination networks based on metrics such as link cost.

Key features

Key features of IS-IS include its support for hierarchical routing, fast convergence, scalability, and support for both IPv4 and IPv6 addressing. It is often used in conjunction with other routing protocols like OSPF (Open Shortest Path First) in larger networks.

1. **Hierarchical Design**: IS-IS supports hierarchical routing, dividing the network into areas to scale routing information. This hierarchical structure helps manage network growth and reduce the amount of routing information exchanged between routers.
2. **Link-State Protocol**: IS-IS is a link-state routing protocol, meaning routers exchange information about their directly connected links and the status of those links. This information is flooded throughout the network, allowing each router to build a complete map of the network topology.
3. **Two-Level Hierarchy**: IS-IS employs a two-level hierarchy consisting of Level 1 and Level 2 routing. Level 1 routers exchange routing information within their area, while Level 2 routers exchange routing information between areas.
4. **SPF Algorithm**: IS-IS routers use the Shortest Path First (SPF) algorithm, also known as the Dijkstra algorithm, to calculate the best path to reach destination networks based on link costs. This algorithm ensures efficient path selection and optimal routing.
5. **Addressing Support**: IS-IS supports both IPv4 and IPv6 addressing, making it suitable for networks transitioning to IPv6 or running dual-stack configurations.
6. **Fast Convergence**: IS-IS is known for its fast convergence capabilities, quickly adapting to changes in the network topology and recalculating routes as needed. This helps minimize network downtime and ensures efficient traffic forwarding.
7. **Scalability**: IS-IS is designed to scale to large networks, making it suitable for service provider and enterprise environments with complex network topologies and high traffic volumes.
8. **Authentication**: IS-IS supports authentication mechanisms to secure routing information exchanges between routers, helping prevent unauthorized access and malicious attacks on the network.

IS-IS provides a robust and scalable routing solution for large networks, offering efficient routing, fast convergence, and support for both IPv4 and IPv6 addressing. Its hierarchical design and link-state operation make it well-suited for modern networking environments.

Application Scenarios

IS-IS is a robust link-state routing protocol widely used in large-scale networks. It's particularly favored in service provider and large enterprise environments due to its scalability, flexibility, and rapid convergence. Here are some key application scenarios where IS-IS is particularly effective:

- **Service Provider Networks**

IS-IS can support large-scale networks with thousands of routes, making it ideal for the core backbone of service providers. IS-IS can be used for both Layer 2 (bridging) and Layer 3 (routing) functionalities, providing a versatile solution for Metro Ethernet deployments. Its rapid convergence ensures minimal downtime and quick recovery in the event of link failures, which is crucial for maintaining high availability and reliability.

- **Large Enterprise Networks**

IS-IS supports multi-level hierarchical network design (Level 1 and Level 2), enabling efficient routing in large enterprise networks with multiple branches and campuses. A multinational corporation uses IS-IS to interconnect its global offices, data centers, and remote branches, providing a resilient and scalable routing framework.

- **Data Center Networks**

IS-IS can handle high-throughput environments typical of data centers, ensuring efficient data flow between servers and storage systems. Its simple and flexible configuration options make it suitable for dynamic data center environments where network changes are frequent.

- **Campus Networks**

IS-IS can handle the large number of nodes and devices typically found in campus networks. Many educational and research institutions are early adopters of IPv6, and IS-IS provides a seamless transition from IPv4 to IPv6. For example, a university deploys IS-IS to connect its various buildings, ensuring reliable and efficient communication for academic and administrative purposes.

Configuring IS-IS Basic Function

Only after configuring the basic functions can an IS-IS network be established.

Prerequisites
Configure Network Entity Title (NET)
Enable IS-IS Instance on the Interface
Configure the Level of the IS-IS Switch

NOTEs:

- A maximum of 128 IS-IS routing instances can be configured on a Pica8 switch.
- only up to 3 NETs can be configured.

Prerequisites

Before configuring the basic functions of IS-IS, the following task must be completed:

Configure the IP addresses of the interfaces to ensure network layer reachability between adjacent nodes.

Configure Network Entity Title (NET)

Network Entity Title (NET) is a key component of the addressing scheme. It uniquely identifies each Intermediate System (IS) within the IS-IS routing domain.

The NET consists of three parts:

- Area ID: The length of the Area ID can vary from 1 to 13 bytes.
- System ID: This part has a fixed length of 6 bytes.
- NSAP Selector (SEL): The last byte, different transport protocols correspond to different SELs. For IP, the SEL is always 00.

NOTEs:

- The area address is used to uniquely identify different areas within a routing domain. All switches within the same Level-1 area must have the same area address, while switches within Level-2 areas can have different area addresses.
- Throughout the entire domain and backbone area, it is required to maintain a unique system ID.
- Since a maximum of 3 area addresses can be configured in an IS-IS process, only up to 3 NETs can be configured.

The **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **network-entity** <*network-entity*> command configures network entity title (NET) provided in ISO format. When configuring the NET parameter in IS-IS, ensure that these three components are properly defined according to your network requirements.

Define the IS-IS instance by specifying the **area-tag** <*text*>. This **area-tag** <*text*> helps identify the IS-IS instance on the router.

The following command defines the NET as 32.0001.0040.0220.2030.00. The system ID is 0040.0220.2030 and the region ID is 32.0001.

```
admin@PICOS# set protocols isis area-tag instance1 network-entity 32.0001.0040.0220.2030.00
admin@PICOS# commit
```

Enable IS-IS Instance on the Interface

After configuring the IS-IS instance, to ensure the proper operation of the IS-IS protocol, you also need to enable IS-IS on the link interfaces where IS-IS is running and associate them with the specified instance. The **set protocols isis area-tag** <*text*> **interface** <*interface-name*> <**ipv4-routing | ipv6-routing**> command enables IS-IS instance on a specific L3 interface.

The following command enables IS-IS instance on a specific interface.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 ipv4-routing
admin@PICOS# commit
```

Configure the Level of the IS-IS Switch

IS-IS switches can be categorized into the following three levels:

- Level-1 switches: Responsible for routing within an area, they only form neighbor relationships with Level-1 and Level-1-2 switches belonging to the same area. Level-1 switches must connect to other areas through Level-1-2 switches.
- Level-2 switches: Responsible for routing between areas, they can form neighbor relationships with Level-2 switches or Level-1-2 switches from other areas. All Level-2 switches constitute the backbone network of the routing domain, facilitating communication between different areas. Level-2 switches within the routing domain must be contiguous to ensure the continuity of the backbone network.
- Level-1-2 switches: They can form Level-1 neighbor relationships with Level-1 and Level-1-2 switches within the same area, as well as Level-2 neighbor relationships with Level-2 and Level-1-2 switches from other areas.

The **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **is-type** <**level-1** | **level-1-2** | **level-2-only**> command configures the level of the IS-IS switch.

It is advisable for users to complete the configuration of the switch level when configuring IS-IS before network operation.

If the switch level is not specified using this command during the IS-IS configuration process, the router defaults to being a Level-1-2 router. This means it participates in both Level-1 and Level-2 routing calculations, maintaining two LSDBs for Level-1 and Level-2.

The following command configures the level of the IS-IS switch.

```
admin@PICOS# set protocols isis area-tag instance1 is-type level-1
admin@PICOS# commit
```

Configuring IS-IS Authentication

Configuring Authentication for IS-IS Area
Configuring Authentication for IS-IS Routing Domain
Configuring IS-IS Authentication per Interface

IS-IS authentication involves **IS-IS authentication per interface**, **IS-IS area authentication** and **IS-IS routing domain authentication**.

- **IS-IS Authentication per Interface**

IS-IS authentication per interface refers to the interface that enables the IS-IS protocol to authenticate Level 1 and Level 2 Hello messages in a specified manner and password.

- **Area Authentication**

Area authentication encapsulates authentication passwords in IS-IS packets within the Level-1 area, ensuring that only authenticated packets are received. Therefore, when authentication is required for the Level-1 area, IS-IS area authentication needs to be configured on all IS-IS devices within that area.

- **Domain Authentication**

Domain authentication encapsulates authentication passwords in IS-IS packets within the Level-2 area, ensuring that only authenticated packets are received. Therefore, when authentication is required for the Level-2 area, IS-IS domain authentication needs to be configured on all IS-IS devices within that area.

Typically, the IS-IS protocol does not encapsulate authentication information in the sent IS-IS packets, nor does it perform authentication checks on received packets. However, in the event of malicious packet attacks that could lead to the theft of network information, configuring IS-IS authentication can enhance network security.

NOTEs:

- When configuring IS-IS authentication per interface, it is required that the authentication type and password of all devices in the same area or routing domain must be consistent for IS-IS packets to propagate normally.
- Regardless of whether area authentication or routing domain authentication is passed, it does not affect the establishment of Level-1 or Level-2 neighbor relationships.

Configuring Authentication for IS-IS Area

- When configuring, **authentication-type** and **authentication-key** should be submitted in the same commit.
- When deleting, the command is **delete protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **area-password**, and all the **area-password** configuration of **authentication-type** and **authentication-key** will be removed.

To configure the authentication type for the IS-IS area, users can use command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **area-password authentication-type** <**simple | md5**>. The authentication type can be **simple** or **md5**.

To configure the authentication password for the IS-IS area, users can use command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **area-password authentication-key** <*password*>. IS-IS encapsulates authentication information for the sent IS-IS messages and performs authentication checks on the received messages.

By default, IS-IS does not encapsulate authentication information for the sent CSNP and PSNP messages, nor perform authentication checks on the received messages. Users can use command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **area-password authenticate-snp** <**send-only**|**validate**> to change this behavior.

The following commands configure the authentication type, authentication password for the IS-IS area, and configures the system only to encapsulate authentication information for the sent IS-IS messages but will not perform authentication checks on the received messages.

```
admin@PICOS# set protocols isis area-tag instance1 area-password authentication-type md5
admin@PICOS# set protocols isis area-tag instance1 area-password authentication-key picos123456
admin@PICOS# set protocols isis area-tag instance1 area-password authenticate-snp send-only
admin@PICOS# commit
```

Configuring Authentication for IS-IS Routing Domain

To configure the authentication type for the IS-IS domain, users can use command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **domain-password authentication-type** <**simple | md5**>. The authentication type can be **simple** or **md5**.

To configure the authentication password for the IS-IS domain, users can use command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **domain-password authentication-key** <*password*>.

By default, IS-IS does not encapsulate authentication information for the sent CSNP and PSNP messages, nor perform authentication checks on the received messages. Users can use command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **domain-password authenticate-snp** <**send-only**|**validate**> to change this behavior.

The following commands configure the authentication type, authentication password for the IS-IS domain, and configures the system only to encapsulate authentication information for the sent IS-IS messages but will not perform authentication checks on the received messages.

```
admin@PICOS# set protocols isis area-tag instance1 domain-password authentication-type md5
admin@PICOS# set protocols isis area-tag instance1 domain-password authentication-key picos123456
admin@PICOS# set protocols isis area-tag instance1 domain-password authenticate-snp send-only
admin@PICOS# commit
```

Configuring IS-IS Authentication per Interface

Make sure that the authentication configuration per interface on both ends of IS-IS neighbor is consistent, otherwise neighbors cannot be established.

To configure IS-IS authentication type per interface, users can use command **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **password authentication-type** <**simple | md5**>. The authentication type can be **simple** or **md5**.

To configure IS-IS authentication password per interface, users can use command **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **password authentication-key** <*password*>.

The following commands configure the authentication type, authentication password for the IS-IS interface.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 password authentication-type md5
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 password authentication-key picos123456
admin@PICOS# commit
```

Configuring LSP Packet Attributes

- Configure the Maximum Size of Generated LSPs
- Configure the Minimum Interval between Regenerating LSP
- Configure the Refresh Period for LSPs
- Configure the Maximum Valid Time for the LSPs

LSP messages are used to exchange link status information. By configuring the basic properties of LSP, the size and maximum valid time of LSP packets can be controlled. It is also possible to adjust the interval between LSP generations, which can enable the network to converge quickly. Additionally, you can configure configuring the refresh period for LSPs to send LSP packets and the refresh cycle of LSP packets.

NOTE:

The LSP maximum lifetime must exceed the refresh interval by more than 300.

Configure the Maximum Size of Generated LSPs

NOTE:

Make sure that the length of the LSP is smaller than the MTU (Maximum Transmission Unit) of the IS-IS interface, otherwise, the LSP messages cannot be sent properly.

When the link state information becomes larger, the length of the generated LSP message can be increased, allowing each LSP to carry more information. Users can control the size of LSP generation and reception through the following commands.

set protocols isis area-tag <*text*> [**vrf** <*vrf-name*>] **lsp-mtu** <*max-size*>

The following example configures the maximum size of generated LSPs to 1024 bytes.

```
admin@PICOS# set protocols isis area-tag instance1 lsp-mtu 1024
admin@PICOS# commit
```

Configure the Minimum Interval between Regenerating LSP

When there are changes in local routing information, the device needs to generate new LSPs to announce these changes. When changes in local routing information occur frequently, immediately generating new LSPs consumes a large amount of system resources. To speed up network convergence without affecting system performance, you can adjust the interval between LSP generations using **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **lsp-timers gen-interval** <*lsp-gen-interval*> command.

Configure the Refresh Period for LSPs

The IS-IS network primarily achieves synchronization of link states through the flooding of LSPs. Flooding entails a device sending its LSP to neighbor devices, which then forward the same LSP to all neighbors except the one from which they received it, thus progressively disseminating the LSP throughout the entire hierarchy. This ensures that every device within the hierarchy possesses identical LSP information, thereby maintaining synchronization of the Link State Database (LSDB).

The flooding of LSPs requires periodic refreshing because when a device generates its system LSP, it includes the maximum valid time for the LSP. As other devices receive this LSP, its valid time decreases over time. If a device does not receive an updated LSP, once the valid time of the LSP reaches 0, it will be retained for an additional 60 seconds. If a new LSP is not received within this time, the LSP will be deleted.

Use the command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **lsp-timers refresh-interval** <*lsp-refresh-interval*> to configure the refresh period for LSPs. This interval determines how often the router will re-advertise its LSPs to ensure that other routers in the network have up-to-date information about the network topology. Adjusting this interval can help balance the need for up-to-date information with the desire to minimize unnecessary network traffic.

Configure the Maximum Valid Time for the LSPs

When the switch generates system LSP, the maximum valid time of this LSP will be filled in the LSP. When this LSP is received by other switches, its valid time will continuously decrease over time. If the switch has not received an updated LSP and the valid time of this LSP has decreased to 0, the LSP will remain for another 60 seconds. If a new LSP has not been received yet, it will be deleted.
The **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **lsp-timers max-lifetime** <*lsp-refresh-interval*> command can adjust the maximum valid time of LSP to ensure the validity of old LSP before receiving updated LSP.

Customizing Routes for IS-IS

Configure IS-IS Overload
Configure Attached-bit
Configure Default Metric Value for IS-IS Interface
Configure the Priority for Designated Router Election
Configure IS-IS Passive Interface

Configure IS-IS Overload

There are some circumstances in which it is advantageous to have an IS-IS intermediate system not fully participate in forwarding traffic. For example:

- During startup this intermediate system may be temporarily too busy with the tasks associated with convergence to forward traffic.
- The intermediate system is in a test network that has connections to a production network. The overload bit prevents traffic from moving between the two networks.

You can configure the intermediate system to not forward traffic by enabling the overload bit.

When enabled, the overload bit instructs other intermediate systems not to use this intermediate system as an intermediate hop in their SPF computations. No paths through this intermediate system are visible to other intermediate systems in the domain. IP and CLNS prefixes directly connected to this intermediate system are reachable.

The command **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **set-overload-bit** <**true** | **false**> can be used to configure the overload bit for non-pseudonode LSPs.

Configure Attached-bit

The ATT bit is a field in IS-IS LSP (Link State Packet) messages used to indicate whether a Level-1 area is connected to other areas. Level-1-2 routers set this field in their generated Level-1 LSPs to inform Level-1 routers within the same area that they are connected to other areas, specifically to the Level-2 backbone area. When routers in a Level-1 area receive Level-1 LSPs with the ATT bit set from Level-1-2 routers, they create a default route pointing to the Level-1-2 router as the destination, allowing data to be routed to other areas.

The **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **attached-bit send** <**true** | **false**> command can be used to configure whether the Level-1 routers will send default routes in the routing table due to the ATT bit or not.

The following command configures the Level-1 routers to send default routes in the routing table due to the ATT bit.

```
admin@PICOS# set protocols isis area-tag instance1 attached-bit send true
admin@PICOS# commit
```

Configure Default Metric Value for IS-IS Interface

IS-IS uses metrics to determine the best path to a destination. By configuring a default metric value, you influence the path selection process and ensure that traffic follows the desired route.

Configuring different metric values on multiple interfaces can facilitate load balancing. IS-IS can distribute traffic across multiple paths based on their metric values, allowing for efficient utilization of network resources.

The **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **metric** <*metric*> command configures default metric value for IS-IS interface.

If the **metric-style** is not ***wide***, the metric value for IS-IS interface must be less than 64.

The following command configures the default metric value for IS-IS interface.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 metric 100
admin@PICOS# commit
```

Configure the Priority for Designated Router Election

Configuring a priority for Designated Router (DR) election in an IS-IS network allows you to influence the selection process for the DR. By assigning different priority values to routers, you can control which routers are more likely to be elected as the DR or BDR. Routers with higher priority values have a greater chance of winning the election.

You can designate certain routers with higher priority values as the preferred DR for critical segments of the network. This ensures that key routers take on leadership roles and helps maintain network stability and performance.

The **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **priority** <*priority*> command configures priority for Designated Router election.

The following command configures the priority for Designated Router election.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 priority 85
admin@PICOS# commit
```

Configure IS-IS Passive Interface

Configuring an layer 3 interface as a passive IS-IS interface prevents the IS-IS process from sending or receiving IS-IS hello packets on the specified interface, effectively making it passive in the IS-IS routing process.

Passive interfaces do not participate actively in IS-IS routing updates. This can be useful in scenarios where you want to limit the exposure of your IS-IS topology to specific interfaces for security reasons.

By marking certain interfaces as passive, you can reduce the amount of IS-IS hello packets exchanged on those interfaces. This can help in conserving network resources and reducing unnecessary control plane traffic.

The **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **passive** command configures the specified layer 3 interface as passive IS-IS interface.

The following command configures the specified layer 3 interface as passive IS-IS interface.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 passive
admin@PICOS# commit
```

Configuring IS-IS Timers

- Configuring the Interval for Sending Hello Messages
- Configuring the Hello-Multiplier for the Neighbor Holding Time
- Configuring the Interval for Sending CSNP Messages
- Configuring the Interval for Sending PSNP Messages

Configuring the Interval for Sending Hello Messages

The IS-IS protocol maintains neighbor relationships with neighboring devices through the sending and receiving of Hello messages. When neighboring devices do not receive the Hello message sent by the local end for a period of time, it will be considered that the neighbor has expired. The command **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **hello-interval** <*hello-interval*> can be used to specify the interval time for sending Hello messages on an IS-IS interface. The **hello-interval** <*hello-interval*> value is an integer ranging from 1 to 600 seconds. The default value is 3 seconds.

The following commands configure the interval time for sending Hello messages on an IS-IS interface.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 hello-interval 30
admin@PICOS# commit
```

Configuring the Hello-Multiplier for the Neighbor Holding Time

The devices at both ends of the link establish a neighbor relationship by sending Hello messages. Once the neighbor relationship is established, periodic Hello messages need to be sent to maintain the neighbor relationship. If the device at one end of the link does not receive the Hello message within a certain interval of time, it is considered that the neighbor has failed. This interval is called neighbor holding time.

For example, if the local device has configured the sending interval of Hello messages to 30 seconds by using command **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **hello-interval** <*hello-interval*> , and then using command **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **hello-multiplier** <*integer*> to set the multiplier value to 4, the neighbor holding time is 120 seconds (4 * 30=120). When modifying the sending interval of Hello messages, the neighbor holding time also changes accordingly.

The **hello-multiplier** <*integer*> value is an integer ranging from 2 to 100. The default value is 10.

The following commands the interval time for sending Hello messages on an IS-IS interface and configure the multiplier for the interval time between Hello messages. Then the neighbor holding time is 120 seconds (4 * 30=120).

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 hello-interval 30
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 hello-multiplier 4
admin@PICOS# commit
```

Configuring the Interval for Sending CSNP Messages

In an IS-IS broadcasting network, all devices synchronize their Link State Database (LSDB) by periodically broadcasting CSNP (Complete Sequence Number PDU) packets through the Designated Intermediate System (DIS). Upon receiving a CSNP message, if other devices discover that a specific Link State Packet (LSP) is missing from their local LSDB or the locally stored LSP is outdated, they will send a PSNP (Partial Sequence Number PDU) message to request the corresponding LSP. Since only the DIS periodically sends CSNP messages, this command can only be configured on the broadcast network interface of the DIS to be effective. The interval for sending CSNP messages can be adjusted using the **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **csnp-interval** <*csnp-interval*> command. The **csnp-interval** <*csnp-interval*> value is an integer ranging from 1 to 600 seconds. The default value is 10 seconds.

The following commands configure the interval for sending CSNP messages on a broadcast network.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 csnp-interval 50
admin@PICOS# commit
```

Configuring the Interval for Sending PSNP Messages

Partial sequence number message PSNP (Partial SNP): It only lists the sequence numbers of the most recently received LSPs, and can confirm multiple LSPs at once. When it is found that the LSDB is not synchronized, PSNP is also used to request neighbors to send a new LSP. Users can use the command **set protocols isis area-tag** <*text*> **interface** <*interface-name*> **psnp-interval** <*psnp-interval*> to configure the PSNP interval in seconds. The **psnp-interval** <*psnp-interval*> value is an integer ranging from 1 to 120 seconds. The default value is 10 seconds.

The following commands configure the PSNP interval.

```
admin@PICOS# set protocols isis area-tag instance1 interface vlan10 psnp-interval 50
admin@PICOS# commit
```

Controlling IS-IS Routing Information Exchange

Usually, when IS-IS and other routing protocols are deployed in a network, to ensure that traffic from within the IS-IS domain can reach outside the domain, there are typically two approaches:

- Configure edge IS-IS devices to advertise default routes into the IS-IS domain.
- Redistribute routes from other routing domains into IS-IS on edge devices.

You can go to the following pages for detailed information.

- Configuring IS-IS Advertising Default Routes
- Configuring IS-IS Introducing External Routes

Configuring IS-IS Advertising Default Routes

On edge devices with external routes, using the following commands configure to advertise a default route. This allows the device to advertise a default route (0.0.0.0/0) within the IS-IS routing domain.

set protocols isis area-tag <*text*> [**vrf** <*vrf-name*>] **default-information originate** <**ipv4-routing** | **ipv6-routing**> <**level-1** | **level-2**> **route-map** <*route-map*>

set protocols isis area-tag <*text*> [**vrf** <*vrf-name*>] **default-information originate** <**ipv4-routing** | **ipv6-routing**> <**level-1** | **level-2**> **always**

set protocols isis area-tag <*text*> [**vrf** <*vrf-name*>] **default-information originate** <**ipv4-routing** | **ipv6-routing**> <**level-1** | **level-2**> **metric** <*metric*>

If there are multiple edge devices, you can configure a route policy with the parameter **route-map** <*route-map*> to specify the conditions under which a particular edge device should advertise the default route. This helps prevent routing black-holing. Additionally, you can use the parameter **metric** <*metric*> to set the cost value for the default route.

After applying this configuration, other devices within the IS-IS domain will forward traffic destined for external routing domains to this device first. Then, the traffic will be forwarded to the external routing domain through this device.

Configuring IS-IS Introducing External Routes

You can use the following command on the edge devices to introduce routes from other routing domains into IS-IS.

set protocols isis area-tag <*text*> **[vrf** <*vrf-name*>**] redistribute ipv4-routing {bgp|connected|kernel|static|ospf|rip|table** <*table-id*>**} <level-1 | level-2> [metric** <*metric*>**]**

set protocols isis area-tag <*text*> **[vrf** <*vrf-name*>**] redistribute** <**ipv4-routing {bgp|connected|kernel|static|ospf|rip|table** <*table-id*>**} <level-1 | level-2>** [**route-map** <*route-map*>]

set protocols isis area-tag <*text*> **[vrf** <*vrf-name*>**] redistribute ipv6-routing {bgp|connected|kernel|static|ripng|ospf6|table** <*table-id*>**} <level-1 | level-2> [metric** <*metric*>**]**

set protocols isis area-tag <*text*> **[vrf** <*vrf-name*>**] redistribute ipv6-routing {bgp|connected|kernel|static|ripng|ospf6|table** <*table-id*>**} <level-1 | level-2>** [**route-map** <*route-map*>]

When introducing other protocol routes, **route-map** <*route-map*> can be used to only introduce partial routes from other routing domains. Additionally, the configuration parameter **metric** <*metric*> sets the cost value of the introduced route.

You can refer to Configuration Example of Interaction Between IS-IS and BGP to see an example of IS-IS introducing external routes configuration.

Adjusting SPF Calculation Time

- When configuring, the **spf-delay-ietf** set of **init-delay**, **short-delay**, **long-delay**, **holddown** and **time-to-learn** should be submitted in the same commit.
- When deleting, the command is **delete protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-delay-ietf**, and all the **spf-delay-ietf** configuration of **init-delay**, **short-delay**, **long-delay**, **holddown** and **time-to-learn** will be removed.

Adjusting SPF (Shortest Path First) calculation time in IS-IS allows for controlling the frequency of route computation when there are changes in the network's link-state database (LSDB). By modifying the SPF calculation time, network administrators can balance between route convergence speed and system resource utilization. If SPF calculation delay is too long, it may slow down route convergence, while if it's too short, it might consume excessive system resources. Adjusting this parameter is crucial for optimizing network performance.

SPF calculation time includes the following parameter configurations:

- **spf-interval:** To configure the interval time for SPF calculation in IS-IS, you can use the **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-interval** <*spf-interval*> command. This command allows you to specify the time interval between consecutive SPF calculations. Adjusting this interval can impact route convergence speed and system resource utilization. Here's an example of how to configure it:

```
admin@PICOS# set protocols isis area-tag instance1 spf-interval 60
admin@PICOS# commit
```

- **init-delay:** To configure the initial wait interval before SPF starts after receiving an updated LSA, you can use the **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-delay-ietf init-delay** <*init-delay*> command.
- **short-delay** and **long-delay:** To configure the minimum and maximum time between two SPF runs, used to cap the spf holddown value. It also defines how long the network has to be stable before the wait interval is reset to the init-delay and holddown values, you can use the **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-delay-ietf short-delay** <*short-delay*> and **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-delay-ietf long-delay** <*long-delay*> commands.
- **holddown:** To configure the time to hold down, or wait, before running another SPF calculation after the SPF algorithm has run in succession the configured maximum number of times, you can use the **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-delay-ietf holddown** <*holddown*> command.
- **time-to-learn:** To configure the maximum duration typically needed to learn all the IGP events related to a single component failure (such as router failure or SRLG failure), you can use the **set protocols isis area-tag** <*text*> [**vrf** <*vrf-name*>] **spf-delay-ietf time-to-learn** <*time-to-learn*> command.

Configuration Examples of IS-IS

- Basic IS-IS Configuration Example
- Configuration Example of Interaction Between IS-IS and BGP

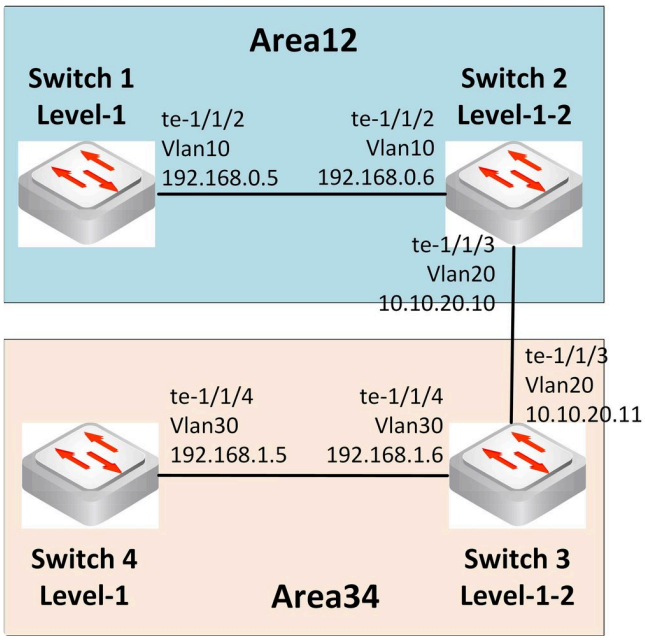
Basic IS-IS Configuration Example

- Network Requirement
- Procedure
  - Switch 1
  - Switch 2
  - Switch 3
  - Switch 4
- Verify the Configuration

Network Requirement

As shown in **Figure 1**, we have four switches. Switch 1 and Switch 2 are in area 12, Switch 3 and Switch 4 in area 34. Switch1 and Switch 4 are intra-area switches so they will be configured as level-1 switches. Switch 2 and Switch 3 form the backbone, so these switches will be configured as level-1-2 switches.

Figure 1. Basic IS-IS Configuration Example



Procedure

This section describes the steps of how to configure basic IS-IS functions on Switch 1, Switch 2, Switch 3 and Switch 4.

Switch 1

Step1 Configure the VLANs and VLAN interfaces.

```
admin@Switch1# set vlans vlan-id 10 l3-interface vlan10
admin@Switch1# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 10
admin@Switch1# set l3-interface vlan-interface vlan10 address 192.168.0.5 prefix-length 24
```

Step2 Configure IS-IS basic function.

```
admin@Switch1# set protocols isis area-tag instance1 network-entity 12.0000.0000.0001.00
admin@Switch1# set protocols isis area-tag instance1 is-type level-1
admin@Switch1# set protocols isis area-tag instance1 interface vlan10 ipv4-routing
```

Step3 Enable IP routing.

```
admin@Switch1# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@Switch1# commit
```

Switch 2

Step1 Configure the VLANs and VLAN interfaces.

```
admin@Switch2# set vlans vlan-id 10 l3-interface vlan10
admin@Switch2# set vlans vlan-id 20 l3-interface vlan20
admin@Switch2# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 10
admin@Switch2# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 20
admin@Switch2# set l3-interface vlan-interface vlan10 address 192.168.0.6 prefix-length 24
admin@Switch2# set l3-interface vlan-interface vlan20 address 10.10.20.10 prefix-length 24
```

Step2 Configure IS-IS basic function.

```
admin@Switch2# set protocols isis area-tag instance1 network-entity 12.0001.0000.0000.0002.00
admin@Switch2# set protocols isis area-tag instance1 interface vlan10 ipv4-routing
admin@Switch2# set protocols isis area-tag instance1 interface vlan20 ipv4-routing
```

Step3 Enable IP routing.

```
admin@Switch2# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@Switch2# commit
```

Switch 3

Step1 Configure the VLANs and VLAN interfaces.

```
admin@Switch3# set vlans vlan-id 20 l3-interface vlan20
admin@Switch3# set vlans vlan-id 30 l3-interface vlan30
admin@Switch3# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 20
admin@Switch3# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 30
admin@Switch3# set l3-interface vlan-interface vlan20 address 10.10.20.11 prefix-length 24
admin@Switch3# set l3-interface vlan-interface vlan30 address 192.168.1.6 prefix-length 24
```

Step2 Configure IS-IS basic function.

```
admin@Switch3# set protocols isis area-tag instance1 network-entity 34.0000.0000.0003.00
admin@Switch3# set protocols isis area-tag instance1 interface vlan20 ipv4-routing
admin@Switch3# set protocols isis area-tag instance1 interface vlan30 ipv4-routing
```

Step3 Enable IP routing.

```
admin@Switch3# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@Switch3# commit
```

Switch 4

Step1 Configure the VLANs and VLAN interfaces.

```
admin@Switch4# set vlans vlan-id 30 l3-interface vlan30
admin@Switch4# set interface gigabit-ethernet te-1/1/4 family ethernet-switching native-vlan-id 30
admin@Switch4# set l3-interface vlan-interface vlan30 address 192.168.1.5 prefix-length 24
```

Step2 Configure IS-IS basic function.

```
admin@Switch4# set protocols isis area-tag instance1 network-entity 34.0000.0000.0004.00
admin@Switch4# set protocols isis area-tag instance1 is-type level-1
admin@Switch4# set protocols isis area-tag instance1 interface vlan30 ipv4-routing
```

Step3 Enable IP routing.

```
admin@Switch4# set ip routing enable true
```

Step4 Commit the configurations.

```
admin@Switch4# commit
```

Verify the Configuration

- View the Link State Database (LSDB) information of IS-IS. Take Switch 1 and Switch 2 as an example. From the result, it can be seen that there are Level-1 and Level-2 Link-State databases on Switch 2.

```
admin@Switch1# run show isis database
Area instance1:
IS-IS Level-1 link-state database:
LSP ID                  PduLen  SeqNumber   Chksum  Holdtime  ATT/P/OL
localhost.00-00      *     74   0x00000004  0xa71c     773    0/0/0
    1 LSPs

admin@Switch2# run show isis database
Area instance1:
IS-IS Level-1 link-state database:
LSP ID                  PduLen  SeqNumber   Chksum  Holdtime  ATT/P/OL
localhost.00-00      *     84   0x00000005  0x6af2     917    1/0/0
    1 LSPs

IS-IS Level-2 link-state database:
LSP ID                  PduLen  SeqNumber   Chksum  Holdtime  ATT/P/OL
localhost.00-00      *     97   0x00000005  0x4785     906    0/0/0
PICOS.00-00               91   0x00000006  0xe911    1134    0/0/0
PICOS.6a-00               51   0x00000001  0xb1ab     677    0/0/0
    3 LSPs
```

- Display IS-IS routing information on switches. Take Switch 2 as an example.

```
admin@Switch2# run show isis route
Area instance1:
IS-IS L1 IPv4 routing table:

 Prefix          Metric  Interface  Nexthop  Label(s)
 -----------------------------------------------------
```

```
 10.10.20.0/24   0       -          -        -
 192.168.0.0/24  0       -          -        -

IS-IS L2 IPv4 routing table:

 Prefix          Metric  Interface  Nexthop      Label(s)
 -----------------------------------------------------------
 10.10.20.0/24   20      vlan20     10.10.20.11  -
 192.168.0.0/24  0       -          -            -
 192.168.1.0/24  20      vlan20     10.10.20.11  -
```

Configuration Example of Interaction Between IS-IS and BGP

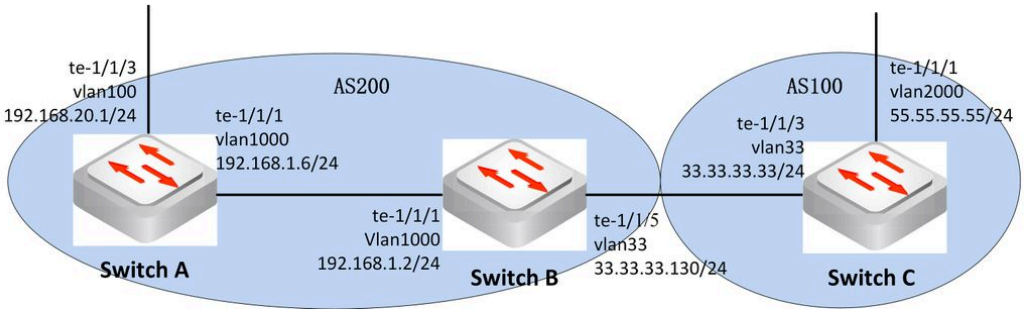
Configuring Switch B to Import Route between BGP and IS-IS
View IS-IS Route Table on Switch A

Networking Requirements

Figure 1. Configuration Example of Interaction Between IS-IS and BGP



As shown in **Figure 1**, there are three switches (Switch A, Switch B and Switch C) in this sample network. IS-IS routing protocol runs between Switch A and Switch B, and EBGP routing protocol runs between Switch B and Switch C. To enable communication between Switch A and Switch C, you need to configure to redistribute IS-IS routes to BGP routes, and BGP routes to IS-IS routes on Switch B.

Follow the configuration roadmap below to complete the configuration:

1. Configure VLAN interface and IP address for each interface to make the network reachable.
2. Enable IS-IS on Switch A and Switch B, and enable EBGP on Switch B and Switch C.
3. On Switch B, configure route redistribution between route protocol IS-IS and BGP.

Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 100 l3-interface vlan100
admin@SwitchA# set vlans vlan-id 1000 l3-interface vlan1000
admin@SwitchA# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 100
admin@SwitchA# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 1000
admin@SwitchA# set l3-interface vlan-interface vlan100 address 192.168.20.1 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan1000 address 192.168.1.6 prefix-length 24
```

Step2 Enable IS-IS for the network segment.

```
admin@SwitchA# set protocols isis area-tag instance1 network-entity 32.0001.0040.0220.0001.00
admin@SwitchA# set protocols isis area-tag instance1 interface vlan100 ipv4-routing
admin@SwitchA# set protocols isis area-tag instance1 interface vlan1000 ipv4-routing
```

Step3 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 1000 l3-interface vlan1000
admin@SwitchB# set vlans vlan-id 33 l3-interface vlan33
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 1000
admin@SwitchB# set interface gigabit-ethernet te-1/1/5 family ethernet-switching native-vlan-id 33
admin@SwitchB# set l3-interface vlan-interface vlan1000 address 192.168.1.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan33 address 33.33.33.130 prefix-length 24
```

Step2 Enable IS-IS for the specified network segment.

```
admin@SwitchB# set protocols isis area-tag instance1 network-entity 32.0001.0040.0220.0002.00
admin@SwitchB# set protocols isis area-tag instance1 interface vlan33 ipv4-routing
admin@SwitchB# set protocols isis area-tag instance1 interface vlan1000 ipv4-routing
```

Step3 Configure EBGP connection between Switch B and Switch C.

```
admin@SwitchB# set protocols bgp local-as 200
admin@SwitchB# set protocols bgp router-id 2.2.2.2
admin@SwitchB# set protocols bgp ebgp-requires-policy false
admin@SwitchB# set protocols bgp ipv4-unicast network 192.168.1.0/24
admin@SwitchB# set protocols bgp neighbor 33.33.33.33 remote-as 100
```

Step4 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step5 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN interface.

```
admin@SwitchC# set vlans vlan-id 33 l3-interface vlan33
admin@SwitchC# set vlans vlan-id 2000 l3-interface vlan2000
admin@SwitchC# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 33
admin@SwitchC# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 2000
admin@SwitchC# set l3-interface vlan-interface vlan33 address 33.33.33.33 prefix-length 24
admin@SwitchC# set l3-interface vlan-interface vlan2000 address 55.55.55.55 prefix-length 24
```

Step2 Configure EBGP connection between Switch B and Switch C.

```
admin@SwitchC# set protocols bgp local-as 100
```

```
admin@SwitchC# set protocols bgp router-id 3.3.3.3
admin@SwitchC# set protocols bgp ebgp-requires-policy false
admin@SwitchC# set protocols bgp ipv4-unicast network 55.55.55.0/24
admin@SwitchC# set protocols bgp neighbor 33.33.33.130 remote-as 200
```

Step3 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step4 Commit the configuration.

```
admin@SwitchC# commit
```

View IS-IS Route Table on Switch A

- On Switch A, use command **run show isis route** to check IS-IS route table, the route 55.55.55.0/24 does not exist.

```
admin@SwitchA# run show isis route
Area instance1:
IS-IS L1 IPv4 routing table:

 Prefix          Metric  Interface  Nexthop      Label(s)
 ------------------------------------------------------------
 33.33.33.0/24   20      vlan1000   192.168.1.2  -
 192.168.1.0/24  20      vlan1000   192.168.1.2  -

IS-IS L2 IPv4 routing table:

 Prefix          Metric  Interface  Nexthop      Label(s)
 ------------------------------------------------------------
 33.33.33.0/24   20      vlan1000   192.168.1.2  -
 192.168.1.0/24  20      vlan1000   192.168.1.2  -
```

Configuring Switch B to Import Route between BGP and IS-IS

```
admin@SwitchB# set protocols isis area-tag instance1 redistribute ipv4-routing bgp level-1
admin@SwitchB# set protocols isis area-tag instance1 redistribute ipv4-routing bgp level-2
admin@SwitchB# set protocols bgp ipv4-unicast redistribute isis
admin@SwitchB# commit
```

View IS-IS Route Table on Switch A

- On Switch A, use command **run show isis route** to view IS-IS route table again, route 55.55.55.0/24 has been inserted to Switch A's routing table with metric value 10. Switch A and Switch C can communicate with each other now.

```
admin@SwitchA# run show isis route
Area instance1:
IS-IS L1 IPv4 routing table:

 Prefix          Metric  Interface  Nexthop      Label(s)
 ------------------------------------------------------------
 33.33.33.0/24   20      vlan1000   192.168.1.2  -
 55.55.55.0/24   10      vlan1000   192.168.1.2  -
 192.168.1.0/24  20      vlan1000   192.168.1.2  -

IS-IS L2 IPv4 routing table:

 Prefix          Metric  Interface  Nexthop      Label(s)
```

```
-------------------------------------------------------------
33.33.33.0/24   20      vlan1000   192.168.1.2  -
55.55.55.0/24   10      vlan1000   192.168.1.2  -
192.168.1.0/24  20      vlan1000   192.168.1.2  -
```

IP Multicast Routing Configuration

IGMP Configuration

In admin@XorPlus, IGMPv1/v2/v3 is supported.

Configuring an IGMP Interface

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan2 address 10.10.60.10 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan3 address 10.10.61.10 prefix-length 24
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set protocols igmp interface vlan2
admin@XorPlus# set protocols igmp interface vlan3
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show igmp interface
Interface   State    Address    V   Querier   QuerierIp      QueryTimer   Uptime
vlan2        up     10.10.60.10 2   local     10.10.60.10    00:00:22     00:00:09
vlan3        up     10.10.61.10 2   local     10.10.61.10    --:--:--     00:36:29
```

Configuring IGMP Parameters for the IGMP Interface

```
admin@XorPlus# set protocols igmp interface vlan2 query-interval 4
admin@XorPlus# set protocols igmp interface vlan2 query-max-response-time 100
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring an IGMPv3 Interface

You can configure IGMPv3 in a specified interface.

```
admin@XorPlus# set protocols igmp interface vlan3 version 3
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show igmp interface
Interface State Address     V   Querier QuerierIp    QueryTimer   Uptime
vlan2     up    10.10.60.10 2   local   10.10.60.10  00:00:22     00:00:09
vlan3     up    10.10.61.10 2   local   10.10.61.10  --:--:--     00:36:29
```

Joining and Leaving a Group and Displaying Group Information

If you send an IGMPv2 report to VLAN 2 and an IGMPv3 report to VLAN 3, for example, you can display the group information of the switch. You should not have to worry about 224.0.0.2, 224.0.0.22, etc., which are used for the system (e.g. OSPF, RIP).

```
admin@XorPlus# run show igmp groups
Total IGMP groups: 3
Watermark warn limit(Not Set): 0
```

```
Interface        Group           Mode Timer    Srcs V Uptime
vlan2            224.0.0.2       INCL --:--:--    1 2 01:12:11
vlan2            224.0.0.22      INCL --:--:--    1 2 01:12:11
vlan2            238.255.0.1     INCL --:--:--    1 2 01:12:11
vlan3            224.0.0.2       INCL --:--:--    1 3 01:33:28
vlan3            224.0.0.22      INCL --:--:--    1 3 01:33:28
vlan3            238.255.0.2     INCL --:--:--    1 3 01:33:28
```

If you send a leaving message for the above group, the specified group will be removed.

```
admin@XorPlus# run show igmp groups
Total IGMP groups: 2
Watermark warn limit(Not Set): 0
Interface        Group           Mode Timer    Srcs V Uptime
vlan2            224.0.0.2       INCL --:--:--    1 2 01:22:11
vlan2            224.0.0.22      INCL --:--:--    1 2 01:22:11
vlan3            224.0.0.2       INCL --:--:--    1 3 01:43:28
vlan3            224.0.0.22      INCL --:--:--    1 3 01:43:28
```

PIM Configuration Guide

This section describes how to configure Protocol Independent Multicast (PIM).

> **NOTE:**
> PIM protocol supports VRF.

- Introduction of PIM
- Configuring PIM-SM
- Example for Configuring PIM-SM
- Example for Configuring PIM-SSM
- Example for Configuring PIM over GRE Tunnel
- RFC List of PIM
- Example for Configuring Basic PIM-SM

Introduction of PIM

Protocol Independent Multicast (PIM) as the name suggests, is a multicast routing protocol independent of the unicast routing protocol. It indicates that PIM does not need to maintain dedicated unicast routing information. As a multicast routing solution, it directly uses the routing information of the unicast routing table to perform the Reverse Path Forwarding (RPF) check on the multicast packets. If the RPF check passed, a multicast routing entry and a forwarding table is built for multicast packets forwarding.

As a multicast routing protocol in an IPv4 network, PIM is mainly used to send multicast data streams to multicast devices which is connected to the group members with multicast data requests, implementing route lookup and forwarding of multicast data.

PIM protocol includes two modes: Sparse Mode (PIM-SM) and Dense Mode (PIM-DM). Note that currently, PICOS only supports PIM-SM mode.

This guide provides a brief description and the configuration procedure about PIM-SM in the following section. For details about the working principle of PIM-SM, please refer to RFC standard in 1.4 RFC List.

> **NOTE:**
> - PIM protocol supports VRF.
> - If PIM is configured on a L3 interface added to a VRF, when delete the VRF or the L3 interface after delete PIM, and then roll back to the original configuration, PIM will not work with no multicast routes generated.

PIM Multicast Routing and Forwarding Table

In the implementation of the PIM multicast protocol, two multicast routing forwarding tables including the Multicast Routing Information Base (MRIB) and Multicast Forwarding Table are used for multicast data forwarding.

- **Multicast Routing Information Base (MRIB)**

MRIB in PIM-SM protocol provides the next-hop route along a multicast-capable path to each destination subnet which indicates the path that a multicast data packet would take from its origin subnet to the router that has the MRIB information. The MRIB is used to determine the next-hop neighbor to which any PIM Join/Prune message is sent. Data flows along the reverse path of the Join messages. You can use **run show pim mrib** command to view the detail information of PIM MRIB.

- **Multicast Forwarding Table**

Multicast Forwarding Table is directly used to control the forwarding of multicast packets. The PIM protocol contains two forwarding entries: (S, G) forwarding entries or (*, G) forwarding entries. S indicates a multicast source, G indicates a multicast group, and * indicates all the Source.

  - The (S, G) forwarding entry is mainly used to build an SPT tree in the PIM network.
  - The (*, G) forwarding entry is mainly used to build an RPT tree in the PIM network.

You can use the **run show pim mfc** command to view the Multicast Forwarding Table information. The information used to guide multicast data forwarding in Multicast Forwarding Table are as follows:

  - Multicast source address.
  - Multicast group address.
  - Incoming interface: The interface on the local router that receives multicast data.
  - Outgoing interfaces: The interface that forwards multicast data out.

Static RP and Dynamic RP

> When the PIM-SM Bootstrap Router mechanism is enabled to dynamically elect an RP, the PICOS switch can receive C-RP advertisement messages sent by other PIM switches. It can then calculate and compare these messages to elect the RP for a specific group from multiple C-RPs. However, the PICOS switch itself does not participate in the election as a BSR or dynamic RP.

Rendezvous Point (RP) is an important PIM-SM router which functions as a conjunction point of the PIM multicast network. RP receives and processes the PIM Register packets from the multicast Source and PIM Join message from the group member to build the PIM Multicast Routing and Forwarding Table for multicast data forwarding.

All PIM routers in the network should know the address of the RP. An RP can serve for multiple multicast Groups at the same time, but a multicast Group can be mapping to one RP. On Pica8 switch, there is two types of RP: static RP and dynamic RP.

- **Static RP**: Statically configured RP by user to specify the location of the RP. The users should configure the same static RP information (including RP address, RP priority and hash mask length) on all PIM-enabled routers in the network.
- **Dynamic RP**: PIM BootStrap Router mechanism is utilized to dynamically elect an RP for the PIM-SM domain. When dynamic RP is deployed, BSR router is responsible for collecting Candidate RP (C-RP) information and summarizing C-RP information into an RP-set. The RP-set is then encapsulated in a BootStrap message and advertised to all the devices in the PIM-SM domain. When received the RP-set, each router in the network selects a corresponding RP for a specific multicast group from among multiple C-RPs provided by the RP-Set.

A PIM-SM router must either run the PIM-SM BootStrap Router mechanism to dynamically elect an RP, or have some RPs configured as static RP settings.

Both the static RP and the dynamic RP participate in the RP election if both are configured. PIM routers elects an RP from multiple C-RPs and the static RPs according to the following rules:

1. The C-RP or static RP with highest priority wins.
2. If multiple C-RPs or static RPs have the same priority, the C-RP or static RP with the largest hash value wins.
3. If all the preceding factors are the same, the C-RP or static RP with the largest address wins.

PIM-SM and PIM-SSM

PIM-SM is widely used in large-scale networks with sparsely distributed group members. The key mechanisms of PIM-SM include Neighbor Discovery, DR Election, RP Discovery, RPT Tree Building, Multicast Source Registration, SPT Switchover and Assertion.

PIM Source-Specific Multicast (PIM-SSM) model uses part of the PIM-SM mode technology in practical deployment to provide a solution for source-specific multicast. It maintains the relationship between the host and the router through IGMPv3.

Since the receiver has already known the location of the multicast source in PIM-SSM mode, there is no need for an RP in the SSM model, no need to build an RPT tree, and the multicast source registration process is not required. The PIM-SSM model uses three working mechanisms of PIM-SM: Neighbor Discovery, DR Election and SPT Tree Building to implement multicast forwarding tasks in the PIM domain.

NOTE:

Enable IGMPv3 on the L3 interfaces of the PIM router connected to the receiver when configuring PIM-SSM.

Configuring PIM-SM

Configuration Notes

- Enable IP routing function before using this feature, for details please refer to Configuring IP Routing.
- Currently, only one scope zone is supported, configuring multiple multicast scope zones is not supported.、
- Only PIM-SM and PIM-SSM are supported, PIM-DM is not supported.

Procedure

Step1 Configure Layer 3 interface. PIM-SM can be enabled on VLAN interface or routed interface.

- Configure VLAN interface.

  a) Configure VLAN ID.

  set vlans vlan-id <*vlan-id*>

  b) Configure the interface to VLAN.

  set interface gigabit-ethernet <*port*> **family ethernet-switching native-vlan-id** <*vlan-id*>

  c) Configure the IP address of the VLAN.

  set l3-interface vlan-interface <*interface-name*> **address** <*address*> **prefix-length** <*number*>

  d) Associate a Layer 3 interface with a VLAN.

  set vlans vlan-id <vlan-id> **l3-interface** <*interface-name*>

- Configure routed interface.

  a) Enable routed interface.

  set interface gigabit-ethernet <*interface-name*> **routed-interface enable** <**true | false**>

  set interface gigabit-ethernet <*interface-name*> **routed-interface name** <*string*>

  b) Configure reserved-vlan for the routed interface.

  set vlans reserved-vlan <*reserved-vlan*>

  c) (Optional) Create the sub-interface and add it into a VLAN.

  set interface aggregate-ethernet <*interface-name*> **routed-interface sub-interface** <*sub-interface-name*> **vlan-id** <*vlan-id*>

  d) Configure the IP address of the routed interface.

  set l3-interface routed-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*prefix-number*>

Step2 Enable IP routing.

set ip routing enable <**true | false**>

Step3 Enable IGMP on the L3 interfaces of the PIM router connected to the receiver.

set protocols igmp interface <*interface-name*>

Step4 Enable PIM-SM on the L3 interfaces.

set protocols pim interface <*interface-name*> **sm**

Step5 Configure RPs.

> - When both static RP and dynamic RP are configured, the static RP is given priority and selected as the RP.
> - When the PIM-SM Bootstrap Router mechanism is enabled to dynamically elect an RP, the PICOS switch can receive C-RP advertisement messages sent by other PIM switches. It can then calculate and compare these messages to elect the RP for a specific group from multiple C-RPs. However, the PICOS switch itself does not participate in the election as a BSR or dynamic RP.

- Configure static RPs.

  a) Configure the IP address of a static RP.

  set protocols pim rp <*rp-address*>

  b) Assign the group prefix address served by the static RP.

  set protocols pim rp <*rp-address*> **group** <*IPv4Net*>

- Enable dynamic RPs.

  a) Enable the PIM interface to process bootstrap messages.

  set protocols pim interface <*interface-name*> **bsm** <**enable** | **disable**>

  b) Enable the PIM interface to process unicast bootstrap messages.

  set protocols pim interface <*interface-name*> **unicast-bsm** <**enable** | **disable**>

Step6 (Optional) Adjust the PIM protocol parameters in Hello message.

set protocols pim interface <*interface-name*> **drpriority** <*dr-priority*>

set protocols pim interface <*interface-name*> **hello interval**<*interval*>

Step7 (Optional) Configure SPT switchover function.

a) Enable the SPT switchover function.

set protocols pim spt-switchover

b) Configure the SPT Switchover filter list to filter updates to/from this neighbor.

set protocols pim spt-switchover infinity-and-beyond prefix-list <*text*>

Step8 Commit the configurations.

commit

Example for Configuring PIM-SM

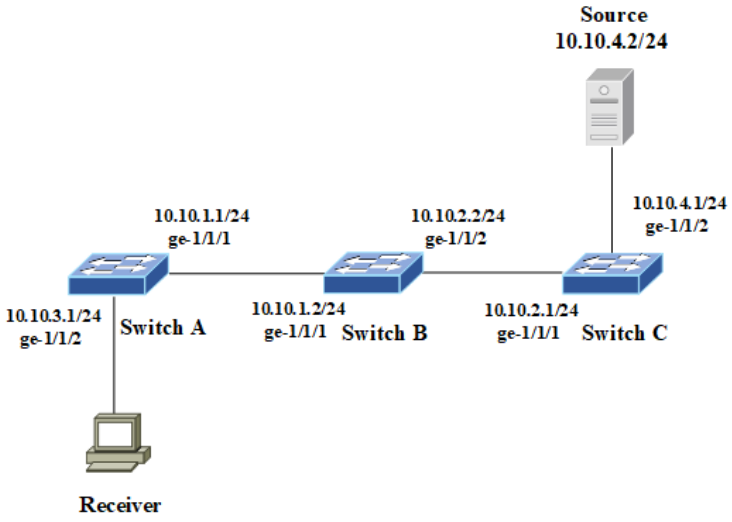
- Networking Requirements
- Procedure
  - Switch A
  - Switch B

Networking Requirements

In the following topology, a multicast Source sends the multicast traffic to the Receiver through Switch C, Switch B and Switch A.

- Configure ge-1/1/2 as an IGMP interface on Switch A which is connected to the Receiver.
- In this example, the static route will be used to make the switches in PIM-SM domain can communicate with each other.

Figure 1. PIM-SM Multicast Routing Configuration



Procedure

Switch A

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.3.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable IGMP on the L3 VLAN interfaces of the PIM router connected to the receiver.

```
admin@XorPlus# set protocols igmp interface vlan-3
```

Step4 Enable PIM-SM on the L3 VLAN interfaces.

```
admin@XorPlus# set protocols pim interface vlan-2 sm
admin@XorPlus# set protocols pim interface vlan-3 sm
```

Step5 Configure the VLAN interface vlan-2 on Switch A as the static RP.

```
admin@XorPlus# set protocols pim rp 10.10.1.1 group 224.0.0.0/8
```

Step6 Configure static routes to other switches.

```
admin@XorPlus# set protocols static route 10.10.2.0/24 next-hop 10.10.1.2
admin@XorPlus# set protocols static route 10.10.4.0/24 next-hop 10.10.1.2
```

Step7 Commit the configurations.

```
admin@Xorplus# commit
```

Step8 Verify the configuration.

- Run **run show pim interface** command to show information about all interfaces on which PIM-SM is enabled.

```
admin@XorPlus# run show pim interface
Interface         State          Address  PIM Nbrs           PIM DR  FHR IfChannels
vlan-2              up       10.10.1.1         1            local    0          1
vlan-3              up       10.10.3.1         2            local    0          0
```

- Run **run show igmp interface** command to show IGMP interface information.

```
admin@XorPlus# run show igmp interface
Interface State Querier Timeout Version Groups
------------ -------- --------------- --------- --------- --------

vlan-2 DISABLED 10.10.1.1 None 2 0
vlan-3 UP 10.10.3.1 None 2 3

Interface         State          Address  V  Querier  Query Timer    Uptime
vlan-2              up       10.10.1.1    3    local     00:00:40  02:13:12
vlan-3             mtrc      10.10.3.1    3    other     --:--:--  00:36:29
```

Switch B

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.1.2 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.2.2 prefix-length 24
admin@XorPlus# set l3-interface loopback lo address 7.6.5.3 prefix-length 32
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable PIM-SM on the L3 VLAN interfaces.

```
admin@XorPlus# set protocols pim interface vlan-2 sm
admin@XorPlus# set protocols pim interface vlan-3 sm
```

Step4 Configure the VLAN interface vlan-2 on Switch A as the static RP.

```
admin@XorPlus# set protocols pim rp 10.10.1.1 group 224.0.0.0/8
```

Step5 Commit the configuration.

```
admin@Xorplus# commit
```

Switch C

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.2.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.4.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable PIM-SM on the L3 VLAN interfaces.

```
admin@XorPlus# set protocols pim interface vlan-2 sm
admin@XorPlus# set protocols pim interface vlan-3 sm
```

Step4 Configure the VLAN interface vlan-2 on Switch A as the static RP.

```
admin@XorPlus# set protocols pim rp 10.10.1.1 group 224.0.0.0/8
```

Step5 Configure static routes to other switches.

```
admin@XorPlus#set protocols static route 10.10.1.0/24 next-hop 10.10.2.2
admin@XorPlus#set protocols static route 10.10.3.0/24 next-hop 10.10.2.2
```

Step6 Commit the configuration.

```
admin@Xorplus# commit
```

Step7 Verify the configuration.

- Run **run show pim interface** command to show information about all interfaces on which PIM-SM is enabled.

```
admin@XorPlus# run show pim interface
Interface         State          Address  PIM Nbrs           PIM DR  FHR IfChannels
vlan-2               up       10.10.2.1         0           local    0          1
vlan-3               up       10.10.4.1         0           local    0          0
```

Example for Configuring PIM-SSM

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Switch C

Networking Requirements

PIM-SM is widely used on large-scale networks with sparsely distributed group members. The key mechanisms of PIM-SM include neighbor discovery, DR election, RP discovery, RPT tree building, multicast source registration, SPT switchover and assertion.

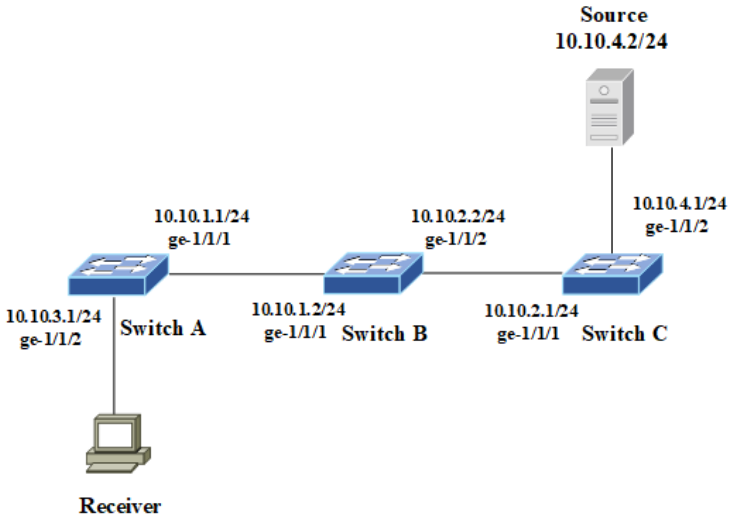
The PIM Source-Specific Multicast (PIM-SSM) model provides a solution for source-specific multicast. It maintains the relationship between the host and the router through IGMPv3 and uses part of the PIM-SM mode technology in practical deployment of the PIM-SSM model.

Since the receiver has already known the location of the multicast source in PIM-SSM mode, there is no need for an RP in the SSM model, no need to build an RPT tree, and the multicast source registration process is not required. The PIM-SSM model uses three working mechanisms: PM-SM neighbor discovery, DR election and SPT tree building to implement multicast forwarding tasks in the PIM domain.

In the following topology, a multicast Source sends the multicast traffic to the Receiver through Switch A, Switch B and Switch C.

- Configure ge-1/1/2 as an IGMPv3 interface on Switch A which connects to the Receiver.
- In this example, the static route in the RIB will be used by PIM-SSM.
- Enable IGMPv3 on the L3 VLAN interfaces of the PIM router connected to the receiver.
- No need for RP configurations in PIM-SSM.

Figure 1. PIM-SSM Multicast Routing Configuration



Procedure

Switch A

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.1.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.3.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable IGMPv3 on the L3 VLAN interfaces of the PIM router connected to the receiver.

```
admin@XorPlus# set protocols igmp interface vlan-3 version 3
```

Step4 Enable PIM-SM on the L3 VLAN interfaces.

```
admin@XorPlus# set protocols pim interface vlan-2 sm
admin@XorPlus# set protocols pim interface vlan-3 sm
```

Step5 Configure static routes to other switches.

```
admin@XorPlus#set protocols static route 10.10.2.0/24 next-hop 10.10.1.2
admin@XorPlus#set protocols static route 10.10.4.0/24 next-hop 10.10.1.2
```

Step6 Commit the configuration.

```
admin@Xorplus# commit
```

Step7 Verify the configuration.

- Run **run show pim interface** command to show information about all interfaces on which PIM-SM is enabled.

```
admin@XorPlus# run show pim interface
Interface         State          Address  PIM Nbrs           PIM DR  FHR IfChannels
vlan-2               up        10.10.1.1         0            local    0          0
vlan-3               up        10.10.3.1         0            local    0          0
```

- Run **run show igmp interface** command to show IGMP interface information.

```
admin@XorPlus# run show igmp interface
Interface         State          Address  V  Querier  Query Timer    Uptime
vlan-2               up        10.10.1.1  3    local     00:00:40  02:13:12
vlan-3             mtrc        10.10.3.1  3    other     --:--:--  00:36:29
```

Switch B

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.1.2 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.2.2 prefix-length 24
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable PIM-SM on the L3 VLAN interfaces.

```
admin@XorPlus# set protocols pim interface vlan-2 sm
admin@XorPlus# set protocols pim interface vlan-3 sm
```

Step4 Configure static routes to other switches.

```
admin@XorPlus#set protocols static route 10.10.3.0/24 next-hop 10.10.1.1
admin@XorPlus#set protocols static route 10.10.4.0/24 next-hop 10.10.2.1
```

Step5 Commit the configuration.

```
admin@Xorplus# commit
```

Step6 Verify the configuration.

- Run **run show pim interface** command to show information about all interfaces on which PIM-SM is enabled.

```
admin@XorPlus# run show pim interface
```

```
Interface         State          Address  PIM Nbrs           PIM DR  FHR IfChannels
vlan-2               up        10.10.1.2         0            local    0          0
vlan-3               up        10.10.2.2         0            local    0          0
```

- Run **run show igmp interface** command to show IGMP interface information.

```
admin@XorPlus# run show igmp interface
Interface         State          Address  V  Querier  Query Timer    Uptime
vlan-2               up        10.10.1.2  2    local     00:00:40  02:13:12
vlan-3             mtrc        10.10.2.2  2    other     --:--:--  00:36:29
```

Switch C

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set vlans vlan-id 3 l3-interface vlan-3
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 3
admin@XorPlus# set l3-interface vlan-interface vlan-2 address 10.10.2.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan-3 address 10.10.4.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable PIM-SM on the L3 VLAN interfaces.

```
admin@XorPlus# set protocols pim interface vlan-2 sm
admin@XorPlus# set protocols pim interface vlan-3 sm
```

Step4 Configure static routes to other switches.

```
admin@XorPlus#set protocols static route 10.10.1.0/24 next-hop 10.10.2.2
admin@XorPlus#set protocols static route 10.10.3.0/24 next-hop 10.10.2.2
```

Step5 Commit the configuration.

```
admin@Xorplus# commit
```

Step6 Verify the configuration.

- Run **run show pim interface** command to show information about all interfaces on which PIM-SM is enabled.

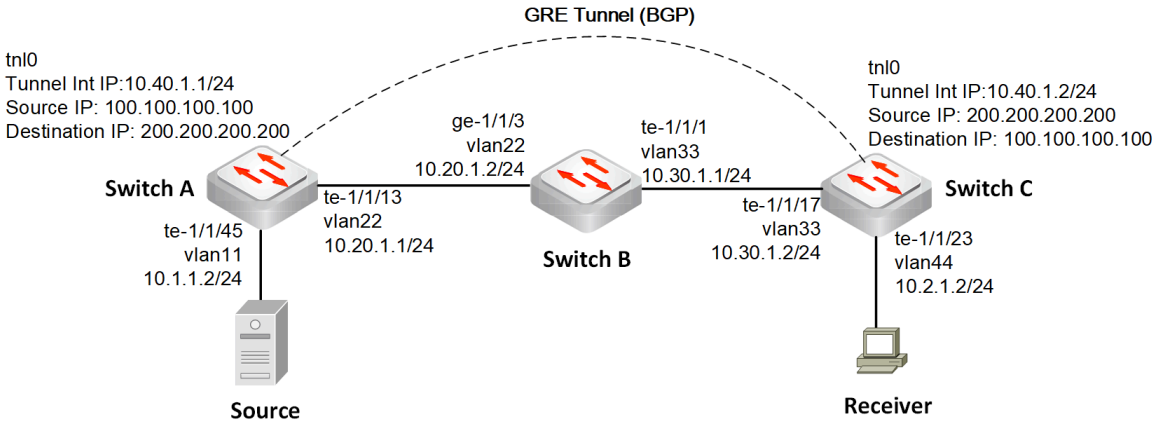
```
admin@XorPlus# run show pim interface
Interface         State          Address  PIM Nbrs           PIM DR  FHR IfChannels
vlan-2               up        10.10.2.1         0            local    0          0
vlan-3               up        10.10.4.1         0            local    0          0
```

Example for Configuring PIM over GRE Tunnel

- Networking Requirements
- Procedure
  - Switch A
  - Switch B
  - Switch C
  - Verifying the Configuration

Networking Requirements

Figure 1. PIM over GRE Tunnel Configuration Example



As shown in **Figure 1**, multicast services are deployed in the network. Switch B does not support multicast protocols, so multicast traffic needs to be transmitted between Switch A and Switch C through a GRE tunnel.

Follow the configuration roadmap below to configure PIM over GRE tunnel.

1. Run OSPF route protocol on Switch A, Switch B and Switch C for underlay communication.
2. Create GRE tunnel interfaces on Switch A and Switch C to establish a GRE tunnel; Run BGP route protocol on GRE tunnel interfaces.
3. Enable PIM function on the GRE tunnel interfaces to enable the transmission of multicast packets by the GRE tunnel.

Procedure

Switch A

Step1 Configure VLAN interface.

```
admin@SwitchA# set vlans vlan-id 11 l3-interface vlan11
admin@SwitchA# set vlans vlan-id 22 l3-interface vlan22
admin@SwitchA# set interface gigabit-ethernet te-1/1/45 family ethernet-switching native-vlan-id 11
admin@SwitchA# set interface gigabit-ethernet te-1/1/13 family ethernet-switching native-vlan-id 22
admin@SwitchA# set l3-interface loopback lo address 100.100.100.100 prefix-length 32
admin@SwitchA# set l3-interface vlan-interface vlan11 address 10.1.1.2 prefix-length 24
admin@SwitchA# set l3-interface vlan-interface vlan22 address 10.20.1.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@SwitchA# set ip routing enable true
```

Step3 Configure OSPF route protocol for underlay communication.

```
admin@SwitchA# set protocols ospf router-id 1.1.1.1
admin@SwitchA# set protocols ospf network 10.20.1.0/24 area 0
admin@SwitchA# set protocols ospf network 100.100.100.100/32 area 0
```

Step4 Configure GRE tunnel name, IP, source IP, destination IP etc.

```
admin@SwitchA# set l3-interface tunnel tnl0 address 10.40.1.1 prefix-length 24
admin@SwitchA# set l3-interface tunnel tnl0 tunnel-mode gre-ip
```

```
admin@SwitchA# set l3-interface tunnel tnl0 source 100.100.100.100
admin@SwitchA# set l3-interface tunnel tnl0 destination 200.200.200.200
```

Step5 Configure BGP route protocol for the GRE tunnel.

```
admin@SwitchA# set protocols bgp local-as 100
admin@SwitchA# set protocols bgp ebgp-requires-policy false
admin@SwitchA# set protocols bgp neighbor 10.40.1.2 remote-as 200
admin@SwitchA# set protocols bgp ipv4-unicast network 10.1.1.0/24
```

Step6 Enable PIM on the GRE tunnel interface, configure Switch A's GRE tunnel interface as the static RP.

```
admin@SwitchA# set protocols pim interface vlan11 sm
admin@SwitchA# set protocols pim interface tnl0 sm
admin@SwitchA# set protocols pim rp 10.40.1.1 group 225.0.0.0/8
```

Step7 Commit the configuration.

```
admin@SwitchA# commit
```

Switch B

Step1 Configure VLAN interface.

```
admin@SwitchB# set vlans vlan-id 22 l3-interface vlan22
admin@SwitchB# set vlans vlan-id 33 l3-interface vlan33
admin@SwitchB# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 22
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 33
admin@SwitchB# set l3-interface vlan-interface vlan22 address 10.20.1.2 prefix-length 24
admin@SwitchB# set l3-interface vlan-interface vlan33 address 10.30.1.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@SwitchB# set ip routing enable true
```

Step3 Configure OSPF for the connections between Switch A, Switch B and Switch C.

```
admin@SwitchB# set protocols ospf router-id 2.2.2.2
admin@SwitchB# set protocols ospf network 10.30.1.0/24 area 0
admin@SwitchB# set protocols ospf network 10.20.1.0/24 area 0
```

Step4 Commit the configuration.

```
admin@SwitchB# commit
```

Switch C

Step1 Configure VLAN interface.

```
admin@SwitchC# set vlans vlan-id 33 l3-interface vlan33
admin@SwitchC# set vlans vlan-id 44 l3-interface vlan44
admin@SwitchC# set interface gigabit-ethernet te-1/1/17 family ethernet-switching native-vlan-id 33
admin@SwitchC# set interface gigabit-ethernet te-1/1/23 family ethernet-switching native-vlan-id 44
admin@SwitchC# set l3-interface loopback lo address 200.200.200.200 prefix-length 32
admin@SwitchC# set l3-interface vlan-interface vlan33 address 10.30.1.2 prefix-length 24
admin@SwitchC# set l3-interface vlan-interface vlan44 address 10.2.1.2 prefix-length 24
```

Step2 Enable IP routing.

```
admin@SwitchC# set ip routing enable true
```

Step3 Configure OSPF routes for underlay communication.

```
admin@SwitchC# set protocols ospf router-id 3.3.3.3
admin@SwitchC# set protocols ospf network 10.30.1.0/24 area 0
```

```
admin@SwitchC# set protocols ospf network 200.200.200.200 area 0
```

Step4 Configure GRE tunnel name, IP, source IP, destination IP etc.

```
admin@SwitchC# set l3-interface tunnel tnl0 address 10.40.1.2 prefix-length 24
admin@SwitchC# set l3-interface tunnel tnl0 tunnel-mode gre-ip
admin@SwitchC# set l3-interface tunnel tnl0 source 200.200.200.200
admin@SwitchC# set l3-interface tunnel tnl0 destination 100.100.100.100
```

Step5 Configure BGP routes for the GRE tunnel.

```
admin@SwitchC# set protocols bgp local-as 200
admin@SwitchC# set protocols bgp ebgp-requires-policy false
admin@SwitchC# set protocols bgp neighbor 10.40.1.1 remote-as 100
admin@SwitchC# set protocols bgp ipv4-unicast network 10.2.1.0/24
```

Step6 Enable PIM on the GRE tunnel interface, configure Switch A's GRE tunnel interface as the static RP.

```
admin@SwitchC# set protocols pim interface vlan33 sm
admin@SwitchC# set protocols pim interface tnl0 sm
admin@SwitchC# set protocols pim rp 10.40.1.1 group 225.0.0.0/8
```

Step7 Configure the IGMP function of the connected receiver interface.

```
admin@SwitchC# set protocols igmp interface vlan44
```

Step8 Commit the configuration.

```
admin@SwitchC# commit
```

Verifying the Configuration

- After the configuration is complete, run **run show pim interface** to view the configuration and operation state of PIM on an interface.

```
admin@switchA# run show pim interface
Interface  State   Address     PIM Nbrs  PIM DR       FHR  IfChannels
 tnl0       up     10.40.1.1   1         10.40.1.2    0    2
 pimreg     up     0.0.0.0     0         local        0    0
 vlan11     up     10.1.1.2    0         local        0    0

admin@switchC# run show pim interface
Interface   State  Address      PIM Nbrs  PIM DR  FHR  IfChannels
 tnl0       up     10.40.1.2    1         local   0    0
 pimreg     up     0.0.0.0      0         local   0    0
 vlan44     up     10.2.1.2     0         local   0    2
```

- Run command **run show l3-interface tunnel** to display information about the GRE tunnel interface.

```
admin@SwitchA# run show l3-interface tunnel tnl0
tnl0        State:UP
            Tunnel Source: 100.100.100.100
            Tunnel Destnation: 200.200.200.200
            Tunnel protocol/transport: gre-ip
            Inet addr: 10.40.1.1
            Traffic statistics:
              5 sec input rate IPv4 1200 packets/sec, IPv6 0 packets/sec
              5 sec forwarding rate IPv4 80 packets/sec, IPv6 0 packets/sec
              IPv4 Input Packets.........................28
              IPv4 Forwarding Packets.....................5
              IPv6 Input Packets.........................0
              IPv6 Forwarding Packets.....................0
```

- Run commands **run show pim neighbor and run show pim rp-info** to that the PIM neighbor information and RP information have been generated correctly.

```
admin@switchA# run show pim neighbor
Interface  Neighbor     Uptime    Holdtime  DR Pri
tnl0       10.40.1.2    03:10:40  00:01:34  1
```

```
admin@switchA# run show pim rp-info
RP address   group/prefix-list  OIF        I am RP  Source  Group-Type
10.40.1.1    225.0.0.0/8       tnl0       yes      Static   ASM
```

- In this example, multicast source 10.1.1.5 sends multicast information to multicast group 225.0.0.2. The multicast routing table generated by PIM protocol can be viewed through the **run show mroute** command, which shows that multicast traffic can be transmitted through the GRE tunnel.

```
admin@switchA# run show mroute
IP Multicast Routing Table
Flags: S - Sparse, C - Connected, P - Pruned
       R - SGRpt Pruned, F - Register flag, T - SPT-bit set
 Source     Group      Flags   Proto  Input      Output     TTL  Uptime
 *          225.0.0.2   S      none   tnl0       none       0    --:--:--
 10.1.1.5   225.0.0.2   SFT    PIM    vlan11     pimreg     1    02:59:50
                               STAR              tnl0       1

admin@switchC# run show mroute
IP Multicast Routing Table
Flags: S - Sparse, C - Connected, P - Pruned
       R - SGRpt Pruned, F - Register flag, T - SPT-bit set
 Source     Group      Flags   Proto    Input      Output  TTL  Uptime
 *          225.0.0.2  SC      IGMP     tnl0       pimreg  1    03:07:44
                               IGMP               vlan44  1
 10.1.1.5   225.0.0.2  ST      STAR     tnl0       vlan44  1    03:07:17
```

RFC List of PIM

The following table lists the RFC documents related to PIM protocol.

RFC	Description
RFC3569	An Overview of Source-Specific Multicast (SSM)
RFC4601	Protocol Independent Multicast - Sparse Mode (PIM-SM): Protocol Specification (Revised)
RFC5059	Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
RFC4607	Source-Specific Multicast for IP

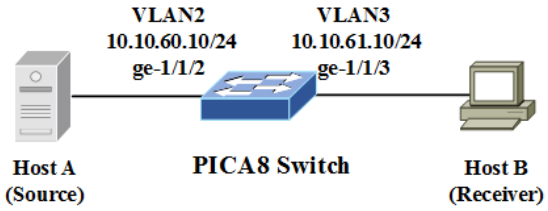
Example for Configuring Basic PIM-SM

- Networking Requirements
- Procedure
  - Host A (Source)
  - Host B (Receiver)
  - PICA8 Switch
- Verify the Configuration
- Verify End to End Connectivity between Host A and Host B

Networking Requirements

As shown in **Figure 1**, Host B wants to receive multicast data from Host A (Source) through the Pica8 Switch.

Figure1. User Configuration Topology of PIM-SM



Follow the configuration roadmap below to complete the configuration on PICA8 Switch.

1. Create the L3 VLAN interfaces.
2. Enable IGMP on the L3 VLAN interfaces.
3. Enable PIM-SM on L3 VLAN interfaces.

Procedure

Host A (Source)

- Add route on Host A to reach Host B.

  For example, use the following command on Linux system,

  sudo route add default gw 10.10.60.10 eth1

- Run iPerf on Host A.

Host B (Receiver)

- Add route on Host B to reach Host A.

  For example, use the following command on Linux system,

  sudo route add default gw 10.10.61.10 eth1

- Run iPerf on Host B.

PICA8 Switch

Step1 Create the L3 VLAN interfaces and assign VLAN to ports.

```
admin@Xorplus# set vlans vlan-id 2 l3-interface vlan2
admin@Xorplus# set l3-interface vlan-interface vlan2 address 10.10.60.10 prefix-length 24
admin@Xorplus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
admin@Xorplus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
```

```
admin@Xorplus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 3
admin@Xorplus# set vlans vlan-id 3 l3-interface vlan3
admin@Xorplus# set l3-interface vlan-interface vlan3 address 10.10.61.10 prefix-length 24
admin@Xorplus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 3
admin@Xorplus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@Xorplus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 2
```

Step2 Enable IP routing.

```
admin@Xorplus# set ip routing enable true
```

Step3 Enable IGMP on the L3 VLAN interfaces.

```
admin@Xorplus# set protocols igmp interface vlan2
admin@Xorplus# set protocols igmp interface vlan3
```

Step4 Enable PIM on the L3 VLAN interfaces and assign the group ID.

```
admin@Xorplus# set protocols pim interface vlan2 sm
admin@Xorplus# set protocols pim interface vlan3 sm
admin@Xorplus# set protocols pim rp 10.10.60.10 group 226.0.0.0/8
admin@Xorplus# set protocols pim rp 10.10.61.10 group 226.0.0.0/8
```

Step5 Configure the log level.

```
admin@Xorplus# set protocols pim traceoption trace
admin@Xorplus# set protocols igmp traceoption trace
admin@Xorplus# set system log-level trace
```

Step6 Commit the configurations.

```
admin@Xorplus# commit
```

Verify the Configuration

- Run the **run show igmp interface** command to check the IGMP interface configuration.

```
admin@XorPlus# run show igmp interface
Interface         State          Address  V  Querier          QuerierIp  Query Timer    Uptime
vlan2               up      10.10.60.10  3    local        10.10.60.10     00:00:14  00:04:28
vlan3               up      10.10.61.10  3    local        10.10.61.10     00:00:14  00:04:28
```

- Run the **run show pim interface** command to check the PIM configuration and status.

```
admin@Xorplus# run show pim interface
Interface  State  Address      PIM Nbrs  PIM DR  FHR  IfChannels
 pimreg     up     0.0.0.0      0         local   0    0
 vlan2      up     10.10.60.10  0         local   0    0
 vlan3      up     10.10.61.10  0         local   0    0
```

- - Run the **run show l3-interface brief** command to check the VLAN interface configuration.

```
admin@XorPlus# run show l3-interface brief
Interface          Vlan ID    Status    Addr                                        Description
---------------    -------    ------    ----------------------------------------    ---------------------------------------
vlan2              2          UP        10.10.60.10/24
                                        fe80::e81:3e20:15c:0/64
vlan3              3          UP        10.10.61.10/24
                                        fe80::e81:3e20:25c:0/64
```

- Run the **run show igmp group** command to show information about multicast group member ports.

```
admin@XorPlus# run show igmp groups
Interface        Group           Mode Timer    Srcs V Uptime
vlan2            224.0.0.2       INCL --:--:--    1 2 01:33:28
vlan2            224.0.0.13      INCL --:--:--    1 2 01:33:28
vlan2            224.0.0.22      INCL --:--:--    1 2 01:33:25
vlan3            224.0.0.2       INCL --:--:--    1 2 00:33:12
vlan3            224.0.0.13      INCL --:--:--    1 2 00:33:12
vlan3            224.0.0.22      INCL --:--:--    1 2 00:33:09
```

Verify End to End Connectivity between Host A and Host B

IGMP Snooping Configuration Guide

- Introduction to IGMP Snooping
- Enable Unknown Multicast Traffic Flooding with IGMP Snooping Enabled
- Configuring IGMP Snooping
- Example for Configuring Basic IGMP Snooping
- Example for Configuring IGMP Snooping with IGMP
- RFC List

Introduction to IGMP Snooping

IGMP snooping is designed to prevent hosts on a local network from receiving traffic for a multicast group they have not explicitly joined. If the switch does not run IGMP snooping, it broadcasts multicast packets at Layer 2. However, if IGMP snooping is enabled, switch forwards multicast packets only to specified host ports based on the Layer 2 multicast forwarding table.

IGMP snooping is a basic Layer 2 multicast function that forwards and controls the link layer multicast data. IGMP snooping runs on a Layer 2 multicast device and analyzes IGMP messages exchanged between a Layer 3 device and hosts to set up and maintain a Layer 2 multicast forwarding table. The Layer 2 multicast device forwards multicast packets based on this Layer 2 multicast forwarding table.

After a Layer 2 multicast forwarding table is set up, the Layer 2 multicast device searches the multicast forwarding table for outbound ports of multicast data packets according to the VLAN IDs and destination addresses (group addresses) of the packets. If there is an outbound port for the multicast data packet, the Layer 2 multicast device forwards the packet to the corresponding multicast group member port. If no outbound port is found, the multicast data packet will be dropped by the Layer 2 multicast device. However, the unknown multicast packet can be forwarded to other router ports except the one receiving the packet.

For more information about IGMP snooping, please refer to RFC 4541.

NOTE:

- PICOS supports IGMP snooping of IGMPv1, IGMPv2 and part of IGMPv3. However, PICOS supports IGMPv3 snooping without considering the additional "include source" or "exclude source" filtering in the packets. For example,
  - When receiving an IGMPv3 snooping report message, the switch parses the packet and records the member port and the multicast group as a Layer 2 forwarding entry without parsing and recording the particular source information.
  - When receiving an IGMPv3 snooping general query packet, the switch parses the packet and records the corresponding router port information. The original packet is then forwarded.
- The report message from the downstream hosts will be treated as IGMPv3 message only when the destination address is 224.0.0.22.
- If the report message from the downstream hosts is IGMPv3 message (Type value is 0x22), but the destination address in the message is not 224.0.0.22, PICOS will not record this member port to the Layer 2 forwarding table.
- In L2/L3, IGMPv2/IGMPv3 Snooping and IGMPv2 Snooping Querier are both supported.
- When the switch receives an unknown multicast, it will forward the data packet to the router port. The unknown multicast data packet refers to multicast data packets that do not exist in the IGMP snooping forwarding table.

Enable Unknown Multicast Traffic Flooding with IGMP Snooping Enabled

Background

When IGMP snooping is enabled, unknown multicast traffic can only be forwarded to the router ports by default. This causes the loss of protocol packets like mDNS or legacy protocols like AppleTalk since packets are not flooded to all ports of the VLAN. To solve this problem, users can enable the function of unknown multicast traffic flooding in a VLAN with IGMP snooping enabled.

The following command can be used:

set protocols igmp-snooping vlan-id <*vlan-id*> **unregistered flood-all** <**true | false**>

When set to true, the function is enabled. Unknown multicast traffic can be flooded to all the ports in a VLAN with IGMP snooping enabled.

This function is disabled by default. Unknown multicast traffic can be forwarded to the router ports.

Examples

- Enable unknown multicast traffic flooding in a VLAN with IGMP snooping enabled.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 100 unregistered flood-all true
admin@Xorplus# commit
```

- Disable unknown multicast traffic flooding in a VLAN with IGMP snooping enabled.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 100 unregistered flood-all false
admin@Xorplus# commit
```

Configuring IGMP Snooping

Procedure

Step1 Enable the global IGMP snooping function.

set protocols igmp-snooping enable <**true** | **false**>

Step2 Enable the VLAN-based IGMP snooping function.

set protocols igmp-snooping vlan-id <*vlan-id*> **enable** <**true** | **false**>

NOTE:

To enable IGMP snooping, both global and VLAN-based IGMP snooping need to be configured.

- If only the global IGMP snooping is enabled, IGMP snooping in the VLAN is disabled by default. To enable IGMP snooping in a VLAN, you also need to enable the VLAN-based IGMP snooping function via **set protocols igmp-snooping vlan-id enable** command.
- After both global and VLAN-based IGMP snooping are enabled, it will take effect only on interfaces that have already been added to this VLAN enabled IGMP snooping.

Step3 Configure the number of times that the querier sends a group-specific query message.

set protocols igmp-snooping last-member-query-count <*last-member-query-count*>

Step4 Configure the interval that the querier sends a group-specific query message.

set protocols igmp-snooping last-member-query-interval <*last-member-query-interval*>

Step5 Configure the maximum response time for IGMP general query message.

set protocols igmp-snooping max-response-time <*max-response-time*>

Step6 Configure the interval of sending IGMP general queries.

set protocols igmp-snooping query-interval <*query-interval*>

Step7 Enable the membership report suppression function.

set protocols igmp-snooping report-suppression <**true | false**>

Step8 Configure the IGMP robustness coefficient.

set protocols igmp-snooping robustness-variable <*robustness-variable*>

Step9 Configure the aging time of dynamic router port.

set protocols igmp-snooping router-aging-time <*router-aging-time*>

Step10 Enable the fast leave function to allow member ports in a VLAN to quickly leave the multicast group.

set protocols igmp-snooping vlan-id <*vlan-id*> **fast-leave** <**true | false**>

Step11 Configure the querier in a VLAN.

a) Enable the querier function in a VLAN.

set protocols igmp-snooping vlan-id <*vlan-id*> **querier enable** <**true | false**>

b) Configure the IGMP snooping querier IP address.

set protocols igmp-snooping vlan-id <*vlan-id*> **querier address** <*querier-address*>

c) Configure the IGMP snooping querier version.

set protocols igmp-snooping vlan-id <*vlan-id*> **querier version** <*querier-version*>

d) Configure the IGMP snooping querier other-querier-timer.

set protocols igmp-snooping vlan-id <*vlan-id*> **querier other-querier-timer** <*other-querier-timer*>

Step12 Configure the interface as a static router port in the specified VLAN.

set protocols igmp-snooping vlan-id <*vlan-id*> **mrouter interface** <*interface-name*>

Step13 Configure a static member interface to the multicast group.

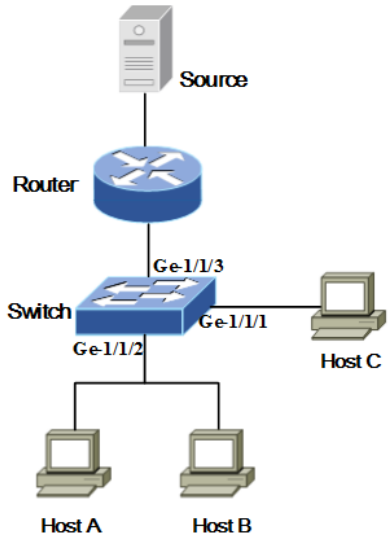
set protocols igmp-snooping vlan-id <*vlan-id*> **static group** <*group-address*> **interface** <*interface-name*>

Example for Configuring Basic IGMP Snooping

- Networking Requirments
- Procedure
- Verify the Configuration

Networking Requirments

Figure 1. IGMP Snooping Networking



As shown in Figure 1, Host A, Host B, and Host C connect to a multicast source through a Layer 2 Switch and a Layer 3 Router to receive multicast data from the Source device.

Perform the following procedures on the Switch to implement IGMP snooping:

- Create a VLAN and add interfaces Ge-1/1/1, Ge-1/1/2 and Ge-1/1/3 to the VLAN.
- Enable global and VLAN-based IGMP snooping function.
- Host C wants to receive multicast data from multicast group 238.255.0.1 stably for a long time, so configure the connecting interface Ge-1/1/1 as a static member port.
- To prevent aging of dynamic routing interfaces, configure Ge-1/1/3 as a static router port.

Procedure

Step1 Configure VLAN.

```
admin@XorPlus# set vlans vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching native-vlan-id 2
```

Step2 Enable the global IGMP snooping function.

```
admin@Xorplus# set protocols igmp-snooping enable true
```

Step3 Enable the VLAN-based IGMP snooping function.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 2 enable true
```

NOTE:

To enable IGMP snooping, both global and VLAN-based IGMP snooping need to be configured.

- If only the global IGMP snooping is enabled, IGMP snooping in the VLAN is disabled by default. To enable IGMP snooping in a VLAN, you also need to enable the VLAN-based IGMP snooping function via **set protocols igmp-snooping vlan-id enable** command.
- After both global and VLAN-based IGMP snooping are enabled, it will take effect only on interfaces that have already been added to this VLAN enabled IGMP snooping.

Step4 (Optional) Configure the number of times that the querier sends a group-specific query message.

```
admin@Xorplus# set protocols igmp-snooping last-member-query-count 2
```

Step5 (Optional) Configure the interval that the querier sends a group-specific query message.

```
admin@Xorplus# set protocols igmp-snooping last-member-query-interval 2
```

Step6 (Optional) Configure the maximum response time for IGMP general queries.

```
admin@Xorplus# set protocols igmp-snooping max-response-time 10
```

Step7 (Optional) Configure the interval of sending an IGMP general queries.

```
admin@Xorplus# set protocols igmp-snooping query-interval 60
```

Step8 (Optional) Enable the membership report suppression function.

```
admin@Xorplus# set protocols igmp-snooping report-suppression true
```

Step9 (Optional) Configure the IGMP robustness coefficient.

```
admin@Xorplus# set protocols igmp-snooping robustness-variable 2
```

Step10 (Optional) Configure aging time of dynamic router port.

```
admin@Xorplus# set protocols igmp-snooping router-aging-time 260
```

Step11 (Optional) Enable the fast leave function to allow member ports in a VLAN to quickly leave the multicast group.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 2 fast-leave true
```

Step12 (Optional) Configure the querier in the VLAN.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 2 querier enable true
admin@Xorplus# set protocols igmp-snooping vlan-id 2 querier address 192.168.12.100
admin@Xorplus# set protocols igmp-snooping vlan-id 2 querier version 2
admin@Xorplus# set protocols igmp-snooping vlan-id 2 querier other-querier-timer 120
```

Step13 Configure the interface as a static router port in the specified VLAN.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 2 mrouter interface ge-1/1/3
```

Step14 Configure a static member interface to the multicast group.

```
admin@Xorplus# set protocols igmp-snooping vlan-id 2 static group 238.255.0.1 interface ge-1/1/1
```

Verify the Configuration

- You can use the **run show igmp-snooping** command to view the configuration information of IGMP snooping.

```
admin@XorPlus# run show igmp-snooping
Global IGMP Snooping configuration:
----------------------------------------
IGMP snooping             : Enabled
Report suppression           : Enabled
Robustness variable          : 2
Router aging time            : 260
Max response time            : 10
Query interval               : 60
Last member query count      : 2
Last member query interval    : 2

admin@XorPlus# run show igmp-snooping vlan 2
Vlan 2:
```

```
-------------------------------------------
IGMP snooping                    : Enabled
IGMPv2 fast leave                  : Enabled
IGMP querier state                  : Enabled
IGMP querier source ip address        : 192.168.12.100
IGMP other querier timer             : 120
IGMP querier version                : 2
```

- You can use the run show igmp-snooping groups command to show information about multicast group member ports which is used for Layer 2 forwarding, namely, the Layer 2 forwarding table.

```
admin@XorPlus# run show igmp-snooping groups
Vlan      Group                Port List          Type
--------  ------------------      -----------------   ----------------------
 2      238.255.0.1              ge-1/1/1           Static
                                   ge-1/1/3           Mrouter
```

- You can use the **runshow igmp-snooping querier** command to show the configuration information and status of the querier.

```
admin@XorPlus# run show igmp-snooping querier vlan 2
Vlan 2:   IGMP switch querier status
-----------------------------------------------------------
admin state                    : Enabled
admin version                  : 2
source IP address              : 192.168.12.100
other querier timer            : 120
operational state              : Active
```

- You can use the **run show igmp-snooping mrouter** command to show the information about IGMP snooping router port.

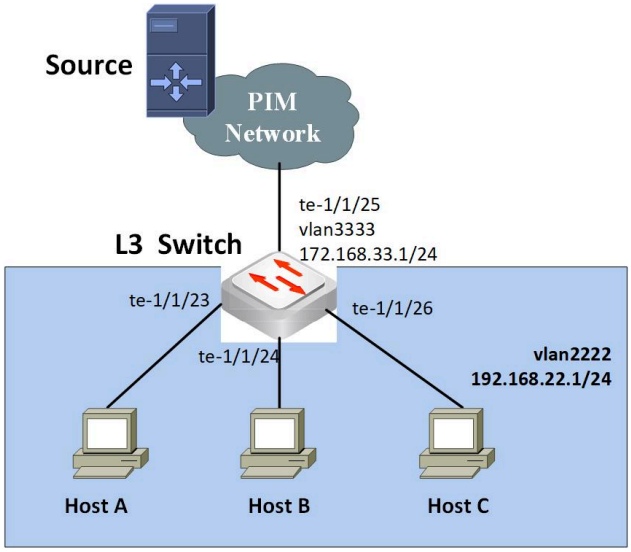
```
admin@XorPlus# run show igmp-snooping mrouter
Vlan      Ports            Type
--------    -------------     ---------
1         ge-1/1/3         Static
```

Example for Configuring IGMP Snooping with IGMP

- Networking Requirements
- Procedure
- Verify Configuration

Networking Requirements

Figure 1. Example for Configuring IGMP Snooping with IGMP



As shown in Figure 1, there are three hosts, Host A, Host B and Host C, in the same network segment, which are multicast receivers. They are connected to the multicast source through the L3 switch and PIM network. The multicast source sends data to the multicast group 224.1.1.1.

In this scenario, the necessary requirement needed to be satisfied is that multicast traffic from the source is forwarded only to the member ports that have sent the IGMP Report messages.

For example, in above figure, assuming that only Host A has sent IGMP Report messages to join the multicast group or replied to a query message, the multicast traffic sent from the source device is expected to be forwarded only to port te-1/1/23, instead of being flooded to all ports of the same VLAN.

To achieve above network requirement, complete the following configurations on the Layer 3 Switch:

- Enable PIM on all the VLAN interfaces (vlan2222 and vlan3333), configure IGMP on host-side VLAN interface (vlan2222).
- Enable IGMP snooping on host VLAN (VLAN ID: 2222).

IGMP snooping establishes and maintains a Layer 2 multicast forwarding table to guide multicast data to be forwarded on demand at the data link layer. By configuring IGMP snooping on the switch, multicast data will not be broadcast at Layer 2, but will be sent to the concerned receiver by the switch.

Procedure

Step1 Configure VLAN and VLAN interface.

```
admin@XorPlus# set vlans vlan-id 2222
admin@XorPlus# set vlans vlan-id 3333
admin@XorPlus# set interface gigabit-ethernet te-1/1/23 family ethernet-switching native-vlan-id 2222
admin@XorPlus# set interface gigabit-ethernet te-1/1/24 family ethernet-switching native-vlan-id 2222
admin@XorPlus# set interface gigabit-ethernet te-1/1/25 family ethernet-switching native-vlan-id 3333
admin@XorPlus# set interface gigabit-ethernet te-1/1/26 family ethernet-switching native-vlan-id 2222
admin@XorPlus# set vlans vlan-id 2222 l3-interface vlan2222
admin@XorPlus# set vlans vlan-id 3333 l3-interface vlan3333
admin@XorPlus# set l3-interface vlan-interface vlan3333 address 172.168.33.1 prefix-length 24
admin@XorPlus# set l3-interface vlan-interface vlan2222 address 192.168.22.1 prefix-length 24
```

Step2 Enable IP routing.

```
admin@XorPlus# set ip routing enable true
```

Step3 Enable PIM on all the VLAN interfaces, configure IGMP on host-side VLAN interface.

```
admin@XorPlus# set protocols pim interface vlan3333
admin@XorPlus# set protocols pim interface vlan2222
admin@XorPlus# set protocols igmp interface vlan2222 version 3
```

Step4 Enable IGMP snooping on host VLAN.

```
admin@XorPlus# set protocols igmp-snooping enable true
admin@XorPlus# set protocols igmp-snooping vlan-id 2222 enable true
```

Step5 Commit the configurations.

```
admin@XorPlus# commit
```

Verify Configuration

- Run the command **run show igmp groups** to show information about multicast groups and member ports.

```
admin@XorPlus# run show igmp groups
Total IGMP groups: 1
Watermark warn limit(Not Set): 0
Interface        Address         Group           Mode Timer    Srcs V Uptime
vlan2222         192.168.22.1    224.1.1.1       INCL --:--:--    1 3 00:03:01
```

- Run the command **run show mroute** to show the PIM routing table information.

```
admin@XorPlus# run show mroute
IP Multicast Routing Table

```

RFC List

The following table lists the RFC documents related to IGMP snooping.

RFC	Description
RFC4541	Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches
RFC1112	Host Extensions for IP Multicasting
RFC2236	Internet Group Management Protocol, Version 2
RFC3376	Internet Group Management Protocol, Version 3

Multicast Source Discovery Protocol (MSDP)

- Introduction of MSDP
- Example for Configuring PIM-SM Inter-domain Multicast Using MSDP
- Example for Configuring Anycast RP
- RFC Lists of MSDP

Introduction of MSDP

Multicast Source Discovery Protocol (MSDP) establishes MSDP peers between routers (usually on RP) in different PIM-SM domains. MSDP peers interchange SA (Source-Active) messages and share multicast source information. Finally, multicast users in one domain can receive multicast data sent by multicast sources in other domains.

Anycast RP is the application of MSDP in a PIM-SM domain. Anycast RP sets up two or more RPs with the same IPv4 address on loopback interfaces in one PIM-SM domain, and establishes MSDP peer relationship between these RPs to achieve load sharing and redundancy backup among the RPs in the domain.

To establish MSDP peers, use the following command lines to configure the MSDP source and member.

set protocols msdp mesh-group < *mesh-group-name*> **member** <*peer-address*>

set protocols msdp mesh-group < *mesh-group-name*> **source** <*source-address*>

Only one mesh group is allowed in a single PIM-SM domain.

When configuring MSDP peers, configure the local MSDP device as the source and all the other remote MSDP peer devices in the same mesh group as the members.

For Anycast RP, MSDP source and member should be configured on the loopback interface.

> **NOTE:**
> MSDP applies only to IPv4 networks.

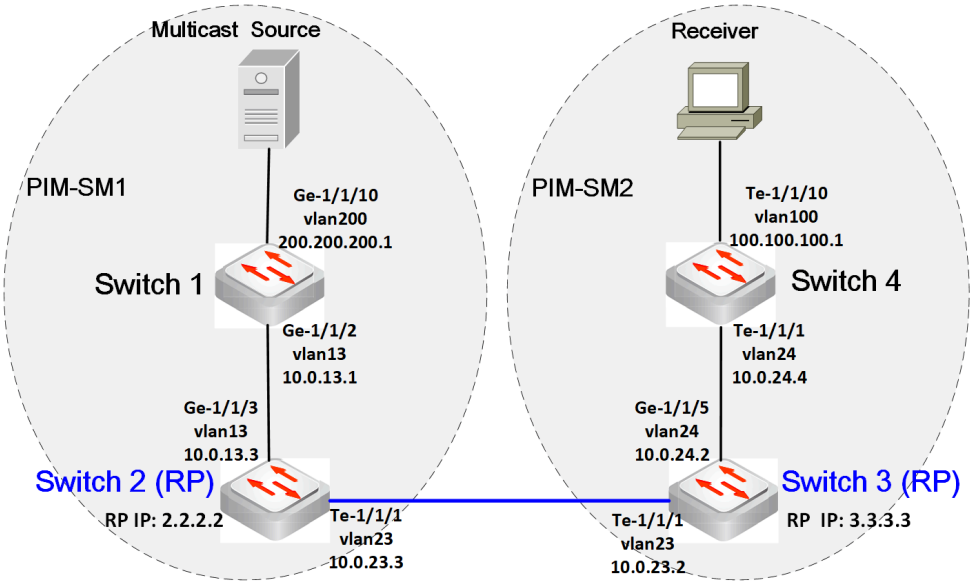
Example for Configuring PIM-SM Inter-domain Multicast Using MSDP

- Network Requirement
  - Figure 1 Network Diagram for Configuring PIM-SM Inter-domain Multicast Using MSDP
- Procedure
  - Switch 1
  - Switch 2
  - Switch 3
  - Switch 4
- Verify the Configuration

Network Requirement

As shown in **Figure 1**, there are two autonomous systems in the network. Each AS contains a PIM-SM domain, the multicast source is in PIM-SM1, the receiver is in PIM-SM2. The network requirement is that the receiver in domain PIM-SM2 can receive multicast data sent by the multicast source in domain PIM-SM1.

Figure 1 Network Diagram for Configuring PIM-SM Inter-domain Multicast Using MSDP



Configuration Roadmap

Configuring MSDP to establish MSDP peer relationship between RPs in each PIM-SM domain to achieve inter-domain multicast communication.

1. Configure the IP address for each switch interface and configure OSPF protocol in the ASs to ensure route reachability within each AS.
2. To ensure route reachability between ASs, configure eBGP peers between ASs and import OSPF routes into BGP.
3. Enable PIM-SM on each multicast interface, and enable IGMP on the host-side interface.
4. Configure static RP on each PIM-SM router in domains PIM-SM1 and PIM-SM2, and specify the loopback interface address of Switch 2 and Switch 3 as the RP address.
5. Configure MSDP source and member on each RP to establish MSDP peer relationship between RPs in each domain.

Procedure

Switch 1

```
admin@Switch1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13

- You can view (S, G) entries cache on MSDP peer switches by using the **run show msdp sa** "**RP**" is the source RP address that advertises the (S, G) entry. "**RP**" value "-" indicates that the device running the show command is the source RP advertising the (S, G) entry.

```
admin@Switch3# run show msdp sa

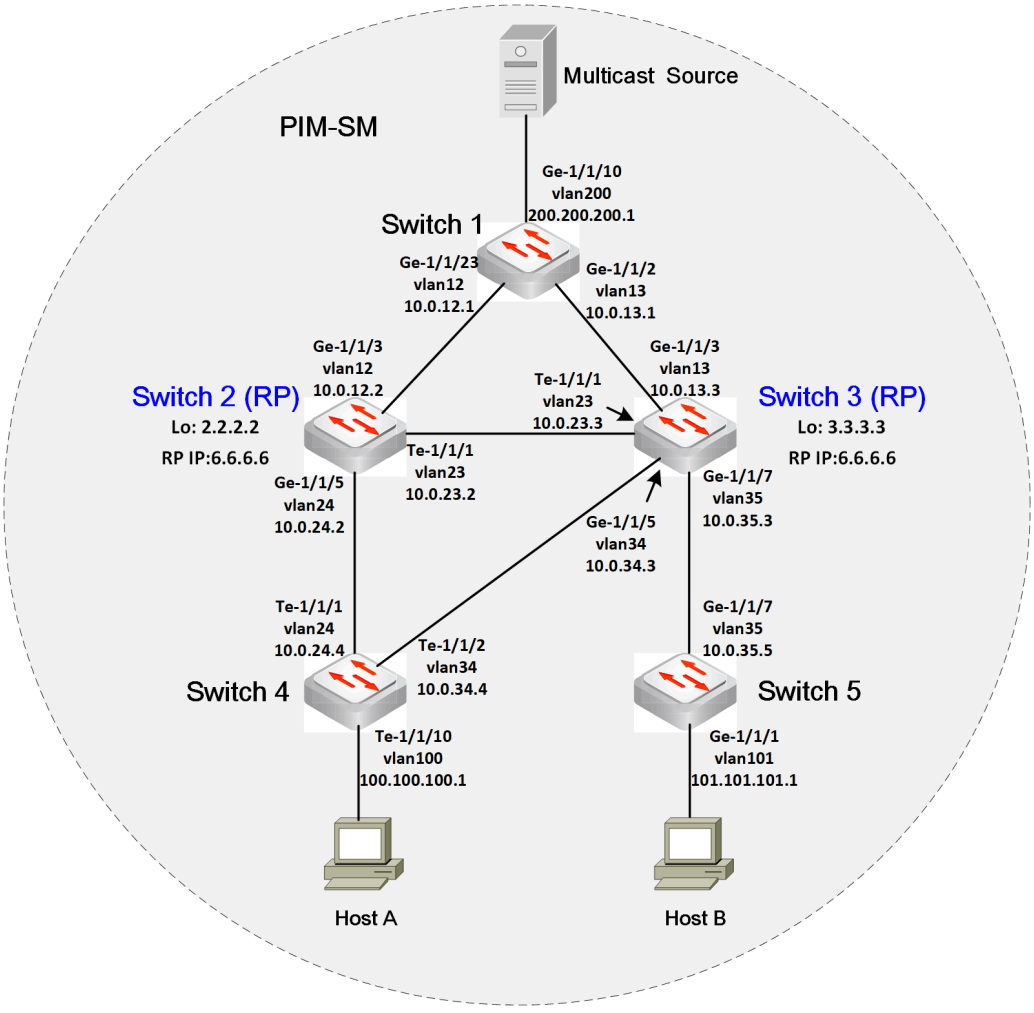
Example for Configuring Anycast RP

- Network Requirement
  - Figure 1 Network Diagram for Configuring Anycast RP
- Procedure
  - Switch 1
  - Switch 2
  - Switch 3
  - Switch 4
  - Switch 5
- Verify the Configuration

Network Requirement

As shown in **Figure 1**, in the PIM-SM domain, the multicast source sends multicast data to group 238.0.0.1, and Host A and Host B are members of this multicast group.

Figure 1 Network Diagram for Configuring Anycast RP



Apply Anycast RP in the PIM-SM domain to achieve load sharing and backup among multiple RPs.

1. Select Switch 2 and Switch 3 as the anycast RPs in the PIM-SM domain.
2. Prepare a loopback interface address respectively on Switch 2 and Switch 3 with the same value.
3. Configure the RP. Configure static RP on each PIM-SM router in the whole domain, specifying the loopback interface address of Switch 2 and Switch 3 as the RP address.
4. Prepare another loopback interface address on Switch 2 and Switch 3 respectively, which will be used to establish MSDP peer connection. Do not use the loopback interface address used for the RP.
5. Use the following command lines to establish the MSDP peer connection between Switch 2 and Switch 3.

set protocols msdp mesh-group < *mesh-group-name*> **member** <*peer-address*>

set protocols msdp mesh-group < *mesh-group-name*> **source** <*source-address*>

Procedure

Switch 1

```
admin@Switch1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 13
admin@Switch1# set interface gigabit-ethernet ge-1/1/10 family ethernet-switching native-vlan-id 200
admin@Switch1# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching native-vlan-id 12
admin@Switch1# set ip routing enable true
admin@Switch1# set l3-interface vlan-interface vlan12 address 10.0.12.1 prefix-length 24
admin@Switch1# set l3-interface vlan-interface vlan200 address 200.200.200.1 prefix-length 24

```

Verify the Configuration

- You can use command **run show msdp mesh-group** to check the establishment state for MSDP peers.

```
admin@Switch2# run show msdp mesh-group
Mesh group : 6.6.6.6
  Source : 2.2.2.2
  Member         State
  3.3.3.3          established
```

- You can use command **run show msdp peer** command to view the detail information about the remote MSDP peer.

```
admin@Switch2# run show msdp peer detail
Peer : 3.3.3.3
  Local               : 2.2.2.2
  Mesh Group          : 6.6.6.6
  State               : established
  Uptime              : 06:10:52
  Keepalive Timer     : 00:00:08
  Conn Retry Timer    : --:--:--
  Hold Timer          : 00:00:46
  Last Reset          : -
  Conn Attempts       : 22
  Established Changes : 1
  SA Count            : 2
  Statistics          :
                       Sent       Rcvd
    Keepalives :        371          4
  SAs        :          0        748
```

- You can view PIM routes on the switches by using the **run show mroute** Multicast source 200.200.200.2 in the PIM-SM domain sends multicast data to multicast group 238.0.0.1, and Host A joins multicast group 238.0.0.1 to receive multicast data sent to group 238.0.0.1.

By comparing the PIM routes on Switch 2, Switch 3 and Switch 4, we can see that the current valid RP is Switch 2: the multicast source registers with Switch 2 and Host A joins Switch 2. No PIM routes are displayed on Switch 3.

```
admin@Switch2# run show mroute
IP Multicast Routing Table
Flags: S - Sparse, C - Connected, P - Pruned
       R - RP-bit set, F - Register flag, T - SPT-bit set

RFC Lists of MSDP

The development of PICOS MSDP and anycast RP are based on FRR and implemented according to IETF standard protocols described in RFC 3618 and RFC 3446.

RFC	Description
RFC 3618	Multicast Source Discovery Protocol (MSDP)
RFC 3446	Anycast Rendevous Point (RP) mechanism using Protocol Independent Multicast (PIM) and Multicast Source Discovery Protocol (MSDP)

Multicast VLAN Registration (MVR)

- Overview of MVR
- Configuration Notes and Constraints of MVR
- Configuring MVR

Overview of MVR

- Overview
- Terminology
- MVR Operation Mechanism

Overview

Multicast VLAN Registration (MVR) is designed for different end user devices, such as IPTVs to receive the same source multicast traffic across the Ethernet network with different service VLAN tags. Usually, different end users are isolated with different service VLAN ID for security reason. Multicast stream from the upstream port is forwarded to multi-access ports tagged with different service VLAN ID.

On the other hand, the IGMP report packets from access ports for joining or leaving the multicast group, are tagged with different service VLAN IDs. When forwarding the IGMP packets to multicast router, the VLAN ID of the packets should be changed to upstream VLAN ID so as to talk to IGMP router.

Terminology

MVR

Multicast VLAN Registration is designed for delivering IPTV multicast streams over ethernet network from the same source, group and VLAN ID to different receivers in different VLAN. The VLAN ID translation should be done for the multicast traffic data and IGMP control packets between the upstream port and access ports.

MVR VLAN

It is the VLAN ID of the multicast traffic from the upstream ports connected to the multicast router. The IGMP control packets from the multicast router also use the same VLAN ID to talk to any receiver devices.

Receiver VLAN

It is the service VLAN ID allocated for one end user/device, which is connected to access port of the switch for receiving the multicast traffic.

Mrouter Port

Mrouter port is the upstream port of the switch that is connected to the multicast router for delivering the multicast traffic to end users.

IGMP Snooping

IGMP Snooping listens to IGMP packets between router and access ports of the interested multicast groups, so as to do L2 forwarding accordingly without flooding.

IGMP Packet

IGMP packet is the control message packets between IGMP router and receiver devices for joining or leaving the multicast stream.

MVR Operation Mechanism

MVR does the VLAN translation of multicast traffic on both directions from mrouter to user access port, and from access to mrouter port. There are two types of packets, multicast IGMP control packets and multicast data packets.

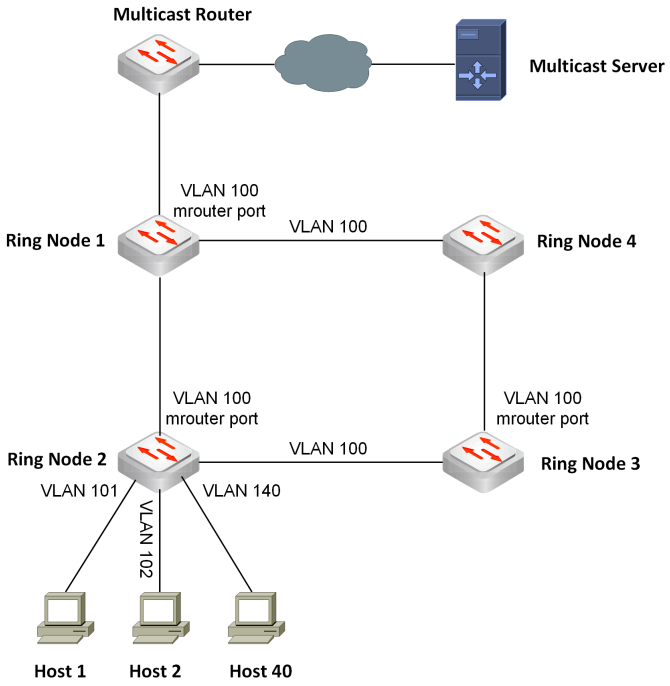
The multicast protocol control packets from upstream router, such as IGMP Query packets from mrouter port will be intercepted and sent out to all ports in the mapped VLAN list of the corresponding multicast group. On the other hand, the IGMP multicast group join/leave packets from receiver devices will be intercepted and translated to MVR VLAN and sent out from the mrouter port. The upstream multicast router doesn't feel any difference if the MVR is enabled or not on the switch side.

The multicast data traffic from upstream ports will be translated to the receiver VLAN ID accordingly based on IGMP Snooping messages from each access port.

On the other hand, the multicast traffic will be forwarded to the trunk ports with same VLAN ID as the MVR VLAN.

For example, in **Figure 1** sample MVR topology, the multicast router will send IGMP Query packets to Ring Node 1. If RPL link of the ERPS instance VLAN 100 is between Node 1 and Node 4, the IGMP Query packets will be forwarded to Node 2. Node 2 will forward the Query to Host 1 to Host 40, and another ERPS port1 to Node 3, and node 3 to Node 4 as well.

Figure 1. Sample MVR Topology



On ERPS Node 3, the IGMP Query packets will be forwarded to all access ports in the VLAN list with VLAN changed accordingly. When the host sends back the IGMP report packets, the VLAN will be modified to MVR VLAN and sent out from upstream port0 to multicast router.

The multicast data traffic from Node 1 will be forwarded out to Node 3 through ERPS port1 without changing of the data VLAN.

Configuration Notes and Constraints of MVR

When configure the MVR, please pay attention to the following notes:

- Static MVR configuration is not supported in current MVR version.
- PICOS supports a maximum of 255 multicast groups in IGMP snooping forwarding table for MVR.
- The IGMP snooping is by default automatically enabled for all receiver VLAN IDs.
- Group overlapping is not allowed when configuring multiple MVLANs.
- One receiver VLAN can only be mapped to one MVLAN on one interface.
- The multicast traffic will be forwarded to the trunk ports which have the same VLAN ID as MVLAN.
- The MVLAN and its binding receiver VLANs should be in the same spanning tree instance.

Configuring MVR

- Configuring MVR
- Configuration Example
  - Networking Requirements
  - Procedure
  - Verifying the Configuration

Configuring MVR

Step1 Configure VLANs for upstream port and access port respectively.

set interface gigabit-ethernet *<interface-name>* **family ethernet-switching port-mode** *<port-mode>*

set interface gigabit-ethernet *<interface-name>* **family ethernet-switching vlan members** *<vlan-id>*

Step2 Enable IGMP snooping globally.

set protocols igmp-snooping enable true

Step3 Configure mrouter port.

set protocols igmp-snooping vlan-id *<vlan-id>* **mrouter interface** *<interface-name>*

Step4 Configure MVR source group.

set protocols igmp-snooping vlan-id *<vlan-id>* **mvr source group** *<multicast-network-address>/<prefix-length>*

Step5 Configure receiver VLAN list.

set protocols igmp-snooping vlan-id *<vlan-id>* **mvr receiver vlan-list** *<vlan range string>*

Step6 Commit the configuration.

commit

Step7 View the configuration information of MVR.

run show igmp-snooping mvr mvlan *<vlan-id>*

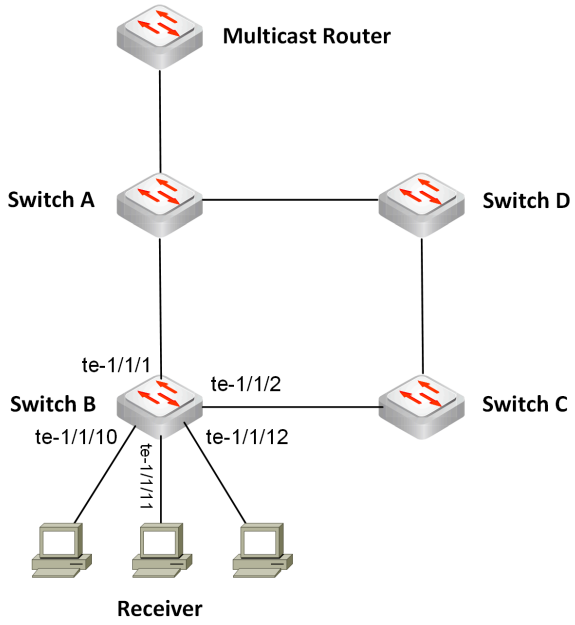
run show igmp-snooping mvr receiver-vlan *<vlan-id>*

Configuration Example

Networking Requirements

Switch B is one node of the ERPS ring, of which VLAN 100 is the ring instance member (Please refer to ERPS section for how to configure the ERPS ring and instance). The two ports, te-1/1/1/1 and te-1/1/2 are ring port0 and port1, both are mrouter ports as well.

Figure 1. MVR Configuration Example



Port te-1/1/10, te-1/1/11 and te-1/1/12 are the access ports with VLAN ID as 101, 102 and 103 respectively.

Procedure

Switch B

Step1 Enable IGMP snooping globally.

```
admin@SwitchB# set protocols igmp-snooping enable true
```

Step2 Configure upstream mrouter ports.

```
admin@SwitchB# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@SwitchB# set protocols igmp-snooping vlan-id 100 mrouter interface te-1/1/1
admin@SwitchB# set protocols igmp-snooping vlan-id 100 mrouter interface te-1/1/2
```

Step3 Configure MVLAN and source groups.

```
admin@SwitchB# set protocols igmp-snooping vlan-id 100 mvr source group 225.0.0.1/32
```

Step4 Configure access ports.

```
admin@SwitchB# set interface gigabit-ethernet te-1/1/10 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/10 family ethernet-switching vlan members 101
admin@SwitchB# set interface gigabit-ethernet te-1/1/11 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/11 family ethernet-switching vlan members 102
admin@SwitchB# set interface gigabit-ethernet te-1/1/12 family ethernet-switching port-mode trunk
admin@SwitchB# set interface gigabit-ethernet te-1/1/12 family ethernet-switching vlan members 103
```

Step5 Configure MVR receiver VLAN IDs.

```
admin@SwitchB# set protocols igmp-snooping vlan-id 100 mvr receiver vlan-list 101-103
```

Step6 Commit the configurations.

```
admin@SwitchB# commit
```

Verifying the Configuration

- The command **run show igmp-snooping mvr mvlan** <*vlan-id*> can be used to check the MVLAN(s) of the MVR.

```
admin@SwitchB# run show igmp-snooping mvr mvlan 100
Mvlan      Receiver-vlan
--------  ------------------
100       101, 102, 103
```

- The command **run show igmp-snooping mvr receiver-vlan** <*vlan-id*> will show the receiver VLAN and MVR VLAN information.

```
admin@SwitchB# run show igmp-snooping mvr receiver-vlan 101
Receiver-vlan   Mvlan
-------------  ----------
101             100
```

- You can use the **run show igmp-snooping groups** command to show information about multicast group member ports which is used for Layer 2 forwarding, namely, the Layer 2 forwarding table. **Port List** shows the egress ports for multicast packets.

```
admin@SwitchB# run show igmp-snooping groups
Vlan      Group                 Port List          Type
--------  ------------------    -----------------   ----------------------
100       225.0.0.1              te-1/1/10          Dynamic
                                 te-1/1/11          Dynamic
                                 te-1/1/1           Mrouter
```

ACL Configuration

- Configuring Basic ACL
- Configuring Time Range

Configuring Basic ACL

In L2/L3, ACLs support destination-address-ipv4, destination-address-ipv6, destination-mac-address, destination-port, ether-type, ip, protocol, source-address-ipv4, source-address-ipv6, source-mac-address, source-port, and vlan-id.

TCP flags are also supported. These ACLs can be applied to physical ports, LAG ports, and VLAN interfaces. One ACL can be applied to multiple ports (the properties of the ports can be same or different), but only one port can be matched to one ACL.

- It does not allow to configure different firewall filters to the same VLAN interface on ingress side or egress side.
- ACL can't filter layer 2 protocol packets, for example BPDU, LLDP, LACP and so on.
- Packets with any of the following destination MACs will always be sent to CPU even if ACL policy has been configured to discard the packets.

  01:80:c2:00:00:10
  01:80:c2:00:00:20/ff:ff:ff:ff:ff:f0
  01:80:c2:00:00:00/ff:ff:ff:ff:ff:f0
- Matching field **protocol icmp** of ACL rules on output interface are not supported on all the platforms.
- Matching fields **destination-mac-address**, **ether-type**, **vlan**, **first-fragment**, **ip-fragment** and **source-mac-address** of ACL rules on output interface inbound-control-plane are not supported on all the platforms.
- The match counter statistics information of the ACL filter is cleared when adding a new filter, modifying, or deleting an old filter. When there is a new packet, new match counter statistics information will be generated.
- **set firewall filter sequence from protocol icmp** and **set firewall filter sequence from protocol igmp** commands configure the firewall filter rules based on the ICMP or IGMP protocol type for only IPv4 traffic classification. To configure the firewall filter rule based on the ICMP or IGMP protocol type for IPv6 traffic classification, use the **set firewall filter sequence from protocol others** command with the protocol number.
- When matching ACL rules, the system processes IPv6 rules (**destination-address-ipv6/source-address-ipv6**) with higher priority than other ACL rules. Even if the sequence number of IPv6 rule is larger than the other rules', the IPv6 rule will be processed first.
  For example, confider the ACL rules shown below. The **destination-address-ipv6** rule will be processed first then all the other rules will be processed.

  admin@XorPlus# set firewall filter MyFilter sequence 100 from destination-mac-address 44:44:44:44:44:44
  admin@XorPlus# set firewall filter MyFilter sequence 100 then action discard
  admin@XorPlus# set firewall filter MyFilter sequence 200 from destination-address-ipv6 2001::1/128
  admin@XorPlus# set firewall filter MyFilter sequence 200 then action forward

  Therefore, when planning ACL rules, it is recommended to configure IPv6 source/destination rules with smaller sequence numbers. If not then it is highly stressed to keep this exception in mind while trying to achieve the desired effect.
- IPv6 ACL rules cannot be configured with the following rules at the same time:
  - Configuration with ether-type or destination-port is not supported on the ingress port.
  - Configuration with destination-mac-address or source-mac-address or ether-type is not supported on the egress port.
- Please note: There is always an implicit discard action rule at the end of all ACL rules.
- If all the ACL rules specify discard actions only, then add a forward all action rule at the end of the ACL to specify that all "unmatched" packets will be forwarded. Example: set firewall filter bad-net sequence 999 then action forward

Configuring ACLs

```
admin@XorPlus# set firewall filter bad-net sequence 111 from source-address-ipv4 1.1.1.0/24
admin@XorPlus# set firewall filter bad-net sequence 111 then action discard
admin@XorPlus# set firewall filter bad-net sequence 112 from source-address-ipv4 1.1.2.0/24
admin@XorPlus# set firewall filter bad-net sequence 112 then action discard
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
admin@XorPlus# set firewall filter bad-net input interface ge-1/1/1
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set firewall filter bad-net input interface ae1
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

When the switch receives a packet in ingress and egress, it will attempt to match ACLs by sequence number, with smaller values representing higher priorities. If the matched ACL's action is "forward" or "discard," the switch will forward or discard the packet and will not match the remaining ACLs. If there is no matching ACL, the packet will be dropped.

Configuring ACLs in VLANs

Every member port in the VLAN interface will be applied with the ACLs configured in the VLAN interface.

```
admin@XorPlus# set firewall filter bad-net sequence 221 from source-address-ipv4 1.1.1.0/24
```

```
admin@XorPlus# set firewall filter bad-net sequence 221 then action discard
admin@XorPlus# set firewall filter bad-net sequence 222 from source-address-ipv4 1.1.2.0/24
admin@XorPlus# set firewall filter bad-net sequence 222 then action discard
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set vlans vlan-id 2 l3-interface vlan-2
admin@XorPlus# set l3-interface vlan-interface vlan-2
admin@XorPlus# set firewall filter bad-net input vlan-interface vlan-2
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring ACL Discard TCP ACK

You can configure ACL TCP flags (ACK/FIN/PSH/RST/SYN/URG/TCP-ESTABLISHED/TCP-INITIAL) to specify what action (forward/discard) to perform on which packets (true/false).

```
admin@XorPlus# set firewall filter bad-net sequence 331 then action discard
admin@XorPlus# set firewall filter bad-net sequence 331 from protocol tcp flags ack true
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set firewall filter bad-net output interface ge-1/1/1
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Configuring ACL logging for Match Statistics

```
admin@XorPlus# set firewall filter bad-net sequence 441 then action discard
admin@XorPlus# set firewall filter bad-net sequence 441 from destination-address-ipv4 192.168.100.0/24
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set firewall filter bad-net input interface ge-1/1/1
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set firewall filter bad-net sequence 441 log interval 10
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
admin@XorPlus# run syslog monitor on
admin@XorPlus#
```

Check the Configuration

```
admin@XorPlus# run show filter
Filter: bad-net
          Description:
          Sequence: 111
              Description:
              match counter:  0 packets
              match-condition:
                 source-address-ipv4:                1.1.1.0/24
              action: discard
              forwarding_class:
          Sequence: 112
```

```
               Description:
               match counter:  0 packets
               match-condition:
                  source-address-ipv4:                1.1.2.0/24
               action: discard
               forwarding_class:
              Input interface: ge-1/1/1
Filter: copp
          Description:
          Sequence: 10
              Description:
              match counter:  0 packets
              match-condition:
                 protocol:                bpdu
              action: forward
              forwarding_class: bpdu-class
             ......
```

Configuring Time Range

- Overview
- Example for Configuring ACL Rule of Time Range
  - Networking Requirements
  - Procedure
  - Verify Configuration

Overview

Time range is a periodic time period configured on the switch. It's a fixed time period for each week. For example, from 8:00 to 18:00 from Monday to Friday. The system starts this time at a fixed time of the week. Time ranges are used in ACL rules as a filtering condition to restrict the effective time period of an ACL filtering rule, so as to filter traffic flows within a certain time period. For example, restrict users accessing to a server at a specific time period. The system starts the time at a fixed time of the week according to the system clock after applied the time range to the ACL rules.

Users can use the following two command to configure a pair of starting time and ending time to define a time range.

set firewall time-range <*time-range-name*> **periodic** <*periodic*> <**daily** | **friday | monday | saturday | sunday | thursday | tuesday | wednesday | weekdays | weekend**> **start** <*starting-time*>

set firewall time-range <*time-range-name*> **periodic** <*periodic*> <**daily** | **friday | monday | saturday | sunday | thursday | tuesday | wednesday | weekdays | weekend**> **end** <*ending-time*>

The following example configures a time range, which ranges from 8:00 to 18:00 during weekly working hours.

```
admin@Xorplus# set firewall time-range timerange1234 periodic 400 weekdays start 8:00:00
admin@Xorplus# set firewall time-range timerange1234 periodic 400 weekdays end 18:00:00
admin@Xorplus# commit
admin@Xorplus# run show timerange timerange1234
TimeRange: timerange1234
Periodic: 400
    Week: weekdays, start:08:00:00, end:18:00:00
```

NOTEs:

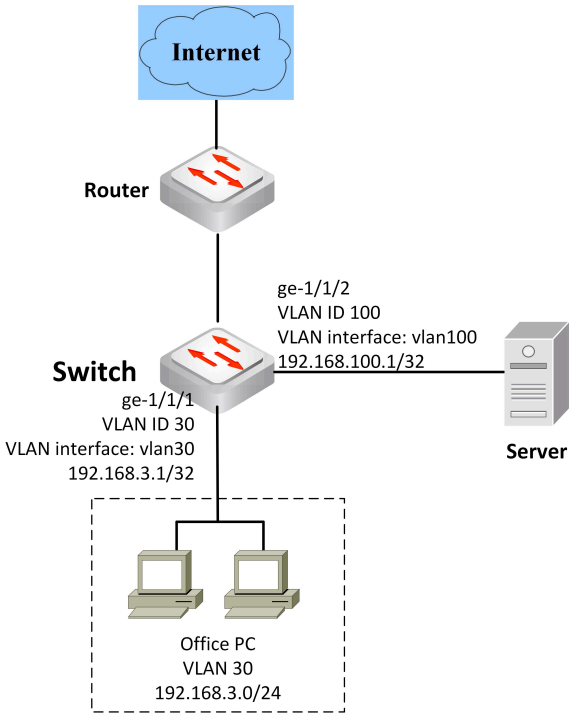
- A pair of start time and end time forms a time range.
- Currently only one **periodic** can be configured under a **time range**. However, multiple time periods can be configured under one **periodic**. All the time periods under the same time range take effect.
- In the same **periodic**, you cannot configure **daily**, **weekdays**, **weekend** at the same time.

```
admin@Xorplus# set firewall time-range time_range3 periodic 1 weekdays start 8:00:00
admin@Xorplus# set firewall time-range time_range3 periodic 1 weekdays end 18:00:00
admin@Xorplus# commit
Commit OK.
Save done.
admin@Xorplus# set firewall time-range time_range3 periodic 1 daily start 1:00:00
admin@Xorplus# set firewall time-range time_range3 periodic 1 daily end 3:00:00
admin@Xorplus# commit
Commit OK.
```

Example for Configuring ACL Rule of Time Range

Networking Requirements

Figure 1. Example for Configuring ACL Rule of Time Range



As shown in **Figure 1**, Office PCs access the Internet and the company Server through Switch. To restrict Office PCs to access the company Server only during business hours (08:00-18:00) on weekdays, configure filtering conditions of time range, source address and destination address of a ACL rule to achieve this requirement.

Procedure

The following are the configuration steps on the device Switch.

Step 1 Configure VLANs and VLAN interfaces.

```
admin@Switch# set vlans vlan-id 30
admin@Switch# set vlans vlan-id 100
admin@Switch# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 30
admin@Switch# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 100
admin@Switch# set vlans vlan-id 30 l3-interface vlan30
admin@Switch# set vlans vlan-id 100 l3-interface vlan100
admin@Switch# set l3-interface vlan-interface vlan30 address 192.168.3.1 prefix-length 32
admin@Switch# set l3-interface vlan-interface vlan100 address 192.168.100.1 prefix-length 32
```

Step 2 Configure time range.

```
admin@Xorplus# set firewall time-range timerange1234 periodic 400 weekdays start 8:00:00
admin@Xorplus# set firewall time-range timerange1234 periodic 400 weekdays end 18:00:00
```

Step 3 Configure ACL rule.

```
admin@Switch# set firewall filter f1 sequence 1 from destination-address-ipv4 192.168.100.1/32
admin@Switch# set firewall filter f1 sequence 1 from source-address-ipv4 192.168.3.0/24
admin@Switch# set firewall filter f1 sequence 1 from time-range timerange1234
admin@Switch# set firewall filter f1 sequence 1 then action forward
```

Step 4 Apply the ACL filter rules to the access port.

```
admin@Switch# set firewall filter f1 input interface ge-1/1/1
```

Step 5 Commit the configurations.

```
admin@Switch# commit
```

Verify Configuration

- On Switch, run command **run show timerange** to view the configuration information about time range.

```
admin@Switch# run show timerange timerange1234
TimeRange: timerange1234
Periodic: 400
    Week: weekdays, start:08:00:00, end:18:00:00
```

- On Switch, run command **run show filter** to view the information about the ACL filter rule.

```
admin@Switch# run show filter f1
Filter: f1
    Description:
    Sequence: 1
        Description:
        match counter:  0 packets
        match-condition:
            destination-address-ipv4: 192.168.100.1/32
            source-address-ipv4:    192.168.3.0/24
            time-range:            timerange1234
        action: forward
        forwarding_class:
    Input interface: ge-1/1/1
```

Weighted Random Early Detection

WRED (Weighted Random Early Detection) is a congestion avoidance mechanism that makes use of the congestion control mechanism of TCP (Transmission Control Protocol). By selectively dropping packets before periods of congestion, WRED tells TCP senders to reduce their transmission rates.

This chapter provides an overview of WRED, describes WRED configuration tasks, and presents a configuration example.

- WRED Overview
- WRED Configuration Tasks
- WRED Configuration Example

WRED Overview

You can monitor the network traffic load on an interface to anticipate congestion. Congestion can be avoided by dropping packets when needed. Tail drop is the most basic mechanism for avoiding congestion. Interface output queues fill during periods of congestion. When an output queue is full, the tail drop mechanism kicks in, and packets are dropped from the tail of the queue until congestion is reduced and the queue is no longer full. Tail drop does not differentiate between classes of traffic and drops packets at the tail of an output queue indiscriminately.

Global synchronization is a problem that occurs when tail drop is used as the congestion avoidance mechanism. Tail drop results in a large number of packets getting dropped at once. In response to packet drops, multiple senders of TCP (Transmission Control Protocol) traffic reduce their transmission rates at around the same time. The same TCP senders then increase their transmission rates around the same time when congestion is reduced. It results in periods of high link utilization followed by periods of low utilization.

WRED (Weighted Random Early Detection) is a congestion avoidance mechanism that prevents the problem of global synchronization associated with tail drop. When an output queue begins to experience congestion, WRED starts dropping packets *selectively*. A TCP sender experiencing packet drops reduces its transmission rate. By dropping some packets earlier than the point when the queue is full, WRED prevents the situation where a large number of packets get dropped at once. WRED not only reduces the chances of global synchronization, it also increases the utilization of transmission bandwidth.

WRED should be configured on egress ports.

WRED Configuration Tasks

When a packet arrives at a WRED-enabled output interface, the following chain of events takes place:

1. The length of the queue is calculated.
2. If the queue length is less than the minimum threshold, the packet is placed in the queue.
3. If the queue length is more than the maximum threshold, the packet is dropped.
4. If the queue length is more than the minimum threshold but less than the maximum threshold, the packet is either dropped or queued, based on the packet drop probability.

The following command can be used to enable or disable WRED:

set interface gigabit-ethernet <*port*> **wred queue** <*value*> **enable** <*bool*>

The following example demonstrates how to enable WRED on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 enable true
admin@XorPlus# commit
Commit OK.
Save done.
```

The following example demonstrates how to disable WRED on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 enable false
admin@XorPlus# commit
Commit OK.
Save done.
```

The following command can be used to set the maximum threshold:

set interface gigabit-ethernet <*port*> **wred queue** <*value*> **max_thresh** <*int*>

The following example demonstrates how to set the maximum threshold to 400 on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 max_thresh 400
admin@XorPlus# commit
Commit OK.
Save done.
```

The following command can be used to set the minimum threshold:

set interface gigabit-ethernet <*port*> **wred queue** <*value*> **min_thresh** <*int*>

The following example demonstrates how to set the minimum threshold to 200 on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 min_thresh 200
admin@XorPlus# commit
Commit OK.
Save done.
```

The following command can be used to to configure drop probability:

set interface gigabit-ethernet <*port*> **wred queue** <*value*> **drop_probability** <*int*>

The following example demonstrates how to set the drop probability to 50% on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 drop_probability 50
admin@XorPlus# commit
Commit OK.
Save done.
```

When congestion occurs, WRED drops packets based on the queue length exceeding certain threshold value. ECN (Explicit Congestion Notification) can enhance basic WRED operation by marking packets instead of dropping them when the queue length exceeds certain threshold value. Downstream routers and hosts would see this marking as an indication of network congestion and slow down their packet transmission rates.

ECN is a value in the DS (Differentiated Services) field of the IPv4 protocol header. ECN uses the two least significant (right-most) bits of the 8-bit DF field to encode four different codepoints:

1. 00 - Not ECN-Capable Transport
2. 01 - ECN-Capable Transport(1)
3. 10 - ECN-Capable Transport(0)
4. 11 - Congestion Experienced

When both end hosts support ECN, they mark their packets with either 10 or 01. When ECN is enabled, PicOS changes the ECN field of all such packets to 11. When ECN is not enabled, the ECN bits are not changed.

The following command can be used to enable or disable ECN:

set interface gigabit-ethernet <*port*> **wred queue** <*value*> **ecn_thresh** <*int*>

The following example demonstrates how to enable ECN on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 ecn_thresh 1
admin@XorPlus# commit
Commit OK.
Save done.
```

The following example demonstrates how to disable ECN on queue 0 of interface ge-1/1/1:

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 wred queue 0 ecn_thresh 0
admin@XorPlus# commit
Commit OK.
Save done.
```

WRED Configuration Example

As shown in Fig 1, interfaces ge-1/1/1, ge-1/1/2, and ge-1/1/3 are connected to end hosts PC1, PC2, and PC3, respectively. Ports ge-1/1/1 and ge-1/1/12 are ingress ports, while ge-1/1/3 is an egress port. In this example, WRED is configured on ge-1/1/3.

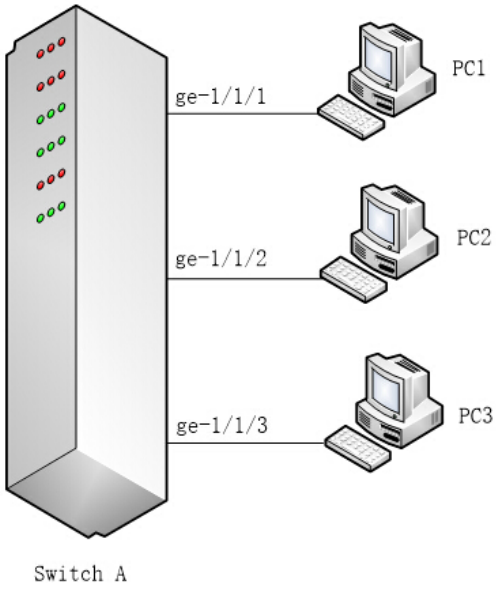

Fig 1. Configure WRED

Enable WRED

Enable WRED on queue 0 of interface ge-1/1/3.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 wred queue 0 enable true
admin@XorPlus# commit
Commit OK.
Save done.
```

Set Maximum and Minimum Thresholds

Set the maximum threshold to 400 and the minimum threshold to 200 on queue 0 of interface ge-1/1/3.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 wred queue 0 max_thresh 400
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 wred queue 0 min_thresh 200
admin@XorPlus# commit
Commit OK.
Save done.
```

Set Drop Probability

Set the drop probability to 50% on queue 0 of interface ge-1/1/3.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 wred queue 0 drop_probability 50
admin@XorPlus# commit
Commit OK.
Save done.
```

Enable ECN

Enable ECN (Explicit Congestion Notification) on queue 0 of interface ge-1/1/3.

```
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 wred queue 0 ecn_thresh 1
```

```
admin@XorPlus# commit
Commit OK.
Save done.
```

QoS Principle

SP Queue Principle

When the scheduler mode is SP, the egress port has eight queues: 7, 6, 5, 4, 3, 2, 1, and 0, queue 7 being the highest priority and queue 0 being the lowest priority. The advantage is that it can give priority to the transmissions of a key business group. This scheduler mode also has disadvantages. During times of congested conditions, if higher the priority queue has groups for a long time, the low priority queues will not get service all the time.

WRR Principle

The full name of WRR is Weighted Round Robin. In order to ensure that every queue has certain servicing time, WRR uses a round robin scheduling algorithm between the queues. When the scheduler mode is WRR, every queue can have a weighted value, which is also known as scheduling weight. Scheduling weight means that when the egress port schedules, the queue messages the proportion of scheduling resources to be used. Scheduling unit is Kbps.The example of a WRR scheduling algorithm is as follows:

On the 1000 Mbps egress port, the scheduling weights of eight queues are 5, 4, 3, 3, 2, 1, 1, 1; this ensures that even the lowest priority queue gets bandwidth.

The calculation method is as follows:

1/(5+4+3+3+2+1+1+1)*1000 Mbps=50 Mbps.

This can avoid the problem of the packets in the lower priority queues not getting service for a long time. The advantage is that although the queue scheduling uses round robin scheduling, every queue does not distribute at a fixed service time—if a queue is empty, the next queue should be scheduled immediately. In this way, it makes full use of bandwidth resources. When using WRR scheduling mode, user can define the weighted value for each queue.

WFQ Principle

The full name of WFQ is Weighted Fair Queuing. It is similar to WRR. The only difference between WFQ and WRR is that the scheduling mode in WFQ supports a minimum bandwidth guarantee, making this scheduling scheme more flexible. Configuring a minimum guaranteed bandwidth assures that every queue working in WFQ mode has a minimum bandwidth guarantee. In addition, the bandwidth available for distribution allocates according to the weighted proportion in the corresponding queue.

The distributable bandwidth calculation method is as follows:

distributable bandwidth = total bandwidth - minimum bandwidth

The example of the WFQ scheduling algorithm as follows:

Assuming that the total bandwidth of the egress port is 100M, there are 3 flows in the queue of this port.

Their scheduling weighted values are 1,2,4; the minimum bandwidth guarantees of these 3 flows are 10000Kbps,10000Kbps, and 20000Kbps.

Proportions of each flow are 10%,10%, 20%.

Distributable bandwidth = 100M-(10M+10M+20M)=60M.

Proportion of distributable bandwidth is 60%

Total distributable bandwidth = the sum of each flow weighted value.

In this example, the total distributable bandwidth is 7(that is 1+2+4).

Formula to calculate the proportion of distributable bandwidth which is occupied by each flow is as follows:

Proportion of distributable bandwidth = (the own weight of flow)/(distributable bandwidth).

Proportions of the distributable bandwidth for each flow are 1/7, 2/7, 4/7.

Bandwidth ratio of the flows is (10%+60%*(1/7)) : (10%+60%*(2/7)) : (20%+60%*(4/7)),that is 13:19:38.

SP Configuration Example

As shown in Fig 1, ge-1/1/1 and ge-1/1/2 are ingress ports, and ge-1/1/3 is an egress port. Use default scheduling model: priority trust model is IEEE 802.1.

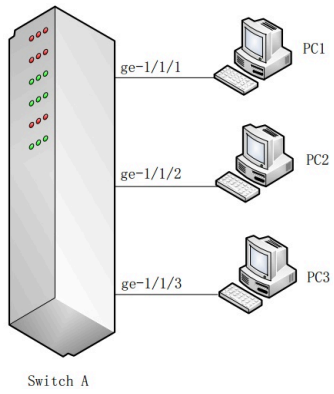

Fig 1. Configure SP

Configure two forwarding-classes

Configure forwarding-class f1 and f2 and their local-priorities.

```
admin@XorPlus# set class-of-service forwarding-class f1 local-priority 3
admin@XorPlus# set class-of-service forwarding-class f2 local-priority 6
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring classifier

Configure classifier c1, c2, and trust mode. Also configure classifier relevant to forwarding class and code point.

```
admin@XorPlus# set class-of-service classifier c1 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c1 forwarding-class f1 code-point 5
admin@XorPlus# set class-of-service classifier c2 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c2 forwarding-class f2 code-point 7
admin@XorPlus# commit
Commit OK.
Save done.
```

Apply classifiers to two ingress ports

Configure classifier c1 and apply it to port ge-1/1/1. Configure classifier c2 and apply it to port ge-1/1/2.

```
admin@XorPlus# set class-of-service interface ge-1/1/1 classifier c1
admin@XorPlus# set class-of-service interface ge-1/1/2 classifier c2
admin@XorPlus# commit
Commit OK.
Save done.

Generate Traffic

PC1 and PC2 generates traffic, which is matched with the corresponding classifier. Port PC1 and PC2 send 100% traffic to PC3 at the same time.

The expected result is that PC3 only can receive packets from PC2.

QoS Configuration Example

- Configuring Classifier-based QoS
- Configuring ACL-based QoS

Configuring Classifier-based QoS

> **NOTE:**
> On Trident and Trident+ based switches, known unicast packets can be assigned to a specific queue between queues from 0 to 7, while unknown unicast packets, multicast packets, and broadcast packets can be assigned to a specific queue between queues from 0 to 3.

Configure a Scheduler

A scheduler, which determines the QoS working mode and weight, should be configured first when you configure QoS. The working mode can be SP, WRR, or WFQ, and the weight is 1 to 15.

SP is strictly a priority queue. When two PCs send 100% traffic to a same PC, all packets from the lower priority PC will be discarded. The default working mode is SP.

WRR is a weighted round robin queue, and under this mode, user can configure weight. If PCA and PCB sends 100% traffic to the same PCC, the PCC will receive packets from PCA and PCB according to the weight proportion in the corresponding queue.

WFQ is weighted fair queuing. Under this mode, user can configure guaranteed-rate and weight, and the guarantee is only available in WFQ mode. If PCA and PCB send 100% traffic to the same PCC, the PCC will receive packets from PCA and PCB according to the weight proportion and the guaranteed-rate in the corresponding queue.

```
admin@XorPlus# set class-of-service scheduler s1 mode WRR
admin@XorPlus# set class-of-service scheduler s1 weight 3
admin@XorPlus# commit
Commit OK.
Save done.
```

```
admin@XorPlus# set class-of-service scheduler s1 mode WFQ
admin@XorPlus# set class-of-service scheduler s1 weight 4
admin@XorPlus# set class-of-service scheduler s1 guaranteed-rate 8
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure a Forwarding Class

A forwarding class, which determines the queue number of the specified traffic type, should be configured after the scheduler when configuring QoS. The effective local-priority is 0 to 7.

```
admin@XorPlus# set class-of-service forwarding-class f1 local-priority 3
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure Scheduler Profile

Scheduler profile, which defines a queue used as a kind of scheduler on egress port, is the map of a forwarding class and a scheduler.

```
admin@XorPlus# set class-of-service scheduler-profile p1 forwarding-class f1 scheduler s1
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure Scheduler Profile to Specified Port

Scheduler profile should be configured to egress port. It only applies to egress packet. Ingress packet is invalid.

```
admin@XorPlus# set class-of-service interface ge-1/1/1 scheduler-profile p1
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure a Classifier with IEEE 802.1/DSCP/ToS

A classifier should be configured first, which is used to specify the associated forwarding class. User can select a classifier trust mode, such as IEEE 802.1, DSCP, or ToS, according to need. It decides the priority trust model. Configure trust mode IEEE 802.1 as follows:

```
admin@XorPlus# set class-of-service classifier c1 trust-mode ieee-802.1
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure Classifier Relevant to Forwarding Class

After configuring a classifier trust mode, user can configure the classifier relevant to the specified forwarding class. Code point and scheduler should be configured at the same time. The code-point is matched with the forwarding class local-priority, meaning that when the flow matches the specified code point, the flow will enter the specified queue. When the classifier trust mode is IEEE 802.1 or ToS, the code point is 0 to 7. When the classifier trust mode is dscp, the code point is 0 to 63.

```
admin@XorPlus# set class-of-service classifier c1 forwarding-class f1 code-point 5
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure Classifier to Specified Port

After configuring as above, the classifier should be applied to specified ports. It determines the port priority trust model, data stream and queue matching rules, scheduling model, weight, and guaranteed-rate. When the classifier configures the scheduler, the classifier should be used in the egress port. When the classifier configures code point, the classifier should be used in ingress port.

```
admin@XorPlus# set class-of-service interface ge-1/1/1 classifier c1
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring ACL-based QoS

NOTE:

On Trident and Trident+ based switches, known unicast packets can be assigned to a specific queue between queues from 0 to 7, while unknown unicast packets, multicast packets, and broadcast packets can be assigned to a specific queue between queues from 0 to 3.

Procedure

Step1 Configure firewall filter rule for traffic classification.

set firewall filter <*filter-name*> **sequence** <*number*> **from destination-mac-address** <*mac-address*>

NOTE:

- The matching fields of firewall filter rule could be **destination-mac-address**, **source-mac-address**, **destination-address-ipv4** (for IPv4 matching rule), **destination-address-ipv6** (for IPv6 matching rule), **source-address-ipv4** (for IPv4 matching rule), **source-address-ipv6** (for IPv6 matching rule), **protocol**, **destination-port**, **source-port**, **ether-type**, **vlan**, **ip trust-mode**, **ip value**.
- **and** is the logical operator between the matching fields with the same sequence number, that is, packets must match all of the matching fields with the same sequence number to be included in one class.

Step2 Configure queue mapping between firewall filter and forwarding class.

set firewall filter <*filter-name*> **sequence** <*number*> **then forwarding-class** <*forwarding-class-name*>

Step3 Configure DSCP remark.

set firewall filter <*filter-name*> **sequence** <*number*> **then dscp** <*dscp-value*>

Step4 Apply firewall filter to a switch physical interface.

set firewall filter <*filter-name*> **input interface** <*interface-name*>

Step5 Configure mapping between forwarding class and local priority.

set class-of-service forwarding-class <*forwarding-class-name*> **local-priority <***int*>

Step6 Configure queue scheduler weight.

set class-of-service scheduler <*scheduler-name*> **weight** <*int*>

Step7 Configure WRR scheduling algorithm for queue scheduling.

set class-of-service scheduler <*scheduler-name*> **mode** <**SP | WFQ | WRR>**

Step8 Configure guaranteed-rate for queue.

set class-of-service scheduler <*scheduler-name*> **guaranteed-rate** <*value*>

Step9 Configure scheduler profile.

set class-of-service scheduler-profile <*scheduler-profile-name***> forwarding-class** <*forwarding-class-name*> **scheduler <***scheduler-name*>

Step10 Apply scheduler profile to a switch physical interface.

set class-of–service interface <*interface-name*> **scheduler-profile** <*scheduler-profile-name*>

Step11 Commit the configuration.

commit

Configuration Example

The following example configures ACL-based QoS policy for NTP protocol, and applies it to the interface ge-1/1/1.

Procedure

Step1 Configure destination-port, protocol and ether-type to classify NTP (Network Time Protocol) flow, and mapping to forwarding class class1.

```
admin@Xorplus# set firewall filter f1 sequence 91 from destination-port 123
admin@Xorplus# set firewall filter f1 sequence 91 from protocol udp
admin@Xorplus# set firewall filter f1 sequence 91 then forwarding-class class1

admin@Xorplus# set firewall filter f1 sequence 92 from destination-port 123
admin@Xorplus# set firewall filter f1 sequence 92 from ether-type 34525
admin@Xorplus# set firewall filter f1 sequence 92 from protocol udp
admin@Xorplus# set firewall filter f1 sequence 92 then forwarding-class class1
```

Step2 Configure CoPP queue mapping, scheduling weight, scheduling algorithm and queue guaranteed-rate.

```
admin@Xorplus# set class-of-service scheduler scheduler180 mode WFQ
admin@Xorplus# set class-of-service scheduler scheduler180 guaranteed-rate 10000
admin@Xorplus# set class-of-service scheduler scheduler180 weight 5
admin@Xorplus# set class-of-service scheduler-profile s1 forwarding-class class1 scheduler scheduler180

##Configure mapping between forwarding class and local priority.
admin@Xorplus# set class-of-service forwarding-class class1 local-priority 1
```

Step3 Apply firewall filter to a switch physical interface.

```
  admin@XorPlus# set firewall filter f1 input interface ge-1/1/1
```

Step4 Apply scheduler profile to a switch physical interface.

```
admin@XorPlus# set class-of-service interface ge-1/1/1 scheduler-profile s1
```

Step5 Commit the configuration.

```
admin@XorPlus# commit
```

Verify the Configuration

- You can use the **run show filter** command to view the configuration information of all firewall filter rules.

```
admin@XorPlus# run show filter
```

```

```

PFC Configuration Example

Priority Flow Control or PFC is a kind of flow control mechanism. The advantage of PFC over traditional Flow Control mechanisms is that PFC provides flow control based on per code point (priority). In other words, PFC provides a more granular form of flow control. This means that if traffic from one particular priority suffers from congestion, only that traffic is paused until congestion clears away, whereas traffic for other priorities continues unhindered. On each physical port, there are 8 (0 to 7) Class of Service (CoS) queues, if congestion is detected on the egress physical port, the ingress port will send a PAUSE frame to the transmitting node to pause transmission until the receiving node is ready to accept packets again. PFC applies only to packets entering a port.

PFC has a higher priority than flow control. So, for example, if both flow control and PFC are configured on the same port, PFC will have precedence over traditional flow control.

PFC uses the IEEE 802.1p CoS values in the IEEE 802.1Q VLAN tag to generate the flow control frame with corresponding priority on ingress physical port when egress physical port suffers congestion. It indicates the ingress port needs COS classifier configuration.

PFC configuration is applied using PFC profiles. The following is an example of PFC configuration.

Configure PFC Profile

PFC is disabled when drop value is set to true and enabled when drop value is set to false. The default value of drop is false.

For example as below, PFC is enabled on 0，1，3，5，6，7 code-point by default, PFC is disabled on 2，4 code-point.

```
admin@XorPlus# set class-of-service pfc-profile pfc1 code-point 2 drop true
admin@XorPlus# set class-of-service pfc-profile pfc1 code-point 4 drop true
admin@XorPlus# commit
Commit OK.
Save done.
```

Apply PFC Profile to Port

```
admin@XorPlus# set class-of-service interface ge-1/1/1 pfc-profile pfc1
admin@XorPlus# commit
Commit OK.
Save done.
```

Show PFC Frame Statistics on Port

The class 0~7 in PFC frame corresponds to the following "802.1P" item. The value of "RxPFC“ item will be incremented by 1 if ge-1/1/1 receives a PFC frame. The value of "TxPFC“ item will be incremented by 1 if ge-1/1/1 sends out a PFC frame.

```
admin@XorPlus# run show class-of-service interface ge-1/1/1
Interface : ge-1/1/1
802.1P         Priority Flow Control    RxPFC              TxPFC
-----------    ---------------------    ---------------    ---------------
0              true                     0                  0
1              true                     0                  0

ACL-based Traffic Policer

- ACL-based Traffic Policer Implementation
- Rate-limit and Burst Applied in ACL-based Traffic Policer Function
- Interoperability with CoPP Policy
- Configuring ACL-based Traffic Policer
- Configuration Example

ACL-based traffic policer provides the ability to monitor the data rates for a particular class of traffic, and drops the traffic that exceed the user-configured rate-limit and burst limit values.

ACL-based traffic policer defines a rate limiting policy including traffic classification using ACL rules and policer (rate limit, burst limit and action) which can be applied to the management interface(eth0 / eth1) or an Ethernet interface to control the packet bandwidth in or out of the interface.

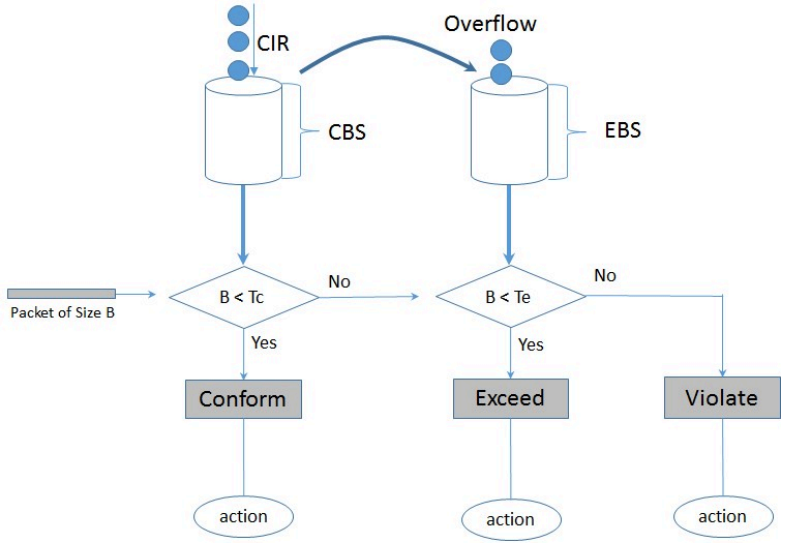
ACL-based Traffic Policer Implementation

When configured the ACL-based traffic policer on PICA8 switch, the sequence of packets processing is as follows:

1. A packet enters the switch configured with ACL-based traffic policer on the ingress port.
2. PICOS performs any applicable firewall filter services on the ingress port.
3. Packets are processed by ACL-based traffic policer module and are dropped or forwarded according to each firewall filter policy.
4. The forwarded packet is sent to the switch CPU if it is destined for the switch CPU.
5. The switch CPU makes a routing or switching decision, determining whether the packet is should be dropped or forwarded.
6. Packets that have destinations other than CPU are forwarded normally.

Rate-limit and Burst Applied in ACL-based Traffic Policer Function

Figure 1. RFC2697 Single-Rate Three-Color Policer Logic



The single-rate three-color policer/marker algorithm with dual buckets is used to implement ACL- based traffic policer rate-limit and burst-limit. Unlike the standard algorithm, the yellow traffic will be discarded as well as red traffic in order to make the implementation simple enough.

Additionally, the action to be applied to a packet, forward or discard, totally depends on the Tc, the token counter of CBS, the instantaneous number of tokens left in the CBS bucket because both yellow and red traffic will be discarded for PICA8 switch, which means the second bucket - EBS bucket - is not used to police the traffic at all.

For example:

set firewall policer 10pps if-exceeding count-mode packet

set firewall policer 10pps if-exceeding rate-limit 10

set firewall policer 10pps if-exceeding burst-limit 5

The above configuration is equal to below :

CIR (Committed Information Rate): 10 pps

CBS (Committed Burst Size): 5 packet

EBS (Excess Burst Size): 5 packet

10 pps is rate-limit value, 5 packet is burst value, the size of the bucket.

Interoperability with CoPP Policy

ACL-based traffic policer can take effect on packets that are both directed and non-directed to the CPU. The CoPP policy takes effect only on the packets directed to the CPU. These are independent functions. You can configure only one of them, or both of them.

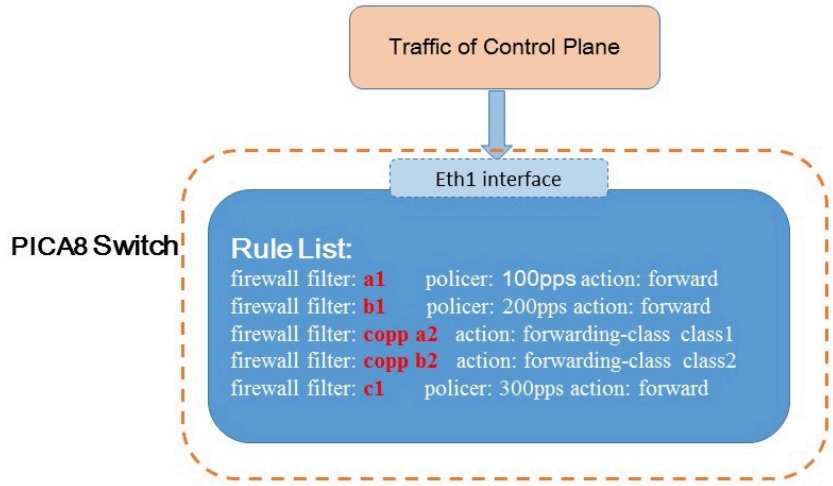
If both ACL-based traffic policer and the COPP policy are configured, for the packets directed to the CPU, the system processing is different in the following two cases: both the policies are applied to the same management interface or both the policies are applied to the same Ethernet interface.

1. When both ACL-based traffic policer and COPP policy are applied to the same management interface.

   In this case, the ACL-based traffic policer and the CoPP policy are in the same rule list in which the rules are ordered by the firewall filter name (for example, firewall filter with name "**a_filter**" is in front of "**b_filter**". Firewall filter name of CoPP policy is fixed to "copp"). The packets are matched against the rules in the ascending order.

   When the configured ACL-based traffic policer conflicts with the CoPP policy, first matched policy takes effect and the other policy will not take effect. Therefore, it is recommended not to configure conflicted ACL-based traffic policer with the CoPP policy.

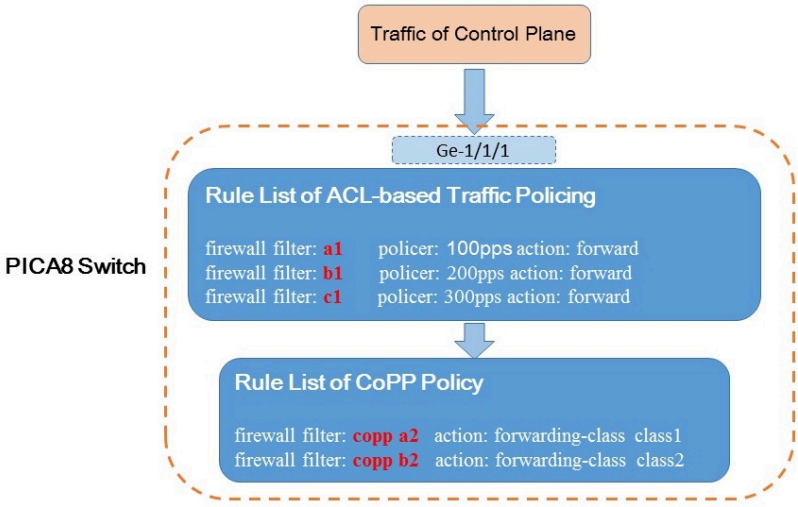
Figure 2. ACL-based traffic policer rules and CoPP policy rules are put in the same rule list



2. When both ACL-based traffic policer and COPP policy are applied to the same Ethernet interface.

   For the packets directed to the CPU, the packet is processed by the ACL-based traffic policer module first, and then is processed by the COPP policy module.

Figure 3. ACL-based traffic policer and CoPP policy are performed one by one



Configuring ACL-based Traffic Policer

NOTE:

- The filter can be configured on one or several interfaces in the inbound and outbound directions. However, a single filter can be configured either in the inbound direction or outbound direction at any given time.
- One policer can be applied to one filter. We can configure one policer on one or several sequences of a filter.
- Multiple sequences of the same filter share the rate limit and burst-limit of the policer. That is, when you configure the same policer to multiple sequences of the same filter, the packets matching the sequence condition of the filter can share the bandwidth rate limit and burst-limit of the policer, following the order in which the traffic arrives.

Step1 Configure ACL-based traffic policer rate-limit and burst-limit.

set firewall policer *<policer-name>* **if-exceeding count-mode** *<count-mode>*

set firewall policer <*policer-name*> **if-exceeding rate-limit** <*value*>

set firewall policer <*policer-name*> **if-exceeding burst-limit** <*value*>

Step2 Configure ACL-based traffic policer action as **discard**. The default action is **discard** if not configured.

set firewall policer <*policer-name*> **then action discard**

Step3 Configure firewall filter match condition and the policer for packets matching a filter sequence.

set firewall filter <*filter-name*> **sequence** <*sequence-number*> **from** <*match-conditions*>

set firewall filter <*filter-name*> **sequence** <*sequence-number*> **then policer** <*policer-name*>
set firewall filter <*filter-name*> **sequence** <*sequence-number*> **then action** {**discard** | **forward**}

Step4 Configure firewall filter applied to an Ethernet interface or a Layer 3 VLAN interface in the inbound or outbound direction.

set firewall filter <*filer-name*> **input interface** <*interface-name*>

set firewall filter <*filter-name*> **output interface** <*interface-name*>

set firewall filter <*filter-name*> **input vlan-interface** <*vlan-interface-name*>

set firewall filter <*filter-name*> **output vlan-interface** <*vlan-interface-name*>

Configuration Example

The following example configures ACL-based traffic policer for ICMP protocol packets and applies to the management port Eth1.

Step1 Configure ACL-based traffic policer rate-limit and burst-limit.

```
admin@Switch# set firewall policer 100pps if-exceeding count-mode packet
admin@Switch# set firewall policer 100pps if-exceeding rate-limit 100
admin@Switch# set firewall policer 100pps if-exceeding burst-limit 5
admin@Switch# set firewall policer 100pps then action discard
```

Step2 Configure firewall filter match and applied policer to firewall filter action.

```
admin@Switch# set firewall filter f1 sequence 1 from protocol icmp
admin@Switch# set firewall filter f1 sequence 1 then policer 100pps
admin@Switch# set firewall filter f1 sequence 1 then action forward
```

Step3 Configure firewall filter applied to the management interface eth1.

```
admin@Switch# set firewall filter f1 input interface eth1
```

Step4 Commit the configuration.

```
admin@Switch# commit
```

Step5 Run **run show policer** command to check the configuration.

```
admin@Switch# run show policer
policer     rate limit   burst limit   count mode   action
------------   ----------    ----------     ----------    ----------
100pps         100          5             packet         discard
```

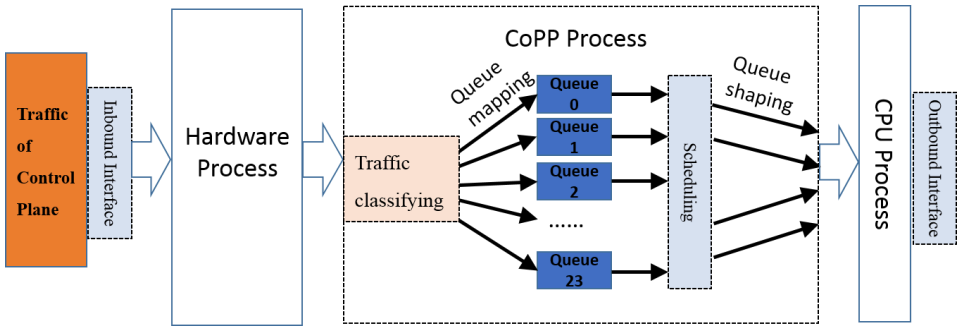
- Queue Shaping

Definition

Control Plane Policing (CoPP) defines the traffic classification, queue mapping, and queue shaping for control plane packets directed to switch CPU, achieving to protect switch from being overwhelmed by malicious attacks and overload, maintaining data forwarding and network topology stability. CoPP uses a dedicated control plane configuration through the QoS module of CoS (Class of Service) and Firewall Filter Rule. **Figure 1** shows the CoPP process.

Figure 1 CoPP Process



CoPP process follows four steps:

Classifying: CoPP identifies and classifies the flow of traffic handled by the switch CPU according to packet information of layer 2, layer 3 and layer4 based on firewall filter rules.

Queue mapping: This action is responsible for sending different types of packets to the specified CPU queue. The packets in different queues have different scheduling priorities according to scheduling weight.

Scheduling: When a network is congested intermittently and delay-sensitive services require higher bandwidth than other services, or when there are packets in multiple queues to be transmitted, scheduling is responsible for selecting a queue with a scheduling algorithm and processing the packets from the queue. CoPP uses the Weighted Round Robin (WRR) scheduling algorithm; please refer to 1.1.3 Queue Mapping and Scheduling for details about WRR.

Queue shaping: Set a minimum and maximum bandwidth for each CPU queue in packets per second (PPS) for queue shaping, this queue bandwidth limit ensures that the CPU will not face excessively loaded conditions in any case.

CoPP Traffic Classification

Based on the firewall filter rules, control plane packets directed to switch CPU are checked to see whether they hit a matching field specified in the firewall filter rules. If the packet matches a specified matching field, it is considered a member of a class and maps to a specified CPU queue according to the queue mapping policy.

and is the logical operator between the matching fields with the same sequence number, that is, to be considered to match a firewall filter rule and included in a class, the packets must match all of the matching fields with the same sequence number.

CoPP supports both IPv4 and IPv6 firewall filters, the descriptions of the supported matching fields are as follows:

- **Destination-mac-address/source-mac-address**: Filter packets with a specific destination/source MAC address.
- **Destination-address-ipv4/source-address-ipv4**: Filter packets with a specific destination/source IPv4 address.
- **Destination-address-ipv6/source-address-ipv6**: Filter packets with a specific destination/source IPv6 address.
- **Protocol**: Protocol is the *Protocol* field of the IPv4 header and the *Next Header* field of the IPv6 header, it could be a protocol name or protocol number identifying the protocol type of packets. Assigned internet protocol numbers 8 for EGP, 9 for IGP, 47 for GRE, 88 for EIGRP, 103 for PIM, and 112 for VRRP are examples.
- **Destination-port/ Source-port**: Filter packets with a specific destination/source port.
- **Vlan**: A switch identifies packets from different VLANs by VLAN ID contained in VLAN tags in Ethernet frame. User can set VLAN ID in the firewall filter rule for traffic classification.
- **Ether-type**: Ether type is a two-octet field used for indicating which protocol is being transported in an Ethernet frame in the Ethernet networking standard. Table 1 shows the Ether type value of the common protocols.

Table 1 Ether Type value of the common protocols

Protocol Type	Ether Type(Hexadecimal)
Internet Protocol, Version 4 (IPv4)	0x0800
Address Resolution Protocol (ARP)	0x0806

Protocol Type	Ether Type(Hexadecimal)
Reverse Address Resolution Protocol (RARP)	0x8035

Novell	0x8138
Internet Protocol, Version 6 (IPv6)	0x86DD
Ethernet Slow Protocols	0x8809

Queue Mapping and Scheduling

Queue Mapping

With CoPP traffic classification, packets that match a firewall filter rule will be sent to a specified CPU queue according to the queue mapping policy.

If a packet matches no class for ACL action **discard** or **forward**, the match processing is as follows. Packet classification included within queue mapping policy is processed top-down. When a packet is found to match a class, no further match processing is performed. That is, a packet can only belong to a single class, and it is the first one to which a match occurs.

If a packet is found to match a class for ACL action **discard or forward**, the match processing is as follows:

- When a packet is found to match a class for action **discard**, then the switch will discard the packet and will not match the remaining ACLs.
- When a packet is found to match a class for action **forward**, then the switch will forward the packet according to the CoPP forward class firstly matched and will not match the remaining ACLs.

When a packet directed to switch CPU matches none of the defined firewall filter rule, it is automatically mapped to CPU queue 0.

The mapping relationships between the firewall filter rule and CPU queue are:

- One or more firewall filter rules can be mapped to one CPU queue (n to one mapping).
- Each firewall filter rules can be matched to at most one queue.

Scheduling

CoPP uses WRR (Weighted Round Robin) to schedule packets in queues.

In order to ensure every queue has certain servicing time, WRR uses a round robin scheduling algorithm between the queues. When the scheduler mode is WRR, every queue can have a weighted value, which is also known as scheduling weight. Scheduling weight implies that when the egress port schedules the queue messages a proportion of scheduling resources are to be used. Scheduling unit is Kbps. The example of a WRR scheduling algorithm is as follows:

On the 1000 Mbps egress port, the scheduling weights of eight queues are 5, 4, 3, 3, 2, 1, 1, 1; this ensures that even the lowest priority queue gets bandwidth.

The calculation method is as follows:

1/ (5+4+3+3+2+1+1+1)*1000 Mbps=50 Mbps.

This can help avoid the problem of packets in the lower priority queues not getting service for longer periods of time. The advantage is that although the queue scheduling uses round robin scheduling, every queue does not distribute at a fixed service time: if a queue is empty, the next queue should be scheduled immediately. In this way, it makes full use of bandwidth resources. When using WRR scheduling algorithm, user can define the weighted value for each queue.

Queue Shaping

Queue shaping adjusts the rate of traffic to switch CPU. It helps to reduce traffic bursts so that packets can be transmitted at a stable rate through to CPU. For queues of different priorities, the device can provide differentiated services using different queue shaping parameter settings of Max-bandwidth-pps and Min-bandwidth-pps.

- **Max-bandwidth-pps**: Max-bandwidth-pps is the maximum packet processing rate of a CPU queue in packets per second (PPS). If there is heavy traffic on the interface caused by malicious attacks or network exceptions, the CPU will be overloaded and services would be interrupted. In order to avoid this situation, user can set Maximum bandwidth to the CPU queue for queue shaping.
- **Min-bandwidth-pps**: Minimum bandwidth means a guaranteed bandwidth of CPU queue for packets in pps. The total value of min-bandwidth-pps of all activated queues should be less than CPU-affordable bandwidth, which should be the maximum bandwidth threshold to the CPU which is different depending on the platform.

Default Settings for CoPP (N2224PX-ON/N2248X-ON/N3208PX-ON)

Default Queue Mapping Policy
Default CLI Settings
Show Default Settings of CoPP

NOTE:

- Default settings for CoPP in this page is only applicable for N2224PX-ON/N2248X-ON/N3208PX-ON.
- CoPP configures control policy of the traffic from the ASIC to CPU. It is a very sensitive process of the whole switch OS. Any incorrect setting could impact the stability or could even paralyze the normal network operation. **It is therefore highly recommended to KEEP the default configurations of CoPP to ensure the system and network stability.**

Default Queue Mapping Policy

By default, CoPP provides 8 CPU queues for data forwarding that would have a default scheduling weight. The system pre-defines 15 types of control plane protocols mapping from queue 8 to 22. The default queue mapping policy is as follows.

Table 1. Default Queue Mapping Policy

Protocols	CPU Queue	Default Scheduling Weight
BPDU	7	32
LACP	6	32
LLDP	5	32
ARP/NDP	4	32
MLAG/MLAG-MAC-SYNC	3	16
SSH/TELNET/SNMP	2	32
DHCP/DHCPv6/IGMP/PIM	1	16
Default*	0	16

Default*: The flow of traffic directed to switch CPU will be sent to CPU queue 0 when the traffic matches no firewall filter rule.

But for the packet with an Inet Precedence or DSCP value, it will not always be sent to CPU queue 0 when the traffic matches no firewall filter rule. When you configure the classifier to classify services on different inbound interfaces by using **set class-of-service classifier trust-mode dscp** and **set class-of-service interface classifier** commands. The packets will be sent to the CPU queue according to the Inet Precedence or DSCP value. Mappings from Inet Precedence/DSCP value to CPU Queue are shown in the following tables.

Table 2. Mapping from Inet Precedence value to CPU Queue

Inet-precedence	CPU Queue
0	0

1	1
2	2
3	3
4	4
5	5
6	6
7	7

Table 3. Mapping from DSCP value to CPU Queue

DSCP	CPU Queue
0,1,2,3,4,5,6,7	0
8,9,10,11,12,13,14,15	1
16,17,18,19,20,21,22,23	2
24,25,26,27,28,29,30,31	3
32,33,34,35,36,37,38,39	4
40,41,42,43,44,45,46,47	5
48,49,50,51,52,53,54,55	6
56,57,58,59,60,61,62,63	7

Default CLI Settings

PicOS will startup with the following CLI commands by default. Users can change the pre-defined CoPP policies but are NOT allowed to delete them.

NOTE: The values of min-bandwidth-pps and max-bandwidth-pps are different on different platforms.

 # Default configurations of forwarding class for CoPP.

CoPP Configuration

- Configuration Notes
- Configuring CoPP
- Configuration Example

Configuration Notes

When configuring CoPP on a device, pay attention to the following points:

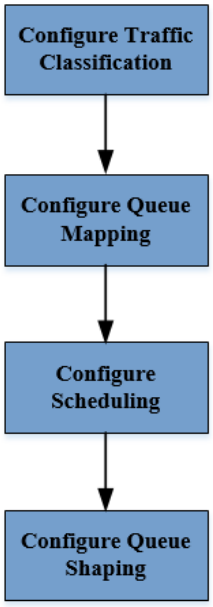
- CoPP configures control policy of the traffic from the ASIC to CPU. It is a very sensitive process of the whole switch OS. Any incorrect setting could impact the stability or could even paralyze the normal network operation. **It is therefore highly recommended to KEEP the default configurations of CoPP to ensure the system and network stability.**
- The CoPP policy takes effect only on the packets directed to the CPU.
- Users should not change the default sequence number of the system pre-defined control plane protocols. Please refer to Default Settings for CoPP for details about the pre-defined control plane protocols.
- For the current PicOS realization, IPv6 firewall filter rules are only supported on switch platforms of PRONTO3295, PRONTO3290, PRONTO3297 and AS4610_54P.
- The total value of min-bandwidth-pps of all activated queues should be less than CPU-affordable bandwidth, which should be the maximum bandwidth threshold to the CPU that is different depending on platform.
- Maximum of 32 CoPP matching rules specified with sequence number can be configured separately for IPv4 and IPv6 in the whole switch system.
- Users can change the pre-defined CoPP policies but are NOT allowed to delete them.
- It is acceptable that packets might be lost when users are making changes to the CoPP policies, such as when queue mapping is being set.
- The prerequisite of the protocol related CoPP policy taking effect is that the protocol function works well. BPDU, LLDP, LACP and ARP are not subject to this limitation.
- BPDU, LLDP, LACP and ARP cannot be classified through the protocol matching field, as they are not an IP protocol. You can classify these protocol packets through other matching fields, such as destination-mac-address, destination-port and ether-type.
- Adding IPv6 firewall filter rule could occupy as many as 128 TCAM ACL entries.
- The ranges of max-bandwidth-pps and min-bandwidth-pps are different on different platform.
- Although the realization and commands of CoPP use the QoS related module of CoS (Class of Service) and Firewall Filter Rule, but CoPP has its own command line with a fixed keyword **copp**, distinguishing it from the ACL feature.
- **set firewall filter copp sequence from protocol icmp** and **set firewall filter copp sequence from protocol igmp** commands configure the firewall filter rules based on the ICMP or IGMP protocol type for only IPv4 traffic classification. To configure the firewall filter rule based on the ICMP or IGMP protocol type for IPv6 traffic classification, use the **set firewall filter copp sequence from protocol others** command with the protocol number.

Configuring CoPP

Figure 1 outlines the CoPP configuration process in the following steps:

1. Configure traffic classification: Define a group of matching rules to classify traffic which is the basis for differentiated services.
2. Configure queue mapping: Configure a forwarding class and local priority for sending different types of packets to a specified CPU queue.
3. Configure scheduling: Select a queue and process the packets from the queue with WRR scheduling algorithm and configure a queue scheduler weight.
4. Configure queue shaping: Set minimum bandwidth and maximum bandwidth for each CPU queue.

Figure 1 CoPP Configuration Process



Procedure

Step1 Configure CoPP firewall filter rule for traffic classification.

set firewall filter copp sequence <*number*> **from destination-mac-address** <*mac-address*>

NOTE:

- The matching fields of firewall filter rule could be **destination-mac-address**, **source-mac-address**, **destination-address-ipv4** for IPv4 matching rule, **destination-address-ipv6** for IPv6 matching rule, **source-address-ipv4** for IPv4 matching rule, **source-address-ipv6** for IPv6 matching rule, **protocol**, **destination-port**, **source-port**, **ether-type** and **vlan**.
- **and** is the logical operator between the matching fields with the same sequence number, that is, packets must match all of the matching fields with the same sequence number to be included in one class.
- Maximum of 32 CoPP matching rules specified with sequence number can be configured separately for IPv4 and IPv6 in the whole switch system.
- It is not allowed to commit the configuration if configured **from** node of matching field without configuring **then** node of the same sequence number. However, it is allowed to configure **then** node without configuring **from** node, the configuration of **then** node is not used.

Step2 Configure queue mapping of CoPP policy.

set firewall filter copp sequence <*number*> **then forwarding-class** <*forwarding-class name*>

Step3 Configure mapping between forwarding class and local priority.

set class-of-service forwarding-class <*forwarding-class-name*> **local-priority** <*int*>

Step4 Configure queue scheduler weight.

set class-of-service scheduler <*scheduler-name*> **weight** <*value*>

NOTE:

It is NOT recommended to use the weight value for CPU queue scheduling due to hardware restrictions.

Step5 Configure WRR scheduling algorithm for queue scheduling.

set class-of-service scheduler <*scheduler-name*> **mode WRR**

Step6 Configure max bandwidth and min bandwidth for queue shaping.

set class-of-service scheduler <*scheduler-name*> **max-bandwidth-pps** <*value*>

set class-of-service scheduler <*scheduler-name*> **min-bandwidth-pps** <*value*>

NOTE:

The total value of min-bandwidth-pps of all activated queues should be less than the CPU-affordable PPS depending on different platforms, which should be the maximum PPS threshold to the CPU.

Step7 Configure the DSCP remark for COPP.

set firewall filter copp sequence <*number*> **then dscp** <*dscp-value*>

Step8 Configure CoPP scheduler profile.

set class-of-service scheduler-profile copp-profile forwarding-class <*forwarding-class-name*> **scheduler** <*scheduler-name*>

Configuration Example

- Networking Requirements
- Procedure
- Verify the Configuration

Networking Requirements

In order to protect switch CPU from attacks and being overloaded by control plane packets, maintaining data forwarding and network topology stability, configure different CoPP policy for flows of different control plane protocols: SSH, NTP, TFTP and SLOW.

Procedure

Step1 Configure CoPP queue mapping, scheduling weight, scheduling algorithm and queue shaping.

```
admin@Xorplus# set class-of-service scheduler copp-scheduler180 mode WRR
admin@Xorplus# set class-of-service scheduler copp-scheduler180 max-bandwidth-pps 180
admin@Xorplus# set class-of-service scheduler copp-scheduler180 min-bandwidth-pps 0
admin@Xorplus# set class-of-service scheduler copp-scheduler180 weight 5
admin@Xorplus# set class-of-service scheduler-profile copp-profile forwarding-class copp-class1 scheduler copp-sche
admin@Xorplus# set class-of-service scheduler-profile copp-profile forwarding-class copp-class2 scheduler copp-sche

admin@Xorplus# set class-of-service scheduler copp-scheduler200 mode WRR
admin@Xorplus# set class-of-service scheduler copp-scheduler200 max-bandwidth-pps 200
admin@Xorplus# set class-of-service scheduler copp-scheduler200 min-bandwidth-pps 0
admin@Xorplus# set class-of-service scheduler copp-scheduler200 weight 10
admin@Xorplus# set class-of-service scheduler-profile copp-profile forwarding-class copp-class3 scheduler copp-sche

admin@Xorplus# set class-of-service scheduler copp-scheduler300 mode WRR
admin@Xorplus# set class-of-service scheduler copp-scheduler300 max-bandwidth-pps 300
admin@Xorplus# set class-of-service scheduler copp-scheduler300 min-bandwidth-pps 0
admin@Xorplus# set class-of-service scheduler copp-scheduler300 weight 20
admin@Xorplus# set class-of-service scheduler-profile copp-profile forwarding-class copp-class4 scheduler copp-sche
```

#Configure a policer 50pps.

```
admin@Xorplus# set firewall policer 50pps if-exceeding rate-limit 50
admin@Xorplus# set firewall policer 50pps if-exceeding burst-limit 50
```

#Configure mapping between forwarding class and local priority.

```
admin@Xorplus# set class-of-service forwarding-class copp-class1 local-priority 1
admin@Xorplus# set class-of-service forwarding-class copp-class2 local-priority 2
admin@Xorplus# set class-of-service forwarding-class copp-class3 local-priority 3
admin@Xorplus# set class-of-service forwarding-class copp-class4 local-priority 4
```

Step2 Configure destination-port and protocol to classify SSH flow, and mapping to forwarding class copp-class3.

```
admin@Xorplus# set firewall filter copp sequence 83 then action forward
admin@Xorplus# set firewall filter copp sequence 83 from destination-port 22
admin@Xorplus# set firewall filter copp sequence 83 from protocol tcp
admin@Xorplus# set firewall filter copp sequence 83 then forwarding-class copp-class3
admin@Xorplus# set firewall filter copp sequence 83 then policer 50pps

admin@Xorplus# set firewall filter copp sequence 84 then action forward
admin@Xorplus# set firewall filter copp sequence 84 from source-port 22
admin@Xorplus# set firewall filter copp sequence 84 from protocol tcp
admin@Xorplus# set firewall filter copp sequence 84 then forwarding-class copp-class3
admin@Xorplus# set firewall filter copp sequence 84 then policer 50pps
```

Step3 Configure destination-port, protocol and ether-type to classify NTP (Network Time Protocol) flow, and mapping to forwarding class copp-class1.

```
admin@Xorplus# set firewall filter copp sequence 91 then action forward
admin@Xorplus# set firewall filter copp sequence 91 from destination-port 123
```

```
admin@Xorplus# set firewall filter copp sequence 91 from protocol udp
admin@Xorplus# set firewall filter copp sequence 91 then forwarding-class copp-class1

admin@Xorplus# set firewall filter copp sequence 92 then action forward
admin@Xorplus# set firewall filter copp sequence 92 from destination-port 123
admin@Xorplus# set firewall filter copp sequence 92 from ether-type 34525
admin@Xorplus# set firewall filter copp sequence 92 from protocol udp
admin@Xorplus# set firewall filter copp sequence 92 then forwarding-class copp-class1
```

Step4 Configure destination-port, protocol and ether-type to classify TFTP flow, and mapping to forwarding class copp-class2.

```
admin@Xorplus# set firewall filter copp sequence 108 then action forward
admin@Xorplus# set firewall filter copp sequence 108 from destination-port 69
admin@Xorplus# set firewall filter copp sequence 108 from protocol udp
admin@Xorplus# set firewall filter copp sequence 108 then forwarding-class copp-class2

admin@Xorplus# set firewall filter copp sequence 109 then action forward
admin@Xorplus# set firewall filter copp sequence 109 from source-port 69
admin@Xorplus# set firewall filter copp sequence 109 from protocol udp
admin@Xorplus# set firewall filter copp sequence 109 then forwarding-class copp-class2
```

Step5 Configure destination-mac-address and ether-type to classify SLOW flow, and mapping to forwarding class copp-class4.

```
admin@Xorplus# set firewall filter copp sequence 111 then action forward
admin@Xorplus# set firewall filter copp sequence 111 from destination-mac-address 01:80:C2:00:00:02
admin@Xorplus# set firewall filter copp sequence 111 from ether-type 34825
admin@Xorplus# set firewall filter copp sequence 111 then forwarding-class copp-class4
```

Step6 Commit the configuration.

```
admin@XorPlus# commit
```

Verify the Configuration

- You can use the **run show copp bandwidth** command to view the bandwidth information, scheduling information and local priority of the forwarding class.

```
admin@Xorplus# run show copp bandwidth
Forwarding Class  Min-Bandwidth Max-Bandwidth Weight Local-Priority Schedule-Mode

Drop Octets.............................0

copp-class4 Traffic statistics:
forwarding-class state: active
Input rate 0 bits/sec, 0 packets/sec
Input Packets............................0
Input Octets.............................0
Drop rate 0 bits/sec, 0 packets/sec
Drop Packets............................0
Drop Octets.............................0
```

- You can use the **run show copp statistics forwarding-class** command to view the statistics information of the specified forwarding class.

```
admin@Xorplus# run show copp statistics forwarding-class copp-class1
copp-class1 Traffic statistics:

forwarding-class state: active
Input rate 0 bits/sec, 0 packets/sec
Input Packets............................0
Input Octets.............................0
Drop rate 0 bits/sec, 0 packets/sec
Drop Packets............................0
Drop Octets.............................0
```

- You can use the **run show interface stm** command to view the total STM resources that are available and how many STM entries are in use. The item **number of firewall egress tables** is used for describing STM resources of CoPP. By default, the value of **number of firewall egress tables** in **Stm resource in use:** is 21 as have been used by the default CoPP configurations.

```
admin@Xorplus# run show interface stm
Total stm resource:
  Share-mode: 5
  number of host routes: 32768
  number of mac unicast addresses: 32768
  number of firewall ingress tables: 896
  number of firewall egress tables: 510
  number of IPv4 unicast routes: 5000
  number of IPv6 unicast routes: 500
Stm resource in use:
  number of firewall ingress tables: 2
  number of firewall egress tables: 29
```

- You can use the **run clear copp statistics** command to clear the past statistics information of CoPP policy.

```
admin@Xorplus# run clear copp statistics
admin@Xorplus# commit
```

Default Settings for CoPP

- Default Queue Mapping Policy
- Default CLI Settings
- Show Default Settings of CoPP

NOTE:

- Default settings for CoPP in this page applies for all the PicOS supported switches except N2224PX-ON/N2248X-ON/N3208PX-ON.
- CoPP configures control policy of the traffic from the ASIC to CPU. It is a very sensitive process of the whole switch OS. Any incorrect setting could impact the stability or could even paralyze the normal network operation. **It is therefore highly recommended to KEEP the default configurations of CoPP to ensure the system and network stability.**

Default Queue Mapping Policy

By default, CoPP provides 27 CPU queues for data forwarding that would have a default scheduling weight. The system pre-defines 16 types of control plane protocols mapping from queue 8 to 26. The default queue mapping policy is as follows.

Table 1. Default Queue Mapping Policy

Protocols	CPU Queue	Default Scheduling Weight
MPLS LDP	29	16
IS-IS	28	16
Loopback Detection	27	32
RIPng	26	16
ERPS	25	32
MVRP	24	32
SSH/SNMP/NTP/TACACS/RADIUS	23	12
BPDU	22	32
LACP	21	32
LLDP	20	32
ARP	19	32
NDP	18	32
BFD	17	16
MLAG	16	16

MLAG-MAC-SYNC	15	16
BGP	14	16
OSPF	13	16
RIP	12	16
DHCP/DHCPv6	11	16
VRRP	10	16
IGMP	9	16
PIM	8	16
Reserved	7	-
Reserved	6	-
Reserved	5	-
Reserved	4	-
Reserved	3	-
Reserved	2	-
Reserved	1	-
Default*	0	0

Reserved: Reserved CPU queues indicate the CPU queues that have not been used by the system pre-defined queue mapping settings. For user-defined CoPP policy, it is recommended to use the reserved queues for queue mapping settings.

Default*: The flow of traffic directed to switch CPU will be sent to CPU queue 0 when the traffic matches no firewall filter rule.

But for the packet with an Inet Precedence or DSCP value, it will not always be sent to CPU queue 0 when the traffic matches no firewall filter rule. When you configure the classifier to classify services on different inbound interfaces by using **set class-of-service classifier trust-mode dscp** and **set class-of-service interface classifier** commands. The packets will be sent to the CPU queue according to the Inet Precedence or DSCP value. Mappings from Inet Precedence/DSCP value to CPU Queue are shown in the following tables.

Table 2. Mapping from Inet Precedence value to CPU Queue

Inet-precedence	CPU Queue
0	0
1	1
2	2
3	3
4	4
5	5
6	6
7	7

Table 3. Mapping from DSCP value to CPU Queue

DSCP	CPU Queue
0,1,2,3,4,5,6,7	0
8,9,10,11,12,13,14,15	1
16,17,18,19,20,21,22,23	2
24,25,26,27,28,29,30,31	3
32,33,34,35,36,37,38,39	4
40,41,42,43,44,45,46,47	5
48,49,50,51,52,53,54,55	6
56,57,58,59,60,61,62,63	7

Default CLI Settings

PicOS will startup with the following CLI commands by default. Users can change the pre-defined CoPP policies but are NOT allowed to delete them.

NOTE: The values of min-bandwidth-pps and max-bandwidth-pps are different on different platforms.

 # Default configurations of forwarding class for CoPP.

Queue-based Rate Limiting

- Configuring Queue-based Rate Limiting
  - Procedure
- Configuration Example
  - Network Requirements
  - Procedure

The queue-based rate limiting controls the rate of the physical interface egress queue to adjust the traffic rates to enable traffic to be transmitted at an even rate, thus preventing congestion on the downstream device. When the transmit rate of packets exceeds the queue-based rate limit, the packets will be discarded.

Configuring Queue-based Rate Limiting

When packets arrive, the system classifies packets and places them into different egress queues. The device can provide differentiated services for queues of different priorities using different rate limiting parameter settings for these queues.

Procedure

Step1 Configure scheduling algorithm for queue scheduling.

set class-of-service scheduler <*scheduler-name*> **mode** <**SP | WRR | WFQ**>

Step2 Configure guaranteed rate and the maximum rate for the interface queue.

set class-of-service scheduler <*scheduler-name*> **guaranteed-rate** <*value*>

set class-of-service scheduler <*scheduler-name*> **max-rate** <*value*>

> **NOTE:**
>
> If both queue-based rate limiting and interface-based rate limiting (configured by the command **set interface gigabit-ethernet** <*port*> **rate-limiting** <**ingress** | **egress**> **kilobits** <*kilobits-ps*>) are configured on the interface, the smaller value of the two will be used for rate limiting.

Step3 Configure scheduler profile associated with the configured scheduler and forwarding class.

set class-of-service scheduler-profile <*scheduler-profile-name*> **forwarding-class** <*forwarding-class-name*> **scheduler** <*scheduler-name*>

Step4 Configure mapping between forwarding class and local priority.

set class-of-service forwarding-class <*forwarding-class-name*> **local-priority** <*int*>

Step5 Apply the scheduler profile to an egress interface.

set class-of-service interface <*interface-name*> **scheduler-profile** <*scheduler-profile-name*>

Configuration Example

Network Requirements

As shown in Figure 1, User1, User2, and User3 are three different types of user devices in the network. They are respectively connected to the interfaces Ge-1/1/1, Ge-1/1/2, and Ge-1/1/3 of the Switch. The Switch is connected to the Router through interface Ge-1/1/4.

On the Switch, configure service classification for different users and queue mapping of egress interface for different services. Set different guaranteed rate and maximum rate for the physical interface egress queues for different services to reduce network congestion and ensure the bandwidth requirements of each service.

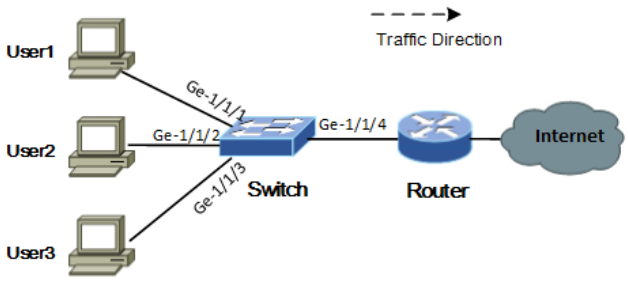

Figure 1. Queue-based Rate Limiting Configuration Example

The configuration process is as follows:

1. Create VLANs and configure VLAN members on each interface to enable the users to access the network through the Switch.
2. Configure classifier to classify services on different inbound interfaces and queue mapping of outbound interface for different services.
3. Configure queue schedulers for the physical interface egress queue.
4. Configure queue-based rate limiting to limit the bandwidth of User1, User2, and User3 services.

Procedure

Step1 Configure VLANs.

```
admin@XorPlus# set vlans vlan-id 199
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 199
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 199
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 family ethernet-switching vlan members 199
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/4 family ethernet-switching vlan members 199
```

Step2 Configure classifier to classify services on different inbound interfaces.

```
admin@XorPlus# set class-of-service classifier c1 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c2 trust-mode inet-precedence
admin@XorPlus# set class-of-service classifier c3 trust-mode dscp
admin@XorPlus# set class-of-service interface ge-1/1/1 classifier c1
admin@XorPlus# set class-of-service interface ge-1/1/2 classifier c2
admin@XorPlus# set class-of-service interface ge-1/1/3 classifier c3
```

Step3 Configuring the queue scheduling algorithm.

```
admin@XorPlus# set class-of-service scheduler s1 mode SP
admin@XorPlus# set class-of-service scheduler s2 mode SP
admin@XorPlus# set class-of-service scheduler s3 mode SP
```

Step4 Configure the guaranteed rate and maximum rate of the interface egress queue.

```
admin@XorPlus# set class-of-service scheduler s1 guaranteed-rate 5000
admin@XorPlus# set class-of-service scheduler s2 guaranteed-rate 15000
admin@XorPlus# set class-of-service scheduler s3 guaranteed-rate 20000
admin@XorPlus# set class-of-service scheduler s1 max-rate 30000
admin@XorPlus# set class-of-service scheduler s2 max-rate 30000
admin@XorPlus# set class-of-service scheduler s3 max-rate 30000
```

Step5 Configure the scheduler-profile and queue mapping of egress interface.

```
admin@XorPlus# set class-of-service forwarding-class f0 local-priority 0
admin@XorPlus# set class-of-service forwarding-class f3 local-priority 3
admin@XorPlus# set class-of-service forwarding-class f7 local-priority 7
admin@XorPlus# set class-of-service scheduler-profile p1 forwarding-class f0 scheduler s1
admin@XorPlus# set class-of-service scheduler-profile p1 forwarding-class f3 scheduler s2
admin@XorPlus# set class-of-service scheduler-profile p1 forwarding-class f7 scheduler s3
```

Step6 Apply scheduler-profile to egress interface Ge-1/1/4.

```
admin@XorPlus# set class-of-service interface ge-1/1/4 scheduler-profile p1
```

Interface-based Rate Limiting

Interface-based rate limiting controls the total rate of all packets passing through an interface to ensure that the bandwidth usage is within the allowed range. For the same interface, you can configure interface-based rate limiting in both ingress and egress directions or in only one direction.

- Configuring Ingress Interface-based Rate Limiting
- Configuring Egress Interface-based Rate Limiting

Configuring Ingress Interface-based Rate Limiting

If you do not limit the traffic sent by users, the continuous burst of data of a large number of users will make the network more crowded. By configuring the ingress interface-based rate limiting on the interface, you can limit the traffic entering the interface to a reasonable range.

set interface gigabit-ethernet <*interface-name*> **rate-limiting ingress kilobits** <*value*>

set interface gigabit-ethernet <*interface-name*> **rate-limiting ingress ratio** <*value*>

set interface gigabit-ethernet <*interface-name*> **rate-limiting ingress burst** <*burst-size*>

NOTE:

- In the same direction of the same interface, kilobits and ratio cannot be configured simultaneously.
- Tomahawk series switches (including Tomahawk, Tomahawk+, Tomahawk2 and so forth) do not support ingress interface-based rate limiting.
- When burst size is not configured, PICOS uses a burst size adapted according to the configured rate limiting value configured by the **set interface gigabit-ethernet** <*interface-name*> **rate-limiting ingress kilobits** <*value*> or **set interface gigabit-ethernet** <*interface-name*> **rate-limiting ingress ratio** <*value*> command.

Configuration Example

- Set the rate limit to 8000 kbit/s on interface te-1/1/1 for the ingress traffic, and use the system adapted burst size.

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/1 rate-limiting ingress kilobits 8000
admin@Xorplus# commit
```

- You can use **run show interface gigabit-ethernet** command to check the configuration, where "**Interface rate limit ingress: , egress:** " and "**Interface burst limit ingress: , egress:** " indicating the configuration of interface-based rate limit and burst size.

```
admin@Xorplus# run show interface gigabit-ethernet te-1/1/1
Physical interface: te-1/1/1, Enabled, error-discard False, Physical link is Down
Interface index: 1, Mac Learning Enabled
Port mode:  access
Description:
Link-level type: Ethernet, MTU: 1514, Speed: Auto, Duplex: Full
Source filtering: Disabled, Flow control: Disabled, Auto-negotiation: Disabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit ingress:8000kbps, egress:unlimited
Interface burst limit ingress:10kb, egress:unlimited
Link fault signaling ignore local fault:false, ignore remote fault:false
force up mode:false
Precision Time Protocol mode:none

5 sec input rate 0 bits/sec, 0 packets/sec
5 sec output rate 0 bits/sec, 0 packets/sec
Input Packets.............................0
Output Packets............................0
Input Octets..............................0
Output Octets............................0
```

Configuring Egress Interface-based Rate Limiting

To control the rate of all outgoing traffic on an interface, configure egress interface-based rate limiting. When the transmit rate of packets exceeds the configured rate limit, the excess packets will be discarded.

set interface gigabit-ethernet <*interface-name*> **rate-limiting egress kilobits** <*value*>

set interface gigabit-ethernet <*interface-name*> **rate-limiting egress ratio** <*value*>

set interface gigabit-ethernet <*interface-name*> **rate-limiting egress burst** <*burst-size*>

> **NOTE**:
>
> - In the same direction of the same interface, kilobits and ratio cannot be configured simultaneously.
> - When burst size is not configured, PICOS uses a burst size adapted according to the configured rate limiting value configured by the **set interface gigabit-ethernet** <*interface-name*> **rate-limiting egress kilobits** <*value*> or **set interface gigabit-ethernet** <*interface-name*> **rate-limiting egress ratio** <*value*> command.

Configuration Example

- Set the rate limit to 8000 kbit/s on interface te-1/1/1 for the egress traffic, and use the system adapted burst size.

```
admin@Xorplus# set interface gigabit-ethernet te-1/1/1 rate-limiting egress kilobits 8000
admin@Xorplus# commit
```

- You can use **run show interface gigabit-ethernet** command to check the configuration, where "**Interface rate limit ingress: , egress:** " and "**Interface burst limit ingress: , egress:** " indicating the configuration of interface-based rate limit and burst size.

```
admin@Xorplus# run show interface gigabit-ethernet te-1/1/1
Physical interface: xe-1/1/1(49), Enabled, error-discard False, Physical link is Down
Interface index: 73, Mac Learning Enabled
Port mode: access
Description:
Link-level type: Ethernet, MTU: 1518, Speed: Auto, Duplex: Full
Cdr: Enabled
Source filtering: Disabled, Flow control: Disabled
Auto-negotiation: Disabled
Interface flags: Hardware-Down SNMP-Traps Internal: 0x0
Interface rate limit  ingress: unlimited, egress: unlimited
Interface burst limit ingress: unlimited, egress: unlimited
Link fault signaling  ignore local fault: false, ignore remote fault: false

  Output Packets.....................0
  Input Octets.....................0
  Output Octets.....................0
```

WRR Configuration Example

As shown in Fig 2, ge-1/1/1 and ge-1/1/2 are ingress ports. ge-1/1/3 is the egress port. Use WRR scheduling model: priority trust mode is IEEE 802.1.

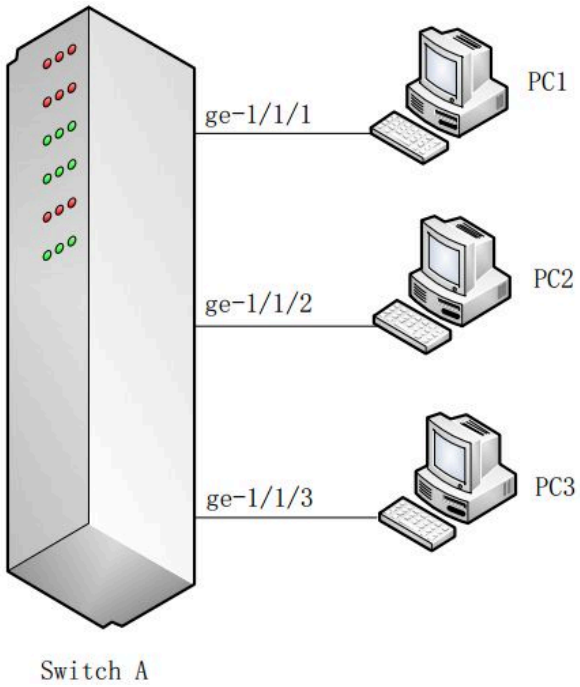

Fig 2. Configure WRR

Configure Scheduler

Configure two schedulers: s1 and s2. Their modes are WRR. Configure scheduler s1's weight as 1 and s2's weight as 3.

```
admin@XorPlus# set class-of-service scheduler s1 mode WRR
admin@XorPlus# set class-of-service scheduler s2 mode WRR
admin@XorPlus# set class-of-service scheduler s1 weight 1
admin@XorPlus# set class-of-service scheduler s2 weight 3
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure Two Forwarding-Classes

Configure forwarding-classes, f1, f2, and their local-priorities.

```
admin@XorPlus# set class-of-service forwarding-class f1 local-priority 3
admin@XorPlus# set class-of-service forwarding-class f2 local-priority 6
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring Classifiers and Apply Classifiers to Ingress Ports

Configure classifier c1, c2, and the trust mode for each. Configure classifier relevant to the forwarding class. Both c1 and c2 are used as ingress ports, and they should contain code point, not scheduler.

```
admin@XorPlus# set class-of-service classifier c1 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c1 forwarding-class f1 code-point 5
admin@XorPlus# set class-of-service classifier c2 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c2 forwarding-class f2 code-point 7
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set class-of-service interface ge-1/1/1 classifier c1
admin@XorPlus# set class-of-service interface ge-1/1/2 classifier c2
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show class-of-service interface ge-1/1/1

7                SP,0kbps
```

Generate Traffic

PC1 and PC2 generate traffic that are matched with the corresponding classifier. PC1 and PC2 send 100% of traffic to PC3 at the same time.

The expected result is that PC3 can receive packets from PC1 and PC2, and their rate is 1:3, that is the weight proportion in the corresponding queue.

Buffer Management

NOTE:

On Trident and Trident+ based switches, known unicast packets can be assigned to a specific queue between queues from 0 to 7, while unknown unicast packets, multicast packets, and broadcast packets can be assigned to a specific queue between queues from 0 to 3.

Introduction

When the network congestion, the port don't send data immediately, to prevent data loss, device can transmit the temporay storage of data to the data buffer.

1. Accounting Resources

The chip has the fixed-sized cells. Each cell is 208 bytes long. The first cell used by a packet contains two payloads. The first payload is a 64-byte packet descriptor, and the second payload contains 144 bytes of packet data. Every cell, after the first one used by a packet, uses the complete 208 bytes for packet data . A packet use at least one cell. The length of packet decides how many cell the packet uses. For example， untagged packeets 64 bytes to 144 bytes long use one cell. A 352-byte packet would require two cells. And packets from 1393-bytes to 1600-bytes long use eight cells.

2. Memory Spaces

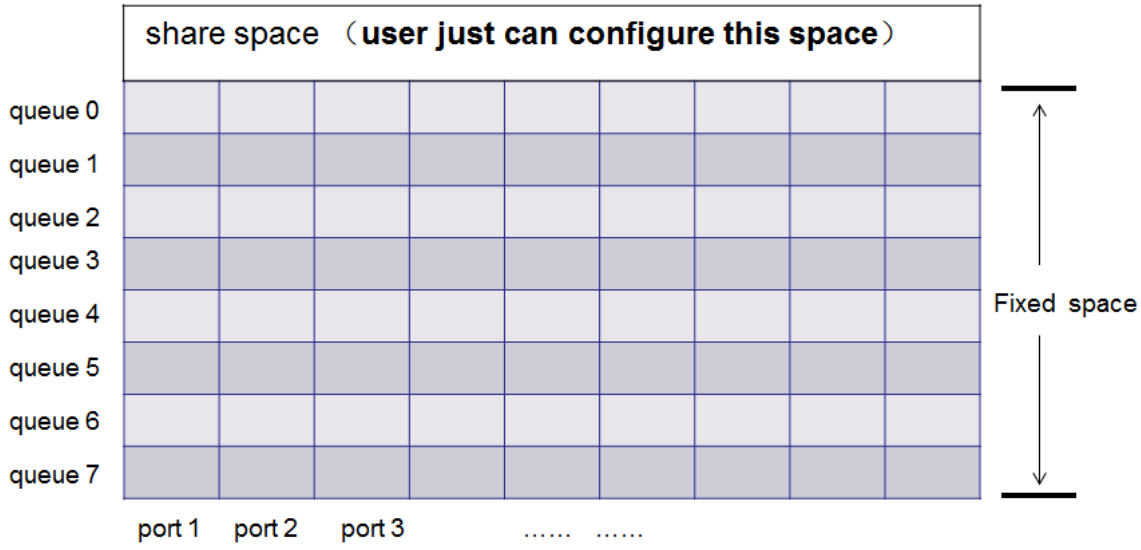
The cell data buffer is divided into fixed and shared spaces.

- Fixed space

Fixed space provide minimum guaranteed space on a per priority group and per port basis. This space cannot be shared with other ports. When the port congestion occurs, it will occupy fixed space first, shared space will be used when the fixed space is full. The Fixed space should not be too big, otherwise it will waste space resources.

- Shared space

The shared space will be used by all ports and priority groups when the fixed space run out. When the shared space is used up, the packet is discarded. If a queue don't store packet, the others queue will grab this queue space. For a queue,all of ports transmit packets will first come first served, if the used resource reach the threhold, packets will be dropped after arrived.The shared space can be configured dynamic or static threshold at the logical level of the queue.



Command configuration

The device provide separate UC (unicast) and MC (multicase) queue. For the unicast queue and multicast queue. The UC queues are used to store known unicast packets and can be flexibly assigned while the MC queues are used to store DLF, multicast, broadcast and mirrored packets. While the CPU port does not support separate UC and MC queues, the CPU port does have a total of 48 queues available, and these queues are eligible for both UC and MC traffic based on CPU Cos mapping. We have different configuration to deal with share space：

1.multicast queue：

static mode: This is the default configuration

- The value of the static threshold is configured for the multicast queue in the shared space.This avoids the case that the port enabled flow control or PFC affects the forwarding of other ports. But the disadvantage is less efficient use of memory.

dynamic mode : Need to configure

- The memory threhold is adjusted dynamically according to the avaliable shared memory in this mode. The threholds will reduce when the remaining shared memory reduces. The threholds will rise up when the remaining shared memory rises up.

For example, enable queue 0 dynamic-shared

```
root@XorPlus# set interface ethernet-switching-options buffer egress-queue 0 mc-queue-dynamic-shared true
root@XorPlus# commit
Commit OK.
Save done.
```

2.unicast queue：

dynamic mode ：

- dynamic threshold is the default mode for the unicast queue，and it can't configure static threshold.

3.dynamic threshold ratio configuration

The dynamic mode both of multicast (must enable dynamic threshold) and unicast queue can configure the max dynamic threshold ratio. The threhold is still dynamically adjusted until reaching the max ratio configured.

For example, configure dynamic threshold ratio 50% for queue 0

```
root@XorPlus# set interface ethernet-switching-options buffer egress-queue 0 shared-ratio 50
root@XorPlus# commit
```

Check the configuration result

```
root@XorPlus# run show interface egress-buffer
Queue UC-Enabled UC-Shared-Ratio MC-Enabled MC-Shared-Ratio
0     true       50              true       50
1     true       33              false      --
2     true       33              false      --
3     true       33              false      --
4     true       33              false      --
5     true       33              false      --
6     true       33              false      --
7     true       33              false      --
```

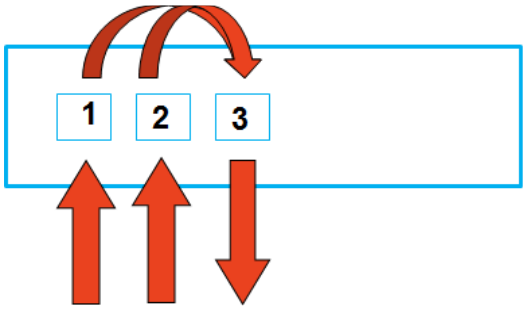
For the maximum shared-area ratio for a queue, the percentage values 0 to 100 are divided into 10 rages.The table below shows the effective values that correspond to the configured values of ratio-value.

Value of *ratio-value*	Effective value
0 to 1	1
2 to 3	3
4 to 7	6
8 to 16	11
17 to 29	20
30 to 42	33
43 to 60	50
61 to 76	67
77 to 86	80
87 to 100	89

notice

Now, multicast queue just support eight （1~67）effective ratio value on all platforms

Application notice



As show above: send packets from port1 and port2 to port3 in 10G speed in queue 0, and port3 will be in congestion.

For the multicast flow, if flow control is enabled on port1 and port2 and configure static threshold, the packets also perhaps will be dropped in port 3 egress queue. Ingress don't send pause frame because egress's shared-ratio is smaller than ingress's and egress reach it's threhold before igress reach.

So if users meet this issue, in this case, we suggest users configure dynamic mode. port1 and port2 will send out pause frame before port3 queue limit is reached, and accept burst packets to avoid packet drop.

WFQ Configuration Example

As shown in Fig 3, ge-1/1/1 and ge-1/1/2 are ingress ports. ge-1/1/3 is the egress port. Use the WFQ scheduling model. Priority trust model is IEEE 802.1. The bandwidth is 100Mbps.

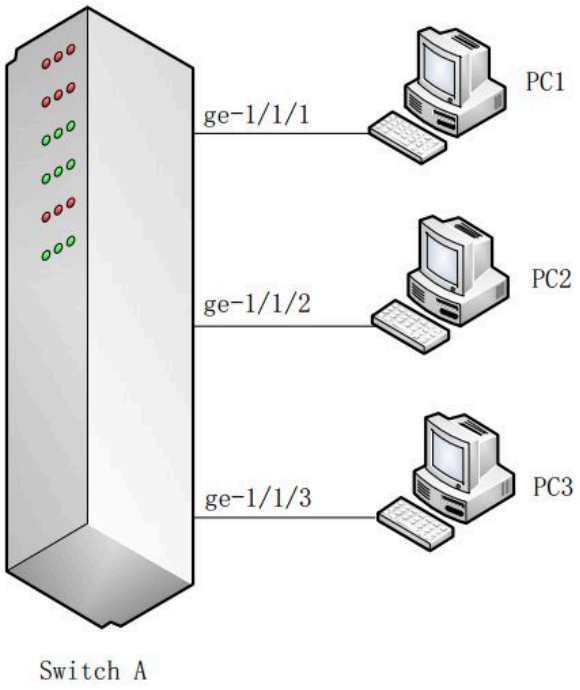


Fig 3. Configure WFQ

Configure Scheduler

Configure two schedulers (s1 and s2) with guaranteed-rates and their modes WFQ. Configure scheduler s1 weighted at 1 and scheduler s2 weighted at 3. The guaranteed-rate of scheduler s1 is 10000, and the guaranteed-rate of scheduler s2 is 30000.

```
admin@XorPlus# set class-of-service scheduler s1 mode WFQ
admin@XorPlus# set class-of-service scheduler s2 mode WFQ
admin@XorPlus# set class-of-service scheduler s1 weight 1
admin@XorPlus# set class-of-service scheduler s1 guaranteed-rate 10000
admin@XorPlus# set class-of-service scheduler s2 weight 3
admin@XorPlus# set class-of-service scheduler s2 guaranteed-rate 30000
admin@XorPlus# commit
Commit OK.
Save done.
```

Configure Two Forwarding-Classes

Configure forwarding-class f1 and f2 and their local-priorities.

```
admin@XorPlus# set class-of-service forwarding-class f1 local-priority 3
admin@XorPlus# set class-of-service forwarding-class f2 local-priority 6
```

```
admin@XorPlus# commit
Commit OK.
Save done.
```

Configuring Classifier and Apply Classifiers to Ingress Ports

Configure classifier c1, c2, and c3, as well as the trust mode. Configure classifiers relevant to the forwarding class. Classifiers c1 and c2 are used as the ingress ports, and they should contain code point, not scheduler.

```
admin@XorPlus# set class-of-service classifier c1 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c1 forwarding-class f1 code-point 5
admin@XorPlus# set class-of-service classifier c2 trust-mode ieee-802.1
admin@XorPlus# set class-of-service classifier c2 forwarding-class f2 code-point 7
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set class-of-service interface ge-1/1/1 classifier c1
admin@XorPlus# set class-of-service interface ge-1/1/2 classifier c2
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# run show class-of-service interface ge-1/1/1
Interface : ge-1/1/1

trust mode : ieee-802.1

7                SP,0kbps
```

Configuring Scheduler Profile and Apply Classifiers to Egress Ports

Scheduler profile p1 is used to egress port ge-1/1/3 and should contain a scheduler not containing code point.

```
admin@XorPlus# set class-of-service scheduler-profile p1 forwarding-class f1 scheduler s1
admin@XorPlus# set class-of-service scheduler-profile p1 forwarding-class f2 scheduler s2
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus# set class-of-service interface ge-1/1/3 scheduler-profile p1
admin@XorPlus# commit
Commit OK.
Save done.

admin@XorPlus# run show class-of-service interface ge-1/1/3
Interface : ge-1/1/3

trust mode : ieee-802.1
Default ieee-802.1 : 0
Default dscp : 0
Default inet-precedence : 0
Local-priority   Queue-Schedule                Code-points
--------------   -------------------------   ------------------------------
0                SP,0kbps
1                SP,0kbps
2                SP,0kbps
3                WFQ,1,10000kbps
4                SP,0kbps
5                SP,0kbps
6                WFQ,3,30000kbps
7                SP,0kbps
```

Generate Traffic

PC1 and PC2 generate traffic which are matched with the corresponding classifier. PC1 and PC2 send 100% traffic to PC3 at the same time.

The expected result is that PC3 can receive packets from PC1 and PC2, and their rate is about 1:3. That is, the weight proportion and the guaranteed-rate have corresponding queues.

set ip routing enable true
```

VXLAN Routing

This section provides how to implement and deploy VXLAN routing for L3 routing.

- Cross-Subnet Packet Forwarding Process
- Example for Configuring VXLAN for Different Subnets

Cross-Subnet Packet Forwarding Process

Cross-subnet packet forwarding between VXLAN and VXLAN subnet or between VXLAN and non-VXLAN subnet can be implemented through a Layer 3 gateway.

Supported Platforms

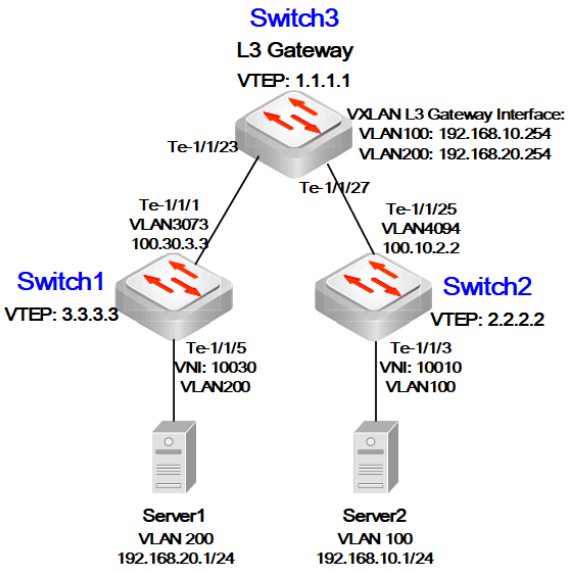
- VXLAN routing is supported on the following ASIC platforms: Trident2+, Trident3-X7, Trident3-X5 (Maverick2) and Trident3-X3 (Helix5).
- For Trident2+ switches, VXLAN routing can not work with non-VXLAN interface (including CPU interface). For example, it is not supported to forward a decapsulated VXLAN packet through a non-VXLAN port (for this example, users can configure the non-VXLAN interface to a VXLAN interface to solve the problem).

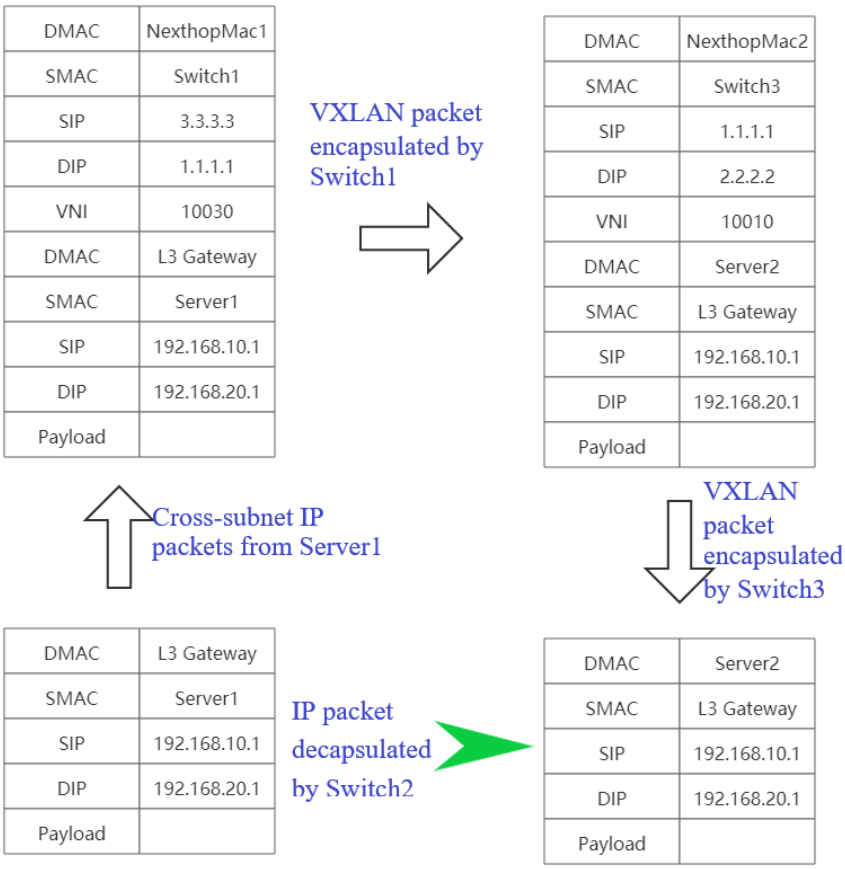
Cross-Subnet Packet Forwarding Process

PicOS supports to apply VXLAN routing on centralized gateway and distributed gateway.

Figure 1 shows the topology of cross-subnet packet forwarding and packet encapsulation in the centralized gateway scenario. A centralized gateway is a Layer 3 gateway deployed centrally on a single device, where all cross-subnet traffic is forwarded through the Layer 3 gateway to achieve centralized management of traffic.

Figure 1 Topology of cross-subnet packet forwarding and packet encapsulation





The packet forwarding process is as follows:

1. Switch 1 receives the message from Server 1, obtains the corresponding layer 2 broadcast domain according to the access port and VLAN information in the message, and finds out the interface and encapsulation information in the corresponding Layer 2 broadcast domain.
2. VTEP on Switch 1 performs VXLAN message encapsulation based on the obtained egress interface and VNI information, and forwards it to Switch 3.
3. After receiving the VXLAN packet, Switch 3 decapsulates it and finds that the destination MAC in the inner packet is the MAC address of VLAN100, which is the VXLAN Layer 3 gateway interface. Switch 3 then determines that Layer 3 forwarding is needed.
4. Switch 3 strips off the Ethernet encapsulation of the inner packet, obtains the destination IP. Then Switch 3 looks up the routing table according to the destination IP to find the next hop address. Then Switch 3 looks up the ARP table entry according to the next hop address to obtain the destination MAC, VXLAN tunnel egress interface and VNI information.
5. Switch 3 re-encapsulates the VXLAN packet and forwards it to Switch 2, in which the source MAC in the Ethernet header of the inner packet is the MAC address of the VXLAN Layer 3 gateway interface VLAN 200.
6. After receiving the VXLAN packet on Switch 2, VTEP determines the validity of VXLAN packet based on UDP destination port number, source/destination IP address and VNI.

   According to the VNI, the corresponding layer-2 broadcast domain is obtained. Switch 2 then obtains the interface and encapsulation information in the corresponding Layer 2 broadcast domain and performs VXLAN decapsulation on the packet.
7. Switch 2 forwards the message to Server 2 based on the egress interface and encapsulation information.

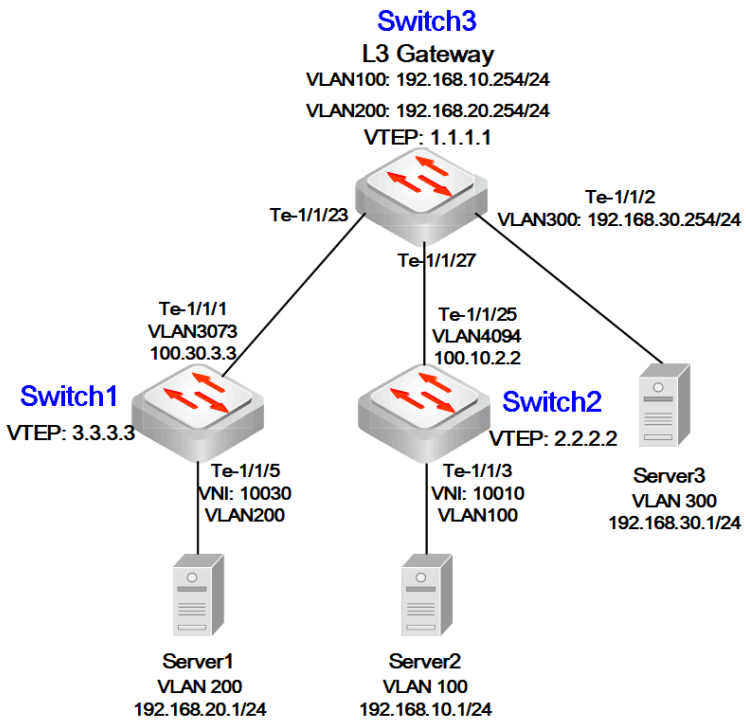
The process of message forwarding from Server 2 to Server 1 is similar and will not be repeated here.

Example for Configuring VXLAN for Different Subnets

- Networking Requirements
  - Figure 1 VXLAN Networking Topology with Centralized Gateway Deployment
- Procedure
  - Switch1
  - Switch2
  - Switch3
- Verify the Configuration

Networking Requirements

Figure 1 VXLAN Networking Topology with Centralized Gateway Deployment



As shown in **Figure 1**, in the centralized gateway scenario, an enterprise has its own servers in different data centers, Server 1 belongs to VLAN 200, Server 2 belongs to VLAN 100 and Server 3 belongs to VLAN 300. Server 1, Server 2 and Server 3 are located in different network segments. Cross-subnet packet forwarding needs to be implemented through a centralized Layer 3 gateway.

Configure different servers on different network segments to communicate with each other through a VXLAN centralized Layer 3 gateway by the following roadmap:

1. Configure static routes on Switch 1, Switch 2, and Switch 3 respectively to ensure network connectivity at the underlay network.
2. Configure VXLAN access network on Switch 1, Switch 2 and Switch 3 respectively to differentiate service flow.
3. Configure VXLAN tunnels on Switch 1, Switch 2 and Switch 3 respectively to forward service flow.
4. To enable users of different network segments to communicate with each other, configure VXLAN Layer 3 gateway on Switch 3. The following steps include how to configure VXLAN Layer 3 gateway:

   a) Configure VXLAN mapping of VNI to VLAN:

   set vxlans vni <*vni_id*> **vlan** <*vlan_id*>

   b) Configure L3 VLAN interface:

   set vlans vlan-id <*vlan_id*> **l3-interface** <*interface_name*>

   c) Configure the IP the L3 VLAN interface:

   set l3-interface vlan-interface <*interface_name*> **address** <*IP_address*> **prefix-length** <*prefix_length*>

Procedure

This section describes the steps of configuring VXLAN for different subnets on Switch1, Switch2 and Switch3.

Switch1

Step 1 Configure the VLANs.

```
admin@Switch1# set vlans vlan-id 200
admin@Switch1# set vlans vlan-id 3073
admin@Switch1# set vlans vlan-id 3073 l3-interface vlan3073
admin@Switch1# set l3-interface vlan-interface vlan3073 address 100.30.3.3 prefix-length 24
admin@Switch1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 3073
admin@Switch1# set interface gigabit-ethernet te-1/1/5 family ethernet-switching port-mode trunk
admin@Switch1# set interface gigabit-ethernet te-1/1/5 family ethernet-switching vlan members 200
```

Step 2 Enable IP routing and configure the route.

```
admin@Switch1# set ip routing enable true
admin@Switch1# set l3-interface loopback lo address 3.3.3.3 prefix-length 32
admin@Switch1# set protocols static route 1.1.1.1/32 next-hop 100.30.3.4
```

Step 3 Configure VXLAN tunnel.

```
admin@Switch1# set vxlans source-interface lo address 3.3.3.3
admin@Switch1# set vxlans vni 10030 vlan 200
admin@Switch1# set vxlans vni 10030 flood vtep 1.1.1.1
```

Step 4 Commit the configurations.

```
admin@Switch1# commit
```

Switch2

Step 1 Configure the VLANs.

```
admin@Switch2# set vlans vlan-id 100
admin@Switch2# set vlans vlan-id 4094
admin@Switch2# set vlans vlan-id 4094 l3-interface vlan4094
admin@Switch2# set l3-interface vlan-interface vlan4094 address 100.10.2.2 prefix-length 24
admin@Switch2# set interface gigabit-ethernet te-1/1/25 family ethernet-switching native-vlan-id 4094
admin@Switch2# set interface gigabit-ethernet te-1/1/3 family ethernet-switching port-mode trunk
admin@Switch2# set interface gigabit-ethernet te-1/1/3 family ethernet-switching vlan members 100
```

Step 2 Enable IP routing and configure the route.

```
admin@Switch2# set ip routing enable true
admin@Switch2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@Switch2# set protocols static route 1.1.1.1/32 next-hop 100.10.2.1
```

Step 3 Configure VXLAN tunnel.

```
admin@Switch2# set vxlans source-interface lo address 2.2.2.2
admin@Switch2# set vxlans vni 10010 vlan 100
admin@Switch2# set vxlans vni 10010 flood vtep 1.1.1.1
```

Step 4 Commit the configurations.

```
admin@Switch2# commit
```

Switch3

Step 1 Configure the VLANs.

```
admin@Switch3# set vlans vlan-id 100 l3-interface vlan100
admin@Switch3# set vlans vlan-id 200 l3-interface vlan200
admin@Switch3# set vlans vlan-id 300 l3-interface vlan300
admin@Switch3# set vlans vlan-id 3073 l3-interface vlan3073
admin@Switch3# set vlans vlan-id 4094 l3-interface vlan4094
admin@Switch3# set l3-interface vlan-interface vlan100 address 192.168.10.254 prefix-length 24
admin@Switch3# set l3-interface vlan-interface vlan200 address 192.168.20.254 prefix-length 24
admin@Switch3# set l3-interface vlan-interface vlan300 address 192.168.30.254 prefix-length 24
admin@Switch3# set l3-interface vlan-interface vlan3073 address 100.30.3.4 prefix-length 24
```

```
admin@Switch3# set l3-interface vlan-interface vlan4094 address 100.10.2.1 prefix-length 24
admin@Switch3# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 300
admin@Switch3# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@Switch3# set interface gigabit-ethernet te-1/1/23 family ethernet-switching native-vlan-id 3073
admin@Switch3# set interface gigabit-ethernet te-1/1/27 family ethernet-switching native-vlan-id 4094
```

Step 2 Enable IP routing and configure the route.

```
admin@Switch3# set ip routing enable true
admin@Switch3# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
admin@Switch3# set protocols static route 2.2.2.2/32 next-hop 100.10.2.2
admin@Switch3# set protocols static route 3.3.3.3/32 next-hop 100.30.3.3
```

Step 3 Configure VXLAN tunnel.

```
admin@Switch3# set vxlans source-interface lo address 1.1.1.1
admin@Switch3# set vxlans vni 10010 flood vtep 2.2.2.2
admin@Switch3# set vxlans vni 10030 flood vtep 3.3.3.3
```

Step 4 Configure VXLAN mapping of VNI to VLAN.

```
admin@Switch3# set vxlans vni 10010 vlan 100
admin@Switch3# set vxlans vni 10030 vlan 200
```

Step 5 Commit the configurations.

```
admin@Switch3# commit
```

Verify the Configuration

- You can use the **run show vxlan tunnel** command to display the VXLAN tunnel information and tunnel state.

```
admin@Switch1# run show vxlan tunnel
Total number of tunnels: 1

VNI 10030, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:3.3.3.3, dst addr:1.1.1.1, state:UP
  traffic type:all
  nexthops:100.30.3.4
  output ports:te-1/1/1

admin@Switch2# run show vxlan tunnel
Total number of tunnels: 1

VNI 10010, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:2.2.2.2, dst addr:1.1.1.1, state:UP
  traffic type:all
  nexthops:100.10.2.1
  output ports:te-1/1/25

admin@Switch3# run show vxlan tunnel
Total number of tunnels: 2

VNI 10010, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:1.1.1.1, dst addr:2.2.2.2, state:UP
  traffic type:all
  nexthops:100.10.2.2
  output ports:te-1/1/27

VNI 10030, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:1.1.1.1, dst addr:3.3.3.3, state:UP
  traffic type:all
  nexthops:100.30.3.3
  output ports:te-1/1/23
```

- You can use the **run show vxlan address-table** command to display the VXLAN MAC address table.

```
admin@Switch1# run show vxlan address-table
VNID           MAC address          Type        Interface          VTEP
-----------    -----------------    -------     ----------------   ---------------
10030          00:00:00:00:22:22    Dynamic     te-1/1/5
10030          50:9a:4c:e6:7b:71    Dynamic                        1.1.1.1
Entries in access port:  1
Entries in network port: 1

admin@Switch2# run show vxlan address-table
VNID           MAC address          Type        Interface          VTEP
-----------    -----------------    -------      ---------------  ---------------
10010          00:00:00:00:44:44    Dynamic     te-1/1/3
10010          50:9a:4c:e6:7b:71    Dynamic                        1.1.1.1
Entries in access port:  1
Entries in network port: 1

admin@Switch3# run show vxlan address-table
VNID           MAC address            Type         Interface            VTEP
-----------    -----------------      -------      ----------------     ---------------

```

VXLAN Configuration Guide

NOTES:

- The switch platforms which use this feature are:
  - Trident2
  - Trident2+
  - Tomahawk
  - Tomahawk+
  - Trident3
  - Maverick
- Tomahawk 2 switches only support VXLAN L2-VNI, not L3-VNI.
- If VXLAN is deployed in an MLAG domain, it behaves a little differently. For details, see MLAG Configuration.

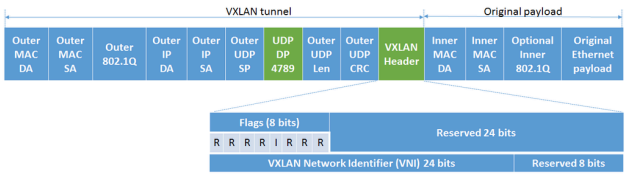
About VXLAN

Virtual Extensible LAN (VXLAN) is an overlay network virtualization technology. An overlay network is a virtual network that is built on top of existing network Layer 2 and Layer 3 technologies to support elastic compute architectures. VXLAN makes it easier for network engineers to scale out a cloud computing environment while logically isolating cloud apps and tenants.

VXLAN Technology

VXLAN uses UDP-based encapsulation to tunnel Ethernet frames and transfers original data packets as tunnel payloads. With the outer UDP tunnel, inner payload data can be quickly transferred on the layer 2 and layer 3 networks. To provide the capability of broadcast domain addressing, the VXLAN technology uses layer 3 IP multicast to replace the Ethernet broadcast. Therefore, the broadcast, unknown unicast, and multicast (BUM) packets can be transferred on virtual networks through broadcasting. For more VXLAN details, please read RFC7348.

VXLAN Packets



As shown in Figure 1-1, a VXLAN packet consists of the outer encapsulation and the inner payloads.

- Flags (8 bits): The flag I must be set to 1 for a valid VXLAN Network Identifier (VNI). The other 7 bits (labeled as R) are reserved fields and must be set to 0 on transmit and ignored on receive.
- VXLAN segment ID or VXLAN VNI: This parameter contains 24 bits and is used to designate the individual VXLAN overlay network on which the VMs are located.
- Reserved fields (24 bits and 8 bits): This parameter must be set to 0 on transmit and ignored on receive.
- The destination port number assigned to the outer tunnel is 4789, which is dedicated.

However, the new addition of VXLAN message encapsulation also introduces a problem with the setting of the MTU value.

In general, the default MTU of a VM or host is 1500 bytes, that is, the maximum original Ethernet message is 1500 bytes.

This message will be encapsulated with a new message header of 50 bytes (VXLAN header 8 bytes + UDP header 8 bytes + external IP h eader 20 bytes + external MAC header 14 bytes) when it is encapsulated with the VXLAN header and goes through the VTEP.
After the encapsulation, the packet size becomes 1550 bytes.
VXLAN packets are not allowed to be fragmented and put back together. It is therefore necessary that all intermediate devices have at least the same MTU if not higher than the originating VXLAN encapsulated packet.

If the original packet of 1500 bytes is encapsulated with VXLAN header, the resulting packet size becomes 1550. If the MTU value of the intermediate device is not convenient to change, then setting the MTU value of the virtual machine to 1450 can also solve this problem temporarily.

VXLAN Inner 802.1Q

Encapsulation mode

Encapsulation means the flow from access ports to network ports. Use one of the following options to specify actions about 802.1Q tag while encapsulation.

- **none**: Nothing will change, untagged packets will stay untagged, tagged packets will stay tagged.
- **service-vlan-add**: Add 802.1Q tag for untagged packets, and nothing changed with tagged packets. Encapsulation vlan is required.
- **service-vlan-add-delete**: Add 802.1Q tag for untagged packets, and delete tag for tagged packets. Encapsulation vlan is required.
- **service-vlan-add-replace**: Add 802.1Q tag for untagged packets, and replace tag for tagged packets. Encapsulation vlan is required.
- **service-vlan-delete**: Delete 802.1Q tag for tagged packets, and nothing changed with untagged packets. This is default value according to RFC 7348.
- **service-vlan-replace**: Replace vlan id of 802.1Q tag for tagged packets, and nothing changed with untagged packets. Encapsulation vlan is required.

Decapsulation-mode

Decapsulation means the flow from network ports to access ports.

- **none**: Nothing will change, untagged packets will stay untagged, tagged packets will stay tagged.
- **service-vlan-add**: From network ports to access ports, add 802.1Q tag for both untagged/tagged packets. If the access port is matched by port and vlan, the vlan id of the tag being added will be that vlan, otherwise will be PVID of that port.
- **service-vlan-add-delete**: From network ports to access ports, add 802.1Q tag for both untagged/tagged packets. If the access port is matched by port and vlan, the vlan id of the tag being added will be that vlan, otherwise will be PVID of that port. From access to access, delete tag for tagged packets.
- **service-vlan-add-replace**: From network ports to access ports, add 802.1Q tag for both untagged/tagged packets. If the access port is matched by port and vlan, the vlan id of the tag being added will be that vlan, otherwise will be PVID of that port. From access to access, replace tag for tagged packets.This is the default value.
- **service-vlan-delete**: From access to access, delete tag for tagged packets.
- **service-vlan-replace**: From access to access, replace tag for tagged packets.
- **service-vlan-per-port**: The decapsulated packet can be tagged or untagged dynamically based on the setting on the output port.

Based on the above description, please see the following three tables for the detailed traffic changes.

The below table shows the traffic changes in the case that vlans in the access side are binded with a vxlan in the network side.

	Access→Access **(configure with decapsulation mode)**	**Access→Network** **(configure with encapsulation mode)**	**Network→Access** **(configure with decapsulation mode)**
none	untag-->tag(PVID) tag-->remain tag	untag-->tag(PVID) tag->remain tag	untag-->untag tag-->remain tag

service-vlan-add	untag-->tag(PVID) tag->remain tag	untag-->tag(PVID) tag->remain tag	untag-->tag(add vxlan-vlan) tag-->double tag(outer layer add vxlan-vlan)
service-vlan-add-delete	untag-->untag tag-->untag	untag-->untag tag->untag(been deleted)	untag-->tag(add vxlan-vlan) tag-->double tag(outer layer add vxlan-vlan)
service-vlan-add-replace	untag-->tag(PVID) tag-->remain tag	untag→tag(configured VLAN) tag->tag(configured VLAN)	untag-->tag(add vxlan-vlan) tag-->double tag(outer layer add vxlan-vlan)
service-vlan-delete	untag-->untag tag-->untag	untag-->untag tag->untag	untag-->untag tag-->remain tag
service-vlan-replace	untag-->tag(PVID) tag-->remain tag	untag→tag(configured VLAN) tag->tag(changed to encapsulation vlan)	untag-->untag tag-->remain tag
service-vlan-per-port	The decapsulated packet can be tagged or untagged dynamically based on the setting on the output port.		

VXLAN ECMP

In L2/L3, VXLAN ECMP is supported. Picos supports up to 32-way ECMP.

- The VXLAN ECMP does not need special configuration. It entirely depends on the routing ECMP. The route ECMP configure link: ECMP (Equal-Cost Multipath Routing) Configuration
- PicOS uses info from VXLAN header for hash calculation to ensure better performance.

VXLAN Mac Learning

The VTEP performs source MAC learning on the VNI as a Layer 2 switch.

- The switch receives traffic from the local VTEP to the remote VTEP, the VTEP learns the source MAC address in the access port.
- The switch receives traffic from the remote VTEP to the local VTEP, the VTEP learns the source MAC address in the network port.

A VNI MAC address table includes the following types of MAC address entries:

- Access port--Dynamic MAC address entries learned from the local VTEP. VXLAN does not support local configure static MAC address.
- Network port--Include static and dynamic MAC entries.

> **Static mac**--Configure static mac address entries on VXLAN tunnel interfaces.
> **Dynamic mac**--The MAC address entries learned from incoming traffic on VXLAN tunnels. The learned MAC addresses are contained in the inner Ethernet header source MAC.

On network port, the configure static mac entry has higher priority than dynamic mac entries.

VXLAN Traffic Forwarding

Unicast Traffic

- The switch receives traffic from the access port. The VTEP encapsulates the original Ethernet frame with an outer MAC header, outer IP header, and a VXLAN header. The source IP address is the source VTEP's VXLAN tunnel source IP address.
- The local VTEP forwards the encapsulates packets to the VXLAN tunnel a destination IP address.
- The remote VTEP decapsulates the packet and forwards the frame to access port.

Broadcast and Unknown Traffic

- The switch receives traffic from the access port. The VTEP encapsulates the original Ethernet frame with an outer MAC header, outer IP header and a VXLAN header. The source IP address is the source VTEP's VXLAN tunnel source IP address.
- The local VTEP flood encapsulates packets to the VXLAN tunnel all destination IP address.
- The all remote VTEP decapsulates the packet and forwards the frame to access port.

Configure to map VLAN to VXLAN VNI Step

VxLAN supported on PicOS L2/L3 switch. To configure Step, pleae see below.

- Configure VXLAN soure interface

```
set vxlans source-interface loopback address 10.10.10.25
commit
```

- Create VXLAN VNI

```
set vxlans vni 10010
commit
```

- Configure vtep address for VXLAN VNI

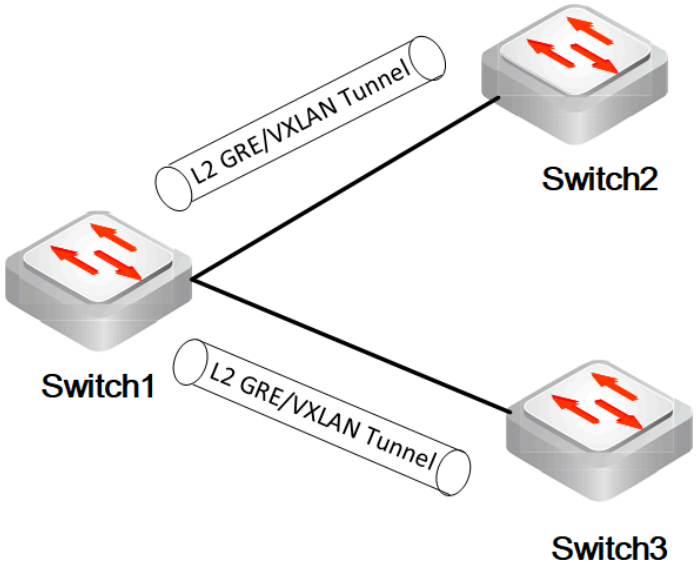
```
set vxlans vni 10010 flood vtep 10.10.10.12
commit
```

- Add vlan into VXLAN VNI

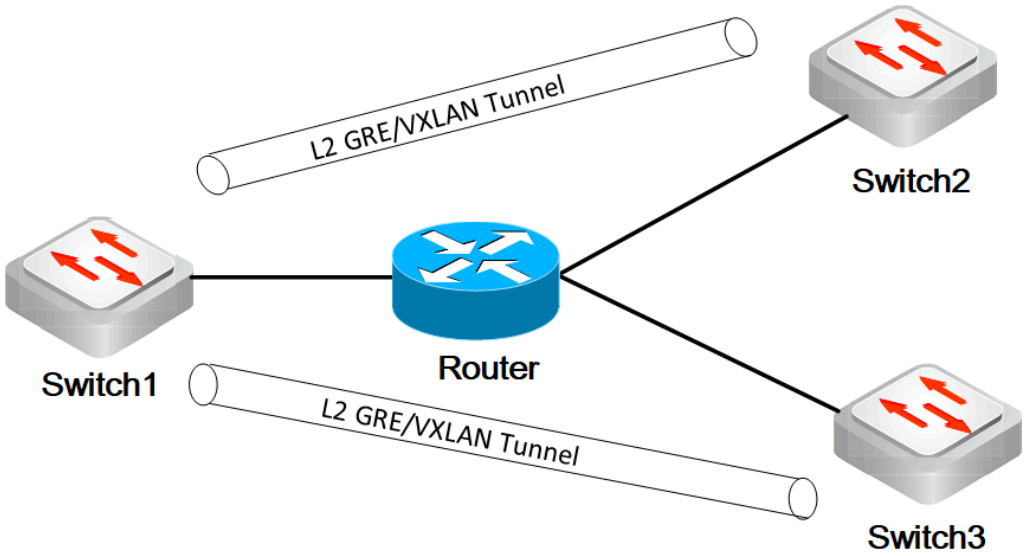
```
set vxlans vni 10010 vlan 100
commit
```

Application Scenario Limitation

In L2 GRE or VXLAN networks, only one next hop is allowed for the same egress interface. In the following figure, the same egress interface on Switch1 has two tunnels, that is, two next hops, which is not allowed.



However, multiple L2 GRE or VXLAN tunnels can exist from the same egress port on Switch1 if connected via the IP router, ensuring that one egress interface has only one next hop, as shown in the figure below.



VXLAN ECMP Configuration

Requirements

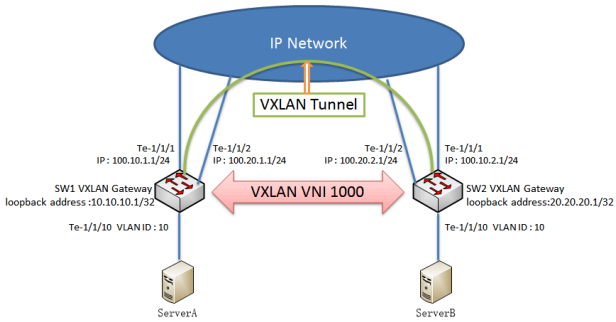
This example uses the following hardware and software components:

- An Trident-II Series switch
- PICOS OS Release more than 2.5 version

Overview

In this example, VXLAN ECMP is configured to run on a VXLAN domain. VTEP interfaces sources are configured to the loopback address. Interfaces are configured for VLAN tagging and encapsulation. Static route protocols is configured to facilitate unicast routing.

Topology



The VXLAN that comprise the networks include:

- SW1 VNI 1000: VTEP 10.10.10.1: VLAN 10
- SW2 VNI 1000: VTEP 20.20.20.1: VLAN 10
- SW1 IP Adress: 100.10.1.1 and IP Address: 100.20.1.1
- SW2 IP Adress: 100.10.2.1 and IP Address: 100.20.2.1

Configuring VXLAN on Trident-II Series Switches

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and copy and paste the commands into the CLI.

SW1 Configure

```
set vlans vlan-id 10
set vlans vlan-id 1000 l3-interface 1000
set vlans vlan-id 2000 l3-interface 2000
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 1000
set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 2000
set interface gigabit-ethernet te-1/1/10 family ethernet-switching native-vlan-id 10
set l3-interface loopback lo address 10.10.10.1 prefix-length 32
set l3-interface vlan-interface 1000 address 100.10.1.1 prefix-length 24
```

```
set l3-interface vlan-interface 2000 address 100.20.1.1 prefix-length 24
set protocols static route 20.20.20.1/32 next-hop 100.10.1.2
set protocols static route 20.20.20.1/32 next-hop 100.20.1.2
set vxlans source-interface lo address 10.10.10.1
set vxlans vni 1000 vlan 10
set vxlans vni 1000 flood vtep 20.20.20.1
commit
```

SW2 Configure

```
set vlans vlan-id 10
set vlans vlan-id 1000 l3-interface 1000
set vlans vlan-id 2000 l3-interface 2000
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 1000
set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 2000
set interface gigabit-ethernet te-1/1/10 family ethernet-switching native-vlan-id 10
set l3-interface loopback lo address 20.20.20.1 prefix-length 32
set l3-interface vlan-interface 1000 address 100.10.2.1 prefix-length 24
set l3-interface vlan-interface 2000 address 100.20.2.1 prefix-length 24
set protocols static route 10.10.10.1/32 next-hop 100.10.2.2
set protocols static route 10.10.10.1/32 next-hop 100.20.2.2
set vxlans source-interface lo address 20.20.20.1
set vxlans vni 1000 vlan 10
set vxlans vni 1000 flood vtep 10.10.10.1
commit
```

Configuring VXLAN Step-by-Step Procedure

The following example shows how to set up a basic VXLAN ECMP configuration with VXLAN domain. To configure VXLAN ECMP on Trident-II Series switches, follow these steps:

Configure VXLAN Step-by-Step for SW1

1. Configure the VLAN ID to 10 for vxlan domain.

```
set vlans vlan-id 10
```

2. Configure the VLAN ID to 1000 and 2000 for ip routing.

```
set vlans vlan-id 1000 l3-interface 1000
set vlans vlan-id 2000 l3-interface 2000
```

3. Configure the te-1/1/1 interface VLAN ID to 1000.

```
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 1000
```

4. Configure the te-1/1/2 interface VLAN ID to 2000.

```
set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 2000
```

5. Configure the te-1/1/10 interface VLAN ID to 10

```
set interface gigabit-ethernet te-1/1/10 family ethernet-switching native-vlan-id 10
```

6. Configure ip address for the loopback interface.

```
set l3-interface loopback lo address 10.10.10.1 prefix-length 32
```

7. Configure ip address and MTU for the vlan-interface 1000.

```
set l3-interface vlan-interface 1000 address 100.10.1.1 prefix-length 24
```

8. Configure ip address and MTU for the vlan-interface 2000.

```
set l3-interface vlan-interface 2000 address 100.20.1.1 prefix-length 24
```

9. Configure static route for the VXLAN ECMP.

```
set protocols static route 20.20.20.1/32 next-hop 100.10.1.2
set protocols static route 20.20.20.1/32 next-hop 100.20.1.2
```

10. Configure VTEP interface sources ip address.

```
set vxlans source-interface lo address 10.10.10.1
```

11. Configure a VLAN ID 10 to a VNI 1000

```
set vxlans vni 1000 vlan 10
```

12. Configure flood vtep ip address for a VNI

```
set vxlans vni 1000 flood vtep 20.20.20.1
```

Configure VXLAN Step-by-Step for SW2

1. Configure the VLAN ID to 10 for vxlan domain.

```
set vlans vlan-id 10
```

2. Configure the VLAN ID to 1000 and 2000 for ip routing.

```
set vlans vlan-id 1000 l3-interface 1000
set vlans vlan-id 2000 l3-interface 2000
```

3. Configure the te-1/1/1 interface VLAN ID to 1000.

```
set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 1000
```

4. Configure the te-1/1/2 interface VLAN ID to 2000.

```
set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 2000
```

5. Configure the te-1/1/10 interface VLAN ID to 10

```
set interface gigabit-ethernet te-1/1/10 family ethernet-switching native-vlan-id 10
```

6. Configure ip address for the loopback interface.

```
set l3-interface loopback lo address 20.20.20.1 prefix-length 32
```

7. Configure ip address and MTU for the vlan-interface 1000.

```
set l3-interface vlan-interface 1000 address 100.10.2.1 prefix-length 24
```

8. Configure ip address and MTU for the vlan-interface 2000.

```
set l3-interface vlan-interface 2000 address 100.20.2.1 prefix-length 24
```

9. Configure static route for the VXLAN ECMP.

```
set protocols static route 10.10.10.1/32 next-hop 100.10.2.2
set protocols static route 10.10.10.1/32 next-hop 100.20.2.2
```

10. Configure VTEP interface sources ip address.

```
set vxlans source-interface lo address 20.20.20.1
```

11. Configure a VLAN ID 10 to a VNI 1000

```
set vxlans vni 1000 vlan 10
```

12. Configure flood vtep ip address for a VNI

```
set vxlans vni 1000 flood vtep 10.10.10.1
```

View the VXLAN tunnel of SW1

Run command **run show vxlan tunnel** to view the information about VXLAN endpoint configuration. Display VXLAN ECMP to the remote vxlan tunnel vtep has two nexthops(100.10.1.2 100.20.1.2).

```
admin@PICOS# run show vxlan tunnel
Total number of tunnels: 1

VNI 1000, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:10.10.10.1, dst addr:20.20.20.1, state:DOWN
  traffic type:all
```

```
  Vtep type:Static
  nexthops:100.10.1.2 100.20.1.2
  output ports:

BGP EVPN Configuration Guide

- BGP EVPN Route Types
- Anycast Gateway for EVPN Distributed Networks
- EVPN Symmetric Routing Configuration Example
- EVPN Asymmetric Routing Example
- EVPN With NAC Configuration Guide
- EVPN Multihoming Configuration Guide
- EVPN Enhancements
- Introduction to BGP EVPN

BGP EVPN Route Types

Note
EVPN feature is currently supported on X86 platforms only.

To share routing information with its peers, BGP uses update packets. Routes with the same path attributes are placed in the Network Layer Reachability Information (NLRI) of the update packet and advertised. Since traditional BGP-4 only supports IPv4 unicast routing information, Multiprotocol Extensions for BGP (MP-BGP) was developed to provide additional support for network layer protocols such as multicast and IPv6. MP-BGP extensions are added to the NLRI after which description for different protocols like IPv6 unicast and VPN instance family are subsequently added.

EVPN defines the EVPN sub-address family in the L2VPN address family with the introduction of EVPN NLRI. Once the routes are advertised, VXLAN tunnels are automatically established to carry packets. EVPN NLRI has the following EVPN route types:

- **Type-1, Ethernet Auto-Discovery Routes:** are used for network wide messaging. The Ethernet auto discovery routes are used when a host or server is multihomed to the EVPN VXLAN fabric. It is used to signal to the upstream VTEPs to change their next hop adjacencies for all the MAC addresses associated with a particular ethernet segment in the event of a link failure. The Type-1 EAD routes has the following makeup shown in Table 1. The Ethernet Segment Identifier (ESI) has a non-zero value for multihomed hosts. In case when a device is single-homed, the value of Ethernet Subnet Identifier (ESI) is set to zero. Type-1 routes are advertised on per ESI and per EVI basis and used to achieve fast convergence.

Route Distinguisher (8 Octets)
Ethernet Segment Identifier (10 Octets)
Ethernet Tag ID (4 Octets)
MPLS Label (3 Octets)

Table 1. Ethernet Auto Discovery Route NLRI

- **Type-2, MAC with IP advertisement Routes:** are used to advertise the MAC and IP addresses of hosts. When a VTEP discovers a new host MAC/IP address, it will use Type-2 routes to share this new host with all the other concerned VTEPs in the EVPN VXLAN fabric. This behavior of BGP EVPN is also known as remote host learning and one of the key benefit of having a control plan for VXLAN. The Type-2 route NLRI has the following fields.

Route Distinguisher (8 Octets)
Ethernet Segment Identifier (10 Octets)
Ethernet Tag ID (4 Octets)
MAC Address Length (1 Octet)
MAC Address (6 Octets)
IP Address Length (1 Octet)
IP Address (0, 4 or 16 Octets)
MPLS Label1 (3 Octets)
MPLS Label2 (0 or 3 Octets)

Table 2. EVPN MAC/IP Advertisement Route

- **Type-3, Inclusive Multicast Routes:** are used for the automatic discovery of VTEPs and dynamically establishing VXLAN tunnels. Specifically, Type-3 routes are used to deliver multicast, unknown unicast and broadcast traffic across the EVPN VXLAN fabric. When a VTEP receives a multicast packet encapsulated with a VLAN tag, the ingress VTEP will distribute the packet to all VTEPs that span this VLAN in the given EVPN instance. Type-3 routes have the following NLRI fields.

Route Distinguisher (8 Octets)
Ethernet Tag ID (4 Octets)
IP Address Length (1 Octet)
Originating Router's IP Address (4 or 16 Octets)

Table 3. EVPN Type-3 Route NLRI

- **Type-4, Ethernet Segment Routes:** are needed in multihoming scenarios and used for Designated Forwarder Election. Designated Forwarder is responsible for sending broadcast, unknown unicast and multicast (BUM) traffic to devices on an Ethernet Segment.

  The EVPN NLRI for Type-4 Ethernet Segment Rout consists of the following four fields. For multihomed hosts, the Ethernet Segment Identifier (ESI) must be set to a non-zero value. A value of zero for the ESI indicates a single homed device.

RD (8 Octets)
Ethernet Segment Identifier (10 Octets)
IP Address Length (1 octet)
Originating Router's IP Address (4 or 16 octets)

Table 2. EVPN Type-4 NLRI

- **Type-5, IP Prefix Route:** provides encoding for inter-subnet forwarding. These routes are used for advertising IP prefixes for connectivity between different subnets across the enterprise. Type-5 routes can advertise both IPv4 and IPv6 prefixes. The NLRI fields of IPv4 is shown below.

Route Distinguisher (8 Octets)
Ethernet Segment Identifier (10 Octets)
Ethernet Tag ID (4 Octets)
IP Prefix Length (1 Octet, 0 to 32)
IP Prefix (4 Octets)
Gateway IP Address (4 Octets)
IP Address (0, 4 or 16 Octets)
MPLS Label (3 Octets)

Table 5. Type-5 IPv4 Route NLRI

The NLRI fields in an IPv6 address are given below.

Route Distinguisher (8 Octets)
Ethernet Segment Identifier (10 Octets)
Ethernet Tag ID (4 Octets)
IP Prefix Length (1 Octet, 0 to 128)
IP Prefix (16 Octets)
Gateway IP Address (16 Octets)
IP Address (0, 4 or 16 Octets)
MPLS Label (3 Octets)

Table 6. Type-5 IPv6 Route NLRI

Anycast Gateway for EVPN Distributed Networks

- Introduction
- Configuration Example
- Anycast Gateway over MLAG
  - Configuration Consistency
  - Configuration Notes
  - Example

Introduction

In a data center or campus networks, it is often necessary to implement a seamless migration of virtual machines (VMs) without changing network settings or disrupting the traffic forwarding. Virtual machine migration is just like changing the location of a MAC address in the network. Network infrastructure devices such as switches need to be aware of this change to refresh their forwarding table entries in time to ensure that traffic forwarding is not interrupted.

In EVPN distributed networks, users can configure the same anycast gateway IP and the same virtual MAC (router MAC) on all distributed gateways to enable the anycast gateway function. And also, configure the same IP default gateway address on all hosts or VMS. After that, irrespective of which VTEP the host connected to, as long as they are within the same VNI, they can always use their connected VTEPs as the default gateway to send and receive traffic. Since all hosts within a VLAN are configured with the same IP default gateway address, all hosts or VMs can be easily moved throughout the data center without changing their configuration. This provides flexible VM mobility between different distributed gateways in the network.

You can configure anycast gateway in one of two ways:

- Use the following commands to configure an identical anycast gateway IP address (VLAN interface IP address) and router MAC for anycast gateway.

  set l3-interface vlan-interface <*vlan-interface-name*> **address** <*address*> **prefix-length** <*number*>

  set l3-interface vlan-interface <*vlan-interface-name*> **router-mac** <*macaddr*>

- Use the following commands to configure the anycast gateway IP address (virtual IP address) and anycast gateway MAC (virtual MAC).

  set l3-interface vlan-interface <*interface-name*> **anycast address** <*ip-address*> **prefix-length** <*prefix*>

  set l3-interface vlan-interface <*interface-name*> **anycast mac** <*mac-address*>

NOTEs:

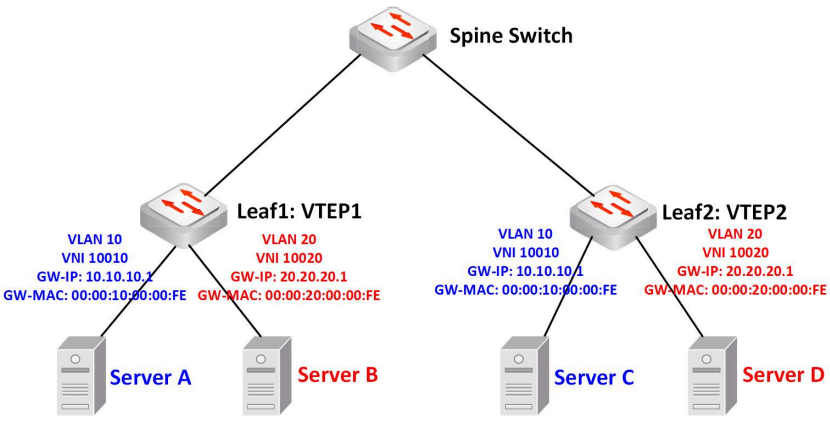
- For anycast gateway over MLAG scenario, only the second way is available.
- When configuring the **Anycast MAC** and **Anycast Address** for an L3 interface, it is necessary to apply both configurations in the same **commit**. This is because these two settings are interdependent, and applying them separately might cause synchronization issues, leading to configuration failures or network instability.

For example,

```
admin@Xorplus# set l3-interface vlan-interface vlan10 anycast address 10.0.1.1 prefix-length 24
admin@Xorplus# set l3-interface vlan-interface vlan10 anycast mac AE:00:10:00:00:FE
admin@Xorplus# commit
```

Configuration Example

For example, as shown in the following simplified EVPN topology, the gateways of the attached servers are on the leaf VTEP switches. Since Server A and Server C are in the same subnet (VLAN: 10/VNI:10010), they should have the same gateway configuration (e.g, gateway IP 10.10.10.1 and gateway MAC 00:00:10:00:00:FE). If Server A moves from Leaf 1 to Leaf 2, the gateway IP configured on Server A doesn't need to be changed. Similarly, Server B and Server D do not need to change their gateway IP and MAC addresses.



When configuring, all VTEPs in the same VNI are required to configure the same anycast gateway IP and virtual MAC.

The example commands below configure anycast gateway on VTEP1 and VTEP2.

```
# Configuring VLAN to VNI mapping
```

```
set vlans vlan-id 10
set vlans vlan-id 20
set vxlans vni 10010 vlan 10
set vxlans vni 10020 vlan 20

# Configuring GW IP
set vlans vlan-id 10 l3-interface vlan10
set vlans vlan-id 20 l3-interface vlan20
set l3-interface vlan-interface vlan10 address 10.10.10.1 prefix-length 24
set l3-interface vlan-interface vlan20 address 20.20.20.1 prefix-length 24

# Configuring GW MAC
set l3-interface vlan-interface vlan10 router-mac 00:00:10:00:00:FE
set l3-interface vlan-interface vlan20 router-mac 00:00:20:00:00:FE
```

NOTEs:

- Anycast gateway can be applied to VTEPs only in the same VLAN/VNI. For example, it is not supported to apply the same anycast gateway within VLAN 10 and VLAN 20 in above case, different gateway configurations for Server A and Server D are required.
- Anycast gateway is mutually exclusive with EVPN **advertise-default-gw** or **advertise-svi-ip** configuration when in the EVPN distributed gateway scenario, they cannot be configured at the same time.

  set protocols bgp [**vrf** <*vrf-name*>] **evpn advertise-default-gw**

  set protocols bgp evpn vni <*vni*> **advertise-svi-ip**

Anycast Gateway over MLAG

Anycast gateway over MLAG function enables VTEP devices to be configured with a single virtual IP address and a single virtual MAC in the form of an anycast IP address and anycast MAC on a pair of MLAG devices. This enables a pair of switches to act as a single VTEP device and seen as such by downstream devices.

In this configuration, two routing devices are combined to form one virtual router, and the virtual IP address is used as the default gateway for hosts to achieve normal communication. When one device in the MLAG pair fails, the other device can still forward traffic normally, thus ensuring reliable network communication.

To ensure proper traffic forwarding, ARP/ND synchronization is performed between the two switches in the MLAG pair every 5 minutes.

MLAG synchronizes ARP/ND entry between the two switches in the MLAG pair; EVPN does not synchronize.

When configuring anycast gateway over MLAG, the following command can be used to configure anycast IP address and anycast MAC address on the MLAG peer devices.

set l3-interface vlan-interface <*interface-name*> **anycast address** <*ip-address*> **prefix-length** <*prefix*>

set l3-interface vlan-interface <*interface-name*> **anycast mac** <*mac-address*>

Besides the anycast IP address and anycast MAC address, IP address of the corresponding access-facing VLAN interface is required to be specified.

set l3-interface vlan-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*prefix*>

NOTE:

For IPv4, the anycast IPv4 address and the VLAN interface IPv4 address should be configured in the same network segment to ensure that the MLAG pair can work normally.

For IPv6, the anycast IPv6 address and the global IPv6 address of the VLAN interface should be configured in the same network segment to ensure that the MLAG pair can work normally.

On the hosts, configure the anycast IP address of the virtual router as the gateway address either statically or through DHCP.

Configuration Consistency

To ensure the pair of MLAG switches continue acting as one single VTEP device, the following configuration needs to be consistent on both devices.

- anycast IP address
- anycast MAC
- VNI on the VXLAN interface (includes both L2 VNI and L3 VNI)
- VTEP address
- RMAC (router MAC), if configured

Configuration Notes

- Anycast gateway over MLAG function and VRRP are mutually exclusive. If anycast gateway over MLAG is configured, VRRP is not allowed to be configured on the same MLAG pair.
- Besides the anycast IP address and anycast MAC address, IP address of the corresponding access-facing VLAN interface is required to be specified through the following command.

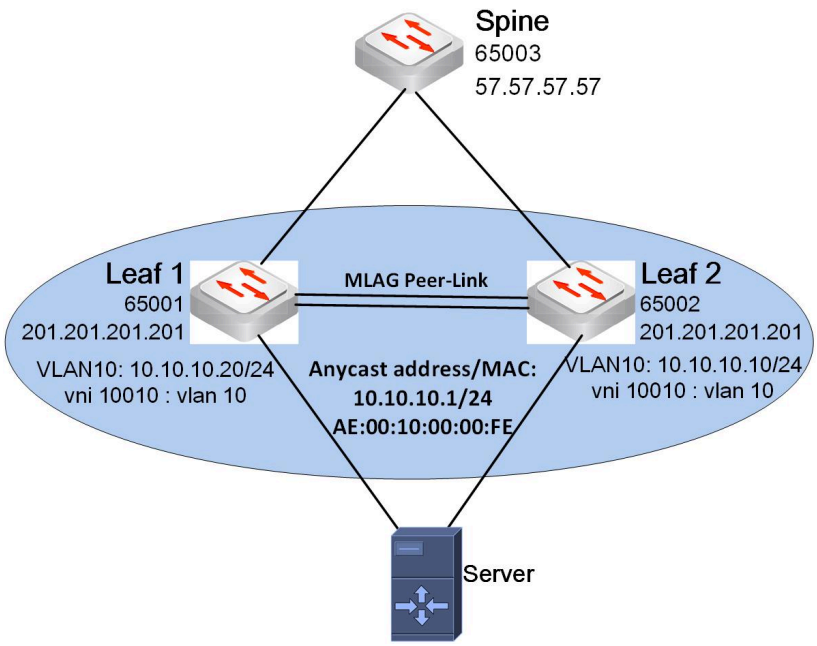
  set l3-interface vlan-interface <*interface-name*> **address** <*ip-address*> **prefix-length** <*prefix*>

- For IPv4, the anycast IPv4 address and the VLAN interface IPv4 address should be configured in the same network segment to ensure that the MLAG pair can work normally.
- For IPv6, the anycast IPv6 address and the global IPv6 address of the VLAN interface should be configured in the same network segment to ensure that the MLAG pair can work normally.
- Anycast IP address list on both devices of MLAG pair must be the same.

Example

As shown in the following simplified EVPN topology, Leaf1 and leaf2 have established VXLAN tunnel with spine. Leaf1 and leaf2 are a pair of MLAG devices.

To enable MLAG pair switches Leaf 1 and Leaf 2 to act as a single virtual router, configure anycast gateway over MLAG on the MLAG pair.



The example commands below can be used to configure anycast gateway over MLAG on Leaf 1 and Leaf 2.

```
# Leaf 1
# Configuring VXLAN source interface.
set l3-interface loopback lo address 201.201.201.201 prefix-length 32
set vxlans source-interface lo address 201.201.201.201

# Configuring VLAN to VNI mapping.
set vlans vlan-id 10
set vxlans vni 10010 vlan 10

# Configuring VXLAN VLAN interface IP address.
set vlans vlan-id 10 l3-interface vlan10
set l3-interface vlan-interface vlan10 address 10.10.10.20 prefix-length 24

# Configuring anycast IP address and anycast MAC.
set l3-interface vlan-interface vlan10 anycast address 10.10.10.1 prefix-length 24
set l3-interface vlan-interface vlan10 anycast mac 00:00:10:00:00:FE

# Leaf 2
# Configuring VXLAN source interface.
set l3-interface loopback lo address 201.201.201.201 prefix-length 32
set vxlans source-interface lo address 201.201.201.201

# Configuring VLAN to VNI mapping.
set vlans vlan-id 10
set vxlans vni 10010 vlan 10

# Configuring VXLAN VLAN interface IP address.
set vlans vlan-id 10 l3-interface vlan10
set l3-interface vlan-interface vlan10 address 10.10.10.10 prefix-length 24

# Configuring anycast IP address and anycast MAC on Leaf 2.
set l3-interface vlan-interface vlan10 anycast address 10.10.10.1 prefix-length 24
set l3-interface vlan-interface vlan10 anycast mac 00:00:10:00:00:FE
```

EVPN Symmetric Routing Configuration Example

- Network Requirments
- Router Configuration
- Verifying Configuration

> **Note**
> EVPN feature is currently supported on X86 platforms only.

Network Requirments

Figure 1 shows our sample topology for EVPN symmetric routing. We have two routers with two servers connected to each router. In this example, Server 1 and Server 2 are in the same network segment, they use L2 VXLAN tunnel for communication. Server 3 and Server 4 are in different network segments, they use L3 VXLAN tunnel for communication. For routed VXLAN traffic within the symmetric IRB model travelling across the same VNI in both directions, same L3 VNI should be configured on Router 1 and Router 2.

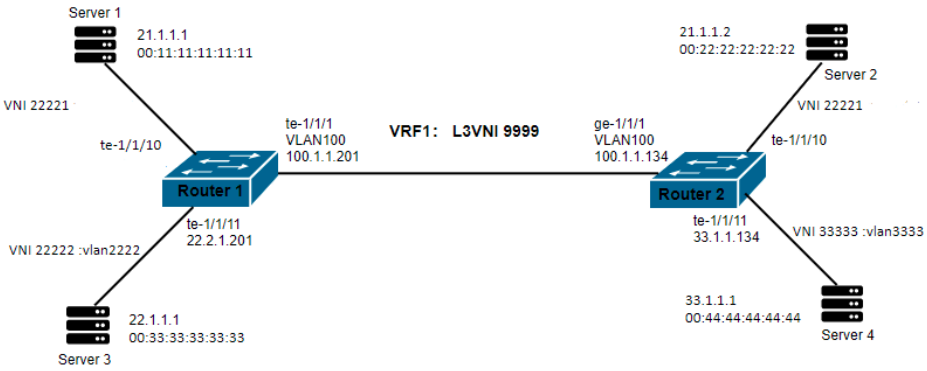


Figure 1. EVPN Symmetric Routing

Router Configuration

The configuration for Router 1 is shown below. The first part of the configuration deals with physical interfaces and assigning VLANs to these interfaces. Router 1 has three physical interfaces configured, two interfaces connecting server 1 and server 3.

Next we setup the layer 3 VLAN interfaces and configure IP addresses for these interfaces.

Then we setup VXLAN VNIs, enable VLAN to VNI mapping and map VNIs to VLAN IDs. Finally we enable IP routing on the device and configure BGP related parameters such as router ID, BGP neighbor and enabling advertising all VNIs.

Follow the detailed configuration steps below.

Router 1 Configuration

Step 1. Configure physical interfaces, VLAN interfaces and assign VLAN IDs and IP addresses.

```
admin@router1# set interface gigabit-ethernet te-1/1/11 family ethernet-switching native-vlan-id 2222
admin@router1# set interface gigabit-ethernet te-1/1/10 family ethernet-switching port-mode trunk
admin@router1# set interface gigabit-ethernet te-1/1/10 family ethernet-switching vlan members 2221
admin@router1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@router1# set l3-interface loopback lo address 201.201.201.201 prefix-length 32
admin@router1# set l3-interface loopback lo address 201.201.201.88 prefix-length 32
admin@router1# set l3-interface vlan-interface vlan100 address 100.1.1.201 prefix-length 24
admin@router1# set l3-interface vlan-interface vlan2222 vrf vrf1
admin@router1# set l3-interface vlan-interface vlan2222 address 22.1.1.201 prefix-length 24
admin@router1# set l3-interface vlan-interface vlan1111 vrf vrf1
admin@router1# set vlans vlan-id 100 l3-interface vlan100
admin@router1# set vlans vlan-id 1111 l3-interface vlan1111
admin@router1# set vlans vlan-id 2221
admin@router1# set vlans vlan-id 2222 l3-interface vlan2222
```

Step 2. Configure VXLAN VNI and map VNI IDs to VLAN IDs. Also create an L3 VNI in vrf1.

> **NOTE:**
> It is recommended to configure the decapsulation mode as "service-vlan-per-port".

```
admin@router1# set vxlans source-interface lo address 201.201.201.201
admin@router1# set vxlans vni 9999 vlan 1111
admin@router1# set vxlans vni 22221 decapsulation mode service-vlan-per-port
admin@router1# set vxlans vni 22221 vlan 2221
admin@router1# set vxlans vni 22222 decapsulation mode service-vlan-per-port
admin@router1# set vxlans vni 22222 vlan 2222
admin@router1# set vxlans vrf vrf1 l3-vni 9999
```

Step 3. Enable IP routing and configure VRF.

```
admin@router1# set ip routing enable true
admin@router1# set ip vrf vrf1
```

Step 4. Configure BGP related configuration.

```
admin@router1# set protocols bgp local-as 201
admin@router1# set protocols bgp ebgp-requires-policy false
admin@router1# set protocols bgp router-id 201.201.201.201
admin@router1# set protocols bgp neighbor 100.1.1.134 remote-as external
admin@router1# set protocols bgp neighbor 100.1.1.134 update-source 100.1.1.201
admin@router1# set protocols bgp neighbor 100.1.1.134 evpn activate true
admin@router1# set protocols bgp ipv4-unicast network 201.201.201.201/32
admin@router1# set protocols bgp ipv4-unicast network 201.201.201.88/32
admin@router1# set protocols bgp evpn advertise-all-vni
admin@router1# set protocols bgp evpn advertise ipv4-unicast
admin@router1# set protocols bgp evpn advertise-svi-ip
admin@router1# set protocols bgp vrf vrf1 local-as 201
admin@router1# set protocols bgp vrf vrf1 router-id 201.201.201.201
admin@router1# set protocols bgp vrf vrf1 ipv4-unicast network 22.1.1.0/24
admin@router1# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
```

Step 5. Commit the configuration.

```
admin@router1# commit
```

Router 2 Configuration

Configuration of Router 2 is shown below. Router 2 also has 3 physical interfaces configured with two interfaces connecting server 2 and server 4. The configuration of Router 2 is almost identical to Router 1 other than the basic configurations like VXLAN VNI and interface IP addresses. The detailed configuration steps are shown below.

Step 1. Configure physical interfaces, VLAN interfaces and assign VLAN ID to physical interfaces and IP addresses.

```
admin@router2# set interface gigabit-ethernet te-1/1/11 family ethernet-switching native-vlan-id 3333
admin@router2# set interface gigabit-ethernet te-1/1/11 family ethernet-switching port-mode trunk
admin@router2# set interface gigabit-ethernet te-1/1/10 family ethernet-switching port-mode trunk
admin@router2# set interface gigabit-ethernet te-1/1/10 family ethernet-switching vlan members 2221
admin@router2# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 100
admin@router2# set l3-interface loopback lo address 134.134.134.134 prefix-length 32
admin@router2# set l3-interface vlan-interface vlan100 address 100.1.1.134 prefix-length 24
admin@router2# set l3-interface vlan-interface vlan3333 vrf vrf1
admin@router2# set l3-interface vlan-interface vlan3333 address 33.1.1.134 prefix-length 24
admin@router2# set l3-interface vlan-interface vlan1111 vrf vrf1
admin@router2# set vlans vlan-id 100 l3-interface vlan100
admin@router2# set vlans vlan-id 1111 l3-interface vlan1111
admin@router2# set vlans vlan-id 2221
admin@router2# set vlans vlan-id 3333 l3-interface vlan3333
```

Step 2: Configure VXLAN VNI and map VNI IDs to VLAN IDs.

```
admin@router2# set vxlans source-interface lo address 134.134.134.134
admin@router2# set vxlans vni 9999 vlan 1111
admin@router2# set vxlans vni 22221 decapsulation mode service-vlan-per-port
admin@router2# set vxlans vni 22221 vlan 2221
admin@router2# set vxlans vni 33333 vlan 3333
admin@router2# set vxlans vni 3333 decapsulation mode service-vlan-per-port
admin@router2# set vxlans vrf vrf1 l3-vni 9999
```

Step 3: Enable IP routing and configure VRF.

```
admin@router2# set ip routing enable true
admin@router2# set ip vrf vrf1
```

Step 4: Configure BGP related configuration

```
admin@router2# set protocols bgp local-as 134
admin@router2# set protocols bgp ebgp-requires-policy false
admin@router2# set protocols bgp router-id 134.134.134.134
admin@router2# set protocols bgp neighbor 100.1.1.201 remote-as external
admin@router2# set protocols bgp neighbor 100.1.1.201 update-source 100.1.1.134
admin@router2# set protocols bgp neighbor 100.1.1.201 evpn activate true
admin@router2# set protocols bgp ipv4-unicast network 134.134.134.134/32
admin@router2# set protocols bgp evpn advertise-all-vni
admin@router2# set protocols bgp evpn advertise-svi-ip
admin@router2# set protocols bgp vrf vrf1 local-as 134
admin@router2# set protocols bgp vrf vrf1 router-id 134.134.134.134
admin@router2# set protocols bgp vrf vrf1 ipv4-unicast network 33.1.1.0/24
admin@router2# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
```

Step 5. Commit the configuration.

```
admin@router2# commit
```

Verifying Configuration

- To check the BGP state and neighbor status on Router 2, we will run the **run show bgp neighbor** command.

```
admin@router2# run show bgp neighbor 100.1.1.201
BGP neighbor is 100.1.1.201, remote AS 201, local AS 134, external link
Hostname: 51.201
 Member of peer-group fabric for session parameters
  BGP version 4, remote router ID 201.201.201.201, local router ID 134.134.134.134
  BGP state = Established, up for 01:22:43
```

- To check the BGP EVPN MAC address table, we will run the command **run show vxlan address-table** as shown below.

```
admin@router1# run show vxlan address-table
VNID           MAC address          Type       Interface          VTEP
-----------    -----------------    -------    ----------------   ---------------
9999           18:5a:58:37:64:61    Dynamic                       134.134.134.134
22221          00:11:11:11:11:11    Dynamic    te-1/1/10
22221          00:22:22:22:22:22    Dynamic                       134.134.134.134
22222          00:33:33:33:33:33    Dynamic    te-1/1/11
Entries in access port:  2
Entries in network port: 2

admin@router2# run show vxlan address-table
VNID           MAC address          Type       Interface          VTEP
-----------    -----------------    -------    ----------------   ---------------
9999           18:5a:58:37:55:e1    Dynamic                       201.201.201.201
22221          00:11:11:11:11:11    Dynamic                       201.201.201.201
22221          00:22:22:22:22:22    Dynamic    te-1/1/10
33333          00:44:44:44:44:44    Dynamic    te-1/1/11
Entries in access port:  2
Entries in network port: 2
```

- To verify the VXLAN tunnel information, run the command **run show vxlan tunnel**.

```
admin@router1# run show vxlan tunnel
Total number of tunnels: 2

VNI 9999, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:201.201.201.201, dst addr:134.134.134.134, state:UP
  traffic type:unicast
  Vtep type:EVPN
```

```
  nexthops:100.1.1.134
  output ports:te-1/1/1

VNI 22221, Encap:service-vlan-delete, Decap:service-vlan-per-port
  src addr:201.201.201.201, dst addr:134.134.134.134, state:UP
  traffic type:all
  Vtep type:EVPN
  nexthops:100.1.1.134
  output ports:te-1/1/1

admin@router2# run show vxlan tunnel
Total number of tunnels: 2

VNI 9999, Encap:service-vlan-delete, Decap:service-vlan-add-replace
  src addr:134.134.134.134, dst addr:201.201.201.201, state:UP
  traffic type:unicast
  Vtep type:EVPN
  nexthops:100.1.1.201
  output ports:ge-1/1/1

VNI 22221, Encap:service-vlan-delete, Decap:service-vlan-per-port
  src addr:134.134.134.134, dst addr:201.201.201.201, state:UP
  traffic type:all
  Vtep type:EVPN
  nexthops:100.1.1.201
  output ports:ge-1/1/1
```

- Run the command **run show vxlan evpn rmac** to display the Router-MAC (rmac) and other VXLAN parameters. Note that to configure rmac for a layer 3 VLAN interface, run the command **set l3-interface vlan-interface** <*interface-name*> **router-mac** <*router-mac*>. The system MAC of the switch is displayed if the router MAC is not configured.

```
admin@router1# run show vxlan evpn rmac
L3-VNI    Interface      SVI-Interface  Remote-VTEP      Neighbor-RMAC      Flags
--------  -------------  -------------  ---------------  -----------------  -----
9999      vxlan9999      vlan1111       134.134.134.134  18:5a:58:37:64:61  0x16

admin@router2# run show vxlan evpn rmac
L3-VNI    Interface      SVI-Interface  Remote-VTEP      Neighbor-RMAC      Flags
--------  -------------  -------------  ---------------  -----------------  -----
9999      vxlan9999      vlan1111       201.201.201.201  18:5a:58:37:55:e1  0x16
```

- To display the VXLAN EVPN routes, run the command **run show vxlan evpn route.**

```
admin@router1# run show vxlan evpn route ipv4
VRF       ROUTE              NextHop          VNI         Interface
--------  -----------------  ---------------  ----------  -----------------
vrf1      33.1.1.1/32        134.134.134.134  9999        vlan1111
vrf1      33.1.1.134/32      134.134.134.134  9999        vlan1111
vrf1      33.1.1.0/24        134.134.134.134  9999        vlan1111

admin@router2# run show vxlan evpn route ipv4
VRF       ROUTE              NextHop          VNI         Interface
--------  -----------------  ---------------  ----------  -----------------
vrf1      22.1.1.1/32        201.201.201.201  9999        vlan1111
vrf1      22.1.1.201/32      201.201.201.201  9999        vlan1111
vrf1      22.1.1.0/24        201.201.201.201  9999        vlan1111
```

- To check the ARP table of a device, run the command **run show vxlan arp.**

```
admin@router1# run show vxlan arp
IP-ADDRESS       MAC-ADDRESS        VNI        Status     Age       Interface      REMOTE-VTEP
---------------  -----------------  --------  ---------   -------   ----------    ------------
22.1.1.1         00:33:33:33:33:33  22222     Dynamic     23         te-1/1/11
```

```
admin@router2# run show vxlan arp
IP-ADDRESS       MAC-ADDRESS        VNI       Status     Age    Interface     REMOTE-VTEP
---------------  -----------------  --------  --------  ------  ----------    ------------
33.1.1.1         00:44:44:44:44:44  33333     Dynamic   26      te-1/1/11
```

EVPN Asymmetric Routing Example

- Network Requirements
- Router Configuration
- Verify Configuration

> **Note**
> EVPN feature is only available on X86 platforms.

Network Requirements

PICOS version 4.0 and higher offer both Symmetric and Asymmetric routing for BGP EVPN hosts. In this document we will examine the case of Asymmetric EVPN routing with two hosts in different VNIs on two devices, R1 and R2.

Figure 1 depicts how packet exchange between two hosts occurs in asymmetric BGP EVPN routing model. In the asymmetric routing model, the two end hosts, Host1 and Host2 are in two different VLANs and different VNIs. Host1 intends to communicate with Host2, sends a packet with destination MAC address of of R1 because R1 is configured as the gateway on Host1. On R1, the gateway is configured on an interface that belongs to VNI 30. The packet from Host1 on ingress at R1 is first routed to VNI 30 within R1 and then bridged to R2 over the VXLAN tunnel VNI 30. On receiving the packet, R2 will strip off the VXLAN header and forward the packet to Host2.

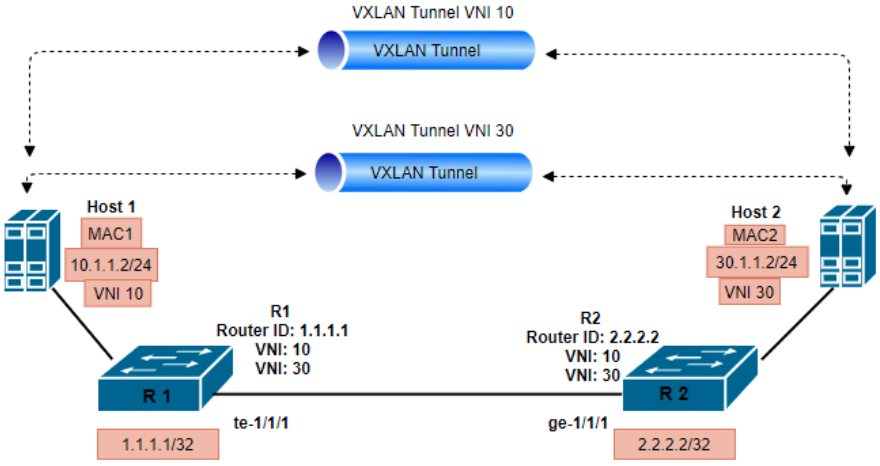

Figure 1. EVPN Asymmetric Routing Model

The one limitation in this model is that both the devices must have the two VXLAN VNIs configured regardless if there are any hosts connected to it. In Figure 1, Host1 belongs to VNI 10 but both VNI 10 and VNI 30 are configured on R1. Similarly, Host2 belongs to VNI 30 but both VNI 10 and VNI 30 are configured on R2 for asymmetric routing to work properly.

Router Configuration

R1 Configuration

Step 1 Configure VLAN ID, L3 VLAN interfaces loopback interfaces and IP addressing. Interface te-1/1/15 connects to Host1.

NOTE: "router-mac" is an optional configuration for anycast gateway.

```
admin@R1# set vlans vlan-id 10 l3-interface vlan10
admin@R1# set vlans vlan-id 30 l3-interface vlan30
admin@R1# set vlans vlan-id 1111 l3-interface vlan1111
admin@R1# set vlans vlan-id 4094 l3-interface vlan4094
admin@R1# set interface gigabit-ethernet te-1/1/15 family ethernet-switching native-vlan-id 10
admin@R1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 4094
admin@R1# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
admin@R1# set l3-interface loopback vrf1 address 201.201.201.201 prefix-length 32
admin@R1# set l3-interface vlan-interface vlan4094 address 40.94.0.2 prefix-length 24
admin@R1# set l3-interface vlan-interface vlan1111 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan10 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan10 router-mac 00:00:10:00:00:FE
admin@R1# set l3-interface vlan-interface vlan10 address 10.1.1.10 prefix-length 24
admin@R1# set l3-interface vlan-interface vlan30 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan30 router-mac 00:00:30:00:00:FE
```

```
admin@R1# set l3-interface vlan-interface vlan30 address 30.1.1.30 prefix-length 24
```

Step 2 Configure VXLAN VNI and map VNI IDs to VLAN IDs.

> **NOTEs:**
> - When anycast gateway is configured, it is recommended to configure ARP/ND suppression at the same time.
> - It is recommended to configure the decapsulation mode as "service-vlan-per-port".

```
admin@R1# set vxlans source-interface lo address 1.1.1.1
admin@R1# set vxlans vni 100 vlan 1111
admin@R1# set vxlans vni 10 decapsulation mode service-vlan-per-port
admin@R1# set vxlans vni 10 vlan 10
admin@R1# set vxlans vni 10 arp-nd-suppress disable false
admin@R1# set vxlans vni 30 decapsulation mode service-vlan-per-port
admin@R1# set vxlans vni 30 vlan 30
admin@R1# set vxlans vni 30 arp-nd-suppress disable false
admin@R1# set vxlans vrf vrf1 l3-vni 100 prefix-routes-only
```

Step 3 Enable IP routing and configure VRF and hostname.

```
admin@R1# set system hostname R1
admin@R1# set ip routing enable true
admin@R1# set ip vrf vrf1
```

Step 4 Configure BGP and OSPF related configuration.

> **NOTE:**
> The **set protocols bgp evpn advertise ipv4-unicast** command is used to announce IPv4 prefixes in the BGP RIB as EVPN Type-5 routes. To announce IPv6 prefixes in the BGP RIB as EVPN Type-5 routes, use command **set protocols bgp evpn advertise ipv6-unicast**.

```
admin@R1# set protocols bgp local-as 65001
admin@R1# set protocols bgp router-id 1.1.1.1
admin@R1# set protocols bgp neighbor 2.2.2.2 remote-as internal
admin@R1# set protocols bgp neighbor 2.2.2.2 update-source 1.1.1.1
admin@R1# set protocols bgp neighbor 2.2.2.2 evpn activate true
admin@R1# set protocols bgp ipv4-unicast
admin@R1# set protocols bgp evpn advertise-all-vni
admin@R1# set protocols bgp evpn advertise ipv4-unicast
admin@R1# set protocols bgp evpn advertise-svi-ip
admin@R1# set protocols bgp vrf vrf1 local-as 65001
admin@R1# set protocols bgp vrf vrf1 router-id 1.1.1.1
admin@R1# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
admin@R1# set protocols ospf router-id 1.1.1.1
admin@R1# set protocols ospf network 40.94.0.0/24 area 0.0.0.0
admin@R1# set protocols ospf network 1.1.1.1/32 area 0.0.0.0
admin@R1# set vlans vlan-id 10 l3-interface vlan10
admin@R1# set vlans vlan-id 30 l3-interface vlan30
admin@R1# set vlans vlan-id 1111 l3-interface vlan1111
admin@R1# set vlans vlan-id 4094 l3-interface vlan4094
```

Step 5 Commit the configuration.

```
admin@R1# commit
```

R2 Configuration

Step 1 Configure VLAN ID, L3 VLAN interfaces loopback interfaces and IP addresses. Interface ge-1/1/15 connects to Host2.

```
admin@R2# set vlans vlan-id 10 l3-interface vlan10
admin@R2# set vlans vlan-id 30 l3-interface vlan30
admin@R2# set vlans vlan-id 1111 l3-interface vlan1111
admin@R2# set vlans vlan-id 4094 l3-interface vlan4094
admin@R2# set interface gigabit-ethernet ge-1/1/15 family ethernet-switching native-vlan-id 30
admin@R2# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 4094
admin@R2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
admin@R2# set l3-interface loopback vrf1 address 134.134.134.134 prefix-length 32
admin@R2# set l3-interface vlan-interface vlan1111 vrf vrf1
```

```
admin@R2# set l3-interface vlan-interface vlan4094 address 40.94.0.1 prefix-length 24
admin@R2# set l3-interface vlan-interface vlan10 vrf vrf1
admin@R2# set l3-interface vlan-interface vlan10 router-mac 00:00:10:00:00:FE
admin@R2# set l3-interface vlan-interface vlan10 address 10.1.1.10 prefix-length 24
admin@R2# set l3-interface vlan-interface vlan30 vrf vrf1
admin@R2# set l3-interface vlan-interface vlan30 router-mac 00:00:30:00:00:FE
admin@R2# set l3-interface vlan-interface vlan30 address 30.1.1.30 prefix-length 24
```

Step 2 Configure VXLAN VNI and map VNI IDs to VLAN IDs.

```
admin@R2# set vxlans source-interface lo address 2.2.2.2
admin@R2# set vxlans vni 100 vlan 1111
admin@R2# set vxlans vni 10 decapsulation mode service-vlan-per-port
admin@R2# set vxlans vni 10 vlan 10
admin@R2# set vxlans vni 10 arp-nd-suppress disable false
admin@R2# set vxlans vni 30 decapsulation mode service-vlan-per-port
admin@R2# set vxlans vni 30 vlan 30
admin@R2# set vxlans vni 30 arp-nd-suppress disable false
admin@R2# set vxlans vrf vrf1 l3-vni 100 prefix-routes-only
```

Step 3 Enable IP routing and configure VRF and hostname.

```
admin@R2# set system hostname R2
admin@R2# set ip routing enable true
admin@R2# set ip vrf vrf1
```

Step 4 Configure BGP and OSPF related configuration

```
admin@R2# set protocols bgp local-as 65001
admin@R2# set protocols bgp router-id 2.2.2.2
admin@R2# set protocols bgp neighbor 1.1.1.1 remote-as internal
admin@R2# set protocols bgp neighbor 1.1.1.1 update-source 2.2.2.2
admin@R2# set protocols bgp neighbor 1.1.1.1 evpn activate true
admin@R2# set protocols bgp evpn advertise-all-vni
admin@R2# set protocols bgp evpn advertise ipv4-unicast
admin@R2# set protocols bgp evpn advertise-svi-ip
admin@R2# set protocols bgp vrf vrf1 local-as 65001
admin@R2# set protocols bgp vrf vrf1 router-id 2.2.2.2
admin@R2# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
admin@R2# set protocols lldp enable true
admin@R2# set protocols spanning-tree enable false
admin@R2# set protocols ospf router-id 2.2.2.2
admin@R2# set protocols ospf network 40.94.0.0/24 area 0.0.0.0
admin@R2# set protocols ospf network 2.2.2.2/32 area 0.0.0.0
```

Step 5 Commit the configuration.

```
admin@R2# commit
```

Verify Configuration

- On R1 and R2, run the command **run show route vrf vrf1 forward-host ipv4 all** to display the host routes.

```
admin@R1# run show route vrf vrf1 forward-host ipv4 all
Address           HWaddress           Port
---------------   -----------------   ---------
10.1.1.2         00:1E:C9:BB:C0:3C   vxlan-0x80000002
30.1.1.2         00:0C:29:77:8B:15   vxlan-0x80000001
Total host count:2

admin@R2# run show route vrf vrf1 forward-host ipv4 all
Address           HWaddress           Port
---------------   -----------------   ---------
10.1.1.2          00:1E:C9:BB:C0:3C   vxlan-0x80000001
30.1.1.2          00:0C:29:77:8B:15   vxlan-0x80000003
```

```
Total host count:2
```

- Run the command **run show vxlan arp** on either R1 or R2 to check VXLAN ARP table.

```
admin@R1# run show vxlan arp
IP-ADDRESS       MAC-ADDRESS        VNI        Status     Age        Interface      REMOTE-VTEP
---------------  -----------------  ---------  --------   ----------  ------------    ----------
10.1.1.2        00:1e:c9:bb:c0:3c  10          Dynamic    135         te-1/1/15
30.1.1.2        00:0c:29:77:8b:15  30          Static                                 2.2.2.2

admin@R2# run show vxlan arp
IP-ADDRESS       MAC-ADDRESS         VNI        Status    Age         Interface      REMOTE-VTEP

  output ports:ge-1/1/1
```

EVPN With NAC Configuration Guide

In this configuration example we will examine the EVPN with NAC use case. As shown in Figure 1 below, we have two Pica8 switches in this topology. Switch R1 has a Cisco IP phone connected with it. Switch1 is also connected with our management network that gives it access to Cisco ISE network access controller. Similarly switch R2 is also connected with a host and an IP phone.

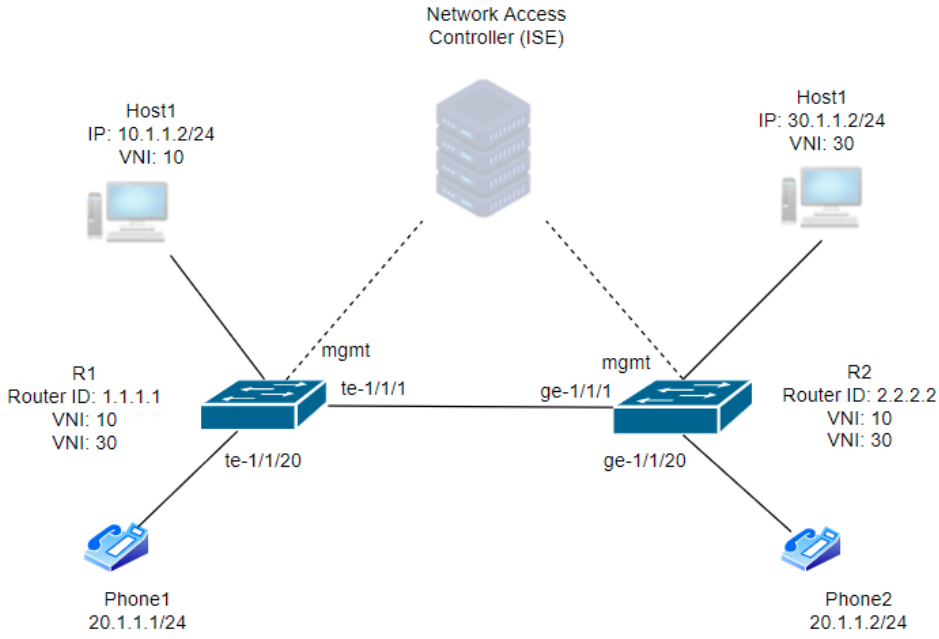

Figure 1. EVPN with NAC Topology

The general idea in this use case is that we will first program ISE to recognize any MAB authentication requests for this IP phone device and assign it a dynamic VLAN through the Access-Accept message. This will cause the switch to put the physical port connecting the IP phone into a VLAN which is part of the VXLAN network through VLAN to VNI mapping. Once part of that VNI, the IP phone can then be accessible throughout the VXLAN network. The communication between the IP phone and other devices will pass through the VXLAN tunnel if the devices are physically located on different switches. The phone can then be managed by some kind of phone management or call manager software to establish phone connectivity throughout the network however, such configuration details are beyond the scope of this document.

The routing model used in this topology for the host computers is the EVPN Asymmetric routing model in which, when two communicating devices reside in two different VNIs, routing will take place locally on the device from one VNI to the target VNI and then data packets are bridged from one switch to the other switch and forwarded to the destination device. Since ISE will usually profile IP phone devices and put them all into a single VLAN or voice VLAN, hence such devices will belong to the same VNI even if they are connected to different switches. In this example topology, ISE will assign the dynamic VLAN ID 20 to both the IP phone devices.

Switch Configuration

This section details the configuration of the two switch devices in this topology.

R1 Switch Configuration

Step 1: Configure VLAN ID, L3 VLAN interfaces loopback interfaces and IP addressing. Interface te-1/1/10 connects to PC1 and interface te-1/1/20 connects to the IP phone.

```
admin@R1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 4094
admin@R1# set interface gigabit-ethernet te-1/1/20 family ethernet-switching port-mode trunk
admin@R1# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 10
admin@R1# set interface gigabit-ethernet te-1/1/10 family ethernet-switching native-vlan-id 10
admin@R1# set l3-interface loopback lo address 1.1.1.1 prefix-length 32
admin@R1# set l3-interface loopback vrf1 address 201.201.201.201 prefix-length 32
admin@R1# set l3-interface vlan-interface vlan4094 address 40.94.0.2 prefix-length 24
admin@R1# set l3-interface vlan-interface vlan10 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan20 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan30 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan10 address 10.1.1.201 prefix-length 24
```

```
admin@R1# set l3-interface vlan-interface vlan20 address 20.1.1.201 prefix-length 24
admin@R1# set l3-interface vlan-interface vlan1111 vrf vrf1
admin@R1# set l3-interface vlan-interface vlan1111 router-mac 00:16:16:16:16:16
admin@R1# set vlans vlan-id 20 l3-interface vlan20
admin@R1# set vlans vlan-id 10 l3-interface vlan10
admin@R1# set vlans vlan-id 30 l3-interface vlan30
admin@R1# set vlans vlan-id 1111 l3-interface vlan1111
admin@R1# set vlans vlan-id 4094 l3-interface vlan4094
```

Step 2: Configure VXLAN VNI and map VNI IDs to VLAN IDs.

```
admin@R1# set vxlans source-interface lo address 1.1.1.1
admin@R1# set vxlans vni 100 vlan 1111
admin@R1# set vxlans vni 10 vlan 10
admin@R1# set vxlans vni 30 vlan 30
admin@R1# set vxlans vni 20 vlan 20
admin@R1# set vxlans vrf vrf1 l3-vni 100 prefix-routes-only
admin@R1# set vxlans source-interface lo address 1.1.1.1
```

Step 3: Enable IP routing and configure VRF and hostname.

```
admin@R1# set ip routing enable true
admin@R1# set ip vrf vrf1
```

Step 4: Configure BGP and OSPF related configuration

```
admin@R1# set protocols bgp local-as 65001
admin@R1# set protocols bgp router-id 1.1.1.1
admin@R1# set protocols bgp neighbor 2.2.2.2 remote-as internal
admin@R1# set protocols bgp neighbor 2.2.2.2 update-source 1.1.1.1
admin@R1# set protocols bgp neighbor 2.2.2.2 evpn activate true
admin@R1# set protocols bgp ipv4-unicast
admin@R1# set protocols bgp evpn advertise-all-vni
admin@R1# set protocols bgp evpn advertise ipv4-unicast
admin@R1# set protocols bgp vrf vrf1 local-as 65001
admin@R1# set protocols bgp vrf vrf1 router-id 1.1.1.1
admin@R1# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
admin@R1# set protocols ospf router-id 1.1.1.1
admin@R1# set protocols ospf network 40.94.0.0/24 area 0.0.0.0
admin@R1# set protocols ospf network 1.1.1.1/32 area 0.0.0.0
```

Step 5: Configure 802.1X and NAC. Specify the NAS IP, the authentication server IP which is the IP address of the ISE server in this case and authentication mode.

```
admin@R1# set protocols dot1x interface te-1/1/20 host-mode multiple
admin@R1# set protocols dot1x interface te-1/1/20 auth-mode mac-radius
admin@R1# set protocols dot1x aaa radius authentication server-ip 10.10.50.65 shared-key test
admin@R1# set protocols dot1x aaa radius nas-ip 10.10.51.201
```

Step 6: Enable POE for interface te-1/1/20. We need this step to power up the phone device using the switch's' POE feature without needing an external power source.

```
admin@R1# set poe interface te-1/1/20
```

R2 Configuration

Step 1: Configure VLAN ID, L3 VLAN interfaces, loopback interfaces and IP addresses. Interface ge-1/1/10 connects to PC2 and interface ge-1/1/20 connects to the IP phone.

```
root@R2# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 4094
root@R2# set interface gigabit-ethernet ge-1/1/10 family ethernet-switching native-vlan-id 30
root@R2# set interface gigabit-ethernet ge-1/1/20 family ethernet-switching port-mode trunk
root@R2# set l3-interface loopback lo address 2.2.2.2 prefix-length 32
root@R2# set l3-interface loopback vrf1 address 134.134.134.134 prefix-length 32
```

```
root@R2# set l3-interface vlan-interface vlan1111 vrf vrf1
root@R2# set l3-interface vlan-interface vlan30 vrf vrf1
root@R2# set l3-interface vlan-interface vlan20 vrf vrf1
root@R2# set l3-interface vlan-interface vlan30 address 30.1.1.134 prefix-length 24
root@R2# set l3-interface vlan-interface vlan20 address 20.1.1.134 prefix-length 24
root@R2# set l3-interface vlan-interface vlan4094 address 40.94.0.1 prefix-length 24
root@R2# set vlans vlan-id 10 l3-interface vlan10
root@R2# set vlans vlan-id 20 l3-interface vlan20
root@R2# set vlans vlan-id 30 l3-interface vlan30
```

Step 2: Configure VXLAN VNI and map VNI IDs to VLAN IDs.

```
root@R2# set vlans vlan-id 1111 l3-interface vlan1111
root@R2# set vlans vlan-id 4094 l3-interface vlan4094
root@R2# set vxlans source-interface lo address 2.2.2.2
root@R2# set vxlans vni 100 vlan 1111
root@R2# set vxlans vni 10 vlan 10
root@R2# set vxlans vni 20 vlan 20
root@R2# set vxlans vni 30 vlan 30
```

Step 3: Enable IP routing and configure VRF and hostname.

```
root@R2# set system hostname R2
root@R2# set ip routing enable true
root@R2# set ip vrf vrf1
```

Step 4: Configure BGP and OSPF related configuration

```
root@R2# set protocols bgp local-as 65001
root@R2# set protocols bgp router-id 2.2.2.2
root@R2# set protocols bgp neighbor 1.1.1.1 remote-as internal
root@R2# set protocols bgp neighbor 1.1.1.1 update-source 2.2.2.2
root@R2# set protocols bgp neighbor 1.1.1.1 evpn activate true
root@R2# set protocols bgp evpn advertise-all-vni
root@R2# set protocols bgp evpn advertise ipv4-unicast
root@R2# set protocols bgp vrf vrf1 local-as 65001
root@R2# set protocols bgp vrf vrf1 router-id 2.2.2.2
root@R2# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
root@R2# set vxlans vrf vrf1 l3-vni 100 prefix-routes-only
root@R2# set protocols ospf router-id 2.2.2.2
root@R2# set protocols ospf network 40.94.0.0/24 area 0.0.0.0
root@R2# set protocols ospf network 2.2.2.2/32 area 0.0.0.0
```

Step 5: Configure 802.1X and NAC. Specify the NAS IP, the authentication server IP which is the IP address of the ISE server in this case and the authentication mode.

```
admin@R2# set protocols dot1x interface ge-1/1/20 host-mode multiple
admin@R2# set protocols dot1x interface ge-1/1/20 auth-mode mac-radius
admin@R2# set protocols dot1x aaa radius authentication server-ip 10.10.50.65 shared-key test
admin@R2# set protocols dot1x aaa radius nas-ip 10.10.51.134
```

Step 6: Enable POE for interface ge-1/1/20. We need this step to power up the phone device using the switch's' POE feature.

```
admin@R2# set poe interface ge-1/1/20
```

Note: In a more realistic network environment, DHCP access needs to be allowed in the VLAN connecting the IP phone devices to automatically assign IP address and other basic network information like DNS and gateway details. Such configurations are not implemented in this example topology.

Verify Configuration

After successful authentication from the ISE server, the switch port is assigned the dynamic VLAN as shown below in the output of the show command on R1.

```
admin@R1# run show dot1x interface gigabit-ethernet te-1/1/20
Interface ge-1/1/20:
===============================================================
Client MAC : cc:98:91:4e:c9:a7
Status : authorized
Success Auth Method : MAB
Traffic Class : Other
Dynamic VLAN ID : 20 (active)
===============================================================
```

On R1 run the command **run show route vrf vrf1** to display the routes. Notice below that there is a route to subnet 30.1.1.0/24.

```
admin@R1# run show route vrf vrf1
show ip route vrf vrf1
======================
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

Introduction

EVPN Multihoming (MH) is a standards based replacement for MLAG to achieve standards based all-active server redundancy in datacenters and enterprise networks. Multihoming eliminates the need to have MLAG and unlike MLAG, does not require the group of devices used to create a multihoming group to have inter-connecting peer links.

EVPN multihoming is based on the concept of forming Ethernet Segments (ES). In the context of BGP EVPN, an Ethernet Segment is a set of links connecting a single end host or server with the EVPN VXLAN fabric. In the Figure below, Server1 is multihomed to the VXLAN fabric through links connecting it to VTEP1 and VTEP2, forming an Ethernet Segment. Similarly, Server2, Server3 and Server4 are connected to the fabric through links forming segment 2, segment 3 and segment 4 respectively.

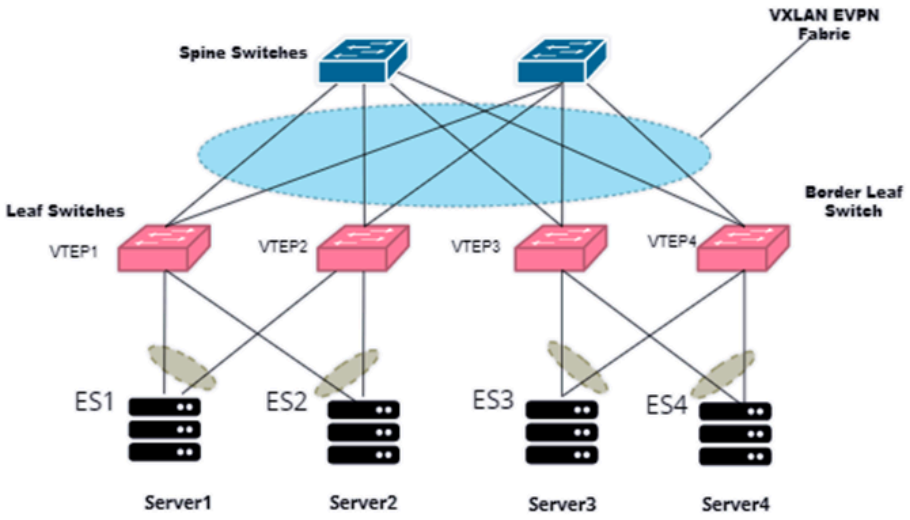

Figure 1. EVPN Multihoming

Key Benefits

- Interconnecting switch links between TOR switches in a redundancy group are not required.
- There can be more than two TOR switches in the redundancy group. A maximum of 8 devices can form one redundancy group as opposed to a maximum of two devices in an MLAG group.
- Ease of management as it provides a single BGP-EVPN control plane.
- Allows multi-vendor interoperability because of standards based implementation.

Brief Mechanism

As shown in Figure 1, if VTEP1 loses direct connection to Server1, it will signal to VTEP2, VTEP3 and VTEP4 that Server1 is no longer accessible and to change their next-hop group for Server1 if there are alternative routes to this ES. Since VTEP2 also has a route to this ES, VTEP3 and VTEP4 will change their next hop groups for Server1 MAC address to go through VTEP2 instead of VTEP1.

EVPN multihoming uses EVPN Type-1, Type-2 and Type-4 routes to discover these Ethernet Segments and deliver traffic to and from these segments. Each Ethernet Segment is identified by a unique ID called Ethernet Segment ID (ESI). ESI is unique across the entire EVPN VXLAN domain on all VTEPs. To configure ESI, we first need to configure the Ethernet Segment System MAC and a local ES-ID. The local ES system MAC and local ES ID are used to automatically generate the ESI. Different ES System MACs can be configured for different Ethernet Segments but the ES System MAC configured on interfaces connecting to the same server or host must be same. In the sections below we will briefly explore EVPN Type-1Auto Discovery and EVPN Type-4 Ethernet Segment Routes.

EVPN Type-1 Ethernet Auto Discovery (A-D) Route

EVPN Type-1 routes are used for fast convergence and aliasing for multihomed sites or end hosts. Fast convergence is important in networks with large number of hosts. When a link failure occurs, devices can signal to upstream PE devices or other VTEPs in the network to change their next-hop groups for the MAC addresses associated with that particular Ethernet Segment. Aliasing is used for load balancing on multiple outgoing links.

Route Distinguisher (RD) (8 octets)
Ethernet Segment Identifier (10 octets)
Ethernet Tag ID (4 octets)
MPLS Label (3 octets)

Table 1. EVPN Type-1 Route NLRI

Type-1 routes are only originated for multihomed devices, i.e. these routes are sent only when the Ethernet Segment ID is set to a non-zero value.

EVPN Type-4 Ethernet Segment Route

Type-4 routes are used for electing the Designated Forwarder (DF) in EVPN multihoming scenarios. The DF is responsible for sending broadcast, unknown unicast and multicast (BUM) traffic to multihomed hosts or servers. If a server is multihomed to two upstream devices in the EVPN fabric, only one would be elected as the DF for sending BUM traffic to the multihomed server on this ES.

The EVPN NLRI for Type-4 Ethernet Segment Route consists of the following four fields. For multihomed hosts, the Ethernet Segment Identifier (ESI) must be set to a non-zero value. A value of zero for the ESI indicates a single homed device.

RD (8 Octets)
Ethernet Segment Identifier (10 Octets)
IP Address Length (1 octet)
Originating Router's IP Address (4 or 16 octets)

Table 2. EVPN Type-4 NLRI

EVPN multihoming works by utilizing EVPN Type-1, Type-2 and Type-4 routes. Three types of EVPN routes are used to fulfill three distinct EVPN multihoming requirements.

The PICOS EVPN multihoming can be summarized in the following three steps

Step1:

EVPN Type-2 routes are used for remote learning of end hosts. As shown in Figure 1 for example, Server1 is multihomed to VTEP1 and VTEP2. Both VTEP1 and VTEP2 will first locally learn Server1's MAC/IP address and then advertise it to VTEP3 and VTEP4 using EVPN Type-2 routes (remote learning).

Step2:

With EVPN multihoming enabled on switch ports connecting Server1 to VTEP1 and VTEP2, both devices will configure the same Ethernet Subnet Identifier (ESI) on the two links and advertise this information to all the other VTEPs using Type-4 routes. This will indicate to remote VTEPs that Server1 is multihomed to the EVPN fabric and is accessible through both VTEP1 and VTEP2.

Step3:

For fast convergence and aliasing, VTEP1 and VTEP2 will advertise Type-1 routes. This type of advertisement is sent in the event of a link failure. If the link connecting VTEP1 and Server1 goes down, VTEP1 will advertise Type-1 route indicating to all the other VTEPs that it has lost connection with Server1 (Ethernet Segment). If VTEP1 was elected the

designated forward (DF) for this segment, VTEP2 will then assume the role of DF for Server1 whereas VTEP3 and VTEP4 will adjust their next-hop groups for Server1 accordingly.

> **Note**
> It is strongly suggested to remove any MLAG related configuration from the overlay devices (VTEPs) if you plan on deploying EVPN MH in your network. The two technologies are designed to address almost similar requirements of redundancy but MLAG is a layer2 technique whereas EVPN MH is deployed in the overlay and is a layer3 technique. The two technologies hence do not mix well and users are urged to stick to EVPN MH for its standards based implementation and interoperability benefits as opposed to MLAG especially in the overlay network design.

Designated Forwarder Election

For BGP EVPN, a Designated Forwarder (DF) is responsible for handling Broadcast, Unknown Unicast and Multicast (BUM) traffic for Ethernet Segments. As shown in Figure 1, Server1 constitutes an Ethernet Segment as it is multihomed to two VTEPs in the EVPN overlay. Only one of the two VTEPs has to be elected a DF to deliver BUM traffic to Server1 from remote VTEPs (VTEP3 and VTEP4). The administrator needs to configure EVPN multihoming preference for the Ethernet Segment. A higher preference value wins the election process and assumes the role of the DF. If the preference on both the VTEPs is same then the VTEP with the smallest IP wins the election. It's important to note that the interface connecting the Ethernet Segment must be an Aggregate-Ethernet interface.

For every Ethernet Segment there must be only one DF.

The following command can be used to set the ES DF preference.

set interface aggregate-ethernet <*interface*> **evpn mh es-df-pref** <*preference*>

VTEP Uplink Status Tracking

Overlay VTEPs are capable of tracking the state of uplinks connecting the overlay leaf devices with underlay spine switches. This feature is automatically enabled when the user enables the EVPN MH. All the downstream links connecting the MH hosts are put in *protocol down* state when all the uplinks go down. In Figure 1, all the links connecting the underlay spine switches must go down before the downstream links are put in *protocol down* state. The links will not be put in *protocol down* state if there is only one link up and active connecting the overlay devices with the underlay.

EVPN MH Split Horizon

Split-horizon technique is used to stop BUM traffic from forming a loop in the EVPN VXLAN network that employs multihoming. Using split-horizon, BUM traffic from the same Ethernet Segment will be dropped by the peer device. As can been seen in Figure 2, Host1 is multihomed into the EVPN VXLAN fabric and connected to both VTEP1 and VTEP2 forming Ethernet Segment ES1.

In the example below, if Host1 sends some BUM traffic to DF and then it is forwarded to the spine switch and then relayed back to VTEP2, that traffic will be discarded at VTEP2 since VTEP2 has an interface configured for the same Ethernet Segment. Split horizon mechanism ensures BUM traffic can't loop back to Host1 if Host1 originates this traffic.

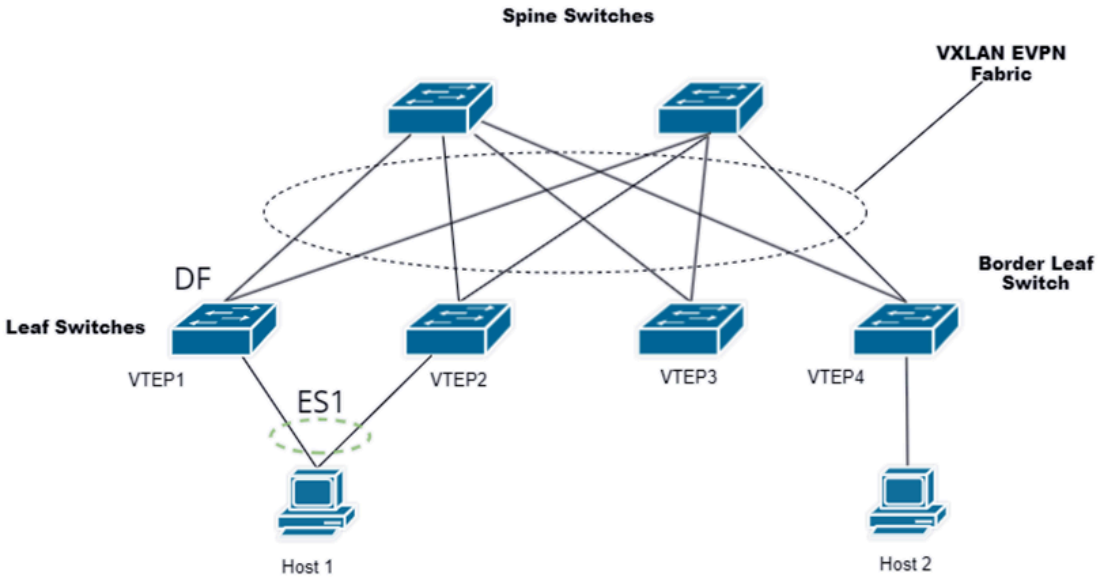

Figure 2. EVPN MH Split-Horizon

Key points to note for EVPN MH Split Horizon and BUM traffic duplication:

1. Only one DF is elected in one ESI (one LAG), so partial connection is not allowed for EVPN MH access connection.
2. Non-DF node will drop the BUM traffic from other nodes, including peer of the same ES. BUM traffic from remote VTEPs is dropped by non-DF nodes to avoid duplication.

> **Note**
> **Note:** Single homed ports connecting a single device with the EVPN VXLAN fabric are not yet supported on VTEP devices. If a server is dual homed to two VTEPs and the connecting link to one of the VTEP fails, the server will still be considered a dual homed device even if there is only one active link connecting it to the fabric.

EVPN MH Basic Configuration

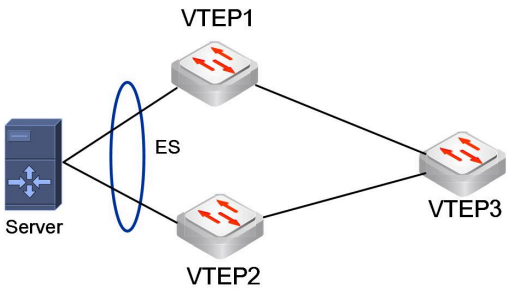
To configure EVPN multihoming on a LAG interface, the user needs to configure an Ethernet Segment identifier (ES-ID) and an Ethernet Segment System MAC. A type-3 ESI value is automatically generated by using these two parameters. The resulting 10-byte ESI value has the following format, where the XXs denote the 6-byte ES System MAC and the YYs denote the 3-byte local ES ID.

03 : XX : XX : XX : XX : XX : XX : YY : YY : YY

For each Ethernet segment, both the ES System MAC and the ES ID must be the same on all the switches forming the EVPN MH redundancy group. However, switches can be configured with different system MACs for different Ethernet segments or share the same system MAC for all Ethernet segments.

Aliasing

The aliasing feature provides remote VTEP devices the ability to load balance Layer-2 unicast traffic through other VTEPs that have configured the same ES (Ethernet Segment). VTEP devices in the EVPN multihoming redundancy group always advertise the communicated information of the same ES to all remote VTEPs via MP-BGP protocol. If one of the VTEP device in an ES, say VTEP1 in the following figure, learns the MAC/ARP information and advertises it to the remote VTEP, say VTEP3. Then, VTEP3 adds not only the IP address of VTEP1 as the next hop, but also adds the IP addresses of other VTEPs in the EVPN multihoming redundancy group as the next hop, to automatically form equivalent paths between different VTEPs.



EVPN multihoming aliasing function uses the ECMP hash fields "ingress-interface","ip-destination", "ip-source," "port-destination," "port-source," and "vlan" for equivalent paths calculation. By default, all these fields are enabled. Users can run the following CLI commands to enable or disable the ECMP hash fields:

set interface ecmp hash-mapping field ingress-interface disable

set interface ecmp hash-mapping field ip-destination disable

set interface ecmp hash-mapping field ip-protocol disable

set interface ecmp hash-mapping field ip-source disable

set interface ecmp hash-mapping field port-destination disable

set interface ecmp hash-mapping field port-source disable

set interface ecmp hash-mapping field vlan disable

On the remote VTEP, run the following EVPN MAC show commands to view the next hop. It shows the next hop interface is *vplag*, including all VTEPs in remote ES.

```
admin@Xorplus# run show mac-address table
Total entries in switching table:   1
Static entries in switching table:  0

Entries in access port:  0
Entries in network port: 1
```

Switch Configuration Example and Topology

In PICOS EVPN multihoming, there are two ways to forward BUM messages. You can choose one of these to apply to your EVPN fabric.

- **Head End Replication.** This is the default way which needs no PIM configurations. The BUM message will be encapsulated and sent to all outgoing ports VTEPs of the same VNI by the access VTEP.
- **BUM tunnel.** All VTEPs of the same VNI join the same multicast group, and use multicast routing protocol PIM to establish a multicast forwarding table entry for the multicast group. This method can reduce the traffic flooding caused by the head end replication of the BUM messages. This way needs to configure PIM protocol.

EVPN Multihoming with Head End Replication

For this example configuration we have the following topology comprising of two spine switches, four leaf switches and four servers that are multihomed to this network. Two servers are multihomed to Leaf1 and Leaf2 switches whereas the other two servers are attached to Leaf3 and Leaf4 switches.

The four leaf switches form two MH redundancy groups for the four ES IDs. Two ES ID's are configured under Leaf1 and Leaf2 whereas, another two ES ID's are configured under Leaf3 and Leaf4. Each leaf switch has one physical interface added to a LAG interface to connect to the downstream server.

The two ES IDs are configured on each peer connected to the two downstream multihomed servers. On Leaf1, two physical ports connect to the multihomed servers; both the physical ports are first added to LAG interfaces. The LAG interface connected to Server1 is "ae2" whereas the interface connecting Server2 is "ae1". For EVPN MH, it is a mandatory that the ports connecting the multihomed hosts must be LAG interfaces. Similarly, on all leaf switches there are two LAG interfaces and two ES IDs configured.

To implement a seamless migration of VMs without changing network settings or disrupting the traffic forwarding, configure the same anycast gateway IP and the same virtual MAC (router MAC) on all four leaf switches to enable the anycast gateway function.

The following configuration examples use the topology illustrated below and configure EVPN multihoming with head end replication.

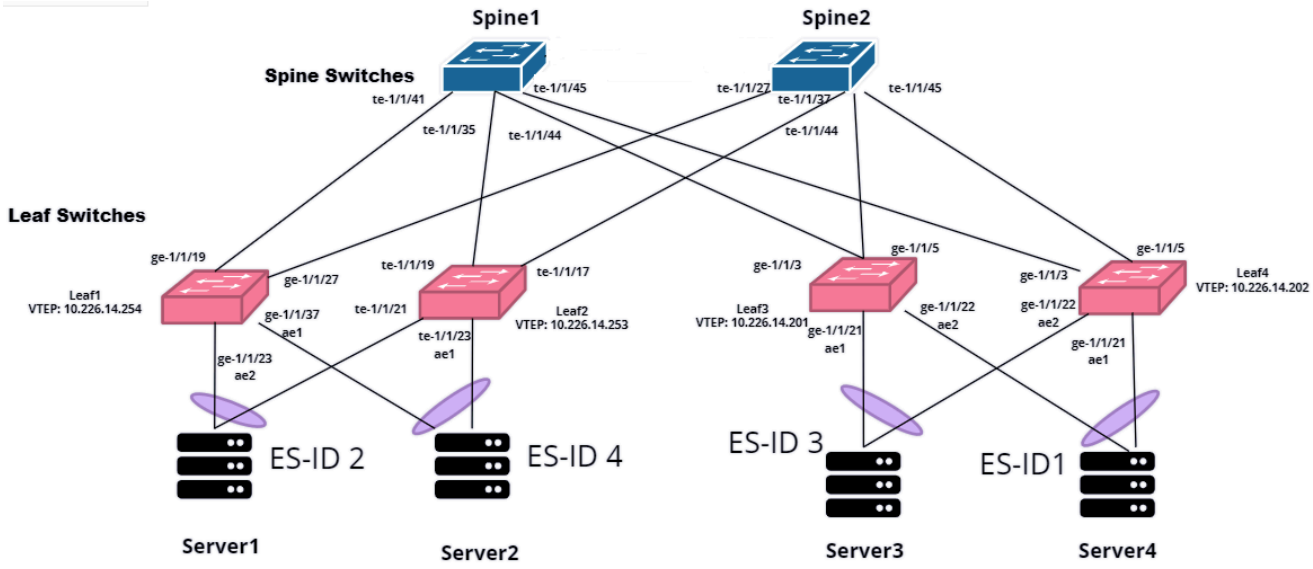

Figure 3. EVPN MH Example Topology

> **Note**
> **Note:** The physical ports connecting the multihomed servers or hosts must be added to a LAG interface and then configured for EVPN MH. Physical interfaces such as ge-1/1/1 cannot be directly used for MH configuration.

Leaf1 Configuration

Step 1. Configure LAG interfaces, set the LAG interface MTU, configure ES ID, configure the LAG interface VLAN membership and the LAG interface trunk mode. MTU configuration is optional, it can be configured when the MTU size needs to be of a particular size based on the customer use case environment. The LACP configuration is also optional.

```
admin@Leaf1# set interface aggregate-ethernet ae1 aggregated-ether-options lacp enable true
admin@Leaf1# set interface aggregate-ethernet ae2 aggregated-ether-options lacp enable true
admin@Leaf1# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@Leaf1# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 30
admin@Leaf1# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 20
admin@Leaf1# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk
admin@Leaf1# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 30
admin@Leaf1# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 20
admin@Leaf1# set interface aggregate-ethernet ae1 evpn mh es-id 4
admin@Leaf1# set interface aggregate-ethernet ae2 evpn mh es-id 2
```

Step2. Configure ES system MAC, it can be the same or different for different ethernet segments. Configure the physical interfaces and VLAN membership and the ports trunk mode. Also add physical interfaces to LAG interfaces.

```
admin@Leaf1# set interface aggregate-ethernet ae1 evpn mh es-sys-mac 00:22:22:22:22:22
admin@Leaf1# set interface aggregate-ethernet ae2 evpn mh es-sys-mac 00:22:22:22:22:22
admin@Leaf1# set interface gigabit-ethernet ge-1/1/19 mtu 3000
admin@Leaf1# set interface gigabit-ethernet ge-1/1/19 family ethernet-switching native-vlan-id 4014
admin@Leaf1# set interface gigabit-ethernet ge-1/1/23 ether-options 802.3ad ae2
admin@Leaf1# set interface gigabit-ethernet ge-1/1/23 family ethernet-switching
admin@Leaf1# set interface gigabit-ethernet ge-1/1/24 disable true
admin@Leaf1# set interface gigabit-ethernet ge-1/1/27 mtu 3000
```

```
admin@Leaf1# set interface gigabit-ethernet ge-1/1/27 family ethernet-switching native-vlan-id 4012
admin@Leaf1# set interface gigabit-ethernet ge-1/1/37 ether-options 802.3ad ae1
```

Step3. Configure VRF and enable IP routing.

```
admin@Leaf1# set ip routing enable true
admin@Leaf1# set ip vrf vrf1
```

Step4. Configure loopback interfaces and assign IP addresses.

```
admin@Leaf1# set l3-interface loopback lo address 10.226.14.254 prefix-length 32
admin@Leaf1# set l3-interface loopback lo address 10.226.14.207 prefix-length 32
admin@Leaf1# set l3-interface loopback vrf1 address 17.17.17.17 prefix-length 32
```

Step5. Configure VLAN interfaces and assign IP addresses, configure anycast gateway.

```
admin@Leaf1# set l3-interface vlan-interface vlan4014 address 10.226.15.65 prefix-length 30
admin@Leaf1# set l3-interface vlan-interface vlan4012 address 10.226.15.29 prefix-length 30
admin@Leaf1# set l3-interface vlan-interface vlan4094 address 10.226.13.26 prefix-length 30
admin@Leaf1# set l3-interface vlan-interface vlan99 vrf vrf1
admin@Leaf1# set l3-interface vlan-interface vlan20 vrf vrf1
admin@Leaf1# set l3-interface vlan-interface vlan20 address 192.168.0.1 prefix-length 24
admin@Leaf1# set l3-interface vlan-interface vlan20 address 2002:0:0:1::1 prefix-length 64
admin@Leaf1# set l3-interface vlan-interface vlan30 vrf vrf1
admin@Leaf1# set l3-interface vlan-interface vlan30 address 172.168.0.1 prefix-length 24
admin@Leaf1# set l3-interface vlan-interface vlan30 address 2003:0:0:1::1 prefix-length 64
admin@Leaf1# set l3-interface vlan-interface vlan20 anycast address 192.168.0.20 prefix-length 24
admin@Leaf1# set l3-interface vlan-interface vlan20 anycast address 2002:0:0:1::20 prefix-length 64
admin@Leaf1# set l3-interface vlan-interface vlan30 anycast address 172.168.0.30 prefix-length 24
admin@Leaf1# set l3-interface vlan-interface vlan30 anycast address 2003:0:0:1::30 prefix-length 64
admin@Leaf1# set l3-interface vlan-interface vlan20 anycast mac 00:00:20:00:00:FE
admin@Leaf1# set l3-interface vlan-interface vlan30 anycast mac 00:00:30:00:00:FE
```

Step6. Configure BGP and EVPN.

```
admin@Leaf1# set protocols bgp local-as 65001
admin@Leaf1# set protocols bgp router-id 10.226.14.207
admin@Leaf1# set protocols bgp neighbor 10.226.14.48 remote-as internal
admin@Leaf1# set protocols bgp neighbor 10.226.14.48 update-source 10.226.14.207
admin@Leaf1# set protocols bgp neighbor 10.226.14.48 evpn activate true
admin@Leaf1# set protocols bgp neighbor 10.226.14.208 remote-as internal
admin@Leaf1# set protocols bgp neighbor 10.226.14.208 update-source 10.226.14.207
admin@Leaf1# set protocols bgp neighbor 10.226.14.208 evpn activate true
admin@Leaf1# set protocols bgp neighbor 10.226.14.24 remote-as internal
admin@Leaf1# set protocols bgp neighbor 10.226.14.24 update-source 10.226.14.207
admin@Leaf1# set protocols bgp neighbor 10.226.14.24 evpn activate true
admin@Leaf1# set protocols bgp ipv4-unicast
admin@Leaf1# set protocols bgp evpn advertise-all-vni
admin@Leaf1# set protocols bgp evpn advertise ipv4-unicast
admin@Leaf1# set protocols bgp evpn advertise ipv6-unicast
admin@Leaf1# set protocols bgp evpn advertise-svi-ip
admin@Leaf1# set protocols bgp vrf vrf1 local-as 65001
admin@Leaf1# set protocols bgp vrf vrf1 router-id 17.17.17.17
admin@Leaf1# set protocols bgp vrf vrf1 evpn advertise ipv4-unicast
admin@Leaf1# set protocols bgp vrf vrf1 evpn advertise ipv6-unicast
admin@Leaf1# set protocols evpn mh
admin@Leaf1# set protocols lldp enable true
```

Step7. Configure OSPF.

```
admin@Leaf1# set protocols ospf router-id 17.17.17.17
admin@Leaf1# set protocols ospf network 10.226.15.64/30 area 0.0.0.0
admin@Leaf1# set protocols ospf network 10.226.15.28/30 area 0.0.0.0
admin@Leaf1# set protocols ospf network 10.226.14.254/32 area 0.0.0.0
admin@Leaf1# set protocols ospf network 10.226.14.207/32 area 0.0.0.0
```

Step8. Configure hostname, inband mode and VLANs.

```
admin@Leaf1# set system hostname Leaf1
admin@Leaf1# set system inband enable true
admin@Leaf1# set vlans vlan-id 20 l3-interface vlan20
admin@Leaf1# set vlans vlan-id 30 l3-interface vlan30
admin@Leaf1# set vlans vlan-id 99 l3-interface vlan99
admin@Leaf1# set vlans vlan-id 4012 l3-interface vlan4012
admin@Leaf1# set vlans vlan-id 4014 l3-interface vlan4014
admin@Leaf1# set vlans vlan-id 4094 l3-interface vlan4094
```

Step9. Configure VXLANs.

```
admin@Leaf1# set vxlans source-interface lo address 10.226.14.254
admin@Leaf1# set vxlans vni 10030 decapsulation mode service-vlan-per-port
admin@Leaf1# set vxlans vni 10030 vlan 30
admin@Leaf1# set vxlans vni 10030 arp-nd-suppress disable false
admin@Leaf1# set vxlans vni 10020 decapsulation mode service-vlan-per-port
admin@Leaf1# set vxlans vni 10020 vlan 20
admin@Leaf1# set vxlans vni 10020 arp-nd-suppress disable false
admin@Leaf1# set vxlans vni 99 vlan 99
admin@Leaf1# set vxlans vrf vrf1 l3-vni 99
admin@Leaf1# commit
```

Leaf2 Configuration

```

admin@Spine2# commit
```

Verify Configuration

- The above configuration uses the same default ES-DF preferences on all the three Leaf switches. The resulting effect is that the leaf switch with the smallest VTEP IP is selected as the DF. In the first EVPN MH redundancy group, Leaf2 is elected as the DF since it has the smallest VTEP IP in the group. Similarly in the second redundancy group, Leaf3 has the smallest VTEP IP and is elected the DF.

```
admin@Leaf1# run show evpn es
Type: B bypass, L local, R remote, N non-DF
```

```
ESI                             Type   ES-IF          VTEPs
03:00:22:22:22:22:22:00:00:04     LRN   ae1          10.226.14.253
03:00:22:22:22:22:22:00:00:02     LRN   ae2          10.226.14.253

admin@Leaf2# run show evpn es
Type: B bypass, L local, R remote, N non-DF

192.168.0.140    04:f8:f8:20:67:7b  10020                                 ae1          Dynamic  315
172.168.0.200    22:11:11:00:00:00  10030   10.226.14.201,10.226.14.202   vplag-0x2    Dynamic  177
```

- Show the BGP EVPN route information with command **run show bgp evpn route**.

EVPN Multihoming with BUM Tunnel

For the topology and figure in the last section, to enable EVPN multihoming with BUM tunnel, besides above configurations of head end replication, we need to add the following configurations:

- Configure PIM on each device, and configure one of the devices as static RP (Spine2 in this example).
- Configure the same VNI to join the same multicast group.

Leaf1 Configuration

Step 1. Configure PIM and configure Spine2 as static RP.

```
admin@Leaf1# set protocols pim rp 202.202.202.202 group 224.1.1.1/32
admin@Leaf1# set protocols pim rp 202.202.202.202 group 230.1.1.1/32
admin@Leaf1# set protocols pim interface lo
admin@Leaf1# set protocols pim interface vlan4014
admin@Leaf1# set protocols pim interface vlan4012
```

Step 2. Configure the same VNI to join the same multicast group.

> **NOTE:**
> PICOS supports only one VXLAN segment mapping to one IP multicast group, which is the way to provide the optimal multicast forwarding. That is, to have multiple VXLAN segments share a single IP multicast group in the core network is not supported.

```
admin@Leaf1# set vxlans vni 10020 mcast-group 224.1.1.1
admin@Leaf1# set vxlans vni 10030 mcast-group 230.1.1.1
admin@Leaf1# commit
```

Leaf2 Configuration

```
admin@Leaf2# set protocols pim rp 202.202.202.202 group 224.1.1.1/32
admin@Leaf2# set protocols pim rp 202.202.202.202 group 230.1.1.1/32
admin@Leaf2# set protocols pim interface lo
admin@Leaf2# set protocols pim interface vlan4014
admin@Leaf2# set protocols pim interface vlan4013
admin@Leaf2# set vxlans vni 10020 mcast-group 224.1.1.1
admin@Leaf2# set vxlans vni 10030 mcast-group 230.1.1.1
admin@Leaf2# commit
```

Leaf3 Configuration

```
admin@Leaf3# set protocols pim rp 202.202.202.202 group 224.1.1.1/32
admin@Leaf3# set protocols pim rp 202.202.202.202 group 230.1.1.1/32
admin@Leaf3# set protocols pim interface lo
admin@Leaf3# set protocols pim interface vlan4016
admin@Leaf3# set protocols pim interface vlan3012
admin@Leaf3# set vxlans vni 10020 mcast-group 224.1.1.1
admin@Leaf3# set vxlans vni 10030 mcast-group 230.1.1.1
admin@Leaf3# commit
```

Leaf4 Configuration

```
admin@Leaf4# set protocols pim rp 202.202.202.202 group 224.1.1.1/32
admin@Leaf4# set protocols pim rp 202.202.202.202 group 230.1.1.1/32
admin@Leaf4# set protocols pim interface lo
admin@Leaf4# set protocols pim interface vlan3011
admin@Leaf4# set protocols pim interface vlan3012
```

```
admin@Leaf4# set vxlans vni 10020 mcast-group 224.1.1.1
admin@Leaf4# set vxlans vni 10030 mcast-group 230.1.1.1
admin@Leaf4# commit
```

Spine1 Configuration

```
admin@Spine1# set protocols pim rp 202.202.202.202 group 224.1.1.1/32
admin@Spine1# set protocols pim rp 202.202.202.202 group 230.1.1.1/32
admin@Spine1# set protocols pim interface lo
admin@Spine1# set protocols pim interface vlan4011
admin@Spine1# set protocols pim interface vlan4092
admin@Spine1# set protocols pim interface vlan4014
admin@Spine1# set protocols pim interface vlan4013
admin@Spine1# set protocols pim interface vlan4015
admin@Spine1# set protocols pim interface vlan4016
admin@Spine1# commit
```

Spine2 Configuration

```
admin@Spine2# set protocols pim rp 202.202.202.202 group 224.1.1.1/32
admin@Spine2# set protocols pim rp 202.202.202.202 group 230.1.1.1/32
admin@Spine2# set protocols pim interface lo
admin@Spine2# set protocols pim interface vlan4011
admin@Spine2# set protocols pim interface vlan4092
admin@Spine2# set protocols pim interface vlan4012
admin@Spine2# set protocols pim interface vlan4014
admin@Spine2# set protocols pim interface vlan4015
admin@Spine2# commit
```

Verify Configuration

In addition to the above show command to verify the results, you can also use the **run show vxlan mcast-tunnel vni** command to view the establishment of the BUM tunnel.

The following example shows the result on Leaf 3:

```
admin@Leaf3# run show vxlan mcast-tunnel vni 10020
VNI       Src-addr         Mcast-addr       Out-Vlan  Out-Interface    Tunnel-ID     Egress-ID
--------  ---------------  ---------------  --------  ---------------  ------------  ------------
10020     10.226.14.201    224.1.1.1        3012      ge-1/1/5         0x4c000000    0

admin@Leaf3# run show vxlan mcast-tunnel vni 10030
VNI       Src-addr         Mcast-addr       Out-Vlan  Out-Interface    Tunnel-ID     Egress-ID
--------  ---------------  ---------------  --------  ---------------  ------------  ------------
10030     10.226.14.201    230.1.1.1        3012      ge-1/1/5         0x4c000001    0
```

EVPN Enhancements

> **Note**
>
> EVPN feature is currently supported on X86 platforms only.

When the switch learns about a local VNI and there is no configuration available in the system regarding this VNI then the import and export route targets (RTs) and route distinguisher (RD) for this VNI will be automatically calculated. The RTs are automatically derived as *AS:VNI,* whereas RD is derived as *Router-ID:VNI-Index.* For Type-2 and Type-3 routes coming from the layer 2 VNI, the RD is calculated as *VXLAN-local0-tunnelip:VNI* instead of *Router-ID:VNI.* Since EVPN routes may have the same MAC and/or the IP address; RDs are used to remove ambiguity in such cases. RTs are used to identify the VPN membership of routes.

For eBGP EVPN peering, since the peers belong to different ASes, using an automatic RT of *AS:VNI* is not suitable for route import. As a result, PICOS uses **:VNI* for the import RT to identify which received routes are relevant to a specific VNI. This behavior occurs only when the switch automatically derives the import RT.

If you do not want that route distinguisher (RD) to be automatically derived, use the command below to manually set the of RD value.

set protocols bgp [vrf <*vrf-name***>] evpn vni** <*vni-id*> **rd** <*rd*>

If you want route target (RT) to be configured manually instead of being auto-configured, run the command below. The value of parameter route-target can have three values, **export**, **import** or **both**. If you choose **both** then the RT is used as both import and export route target.

set protocols bgp [vrf <*vrf-name***>] evpn vni** <*vni-id*> **route-target** <*route-target*> **type <both | export | import>**

Example Configuration

Here's an example of how to configure EVPN RD and RT for a specific VNI in a BGP configuration:

1. **Configuring the Route Distinguisher (RD):**

   The Route Distinguisher is used to distinguish between different VPNs in the BGP table. For example, for VNI 100, you can configure RD as `10.10.10.1:100`.

   ```
   set protocols bgp vrf tenant1 evpn vni 100 rd 10.10.10.1:100
   ```

   In this command:
   - `vrf "tenant1"` specifies the VRF instance name.
   - `vni 100` indicates the VNI for which the RD is being configured.
   - `rd 10.10.10.1:100` defines the Route Distinguisher as `10.10.10.1:100`.
2. **Configuring the Route Target (RT):**

   Route Targets control the import and export of routes in a VRF. You can configure the Route Target for a particular VNI using the following command. For example, we will configure an RT with the value `65000:100` and set it for both import and export.

   ```
   set protocols bgp vrf tenant1 evpn vni 100 route-target 65000:100 type both
   ```

   In this command:
   - `vrf "tenant1"` refers to the same VRF.
   - `vni 100` is the same VNI configured earlier.
   - `route-target 65000:100` sets the Route Target value.
   - `type both` specifies that this RT will be used for both import and export. You could also set it for `import` or `export` only, depending on the use case.

Introduction to BGP EVPN

- Introduction
- EVPN Fundamental Configuration
  - Enable EVPN Between BGP Peers
  - Advertise All VNIs Through BGP
    - Note
- EVPN MAC Learning Process
  - Packet Forwarding Process
- ARP/ND Suppression
- Remove EVPN Configuration

NOTEs:

- EVPN feature is currently supported on X86 platforms only.
- To enable a BGP node as a route reflector for EVPN, you need to configure both of the following two commands:

set protocols bgp [vrf <*vrf-name*>**] neighbor** <*bgp-peer*> **route-reflector-client**

set protocols bgp [vrf <*vrf-name*>**] neighbor** <*bgp-peer*> **evpn route-reflector-client**

- The clear command (**run clear mac-address table all** and **run clear arp all**) does not work for manually clearing the dynamic entries in the EVPN MAC address table or ARP address table. These entries can be aged and removed after the Linux kernel aging timer expires.

Introduction

Ethernet Virtual Private Network or EVPN is a technology designed to carry Layer 2 traffic over wide area network protocols. EVPN is a multi-tenant BGP-based control plane for layer-2 (bridging) and layer-3 (routing) VPNs. It's the unifying L2+L3 equivalent of the traditional L3-only MPLS/VPN control plane. PICOS EVPN implementation leverages VXLAN technology as described in RFC7348.

VXLAN has been the predominant technology used in the enterprise and data center domains to achieve Layer 2 level scalability over an IP overlay backbone. VXLAN has become the technology of choice for separating the virtual network from underlying physical network and has greatly enhanced the network virtualization, easier network management and orchestration. VXLANs provides network segmentation but also helps solve the scalability issue normally associated with VLANs.

The following list describes the list of features that PiCOS BGP EVPN implementation supports.

1. Exchange of VNI membership between VTEPs using EVPN type 3 routes.
2. Exchange of host MAC and IP addresses using EVPN type 2 routes.
3. Exchange of MAC Mobility Extended Community to support host/VM mobility.
4. Dual attached host via VXLAN active-active mode. MAC synchronization between switches is achieved via MLAG.
5. Inter Subnet routing for IPv4. Distributed symmetric and asymmetric routing between different subnets and centralized routing.
6. Prefix-based routing using EVPN type-5 routes (EVPN IP prefix route).
7. Multi-tenancy over layer 3.

Both eBGP and iBGP peerings can be used for the EVPN address family.

EVPN Fundamental Configuration

The following steps represent the fundamental configuration to use EVPN as the control plane for VXLAN. These steps are in addition to configuring VXLAN interfaces, attaching them to a bridge, and mapping VLANs to VNIs.

1. Configure Physical interfaces and assign VLANs to interfaces.
2. Configure L3 interfaces and assign IP addresses to interfaces.
3. Configure VXLAN VNIs and enable VXLAN VNI mapping to VLAN IDs.
4. Enable EVPN route exchange (that is, address-family layer 2 VPN/EVPN) between BGP peers.
5. Enable EVPN on the system to advertise VNIs and host reachability information (MAC addresses learned on associated VLANs) to BGP peers.

Additional configuration is necessary such as provision of inter-subnet routing. The configuration depends on the deployment scenario. You can also configure various other BGP parameters depending on your network requirements.

Enable EVPN Between BGP Peers

The very basic steps needed to enable BGP EVPN between a BGP neighbor is as under.

```
admin@router1# set protocols bgp local-as 65101
admin@router1# set protocols bgp router-id 10.10.10.1
admin@router1# set protocols bgp neighbor 100.1.1.134 remote-as 650101
admin@router1# commit
Commit OK.
Save Done!
```

The configuration below adds the evpn address family to the BGP neighbor address-family so that BGP peers activate exchanging EVPN routes with each other. After this configuration, the BGP still does not know about the local VNI's.

Advertise All VNIs Through BGP

To allow BGP know about all VNIs or hosts associated with those local VNIs, enable the BGP control plane for all VNIs using the configuration shown below.

```
admin@router# set protocol bgp evpn advertise-all-vni
admin@router# commit
Commit OK.
Save Done!
```

> **Note**
>
> Only leaf switches that are VTEPs need this configuration. EVPN routes are still accepted from BGP peers as they reside in the global EVPN routing table, but are only made effective when the VNI corresponding to the received route is locally known.

EVPN MAC Learning Process

In **Figure 1**, when Host 1 is first plugged into R1, Host 1 will start sending ARP and other basic networking traffic like DHCP. When R1 receives a packet from Host 1 for the first time, it will record its MAC address in its local MAC address table. Also, R1 will advertise an EVPN Type-2 route to R2. The route includes the local EVPN instance of R1, the VTEP IP address, the Host 1 MAC address and the L2VNI.

Upon receiving the EVPN Type-2 route from R1, R2 learns the MAC address of Host 1. To accept this route, R2 needs to determine if the Import Route Target (IRT) configured on R2 matches the Export Route Target (ERT). RT is sent as the BGP Extended Community

attribute. In this case the IRT and ERT match hence the route is accepted and the MAC address of Host 1 is learned.

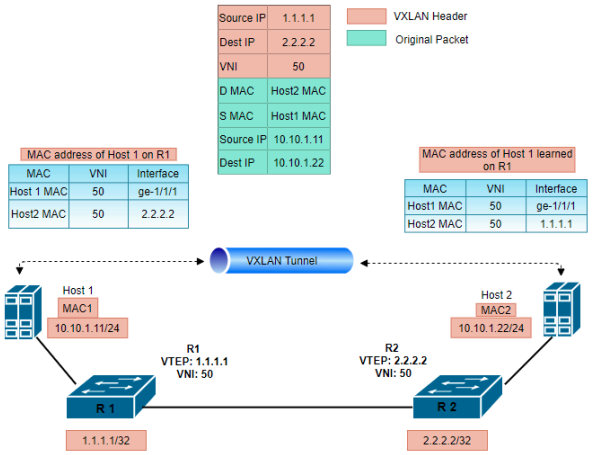

Figure 1. MAC Learning and Packet Forwarding

Packet Forwarding Process

In the case of packet forwarding within the same subnet as depicted in Figure 2, both Host1 and Host2 belong to the same VNI. Host1 wants to send a packet to Host2.

1. If Host1 doesn't have the MAC address of Host1, the MAC address can be learned through the MAC learning process described in the section above. Assuming that Host1 does have the MAC address of Host2, Host 1 sends the packet to R1 destined for Host2.
2. R1 receives the packet and determines the VNI of Host1 based on the ingress interface configuration. R1 learned the Host2 MAC address and the outgoing interface is the VTEP 2.2.2.2 on R2.
3. R1 then encapsulates the original packet from Host1 with the VXLAN header and sends it out.
4. When the packet is received on R2, the outer VXLAN header is stripped off. R2 then searches its local MAC table and finds out the out going interface and delivers the original packet to Host2.

ARP/ND Suppression

Notes:

- ARP/ND suppression does not suppress RA/RS packets.
- When configuring ARP/ND suppression, make sure to configure the L3 VLAN interface corresponding to the VLAN ID associated with the VNI.

In MP-BGP EVPN networks, in order to suppress network storms caused by ARP/ND broadcast message flooding, ARP/ND suppression function can be enabled on VTEP devices to reduce network traffic.

In BGP EVPN networks, VTEPs have the ability to learn both local and remote hosts. When a VTEP learns about a local host from Gratuitous ARP or Reverse ARP, the VTEP will locally record the hosts' MAC and IP address in an ARP Cache Table for that particular VNI. This host MAC and IP address will be shared with remote VTEPs within the same VNI using MP-BGP EVPN Type-2 routes.

When an ARP request broadcast message is received from a host, the local VTEP device with ARP suppression enabled, will actively intercept the message, search the corresponding destination MAC in the VXLAN ARP Cache table, and reply to the ARP message on behalf of the destination host to prevent flooding the entire VXLAN network VNI.

ARP and ND suppression use the same mechanism hence ND suppression is not discussed here.

By default, the ARP/ND suppression function is disabled. Users can use the following command to enable ARP/ND suppression function on VTEP devices.

set vxlans vni <*vni-id*> **arp-nd-suppress disable** <**true** | **false**>

ARP/ND suppression can be enabled on L2 VNI and works only on ARP/ND broadcast messages in the corresponding VNI enabled with this function.

Example configurations:

```
set vlans vlan-id 10
set vxlans vni 10010 vlan 10
set vlans vlan-id 10 l3-interface vlan10
set l3-interface vlan-interface vlan10
set vxlans vni 10010 arp-nd-suppress disable false
```

Remove EVPN Configuration

Warning:

To correctly remove EVPN configuration, the following deletion sequence needs to be followed.

1. First, remove the data plane configuration, that is, VXLAN-related configuration, including commands under the following configuration node: **set vxlans** xxx.
2. Then, remove the control plane configuration, that is, BGP and BGP EVPN related configurations, including commands under the following configuration node: **set protocols bgp** xxx.
3. Last, delete VXLAN related L3 interface configuration, including the following commands:

   set l3-interface vlan-interface xxx

   set l3-interface routed-interface xxx

If you don't follow this deletion order, the configuration in the kernel may still exist after the deletion operation, inconsistency in two systems (PICOS and kernel) may lead to unpredictable problems.

Generic Routing Encapsulation Protocol (GRE)

- Overview
- GRE Configuration Example

Overview

NOTE:

- GRE is not supported on Dell N22xx series switches and N3208PX-ON switch.
- PicOS GRE supports tunneling of IPv4 over IPv4 and IPv6 over IPv4.
- One GRE tunnel source address and destination address form an address pair. Different GRE tunnels cannot be configured with the same address pair.
- In the same VRF, it is not allowed to configure different GRE tunnel interface addresses with the same network segment IP address.
- If a large number of static routes for the GRE tunnel are configured and committed at one time, the background process will take several minutes to successfully complete all these configurations, although the print may immediately show that the commit is OK.
- On AS4610 serial switches, the number of static routes for the GRE tunnel should be not more than 20.
- By default, the MTU value of an L3 interface is 1500. If you want to change the MTU value of the GRE tunnel source interface, its value should be less than 1304.

Generic Routing Encapsulation (GRE) is a tunneling protocol that can encapsulate almost any network layer protocol and delivers it over an IP network. GRE is defined by two tunnel endpoints, the GRE source and destination endpoint. From the common user perspective the two endpoints appear as if they are directly connected in a point-to-point configuration but in reality the packet may traverse a number of hops before it reaches the destination endpoint. The generic packet format of a GRE encapsulated packet is show in Figure 1.

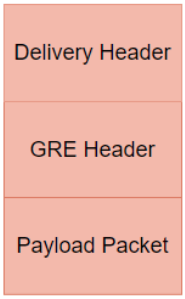

Figure 1. GRE Packet Format

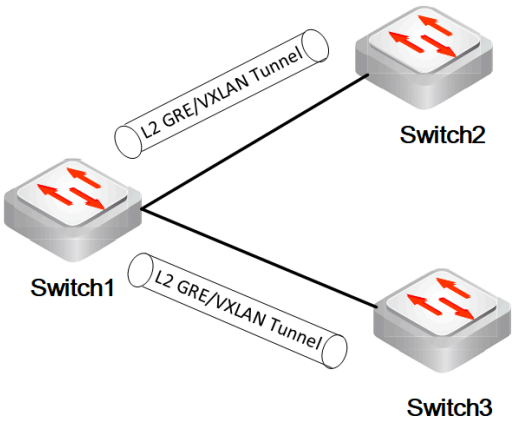
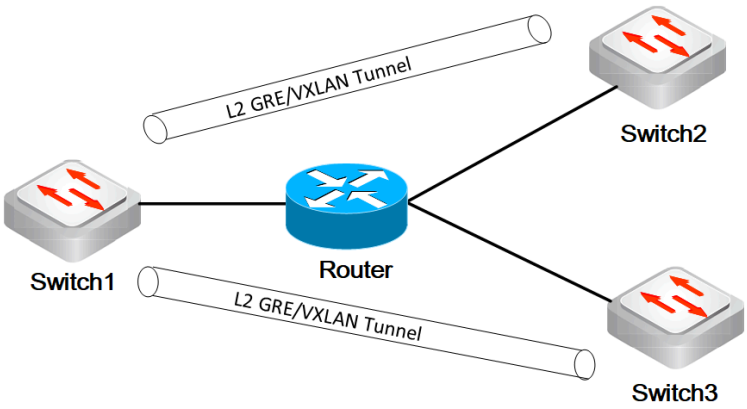
The original payload packet is first encapsulated with the GRE header and then encapsulated again with the delivery protocol header to transport it over the network. For example, if the network doesn't support routing IPv6 packets, the packet can be encapsulated with GRE header and then use IPv4 as the delivery protocol to transport the packet. The packet is decapsulated at the destination endpoint and the actual IPv6 packet is forwarded to the destination. One of the most common issue in enterprise networks is that on local subnets private IP addresses are used but routing packets between different subnets via private IP headers is not supported over public networks such as the internet. This issue is solved by using GRE which can encapsulate packets into a delivery protocol header that can be transported over the public network.

Application Scenario Limitation

In L2 GRE or VXLAN networks, only one next hop is allowed for the same egress interface. In the following figure, the same egress interface on Switch1 has two tunnels, that is, two next hops, which is not allowed.



However, multiple L2 GRE or VXLAN tunnels can exist from the same egress port on Switch1 if connected via the IP router, ensuring that one egress interface has only one next hop, as shown in the figure below.



L2 GRE/VXLAN Tunnel
Switch2
Switch1
Router
L2 GRE/VXLAN Tunnel
Switch3

GRE Configuration Example

NOTE:
GRE tunnel is a logical interface created by Linux kernel on software side. Once created, GRE tunnel stays in "**UP**" state unless it is shut down by CLI command "**set l3-interface tunnel xxx disable**".

For example, as shown in **Figure 1**, if physical port ge-1/1/1 is down, the underlay routing of the associate GRE tunnel is broken. It is not necessary that tunnel interface (tnl0) should be down. In this case, the state of GRE tunnel is "UP" in the display of show command **run show l3-interface tunnel**.

```
admin@R1# run show l3-interface tunnel tnl0
tnl0        State:UP
            Tunnel Source: 100.168.3.1
            Tunnel Destnation:: 100.168.10.2
            Tunnel protocol/transport: gre-ip
            Inet addr: 100.168.4.1
            Traffic statistics:
              5 sec input rate IPv4 0 packets/sec, IPv6 0 packets/sec
              5 sec forwarding rate IPv4 0 packets/sec, IPv6 0 packets/sec
              IPv4 Input Packets.............................28
              IPv4 Forwarding Packets.......................5
              IPv6 Input Packets.............................0
              IPv6 Forwarding Packets.........
```

In this document we will demonstrate a sample use case for GRE tunnels using two PICOS switches. As shown in Figure 1, we have two Pica8 switches connected to each other through a public IPv4 network. A host is connected with each device.

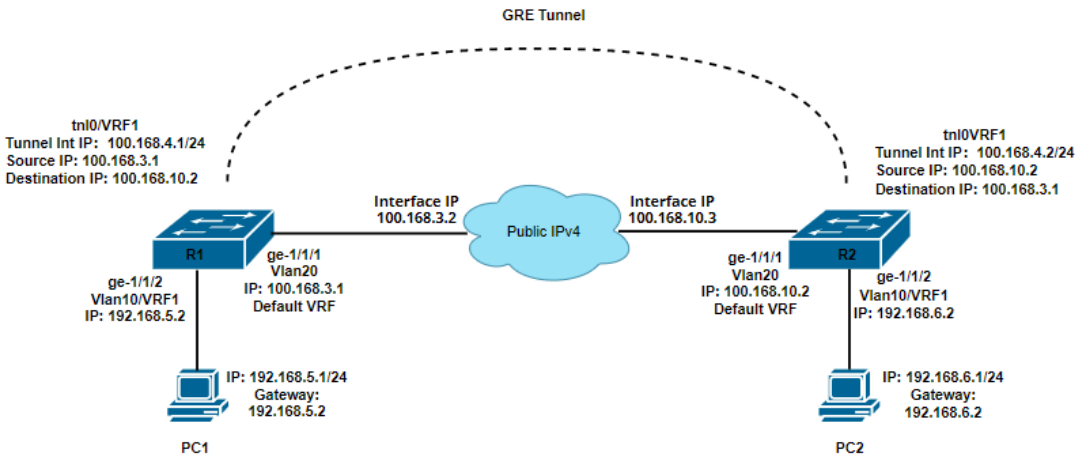


Figure 1. GRE Tunnel Configuration

Switch configurations

Below is the switch R1 and R2 configurations.

R1 Configuration

Step 1: Configure L3 VLAN interface for GRE tunnel.

```
admin@R1# set vlans vlan-id 20 l3-interface "vlan20"
admin@R1# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@R1# set l3-interface vlan-interface vlan20 address 100.168.3.1 prefix-length 24
```

Step 2: Configure L3 VLAN interface for PC1.

```
admin@R1# set vlans vlan-id 10 l3-interface "vlan10"
```

```
admin@R1# set l3-interface vlan-interface vlan10 vrf "vrf1"
admin@R1# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 10
admin@R1# set l3-interface vlan-interface vlan10 address 192.168.5.2 prefix-length 24
```

Step 3: Enable IP routing on R1 and configure VRF.

```
admin@R1# set ip routing enable true
admin@R1# set ip vrf vrf1 description "orange"
```

Step 4. Configure GRE tunnel name, IP, source IP, destination IP etc.

```
admin@R1# set l3-interface tunnel tnl0 address 100.168.4.1 prefix-length 24
admin@R1# set l3-interface tunnel tnl0 tunnel-mode "gre-ip"
admin@R1# set l3-interface tunnel tnl0 source 100.168.3.1
admin@R1# set l3-interface tunnel tnl0 destination 100.168.10.2
admin@R1# set l3-interface tunnel tnl0 vrf "vrf1"
```

Step 5: Create static routes for the GRE tunnel.

```
admin@R1# set protocols static vrf vrf1 route 192.168.6.0/24 next-hop 100.168.4.2
admin@R1# set protocols static route 100.168.10.0/24 next-hop 100.168.3.2
```

Or we can create the static route using the tunnel name as the next hop.

```
admin@R1# set protocols static vrf vrf1 interface-route 192.168.6.0/24 interface tnl0
```

R2 Configuration

Step1. Configure L3 VLAN interface for GRE tunnel.

```
admin@R2# set vlans vlan-id 20 l3-interface "vlan20"
admin@R2# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching native-vlan-id 20
admin@R2# set l3-interface vlan-interface vlan20 address 100.168.10.2 prefix-length 24
```

Step 2: Configure L3 VLAN interface for PC2.

```
admin@R2# set vlans vlan-id 10 l3-interface "vlan10"
admin@R2# set l3-interface vlan-interface vlan10 vrf "vrf1"
admin@R2# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching native-vlan-id 10
admin@R2# set l3-interface vlan-interface vlan10 address 192.168.6.2 prefix-length 24
```

Step 3: Enable IP routing on R1 and configure VRF.

```
admin@R2# set ip routing enable true
admin@R2# set ip vrf vrf1 description "orange"
```

Step 4. Configure GRE tunnel name, IP, source IP, destination IP etc.

```
admin@R2# set l3-interface tunnel tnl0 address 100.168.4.2 prefix-length 24
admin@R2# set l3-interface tunnel tnl0 tunnel-mode "gre-ip"
admin@R2# set l3-interface tunnel tnl0 source 100.168.10.2
admin@R2# set l3-interface tunnel tnl0 destination 100.168.3.1
admin@R2# set l3-interface tunnel tnl0 vrf "vrf1"
```

Step 5: Create static routes for the GRE tunnel.

```
admin@R2# set protocols static vrf vrf1 route 192.168.5.0/24 next-hop 100.168.4.1
admin@R2# set protocols static route 100.168.3.0/24 next-hop 100.168.10.3
```

Or we can also create the static route with the tunnel name as the next hop.

```
admin@R2# set protocols static vrf vrf1 interface-route 192.168.5.0/24 interface tnl0
```

Verify Configuration

- Run command **run show l3-interface tunnel** to display information about the GRE tunnel interface.

```
admin@R1# run show l3-interface tunnel tnl0
tnl0        State:UP
            Tunnel Source: 100.168.3.1
            Tunnel Destnation:: 100.168.10.2
            Tunnel protocol/transport: gre-ip
            Inet addr: 100.168.4.1
            Traffic statistics:
              5 sec input rate IPv4 1400 packets/sec, IPv6 0 packets/sec
              5 sec forwarding rate IPv4 28 packets/sec, IPv6 0 packets/sec
              IPv4 Input Packets.........................28
              IPv4 Forwarding Packets....................5
              IPv6 Input Packets.........................0
              IPv6 Forwarding Packets....................0
```

- To verify the configuration on R1, we can use the command **show l3-interface tunnel tnl0** as shown below.

```
admin@R1# show l3-interface tunnel tnl0
    address 100.168.4.1 {
        prefix-length: 24
    }
    tunnel-mode: "gre-ip"
    source: 100.168.3.1
    destination: 100.168.10.2
    vrf: "vrf1"
```

- Similarly on R2, run the same command.

```
admin@R2# show l3-interface tunnel tnl0
    address 100.168.4.2 {
        prefix-length: 24
    }
    tunnel-mode: "gre-ip"
    source: 100.168.10.2
    destination: 100.168.3.1
    vrf: "vrf1"
```

- Check to see if PC1 can reach PC2.

```
PC1# ping 192.168.6.1
PING 192.168.6.1 (192.168.6.1) 56(84) bytes of data.
64 bytes from 192.168.6.1: icmp_seq=1 ttl=64 time=3.064 ms
64 bytes from 192.168.6.1: icmp_seq=2 ttl=64 time=2.062 ms
64 bytes from 192.168.6.1: icmp_seq=3 ttl=64 time=1.060 ms
```

MPLS Configuration

- MPLS Overview
- Configuration Restrictions and Guidlines
- Basic MPLS LDP Configuration
- (Optional) Configuring MPLS LDP Security
- (Optional) Configuring MPLS LDP Timers
- (Optional) Configuring MPLS LDP to Allocate Labels for Host Routes Only
- (Optional) Configuring MPLS LDP PHP (Penultimate Hop Popping)
- Example for Configuring MPLS LDP
- RFC Lists for MPLS

MPLS Overview

- What is MPLS ?
- MPLS Label Distribution Protocol
  - Core Components and Processes
  - Major LDP Message Types
- Use Cases

What is MPLS ?

Multiprotocol Label Switching (MPLS) is a network transmission technology used to efficiently forward data packets from source to destination. Unlike traditional IP routing, MPLS does not route based on destination addresses but rather on short labels attached to packets, enabling faster and more efficient data forwarding.

MPLS works by attaching short labels to data packets and using these labels to guide the packets through a network. Here's how MPLS works on PICOS switches in more detail:

1. **Label Assignment**: When a packet enters an MPLS network, the ingress router assigns a label to the packet. This label is a short identifier that represents a particular path or route through the network.
2. **Label Switching**: As the labeled packet travels through the MPLS network, each router along the path uses the label to make forwarding decisions. Instead of examining the packet's IP header to determine the next hop, routers only need to look at the label, which makes forwarding decisions much faster and more efficient.
3. **Label Distribution**: MPLS routers use protocols like LDP (Label Distribution Protocol) or RSVP-TE (Resource Reservation Protocol - Traffic Engineering) to exchange label information and establish Label Switched Paths (LSPs) through the network. This ensures that all routers in the network have the necessary label mappings to forward packets correctly.

MPLS Label Distribution Protocol

The Label Distribution Protocol (LDP) is a key protocol within the MPLS framework that is responsible for the distribution and management of labels used in MPLS networks. LDP enables MPLS to establish LSPs, which guide the forwarding of data packets through the network based on these labels.

Core Components and Processes

1. Discovery

- **Discovery Process**: LDP utilizes UDP to discover neighboring LSRs by sending Hello messages.
- **Neighbor Identification**: These Hello messages help LSRs in identifying and validating neighboring routers in the network.

2. Session Establishment

- **TCP Session**: Once neighbors are discovered, LSRs establish a TCP connection to create a control session.
- **Session Initialization**: LDP Initialization messages are exchanged to negotiate protocol parameters, confirming that both LSRs can communicate.

3. Label Distribution

- **Label Binding**: LSRs distribute label bindings via LDP messages. When an LSR receives an IP prefix for a specific destination, it creates a label for that prefix.
- **Message Types**: Key LDP messages include Label Mapping (to distribute the label bindings) and Label Request (to ask for label binding information from peers).

4. **Path Maintenance**

- **Monitoring**: LDP continually monitors the network and updates label bindings as network conditions change.
- **Fault Management**: Notification messages are used to report errors and to help diagnose problems, ensuring the robustness of LSPs.

Major LDP Message Types

LDP itself utilizes a number of message types for its operations. Here are the major LDP message types:

- **Discovery (Hello) Messages**: Facilitate the discovery of neighboring LSRs.
- **Session Establishment Messages**: Manage the establishment and maintenance of LDP sessions, including Initialization and Keepalive messages.
- **Advertisement Messages**: Distribute label bindings using Label Mapping, Label Request, and other advertisement messages.

These LDP messages work together to establish and maintain LSPs that facilitate efficient packet forwarding in an MPLS network. Each type of message plays a specific role in label distribution, session management, and error handling.

Use Cases

MPLS is widely used in various applications across different industries due to its flexibility, efficiency, and reliability. Here are some common use cases of MPLS:

- **Service Provider Networks**

  Service providers use MPLS to offer Layer 3 Virtual Private Networks (VPNs) and Layer 2 VPNs (VPLS), providing private, isolated networks over a shared infrastructure.

  MPLS is used to efficiently route multiple types of internet traffic, including business-critical applications, over the same backbone.

- **Enterprise Networks**

  MPLS is frequently used by enterprises to connect branch offices, data centers, and headquarters over a private WAN, providing secure, reliable, and efficient communication.

  MPLS ensures low latency and high reliability for voice and video traffic, making it ideal for VoIP and unified communications applications.

- **Data Center Interconnection**

  LDP optimizes the flow of data between data centers, enhancing connectivity and performance.

Configuration Restrictions and Guidlines

When you configure MPLS, follow these restrictions and guidelines:

- MPLS is supported only on **Trident3-X7** platforms, which include the following switches: N8550-48B8C, N8550-32C, N8560-32C, S5232F-ON, S5248F-ON and S5296F-ON.
- Currently, PICOS supports only MPLS LDP; static MPLS is not supported.
- MPLS does not support ECMP (Equal-Cost Multi-Path) routing.

  Ensure that ECMP configurations are not applied to MPLS-enabled interfaces or paths to avoid any unexpected behavior or network issues.
- LDP can only be configured in the default VRF (Virtual Routing and Forwarding instance). This means that if all router interfaces are moved to a user-defined VRF, the functionality of LDP may be affected because LDP cannot run in these user-defined VRFs, which could result in the failure of LSPs (Label Switched Paths).

Basic MPLS LDP Configuration

- Enable MPLS on Interfaces
- Configuring a Router ID
- Enable MPLS LDP on the L3 Interface
- Configure MPLS LDP Transport Address
- (Optional) Enable Ordered Control Mode for MPLS LDP
  - Advantages When Using Ordered-Control
  - Example
- Verify LDP Neighbor Discovery

> **NOTE:**
>
> Before configuring MPLS, routing protocols such as OSPF/ ISIS need to be configured on each LSR to achieve IP connectivity between LSRs.

MPLS (Multiprotocol Label Switching) is a technique used in modern networking to improve packet forwarding efficiency by using labels rather than traditional IP routing. **Label Distribution Protocol (LDP)** is the most commonly used protocol for distributing labels in MPLS networks. It is responsible for establishing and maintaining Label-Switched Paths (LSPs) by advertising the mapping between IP prefixes and labels across routers.

This section provides a comprehensive description of basic MPLS LDP configuration and its importance in a typical MPLS network.

Enable MPLS on Interfaces

Before enabling LDP, MPLS must be enabled on each interface that will participate in the MPLS label switching process.

- The following example enables MPLS on VLAN interface *vlan200*.

```
admin@PICOS# set protocols mpls interface vlan200
admin@PICOS# commit
```

This ensures that MPLS forwarding is active on the specified L3 interface (VLAN interface, loopback interface, routed interface or sub-interface). This enables MPLS for all traffic passing through that interface, making it part of the MPLS domain for the labeled packet switching. Usually, both the incoming and outgoing interfaces of the packets need to enable MPLS.

Configuring a Router ID

The router ID should be configured first when you configure MPLS LDP. The router ID is a string similar to the IP address, and is the identifier of a LSR. You should not change the router ID after completing the configuration. By default, the MPLS LDP router ID is not configured.

```
admin@PICOS# set protocols mpls ldp router-id 2.2.2.2
admin@PICOS# commit
```

Enable MPLS LDP on the L3 Interface

LDP must be explicitly enabled on each interface that will be used for label distribution. This ensures that LDP neighbors are discovered on those interfaces and that labels are exchanged.

The following command can be used to enable MPLS LDP on an L3 interface under IPv4/IPv6 address family.

set protocols mpls ldp {ipv4-family|ipv6-family} interface *<interface-name>*

It is required to be configured on all nodes in the MPLS domain.

MPLS can support multiple protocol families (IPv4, IPv6, etc.). By specifying `ipv4-family (ipv6-family)`, you ensure that LDP only distributes labels for IPv4 (IPv6) prefixes over this interface.

- The following commands enable MPLS LDP on interface vlan200 of IPv4 address family.

```
admin@PICOS# set protocols mpls ldp ipv4-family interface vlan200
admin@PICOS# commit
```

- The following commands enable MPLS LDP on interface vlan400 of IPv6 address family.

```
admin@PICOS# set protocols mpls ldp ipv6-family interface vlan400
admin@PICOS# commit
```

Once LDP is enabled on the L3 interface for the IP family, the router starts advertising and learning labels for IP routes over this interface.

Configure MPLS LDP Transport Address

This address is used as the source address in the Hello message of LDP link.
LDP session is based on TCP connection, when two LSRs want to establish an LDP session between them, they need to confirm the LDP transport address of the peer before they can establish a TCP connection.

- The following commands configure MPLS LDP transmission address under IPv4 address family.

```
admin@PICOS# set protocols mpls ldp ipv4-family discovery transport-address 2.2.2.2
admin@PICOS# commit
```

- The following commands configure MPLS LDP transmission address under IPv6 address family.

```
admin@PICOS# set protocols mpls ldp ipv6-family discovery transport-address 1::1
admin@PICOS# commit
```

(Optional) Enable Ordered Control Mode for MPLS LDP

In MPLS LDP, ordered control is one of two label distribution modes (the other being independent control). In **ordered control**, a router only distributes a label for a particular FEC (Forwarding Equivalence Class) if it is the egress router for that FEC, or if it has already received a label for that FEC from its next hop. This ensures a more structured and synchronized label distribution process.

Independent Control (the alternative mode) allows routers to advertise labels for a FEC as soon as they learn about it, without waiting for downstream routers to assign labels. This the default label distribution mode for MPLS LDP.

Advantages When Using Ordered-Control

Enabling ordered control offers the following advantages; therefore, it is recommended to enable the ordered control mode.

- Label distribution is more controlled and happens from downstream routers to upstream routers.
- It helps to avoid issues such as forwarding loops in complex network topologies.
- Useful in situations where label distribution must be tightly synchronized between routers.

Example

- Enable LDP Ordered Label Distribution Control.

```
admin@PICOS# set protocols mpls ldp ordered-control
admin@PICOS# commit
```

This command would typically be configured on MPLS-enabled routers to ensure they follow the ordered control mode for LDP, improving synchronization and reducing potential issues with label assignment.

Verify LDP Neighbor Discovery

- After configuration, check that LDP neighbors are discovered. Run the command **run show mpls ldp neighbor** to display the current LDP neighbors.
- Ensure that the router has assigned labels to IP routes and that the labels are being advertised to LDP neighbors. You can use the command **run show mpls ldp binding** to view Label Information Base (LIB) information.

(Optional) Configuring MPLS LDP Security

Enable MD5 Authentication between MPLS LDP Neighbors
Enable Generalized TTL Security Mechanism (GTSM)

In networks where security requirements are high, network security can be enhanced by configuring LDP MD5 authentication and LDP GTSM.

Enable MD5 Authentication between MPLS LDP Neighbors

In order to enhance the security of LDP session connections, MD5 authentication can be configured for the TCP connections used by LDP.

By setting a password, you enforce authentication for the LDP session between the local router and its neighbor. This adds a layer of security, ensuring that only authorized routers can establish an LDP session and exchange label information.

It helps to prevent unauthorized devices from establishing LDP sessions with your routers, which could potentially lead to routing issues or security vulnerabilities.

NOTE:

Ensure that the same password is configured on both sides of the LDP session. Mismatched passwords will prevent the LDP session from being established.

This example enables message digest5 (MD5) authentication on a TCP connection between two MPLS LDP neighbors.

```
admin@XorPlus# set protocols mpls ldp neighbor 2.2.2.2 password picos12345
admin@XorPlus# commit
```

Enable Generalized TTL Security Mechanism (GTSM)

The Generalized TTL Security Mechanism (GTSM) is a security mechanism used to protect devices from attacks by determining the validity of packets based on their TTL (Time-to-Live) values. When configured on LDP peers, GTSM checks the TTL values of LDP messages exchanged between peers based on the configured TTL range. If the TTL of an LDP message does not fall within the configured range, it is considered an illegal attack packet and is discarded. This helps prevent attacks on the LDP protocol that involve flooding the network with forged packets, thereby protecting the upper-layer protocols.

The **set protocols mpls ldp neighbor ttl-security hops** command enforces Generalized TTL Security Mechanism (GTSM), as specified in RFC 5082. With this command, only neighbors that are the specified number of hops away will be allowed to become neighbors. This command is mutually exclusive with ebgp-multihop.

By default, TTL hop is 0, indicating **ttl-security** is disabled.

NOTE:

- The valid range of TTL values allowed for detection packets varies among devices from different vendors, including 1 to 255 and 1 to 64. Therefore, when interoperating with devices from other vendors, it is necessary to configure different hop values according to the implementation of the other vendor's devices. Otherwise, packets sent by the peer will be discarded, leading to interruption of the LDP session.
- The commands **set protocols mpls ldp neighbor** <*ip*> **ttl-security hops** <*integer*> and **set protocols mpls ldp neighbor** <*ip*> **ttl-security disable** cannot be configured simultaneously.

This following example enables GTSM and configures GTSM valid hops.

```
admin@PICOS# set protocols mpls ldp neighbor 2.2.2.2 ttl-security hops 10
admin@PICOS# commit
```

Disabling GTSM might be necessary if compatibility with older or certain specific devices that do not support TTL security is required. The following command can be used to disable GTSM.

```
admin@PICOS# set protocols mpls ldp neighbor 2.2.2.2 ttl-security disable
admin@PICOS# commit
```

(Optional) Configuring MPLS LDP Timers

Configure the Link Hello Sending Timer
Configure the Link Hello Hold Time
Configure the Hold Time Period for Keepalive
Configure the Interval for Sending Targeted Hello Messages
Configure the Targeted Hello Hold Time

LDP uses the discovery process to identify other LDP-enabled routers in the network. The discovery process involves sending "Hello" messages, which can be of two types:

- **Link Hello**: These are sent to directly connected neighbors over a specific interface.
- **Targeted Hello**: These are sent to establish sessions with non-directly connected peers.

Configure the Link Hello Sending Timer

NOTEs：

- Before configuring the **discovery hello-interval** and **discovery hello-holdtime**, the **discovery transport-address** under the IP family must be configured first.
- The configuration of **discovery hello-interval** and **discovery hello-holdtime** based on the IP family takes precedence over the global configuration.
- For the **discovery hello-interval (discovery hello-holdtime)** configuration, the actual effective timer value equals the smaller of the timers configured on both ends of the LDP peers.

The LSR uses the Hello interval to periodically send Hello messages, notifying neighboring LSRs of its presence in the network and establishing Hello adjacency relationships. The value is an integer which can be configured between 1 and 65535 seconds. The default value is 5 seconds.

- Configure the interval for sending Hello message.

```
admin@PICOS# set protocols mpls ldp ipv4-family discovery hello-interval 10
admin@PICOS# commit
```

Configure the Link Hello Hold Time

LDP peers that have established a Hello adjacency relationship periodically send Hello messages to signify their intention to maintain this adjacency. If no new Hello message is received before the Hello hold timer expires, the adjacency will be terminated. The value is an integer which can be configured between 1 and 65535 seconds. The default value is 15 seconds. It is recommended to use the default value.

- Configure the Hello hold time.

```
admin@PICOS# set protocols mpls ldp ipv6-family discovery hello-holdtime 30
admin@PICOS# commit
```

- Show the configuration result.

```
admin@PICOS# run show mpls ldp interface
AF   Interface   State  Uptime   Hello Timers  ac
ipv6 vlan10      ACTIVE 3d18h21m 5/30           1
```

```
ipv6 vlan20      ACTIVE 3d18h21m 5/30          1
ipv6 vlan30      ACTIVE 01:02:58 5/30          1
ipv6 vlan40      ACTIVE 00:48:21 5/30          0
```

Configure the Hold Time Period for Keepalive

Between LDP peers, LDP sessions are maintained through LDP protocol messages (PDUs). If the Keepalive hold timer expires without receiving any LDP PDUs, the connection is closed, and the LDP session ends. That value is an integer which can be configured between 15 and 65535 seconds. By default, LDP session holdtime 180 seconds.

The Keepalive sent interval is the time for the LSR to periodically send Hello messages, and it is 1/3 of the Keepalive hold timer.

- Configure the hold time period for keepalive.

```
admin@PICOS# set protocols mpls ldp neighbor 3.3.3.3 session-holdtime 210
admin@PICOS# commit
```

- Show the configuration result.

```
admin@PICOS# run show mpls ldp neighbor detail
Peer LDP Identifier: 3.3.3.3:0
  TCP connection: 2::2:646 - 3::3:34795
  Authentication: none
  Session Holdtime: 210 secs; KeepAlive interval: 70 secs
  State: OPERATIONAL; Downstream-Unsolicited
  Up time: 2d19h07m
  Messages sent/rcvd:
   - Keepalive Messages: 4022/4024
   - Address Messages: 1/3
   - Address Withdraw Messages: 3/3
   - Notification Messages: 0/0
   - Capability Messages: 0/0
   - Label Mapping Messages: 128/70
   - Label Request Messages: 0/0
   - Label Withdraw Messages: 16/10
   - Label Release Messages: 10/16
   - Label Abort Request Messages: 0/0
  Capabilities Sent:
   - Dynamic Announcement (0x0506)
   - Typed Wildcard (0x050B)
   - Unrecognized Notification (0x0603)
  Capabilities Received:
   - Dynamic Announcement (0x0506)
   - Typed Wildcard (0x050B)
   - Unrecognized Notification (0x0603)
  LDP Discovery Sources:
    IPv6:
      Interface: vlan30
```

Configure the Interval for Sending Targeted Hello Messages

NOTEs：

- Before configuring the **discovery targeted-hello-interval** and **discovery targeted-hello-holdtime**, the **targeted-hello-accept** under the IP family must be enabled first.
- The configuration of **discovery targeted-hello-interval** and **discovery targeted-hello-holdtime** based on the IP family takes precedence over the global configuration.

- For the **targeted-hello-holdtime (discovery targeted-hello-interval)** configuration, the actual effective timer value equals the smaller of the timers configured on both ends of the LDP peers.

Users can set the interval (in seconds) at which the targeted Hello messages are sent out to maintain LDP sessions with non-directly connected peers. A shorter interval means more frequent Hellos, which can help in quicker detection of peers but may increase the load on the router.

The value is an integer which can be configured between 1 and 65535 seconds. The default value is 5 seconds.

- Configure the interval for sending targeted hello messages.

```
admin@PICOS# set protocols mpls ldp discovery targeted-hello-interval 10
admin@PICOS# commit
```

Configure the Targeted Hello Hold Time

The `targeted-hello-holdtime` parameter sets the amount of time (in seconds) that the router will wait after receiving the last Hello message before considering the neighbor as unreachable. If the router does not receive another Hello message from the neighbor within this period, it will consider the neighbor to be down and will tear down the LDP session associated with that neighbor.

This timer ensures that the LDP session is maintained as long as the neighbor is responsive. It is a fail-safe mechanism that helps in quickly detecting and reacting to network changes.

The value is an integer which can be configured between 1 and 65535 seconds. The default value is 15 seconds.

Administrators can adjust this value to either lengthen or shorten the period before the router considers the neighbor unreachable. A shorter hold time means the router will more quickly declare the neighbor down if no Hello messages are received, while a longer hold time will delay this declaration, potentially allowing more time for transient issues to resolve.

- Configure the targeted hello hold time.

```
admin@PICOS# set protocols mpls ldp discovery targeted-hello-holdtime 50
admin@PICOS# commit
```

(Optional) Configuring MPLS LDP to Allocate Labels for Host Routes Only

LDP can allocate labels for various types of routes in the routing table. These routes can include network prefixes, host routes (which are more specific and typically represent individual IP addresses), and other types of routes.

A host route is a route to a specific IP address with a /32 (in IPv4) or /128 (in IPv6) prefix length. This means that the route is specific to one single host or device on the network, rather than a range of IP addresses.

The **set protocols mpls ldp {ipv4-family|ipv6-family} label-local-allocate host-routes** command instructs the router to allocate MPLS labels specifically for host routes in the IPv4/IPv6 routing table. Without this command, LDP may only allocate labels for network routes (e.g., /24, /40) and not for individual host routes (/32 and /128).

Use Cases

- **Data Centers**: In data center networks where traffic to specific servers or services must be carefully managed, allocating labels to host routes allows for precise traffic engineering.
- **Service Provider Networks**: In service provider networks where certain customers require dedicated paths to their services, host route label allocation can ensure that traffic is routed optimally.
- **Security Considerations**: Allocating labels for host routes can be part of a security strategy where certain traffic is routed through specific security appliances or paths.

Example

- The following command configures the router to allocate MPLS labels for all host routes in the IPv4 routing table. As a result, any route in the routing table with a /32 prefix length will be associated with an MPLS label, allowing for the forwarding of traffic destined for that specific IP address using MPLS.

```
admin@PICOS# set protocols mpls ldp ipv4-family label-local-allocate host-routes
admin@PICOS# commit
```

(Optional) Configuring MPLS LDP PHP (Penultimate Hop Popping)

Penultimate Hop Popping (PHP) is a fundamental concept in MPLS networks. It refers to the process where the second-to-last router (penultimate hop) in a Label Switched Path (LSP) removes (or "pops") the MPLS label from a packet before forwarding it to the last router (the egress router). This technique helps optimize network performance and reduce processing overhead on the egress router.

Purpose and Benefits of PHP

- **Reduced Processing Load**: PHP offloads the task of MPLS label removal from the egress router, reducing its processing burden. This is particularly beneficial in high-throughput environments where the egress router may be handling large amounts of traffic.
- **Simplified Egress Processing**: The egress router receives the packet as a regular IP packet, which simplifies its processing because it no longer needs to look up and remove an MPLS label before making a forwarding decision.
- **Efficiency**: PHP reduces the overhead of MPLS label operations at the final hop, which can improve overall network efficiency.

How PHP Works

In a typical MPLS scenario, each router along the LSP swaps the incoming MPLS label with a new label before forwarding the packet to the next hop. However, when the packet reaches the penultimate hop, instead of swapping the label, the router pops the label (removes it entirely).

The packet is then forwarded as a regular IP packet (or with an explicit null label if that is configured) to the egress router.

PHP and Implicit Null Label

- The mechanism behind PHP is often tied to the use of the **Implicit Null Label** (label value 3). When an MPLS router advertises the implicit null label to its upstream neighbor, it instructs the penultimate hop to pop the MPLS label and forward the packet as a plain IP packet.
- **Implicit Null Label**: This label is not actually carried in the packet. Instead, it tells the penultimate router to remove the label and forward the packet without any MPLS label.

Explicit Null as an Alternative to PHP

Instead of using PHP, an explicit null label (label value 0 for IPv4) can be used. With explicit null, the MPLS label is preserved (though replaced with the explicit null label), allowing the egress router to receive and process the QoS (Quality of Service) information that might be encoded in the MPLS header.

Configuration

The **set protocols mpls ldp {ipv4-family|ipv6-family} label-local-advertise [explicit-null]** command configures the label assigned for the penultimate router under the address family on the egress LSP. The **explicit-null** option assigns an explicit null label(0), to the penultimate router. If **explicit-null** option is not specified, or this command is not configured, the LSR assigns an implicit null label(3), to the penultimate router.

Example

- The following command configures to assign an explicit null label for the penultimate router on the egress LSP.

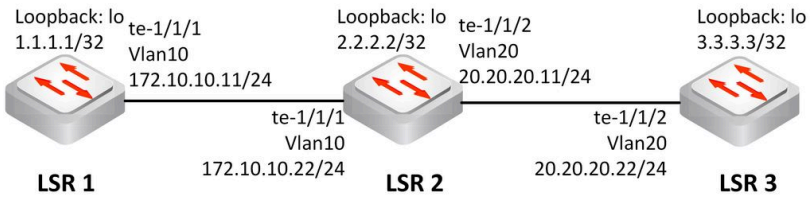
```
admin@PICOS# set protocols mpls ldp ipv4-family label-local-advertise explicit-null
admin@PICOS# commit
```

Example for Configuring MPLS LDP

Network Requirement
Procedure
LSR 1
LSR 2
LSR 3
Verify the Configuration

Network Requirement

Figure 1. MPLS LDP Configuration Example



LSR 1 and LSR 3 serve as the PE (Provider Edge) devices in the IP/MPLS backbone network. MPLS LDP (Label Distribution Protocol) needs to be configured on both LSR 1 and LSR 3 to establish LDP LSPs (Label Switched Paths), enabling the interconnection of LSP networks and supporting business traffic transmission.

Configure MPLS LDP as follows:

1. Configure OSPF on each LSR to ensure IP connectivity in the backbone network. This includes configuring OSPF protocol and relevant network segments, areas, and neighbor relationships.
2. Configure MPLS LDP on each LSR. This involves enabling MPLS functionality and configuring LDP protocol parameters such as LDP session parameters, LDP neighbor relationships, and LDP label distribution policies.

With this configuration, each LSR will be able to establish an IP/MPLS network and create LDP LSPs through MPLS LDP, thereby achieving interconnection and business transmission of LSP networks.

Procedure

LSR 1

Step 1 Configure VLAN interface.

```
admin@LSR1# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
admin@LSR1# set l3-interface vlan-interface vlan10 address 172.10.10.11 prefix-length 24
admin@LSR1# set vlans vlan-id 10 l3-interface vlan10
admin@LSR1# set l3-interface loopback lo1 address 1.1.1.1 prefix-length 32
```

Step 2 Configure the OSPF protocol to advertise the network segments connected to each node's interfaces and the LSR's host routes.

```
admin@LSR1# set protocols ospf router-id 1.1.1.1
admin@LSR1# set protocols ospf network 172.10.10.0/24 area 0
```

```
admin@LSR1# set protocols ospf network 1.1.1.1/32 area 0
```

Step 3 Enable MPLS on the L3 interface.

```
admin@LSR1# set protocols mpls interface vlan10
```

Step 4 Enable MPLS LDP on the L3 interface.

```
admin@LSR1# set protocols mpls ldp ipv4-family interface vlan10
```

Step 5 Configure MPLS router ID.

```
admin@LSR1# set protocols mpls ldp router-id 1.1.1.1
```

Step 6 Configure MPLS LDP transmission address under IPv4 address family.

```
admin@LSR1# set protocols mpls ldp ipv4-family discovery transport-address 1.1.1.1
```

Step 7 Configure LDP ordered label distribution control.

```
admin@LSR1# set protocols mpls ldp ordered-control
```

Step 8 Enable IP routing.

```
admin@LSR1# set ip routing enable true
```

Step 9 Commit the configuration.

```
admin@LSR1# commit
```

LSR 2

Step 1 Configure VLAN interface.

```
admin@LSR2# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 10
admin@LSR2# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@LSR2# set l3-interface vlan-interface vlan10 address 172.10.10.22 prefix-length 24
admin@LSR2# set l3-interface vlan-interface vlan20 address 20.20.20.11 prefix-length 24
admin@LSR2# set vlans vlan-id 10 l3-interface vlan10
admin@LSR2# set vlans vlan-id 20 l3-interface vlan20
admin@LSR2# set l3-interface loopback lo2 address 2.2.2.2 prefix-length 32
```

Step 2 Configure the OSPF protocol to advertise the network segments connected to each node's interfaces and the LSR's host routes.

```
admin@LSR2# set protocols ospf router-id 2.2.2.2
admin@LSR2# set protocols ospf network 172.10.10.0/24 area 0
admin@LSR2# set protocols ospf network 20.20.20.0/24 area 0
admin@LSR2# set protocols ospf network 2.2.2.2/24 area 0
```

Step 3 Enable MPLS on the L3 interface.

```
admin@LSR2# set protocols mpls interface vlan10
admin@LSR2# set protocols mpls interface vlan20
```

Step 4 Enable MPLS LDP on the L3 interface. Usually, both the incoming and outgoing interfaces of the packets need to enable MPLS. By default, MPLS is disabled on the L3 interface.

```
admin@LSR2# set protocols mpls ldp ipv4-family interface vlan10
```

```
admin@LSR2# set protocols mpls ldp ipv4-family interface vlan20
```

Step 5 Configure MPLS router ID.

```
admin@LSR2# set protocols mpls ldp router-id 2.2.2.2
```

Step 6 Configure MPLS LDP transmission address under IPv4 address family.

```
admin@LSR2# set protocols mpls ldp ipv4-family discovery transport-address 2.2.2.2
```

Step 7 Configure LDP ordered label distribution control.

```
admin@LSR2# set protocols mpls ldp ordered-control
```

Step 8 Enable IP routing.

```
admin@LSR2# set ip routing enable true
```

Step 9 Commit the configuration.

```
admin@LSR2# commit
```

LSR 3

Step 1 Configure VLAN interface.

```
admin@LSR3# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 20
admin@LSR3# set l3-interface vlan-interface vlan20 address 20.20.20.22 prefix-length 24
admin@LSR3# set vlans vlan-id 20 l3-interface vlan20
admin@LSR3# set l3-interface loopback lo3 address 3.3.3.3 prefix-length 32
```

Step 2 Configure the OSPF protocol to advertise the network segments connected to each node's interfaces and the LSR's host routes.

```
admin@LSR3# set protocols ospf router-id 3.3.3.3
admin@LSR3# set protocols ospf network 20.20.20.0/24 area 0
admin@LSR3# set protocols ospf network 3.3.3.3/32 area 0
```

Step 3 Enable MPLS on the L3 interface.

```
admin@LSR3# set protocols mpls interface vlan20
```

Step 4 Enable MPLS on the L3 interface. Usually, both the incoming and outgoing interfaces of the packets need to enable MPLS. By default, MPLS is disabled on the L3 interface.

```
admin@LSR3# set protocols mpls ldp ipv4-family interface vlan20
```

Step 5 Configure MPLS router ID.

```
admin@LSR3# set protocols mpls ldp router-id 3.3.3.3
```

Step 6 Configure MPLS LDP transmission address under IPv4 address family.

```
admin@LSR3# set protocols mpls ldp ipv4-family discovery transport-address 3.3.3.3
```

Step 7 Configure LDP ordered label distribution control.

```
admin@LSR3# set protocols mpls ldp ordered-control
```

Step 8 Enable IP routing.

```
admin@LSR3# set ip routing enable true
```

Step 9 Commit the configuration.

```
admin@LSR3# commit
```

Verify the Configuration

- After the configuration is complete, run command **run show mpls ldp neighbor** on each LSR. From the show result, we can see that MPLS LDP state is "`OPERATIONAL`", indicating successful establishment of LDP session. Take LSR 2 as an example:

```
admin@LSR2# run show mpls ldp neighbor
AF   ID              State       Remote Address    Uptime
ipv4 1.1.1.1         OPERATIONAL 1.1.1.1           00:00:39
ipv4 3.3.3.3         OPERATIONAL 3.3.3.3           00:01:14
```

- After the configuration is complete, run command **run show mpls ldp binding** to verify label bindings.

```
admin@LSR2# run show mpls ldp binding
AF   Destination          Nexthop         Local Label Remote Label  In Use
ipv4 1.1.1.1/32           1.1.1.1         17          imp-null         yes
ipv4 2.2.2.2/32           0.0.0.0         imp-null    -                 no
ipv4 3.3.3.3/32           3.3.3.3         16          imp-null         yes
ipv4 10.36.15.0/24        1.1.1.1         imp-null    imp-null          no
ipv4 10.36.15.0/24        3.3.3.3         imp-null    imp-null          no
ipv4 20.20.20.0/24        3.3.3.3         imp-null    imp-null          no
ipv4 172.10.10.0/24       1.1.1.1         imp-null    imp-null          no
```

In the show result, the parameter "`In Use`" indicates whether the label binding entry is effective or not.

- **yes**: indicates the label binding entry is effective.
- **no**: indicates the label binding entry is ineffective.

RFC Lists for MPLS

The following table lists the RFC documents related to MPLS function.

RFC	Description
RFC 3031	Multiprotocol Label Switching Architecture
RFC 3032	MPLS Label Stack Encoding
RFC 3034	Use of Label Switching on Frame Relay Networks Specification
RFC 3036	LDP Specification
RFC 5036	LDP Specification
RFC 3215	LDP State Machine
RFC 5443	LDP IGP Synchronization

Lossless Network Introduction

- Overview
- Advantages
- Versions of RoCE
- Supported Platforms
- Switch Configuration

Overview

Lossless networks are crucial for the implementation of RDMA over Converged Ethernet (RoCE), a network protocol that enables high-throughput and low-latency data communication between nodes in a network. RoCE leverages the advantages of Remote Direct Memory Access (RDMA) technology over standard Ethernet networks, making it highly suitable for applications requiring rapid data transfer and minimal latency, such as high-performance computing, distributed storage, AI deep learning model training and big data analytics.

Advantages

1. **Low Latency**: RoCE reduces the latency of data transfers by bypassing the CPU and the operating system in the data path, allowing direct memory-to-memory data transfers.
2. **High Throughput**: By enabling direct memory access, RoCE can achieve higher data transfer rates compared to traditional Ethernet communications.
3. **Efficient CPU Usage**: Because RoCE offloads data transfer tasks from the CPU, it frees up CPU cycles for other processing tasks, enhancing overall system performance.
4. **Ethernet Compatibility**: RoCE leverages the existing Ethernet infrastructure, making it cost-effective to deploy in data centers without requiring specialized networking equipment.

Versions of RoCE

There are two main versions of RoCE:

1. **RoCEv1**: This version operates at Layer 2 of the OSI model, meaning it is not routable beyond the local Ethernet network. It requires all devices to be in the same Ethernet broadcast domain.
2. **RoCEv2**: This version operates at Layer 3, making it routable over IP networks. RoCEv2 packets can traverse multiple subnets, allowing for greater scalability and flexibility in network design.

Supported Platforms

To achieve lossless network communication, high throughput, and low latency data exchange between nodes, features like PFC Watchdog, Explicit Congestion Notification (ECN), and Dynamic Load Balancing are only supported on **Trident3** and **Tomahawk3** platforms.

Switch Configuration

To effectively leverage RoCE in your network, configuring your switches properly is crucial. Here's the guide to configure lossless network on network switches, focusing on key features: PFC, PFC Watchdog, ECN and Dynamic Load Balancing (DLB).

- **Interface**
  - Enable with PFC on the required priority.
- **Global Configuration**

- Configure ECN via WRED
  - Enable WRED.
  - Set the maximum and minimum thresholds.
  - Set drop probability.
  - Enable ECN.
- Configure PFC Watchdog
  - Enable PFC on the interface before enabling PFC watchdog.
  - Enable PFC watchdog.
  - Configure the time interval of PFC deadlock detection.
  - Configure the restore time and restore action when PFC deadlock occurs.
- Configure Dynamic Load Balancing

Application Scenarios

Application Scenarios 1: High Performance Computing (HPC)

Application Scenarios 2: Distributed Storage

Application Scenarios 3: Artificial Intelligence (AI)

Lossless networks are utilized across various industries and applications due to its ability to provide low-latency, high-throughput communication. Here are some key use cases of lossless networks:

Application Scenarios 1: High Performance Computing (HPC)

Lossless networks are widely used in High Performance Computing (HPC) due to its ability to provide low-latency and high-throughput communication. These attributes are critical for HPC environments, which involve complex computational tasks requiring efficient data transfer between numerous computing nodes.

1. **Parallel Computing**:
   - **Inter-node Communication**: Lossless network is used for fast communication between nodes in a cluster, essential for parallel computing tasks where multiple nodes work on different parts of a problem simultaneously.
   - **MPI Acceleration**: Lossless network enhances the performance of MPI (Message Passing Interface) applications by reducing communication overhead.
2. **Distributed Databases**:
   - **Efficient Data Replication**: Lossless network facilitates high-speed data replication between database nodes, ensuring data consistency and high availability.
   - **Query Processing**: Faster data movement between nodes improves the performance of distributed query processing.
3. **Data Analytics and Machine Learning**:
   - **Large Dataset Handling**: Lossless network enables efficient handling of large datasets, which is crucial for big data analytics and machine learning applications.
   - **Model Training**: Accelerates the training of machine learning models by speeding up data transfer between compute nodes and storage systems.
4. **Scientific Simulations**:
   - **Real-time Data Sharing**: Scientific simulations often require real-time data sharing between nodes, which lossless network supports through its low-latency and high-throughput capabilities.
   - **Collaborative Research**: Facilitates collaborative research by enabling seamless data exchange and communication between geographically distributed research centers.

Application Scenarios 2: Distributed Storage

Lossless network is increasingly being applied in distributed storage systems due to its ability to provide low-latency and high-throughput data transfers. These features are crucial for distributed storage environments, which require efficient and reliable data movement between storage nodes.

1. **Distributed File Systems**:
   - **Fast Data Access**: Lossless network enhances the performance of distributed file systems like HDFS (Hadoop Distributed File System) by enabling fast data access and transfers between nodes.
   - **Efficient Data Replication**: Ensures that data replication between storage nodes is performed quickly and reliably, maintaining data consistency and availability.
2. **Object Storage**:
   - **High-Performance Object Storage**: Lossless network can be used to improve the performance of object storage systems like Ceph, which require efficient handling of large objects across distributed nodes.

- **Reduced Latency**: Low-latency data transfers ensure quick access to stored objects, enhancing the overall user experience and system performance.

3. **Block Storage**:
   - **Enhanced Block Storage Performance**: Lossless network improves the performance of block storage solutions by enabling low-latency access to storage blocks, which is crucial for applications requiring fast I/O operations.
   - **Efficient Volume Management**: Facilitates efficient volume management and data migration between storage devices.
4. **Software-Defined Storage (SDS)**:
   - **Improved SDS Efficiency**: Lossless network can enhance the efficiency of software-defined storage systems by enabling high-speed, low-latency communication between storage nodes and controllers.
   - **Scalable Storage Solutions**: Supports the scalability needs of SDS, allowing for seamless expansion and management of storage resources.

Application Scenarios 3: Artificial Intelligence (AI)

Lossless network is highly beneficial in AI environments, particularly for deep learning and large-scale AI workloads. The need for high-speed, low-latency communication between numerous GPUs or compute nodes makes lossless network an ideal choice for AI applications.

1. **Deep Learning Model Training**:
   - **Distributed Training**: Lossless network facilitates efficient communication between multiple GPUs or nodes during distributed training, reducing training time.
   - **Data Parallelism**: Enhances data parallelism by allowing seamless data exchange between nodes, ensuring that each node has the required data for training.
2. **Inference Serving**:
   - **Low-latency Inference**: Lossless network's low-latency capabilities are critical for real-time inference serving, enabling quick responses in AI-driven applications.
   - **Scalable Inference**: Supports scaling inference workloads across multiple nodes or GPUs, ensuring that large-scale inference tasks are handled efficiently.
3. **AI Data Processing Pipelines**:
   - **High-throughput Data Transfers**: Lossless network can handle the high-throughput data transfers required in AI data processing pipelines, such as ETL (Extract, Transform, Load) operations.
   - **Streamlined Data Movement**: Ensures efficient data movement between storage and compute nodes, enhancing the performance of data preprocessing steps in AI workflows.
4. **Big Data Analytics**:
   - **Accelerated Analytics**: By providing high-speed data transfers, lossless network accelerates the analytics processes that feed into AI models, improving the overall pipeline efficiency.
   - **Integration with Hadoop and Spark**: Enhances the performance of big data frameworks like Hadoop and Spark, which are often used in conjunction with AI workloads.

Key Features of Lossless Network

Lossless network is a powerful networking protocol designed to enable high-performance, low-latency data transfers over Ethernet networks. By leveraging RDMA technology, lossless network offers significant benefits for various high-demand applications, making it a crucial component in modern data centers, high-performance computing environments, and cloud services. Its ability to utilize existing Ethernet infrastructure makes it a cost-effective solution for enhancing network performance.

Lossless network switches are designed to support the unique requirements of RDMA, providing low-latency and high-throughput communication over Ethernet networks. Here are the key technologies and features that are crucial for lossless network switches:

Priority Flow Control (PFC)

Priority Flow Control (PFC) is a network protocol designed to manage congestion on Ethernet networks by allowing for the independent pausing of traffic based on priority levels. It is part of the IEEE 802.1Qbb standard and is particularly useful in data center environments where different types of traffic need to be handled with varying degrees of urgency.

PFC is a critical technology for managing congestion in Ethernet networks, particularly in data center environments. By enabling traffic differentiation and providing lossless transport for high-priority traffic, PFC helps maintain performance and reliability for critical applications.

PFC Watchdog

PFC Watchdog is a critical component in Ethernet networks that use Priority Flow Control to manage congestion. By detecting and mitigating PFC deadlocks, it ensures that the network remains stable and performs optimally. This mechanism is particularly important in data centers and other environments where maintaining high performance and reliability is crucial.

Explicit Congestion Notification (ECN)

Explicit Congestion Notification (ECN) is an effective mechanism for managing network congestion by marking packets instead of dropping them. It is an extension of the IP and TCP protocols, enhancing the way congestion is managed by marking packets instead of discarding them. It helps improve network performance, reduce packet loss, and maintain high throughput, making it especially valuable in data centers and for real-time applications.

Dynamic Load Balance

Dynamic Load Balancing is a network management technique used to distribute network traffic across multiple paths or resources dynamically. Unlike static load balancing, which assigns fixed routes or resources to handle traffic, dynamic load balancing adjusts traffic distribution in real-time based on current network conditions.

It is a vital network management technique that optimizes performance, scalability, and reliability by dynamically distributing traffic across multiple paths or resources. By adapting to changing network conditions in real-time, dynamic load balancing ensures efficient resource utilization and enhances overall network performance and resilience.

In the following sections, we will explain the details of what they are, how they work, and how to configure.

Configuring Priority-based Flow Control (PFC)

- Enabling PFC Function
- Configuring PFC Buffer
- Configuring PFC Watchdog
- Configuring PFC Deadlock Prevention

Enabling PFC Function

Overview

Priority-based Flow Control (PFC) is a type of flow control mechanism. The advantage of PFC over traditional flow control mechanisms is that PFC provides flow control based on per-code-point (priority). In other words, PFC offers a more granular form of flow control. This means that if traffic from one particular priority suffers from congestion, only that traffic is paused until the congestion clears, while traffic for other priorities continues unhindered. On each physical port, there are 8 (0 to 7) Class of Service (CoS) queues. If congestion is detected on the egress physical port, the ingress port will send a PAUSE frame to the transmitting node to pause transmission until the receiving node is ready to accept packets again. PFC applies only to packets entering a port.

PFC has a higher priority than traditional flow control. For example, if both flow control and PFC are configured on the same port, PFC will take precedence over traditional flow control.

PFC uses the IEEE 802.1p CoS values in the IEEE 802.1Q VLAN tag to generate the flow control frame with the corresponding priority on the ingress physical port when the egress physical port suffers congestion. This indicates that the ingress port requires CoS classifier configuration.

Key Features of PFC

1. **Lossless Transmission**: PFC ensures lossless transmission for high-priority traffic classes by pausing traffic when congestion is detected, preventing packet loss.
2. **Per-Priority Flow Control**: Unlike traditional Ethernet flow control, which applies to all traffic on a link, PFC operates on individual traffic priorities, allowing selective flow control.
3. **Congestion Management**: By preventing packet loss for specific traffic classes, PFC helps manage congestion and improve overall network performance.

Working Mechanism of PFC

PFC operates using the following key components and steps:

1. **Traffic Classification**: Network traffic is classified into different priorities based on the IEEE 802.1p standard, which defines eight priority levels (0-7). Each priority level corresponds to a specific type of traffic, such as storage, voice, or best-effort data.
2. **Priority Mapping**: The switch maps traffic to these priority levels using VLAN tags (802.1Q) or Differentiated Services Code Point (DSCP) values. Each priority level is associated with a separate queue within the switch.
3. **Congestion Detection**: When a switch detects congestion in one of its priority queues (e.g., due to high traffic volume or insufficient buffer space), it generates a PFC frame for that specific priority level.
4. **PFC Frame Transmission**: The PFC frame, also known as a PAUSE frame, is sent to the upstream device (e.g., another switch or a network interface card in a server). This frame instructs the upstream device to pause the transmission of traffic for the specified priority level.
5. **Traffic Pause**: Upon receiving the PFC frame, the upstream device temporarily stops sending traffic of the specified priority to the congested switch. Other traffic classes (priorities) continue to flow without interruption, ensuring that only the affected traffic is paused.
6. **Congestion Alleviation**: The switch continues to process and forward the paused traffic until the congestion is alleviated. Once the buffer space is available, the switch sends another PFC frame to the upstream device to resume the paused traffic flow.
7. **Resume Transmission**: The upstream device resumes sending traffic for the previously paused priority, restoring normal traffic flow.

Advantages of PFC

1. **Improved Performance**: By preventing packet loss for high-priority traffic, PFC ensures that critical applications, such as storage and real-time communications, perform reliably.

2. **Enhanced Network Efficiency**: PFC allows network devices to manage congestion more effectively, reducing the likelihood of network bottlenecks and improving overall network efficiency.
3. **Coexistence of Traffic Types**: PFC enables different types of traffic to coexist on the same network infrastructure without interfering with each other, supporting the convergence of storage, data, and voice traffic.

Restrictions and Guidelines

When you configure PFC, follow these restrictions and guidelines:

- It is essential to ensure that the PFC functionality is enabled on all ports through which the packets flow.
- To prevent packet loss due to congestion during transmission, please configure the same PFC settings on all ports through which the packets flow.

Procedure

Step 1 Configure PFC Profile.

By default, PFC is enabled.

PFC is disabled when drop value is set to true and enabled when drop value is set to false. The default value of drop is false.

set class-of-service pfc-profile <*pfc-profile-name*> **code-point** <*cos*> **drop** <**true** | **false**>

Step 2 Apply PFC profile to the interface.

set class-of-service interface <*interface-name*> **pfc-profile** <*pfc-profile-name*>

Step 3 Commit the configuration.

commit

Show PFC Frame Statistics on Port

After complete the configuration, the command **run show class-of-service interface** `<` *interface-name*> can be used to show the class of service statistics information on specified interface.

Configuration Example

The following commands complete the configurations:

- Configure PFC profile `pfc1`.
- Apply PFC profile to the port `ge-1/1/1`.

```
admin@PICOS# set class-of-service pfc-profile pfc1
admin@PICOS#set class-of-service interface ge-1/1/1 pfc-profile pfc1
```

- Show the class of service statistics information on specified interface.

The class 0~7 in PFC frame corresponds to the following "802.1P" item. The value of ”RxPFC“ item will be incremented by 1 if ge-1/1/1 receives a PFC frame. The value of ”TxPFC“ item will be incremented by 1 if ge-1/1/1 sends out a PFC frame.

```
admin@PICOS# run show class-of-service interface ge-1/1/1
Interface : ge-1/1/1

802.1P         Priority Flow Control    RxPFC              TxPFC

```

Configuring PFC Buffer

Overview

The buffer is configured to implement traffic control and PFC watchdog, which is based on interface and priority queue. The storage space of each interface is divided into different buffers independently and a certain action will be executed after the number of accumulated packets reaches the buffer threshold (the unit is cell).

- **Guaranteed**: the dedicated buffer available for a specified queue. This buffer space cannot be used by other queues.
- **Shared**: the public buffer available for all queues. The shared buffer will be occupied when the guaranteed buffer reaches the threshold.
- **Headroom**: the maximum number of cell resources available for packets with a specific 802.1p priority. When the occupied shared buffer reaches the threshold, the packets will be saved in the headroom buffer.

Threshold and Execution Action

After the PFC function is enabled, the default storage space is available for a specified queue of an interface. To flexibly control the PFC function and make good use of the storage space, you can configure the thresholds for different buffer types and the correspongding action will be executed. The detailed information is shown as below.

Figure 1. Communication between upstream and downstream switches

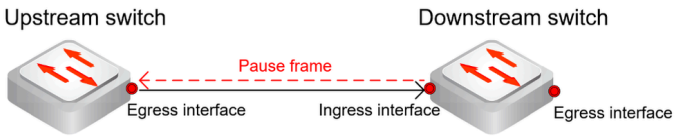

Figure 2. Buffer threshold and execution action of an interface

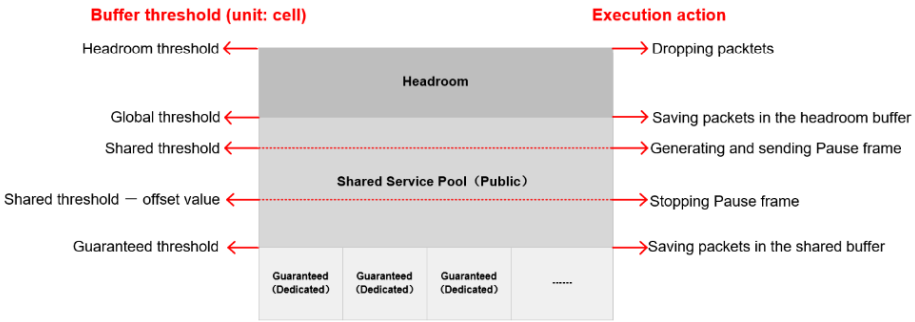

1. Initially, the packets of a specified queue on an interface are saved in the guaranteed buffer. When the occupied space is higher than the guaranteed buffer threshold, the shared buffer will be occupied.
2. When the occupied space is higher than the shared buffer threshold, the ingress interface and egress interface of the downstream switch will execute different actions.

   a) For the ingress interface, it will generate and send Pause frames to the egress interface of the upstream switch to stop sending packets. The Pause frames will stop being generated when the occupied space is reduced to a certain level (the shared threshold minus the offset value). When the occupied space is higher than the global threshold, the packets will be saved in the headroom buffer.

   b) For the egress interface, the packets will be directly saved in the headroom buffer.

3. When the occupied space is higher than the headroom buffer threshold, the packets will be dropped.

Restrictions and Guidelines

When you configure PFC buffer, follow these restrictions and guidelines:

- PFC should be enabled on the interface before configuring PFC buffer.
- Currently, the PFC buffer is only supported on **Trident3-X5, Trident3-X7**, **Tomahawk3** and **Tomahawk5** platforms.
- The values of cell are different on different platforms. The value is **256** bytes on Trident3-X5 and Trident3-X7 platforms, and is **254** bytes on the Tomahawk3 platform.

Procedure

Step 1 Enable PFC on the interface before configuring PFC buffer.

set class-of-service pfc-profile <*pfc-profile-name*> [**code-point** <*cos*> **drop** <**true** | **false**>]

set class-of-service interface <*interface-name*> **pfc-profile** <*pfc-profile-name*>

Step 2 Set the upper threshold of guaranteed buffer for a PFC queue on the **ingress** interface. When the guaranteed buffer threshold is reached, the packets will be saved in the shared service pool.

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer ingress-queue** <*queue-id*> **guaranteed** <*value*>

Step 3 Set the upper threshold of shared buffer for a PFC queue on the **ingress** interface. When the occupied buffer space exceeds the specified threshold, the Pause frame will be generated and sent to the egress interface. You can specify the threshold in the static (a fixed value) or dynamic (percentage) way.

Only one way can be configured, or the error prompt will appear.

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer ingress-queue** <*queue-id*> **shared-ratio** <*value*>

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer ingress-queue** <*queue-id*> **threshold** <*value*>

Step 4 Set the offset value of shared buffer for a PFC queue on the **ingress** interface. The Pause frames will stop being generated when the occupied space is reduced to a certain level (the upper threshold minus the offset value).

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer ingress-queue** <*queue-id*> **reset-offset** <*value*>

Step 5 Set the global threshold of shared buffer for a PFC queue on all **ingress** interfaces. When the global threshold is reached, the packets will be saved in the headroom buffer.

set interface ethernet-switching-options buffer service-pool <*pool-id*> **threshold** <*value*>

Step 6 Set the upper threshold of headroom buffer for a PFC queue on the **ingress** interface. When the headroom buffer threshold is reached, the interface will drop received packets.

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer ingress-queue** <*queue-id*> **headroom** <*value*>

Step 7 Set the upper threshold of shared buffer for a PFC queue on the **egress** interface of the downstream switch. When the occupied buffer space exceeds the specified threshold, the packets will be saved in the headroom buffer. You can specify the threshold in the static (a fixed value) or dynamic (percentage) way.

Only one way can be configured, or the error prompt will appear.

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer egress-queue** <*queue-id*> **shared-ratio** <*value*>

set interface gigabit-ethernet <*interface-name*> **ethernet-switching-options buffer egress-queue** <*queue-id*> **threshold** <*value*>

Step 8 Commit the configuration.

commit

Configuring PFC Watchdog

- Understanding PFC Deadlock
- PFC Watchdog Mechanism
- Key Components and Functions of PFC Watchdog
- Restrictions and Guidelines
- Configuring PFC Watchdog
  - Procedure
- Verifying the Configuration

Priority Flow Control (PFC) is a mechanism used in data center networks to ensure lossless transmission for high-priority traffic by pausing traffic when congestion is detected. While PFC helps in managing traffic congestion, it can potentially lead to a situation known as a **PFC deadlock**. To address this issue, network devices employ a **PFC watchdog** mechanism to detect and mitigate PFC deadlocks.

Understanding PFC Deadlock

A PFC deadlock occurs when multiple devices in a network are continuously sending PFC pause frames to each other, leading to a situation where traffic is indefinitely paused, causing a complete halt in data transmission. This deadlock can severely impact network performance and application availability.

PFC Watchdog Mechanism

The PFC watchdog is designed to detect and resolve PFC deadlocks. It monitors the duration of PFC pause frames and takes corrective actions if a potential deadlock is detected.

PFC Deadlock Detection and Recovery

By configuring the PFC deadlock detection function, the device can periodically check if it is in a PFC deadlock state. When the device detects a PFC deadlock, it will automatically resolve the deadlock within the recovery period. The system will resume sending traffic for the corresponding priority queue, or it can configure to discard the traffic for the corresponding priority queue. After the recovery period, the normal PFC flow control mechanism will be restored. If a deadlock is detected again during the next detection cycle, a new cycle of deadlock recovery procedures will be initiated.

PFC Deadlock Control Process

If the above deadlock recovery procedures are ineffective and PFC deadlocks continue to occur, users can configure the system to forcibly enter the deadlock control process after a certain number of deadlocks within a specified period. For example, if PFC deadlocks are triggered a certain number of times within a set period, indicating a high risk of frequent deadlocks in the network, the system will enter the deadlock control process. At this point, the device will automatically disable the PFC function to ensure normal packet forwarding and to clear the deadlock state.

After the PFC deadlock state is resolved, users have to restore the PFC deadlock detection function manually. Restoring the PFC deadlock detection function reactivates the PFC feature.

Key Components and Functions of PFC Watchdog

1. **Monitoring PFC Pause Frames**: The PFC watchdog continuously monitors the network for PFC pause frames. It keeps track of the duration for which these frames are active for each priority class on each port.

   The following command can be used to enable PFC watchdog functionality:

   set class-of-service interface <*interface-name*> **pfc-watchdog code-point** <*cos*> **enable** <**true** | **false**>

2. **Timeout Threshold**: A configurable timeout threshold is set for PFC pause frames. If a pause frame for a specific priority exceeds this threshold, it indicates a potential deadlock situation.

   The detect timer can be configured by the following commands:

   set class-of-service pfc-watchdog granularity <**10** | **100**>

   set class-of-service pfc-watchdog code-point <*cos*> **detect-interval** <*detect-interval*>

3. **Deadlock Detection**: When the duration of a PFC pause frame surpasses the timeout threshold, the PFC watchdog triggers a deadlock detection process. This process identifies the ports and priority classes involved in the deadlock.
4. **Restore Actions**: Once a potential deadlock is detected, the PFC watchdog takes restore actions to break the deadlock. These actions typically include:

   - **Forward**: During the PFC deadlock recovery process, the received PFC PAUSE frame will be ignored, and the internal scheduler will resume forwarding the traffic.
   - **Drop**: Drops received data packets.

   After a predefined period, the PFC watchdog re-enables PFC for the affected priority class. This period allows the network to stabilize and clear any residual congestion that could cause another deadlock.

   The restore action can be configured by the following commands:

   set class-of-service pfc-watchdog restore-action <**forward** | **drop**>

   set class-of-service pfc-watchdog code-point <*cos*> **restore-interval** <*restore-interval*>

5. **Set the Recovery Mode for a Deadlocked Port**

   The following command can be used to configure the restore mode, the default is automatic recovery.

   set class-of-service interface <*interface-name*> **pfc-watchdog restore-mode <manual | auto>**

   The two different restore modes **Manual** and **Auto** represent different deadlock detection processes and different PFC deadlock recovery methods:

   - **Auto**

   When PFC watchdog functionality is enabled and the restore mode for a port is set to **Auto** recovery, the PFC watchdog continuously monitors the PFC activity on the port. If deadlocks repeatedly occur and the count exceeds the configured threshold within the specified time period, the system determines that the port is in an unstable state and will automatically disable the PFC feature to prevent further network disruption.

   Once PFC is disabled, the port will no longer use PFC to manage congestion until it is manually reset by using the following command:

   run clear class-of-service interface <*interface-name*> **pfc-watchdog auto**

   - **Manual**

   When PFC watchdog functionality is enabled and the restore mode for a port is set to **Manual** recovery, the PFC watchdog continuously monitors the PFC activity on the port, once a PFC deadlock occurs, the PFC function on that port will be automatically disabled.

   Once PFC is disabled, the port will no longer use PFC to manage congestion until it is manually reset by using the following command:

   run clear class-of-service interface <*interface-name*> **pfc-watchdog manual**

   This ensures that persistent deadlocks do not degrade network performance.

6. **Set the Maximum Number of PFC Deadlocks within a Specified Period**
   When the recovery mode for a port is set to automatic recovery, and the number of PFC deadlocks reaches the upper limit within the specified period, the PFC function on that port will be disabled. In this case, users need to do step 7 to re-enable PFC function.

set class-of-service pfc-watchdog threshold period <*time*>

set class-of-service pfc-watchdog threshold count <*count*>

7. **Re-enabling PFC and PFC Watchdog**

   • When a port experiences a deadlock and the recovery mode is set to manual, this command needs to be run to re-enable the PFC function:

   run clear class-of-service interface <*interface-name*> **pfc-watchdog manual**

   • When the deadlock limit is configured and the port deadlock reaches the upper limit, the reset command needs to be executed to re-enable the PFC function:

   run clear class-of-service interface <*interface-name*> **pfc-watchdog auto**

Restrictions and Guidelines

When you configure PFC watchdog, follow these restrictions and guidelines:

- PFC should be enabled on the interface before enabling PFC watchdog.
- PFC watchdog is only supported on **Trident3-X5, Trident3-X7**, **Tomahawk3** and **Tomahawk5** platforms.

Configuring PFC Watchdog

Procedure

Step 1 Enable PFC on the interface before enabling PFC watchdog.

set class-of-service pfc-profile <*pfc-profile-name*> [**code-point** <*cos*> **drop** <**true** | **false**>]

set class-of-service interface <*interface-name*> **pfc-profile** <*pfc-profile-name*>

Step 2 Enable PFC watchdog. By default, PFC watchdog is disabled.

set class-of-service interface <*interface-name*> **pfc-watchdog code-point** <*cos*> **enable** <**true** | **false**>

Step 3 (Optional) Configure the time interval of PFC deadlock detection. The default detection timer is 1.5 seconds. The value of detection time = **granularity** x **detect-interval**.

set class-of-service pfc-watchdog granularity <**10** | **100**>

set class-of-service pfc-watchdog code-point <*cos*> **detect-interval** <*detect-interval*> (On **Trident3** platforms)

set class-of-service interface <*interface-name*> **pfc-watchdog code-point** <*cos*> **detect-interval** <*detect-interval*> (On **Tomahawk3** platforms)

Step 4 (Optional) Configure the restore time and restore action when PFC deadlock occurs. The default restore action is forward. The restore time = **granularity** x **restore-interval**.

set class-of-service pfc-watchdog restore-action <**forward** | **drop**>

set class-of-service pfc-watchdog code-point <*cos*> **restore-interval** <*restore-interval*> (On **Trident3** platforms)

set class-of-service interface <*interface-name*> **pfc-watchdog code-point** <*cos*> **restore-interval** <*restore-interval*> (On **Tomahawk3** platforms)

Step 5 (Optional) Set the restore mode for a deadlocked port. If this command is not configured, the default is automatic recovery.

set class-of-service interface <*interface-name*> **pfc-watchdog restore-mode <manual | auto>**

Step 6 (Optional) Set the maximum number of PFC deadlocks within a specified period.

When the recovery mode for a port is set to automatic recovery, and the number of PFC deadlocks reaches the upper limit within the specified period, the PFC function on that port will be disabled. In this case, users need to do step 8 to re-enable PFC function.

set class-of-service pfc-watchdog threshold period <*time*>

set class-of-service pfc-watchdog threshold count <*count*>

Step 7 Commit the configuration.

commit

Step 8 (Optional) Re-enable PFC and PFC watchdog.

• When a port experiences a deadlock and the recovery mode is set to manual, this command needs to be run to re-enable the PFC function:

run clear class-of-service interface <*interface-name*> **pfc-watchdog manual**

• When the deadlock limit is configured and the port deadlock reaches the upper limit, the reset command needs to be executed to re-enable the PFC function:

run clear class-of-service interface <*interface-name*> **pfc-watchdog auto**

Verifying the Configuration

- After the configuration, use command **run show pfc-watchdog config** to view the configuration information about PFC watchdog.

```
admin@PICOS# run show pfc-watchdog config
    PORT    ACTION      QUEUE    DETECTION TIME   RESTORATION TIME
----------  -----------   ------------  ----------------  ------------------
te-1/1/25     drop       5             150               150
                    6             150               150
                    7             120               110
```

- Use command **run show pfc-watchdog stats** to view the statistics information about PFC watchdog, including the number of PFC pause storms that have been detected and restored, as well as the number of packets that have been dropped, on the PFC queues on an interface.

```
admin@PICOS# run show pfc-watchdog stats
       QUEUE       STATUS    STORM DETECTED/RESTORED        TX OK/DROP    TX LAST OK/DROP
------------  -----------  ------------------------  ----------------  -------------------
te-1/1/25:5       stormed                       9/8      82072626556/0  32053822365/0
te-1/1/25:6       stormed                       9/8      31504345475/0  32053822365/0
te-1/1/25:7   operational                       0/0                0/0  0/0
```

In the show result,

- **STATUS**: The status of PFC watchdog. The value could be **operational** or **stormed**.
  - **operational**: Currently under detection, no deadlock found.
  - **stormed**: Currently in a deadlock state.
- **STORM DETECTED**: Queue deadlock counter.
- **STORM RESTORED**: Queue restore counter.

- **TX DROP** and **TX LAST DROP**: Number of Tx packets dropped due to PFC deadlock.
- **TX OK** and **TX LAST OK**: Number of Tx packets transmitted during deadlock (Forward action).

  - Configuration Example

Overview

Consider a data center running RoCE (RDMA over Converged Ethernet) traffic for high-performance computing workloads. These workloads require low-latency, lossless traffic flow, which PFC is used to enforce. However, as network congestion builds up, PFC pause frames are triggered, potentially leading to a deadlock if multiple paths become blocked.

By employing a PFC deadlock prevention solution, the network can identify RoCE flows that are prone to triggering deadlocks. The solution adjusts the queue priorities so that other critical flows are not blocked, and it reduces the load on congested paths. This prevents the generation of circular wait conditions and ensures the smooth operation of high-priority traffic, ensuring that business-critical applications continue to function smoothly without being interrupted by PFC-induced deadlocks.

How PFC Deadlock Prevention Works in Practice

1. **Monitoring and Analytics**

Figure 1. PFC Hook Flows

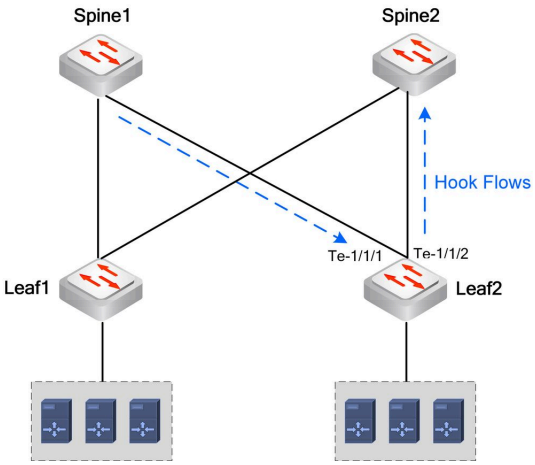

Figure 1 shows a CLOS network, it is a highly scalable and high-performance switching network commonly used in modern data centers. It is a multi-stage network topology, typically with multiple leaf and spine switches, which is designed to handle massive amounts of data with minimal latency and is often used to interconnect thousands of servers. Usually, PFC is deployed to manage flow control and avoid packet loss.

PFC Uplink Port Group

As shown in **Figure 1**, interfaces Te-1/1/1 and Te-1/1/2 are the uplinks connecting Leaf2 to the spines. They are added to the PFC uplink port group so that the system treats them collectively, allowing the device to manage them as a single entity when assessing traffic flow and PFC behavior.

High-Risk Hook Flow

As shown in **Figure 1**, when a leaf device detects that the same business flow (i.e., a specific set of traffic identified by its characteristics, such as source/destination IP, port, etc.) is traversing multiple interfaces within the PFC uplink port group, it marks this flow as a high-risk

hook flow.

When a high-risk hook flow generates congestion across multiple interfaces (uplinks), PFC pause frames may be issued by the leaf to its upstream spine switches. If both interfaces in the uplink group send pause frames, and the upstream spine switches are also congested, it can result in a circular wait scenario (deadlock). The switches are effectively waiting for each other to release the paused traffic, leading to a network stall.

The **Deadlock Prevention** solution proactively monitors the data center network for high-risk hook flow that may lead to the generation of PFC pause frames.

2. **Dynamic Queue Management**

After the device receives the packet, it modifies the DSCP value and the corresponding dot1p priority of the packet, so that the packet is forwarded in the new dot1p priority queue using the new DSCP value.

The **PFC deadlock prevention** function in CLOS networks works by creating **PFC uplink port groups** that combine uplink interfaces on leaf devices together. The system detects high-risk flows that traverse these grouped uplinks and identifies them as potential deadlock triggers (high-risk hook flows). By preemptively modifying queue priorities and managing these flows, the system prevents deadlocks from occurring, ensuring the stability and efficiency of data center networks.

Restrictions and Guidelines

When you configure PFC deadlock prevention, follow these restrictions and guidelines:

- PFC Deadlock Prevention is only supported on **Trident3-X5**, **Trident3-X7**, **Tomahawk3** and **Tomahawk5** platforms.
- To ensure proper functioning, it is important that if any Equal-Cost Multi-Path (ECMP) output interfaces exist within the PFC uplink port group, **all of these ECMP interfaces** must be included in the group. Failing to do so may result in incorrect queue switching for Layer 3 traffic on the PFC uplink port group interfaces, leading to unexpected modifications of the DSCP (Differentiated Services Code Point) values. This could impair traffic handling and potentially lead to inefficiencies or incorrect prioritization.
- Each device supports only one PFC uplink port group.

Configuring PFC Deadlock Prevention

Procedure

Step 1 Create a PFC uplink port group.

set class-of-service interface <*interface-name*> **pfc-uplink-group** <*group-name*>

Step 2 Modify the queue priority of hook flow packets that match the PFC uplink port group and the original DSCP value.

set class-of-service pfc-uplink-group <*group-name*> **original-dscp** <*origin-value*> **to-code-point** <*queue*>

Step 3 Modify the queue priority of hook flow packets that match the PFC uplink port group and the original DSCP value. If this command is not configured, it means the DSCP value carried by the packets will not be adjusted.

set class-of-service pfc-uplink-group <*group-name*> **original-dscp** <*origin-value*> **dscp** <*value*>

> **NOTE**:
>
> When configuring on the Trident3-X5 and Trident3-X7 platforms, the configurations in step 2 and step 3 both need to be configured and submitted in the same commit.

Step 4 Commit the configuration.

commit

Configuration Example

The following commands complete the configurations:

- Create a PFC uplink port group group1.
- Modify the queue priority to 4 and DSCP value to 48 of the hook flow packets that match the PFC uplink port group group1 and the original DSCP value 32.

```
admin@PICOS# set class-of-service interface te-1/1/1 pfc-uplink-group group1
admin@PICOS# set class-of-service interface te-1/1/2 pfc-uplink-group group1
admin@PICOS# set class-of-service pfc-uplink-group group1 original-dscp 32 to-code-point 4
admin@PICOS# set class-of-service pfc-uplink-group group1 original-dscp 32 dscp 48
admin@PICOS# commit
```

Configuring Explicit Congestion Notification (ECN)

Overview

Explicit Congestion Notification (ECN) is a network protocol feature that allows end-to-end notification of network congestion without dropping packets. It is an extension of the IP and TCP protocols, enhancing the way congestion is managed by marking packets instead of discarding them.

How ECN Works

ECN works by marking packets instead of dropping them when network devices detect congestion. This approach allows the sender to reduce its transmission rate proactively, improving overall network performance and reducing packet loss.

Key Concepts

1. **ECN-Capable Transport (ECT)**: Indicates that the endpoints are ECN-aware and can handle ECN markings.
2. **Congestion Experienced (CE)**: Indicates that the network is experiencing congestion.
3. **TCP ECN Echo (ECE)**: A TCP flag used to notify the sender that the receiver has received a packet marked with CE.
4. **Congestion Window Reduced (CWR)**: A TCP flag used by the sender to indicate that it has reduced its congestion window in response to receiving an ECE flag.

ECN Field in the IP Header

ECN uses two bits in the IP header, known as the ECN field, to signal congestion information:

- **00**: Not ECN-Capable Transport (Non-ECT)
- **01**: ECN Capable Transport (ECT(1))
- **10**: ECN Capable Transport (ECT(0))
- **11**: Congestion Experienced (CE)

ECN Operation

1. **Negotiation**: During the TCP three-way handshake, both endpoints negotiate the use of ECN. If both support ECN, they set the appropriate flags in their SYN packets.

2. **Packet Marking**: When an ECN-capable router detects congestion, it marks packets instead of dropping them. It sets the ECN field in the IP header to CE (11).
3. **Receiver Notification**: The receiver detects the CE marking and sets the ECE flag in the TCP header of its acknowledgment (ACK) packets.
4. **Sender Adjustment**: Upon receiving an ACK with the ECE flag, the sender reduces its transmission rate and sets the CWR flag in subsequent packets to indicate that it has responded to the congestion notification.

Therefore, it is necessary to reasonably set the ECN thresholds so that the buffer space between the ECN thresholds and PFC thresholds can accommodate the traffic sent during the time after the ECN congestion marking and before the source end slows down. This helps to avoid triggering PFC flow control as much as possible.

Advantages of ECN

1. **Reduced Packet Loss**: By marking packets instead of dropping them, ECN helps in avoiding packet loss, which is particularly beneficial for applications sensitive to packet drops, such as real-time video or voice.
2. **Improved Network Efficiency**: ECN allows for more efficient use of network resources by preventing congestion before it becomes severe enough to cause packet drops.
3. **Better Performance**: By avoiding packet loss, ECN can lead to better overall performance for TCP connections, resulting in higher throughput and lower latency.
4. **Smooth Traffic Flow**: ECN provides a mechanism for more graceful handling of congestion, leading to smoother traffic flow and improved end-user experience.

Restrictions and Guidelines

When you configure ECN, follow these restrictions and guidelines:

- To use ECN, both the network devices (such as routers and switches) and the endpoints (such as servers and clients) must support ECN.

Configuring ECN via WRED

On PICOS switches, ECN is used in conjunction with Weighted Random Early Detection (WRED) to provide early signals of congestion to avoid packet loss and improve network performance.

WRED is an active queue management (AQM) mechanism that selectively drops packets based on the average queue length, helping to manage congestion before the queue becomes full. When combined with ECN, WRED can mark packets instead of dropping them when congestion is detected.

Procedure

Step 1 Enable WRED.

set interface gigabit-ethernet <*interface-name*> **wred queue** <*queue-value*> **enable** <**true** |**false**>

Step 2 Set the maximum and minimum thresholds.

set interface gigabit-ethernet <*interface-name*> **wred queue** <*queue-value*> **max_thresh** <*max_thresh*>

set interface gigabit-ethernet <*interface-name*> **wred queue** <*queue-value*> **min_thresh** <*min_thresh*>

Step 3 Set drop probability.

set interface gigabit-ethernet <*interface-name*> **wred queue** <*queue-value*> **drop_probability** <*int*>

Step 4 Enable ECN.

set interface gigabit-ethernet <*interface-name*> **wred queue** <*queue-value*> **ecn_thresh** <*int*>

Step 5 Commit the configuration.

commit

Key Configuration Parameters

- **Min_Thresh**: The minimum average queue size at which WRED starts to mark packets.
- **Max_Thresh**: The maximum average queue size at which WRED starts to drop packets with the configured **Drop_Probability**.
- **Drop_Probability**: The probability that a packet will be marked with ECN when the average queue size is between the min and max thresholds.

Verify Configuration

Use the command **run show interface gigabit-ethernet** <*interface-name*> **wred** to check the settings of ECN and WRED .

Monitor and Adjust

Monitor the network to ensure that ECN marking and WRED are effectively managing congestion. Adjust the thresholds and probabilities as needed to optimize performance.

Configuration Example

The following commands complete the configurations:

- Enable WRED on queue 0 of interface ge-1/1/3;
- Set the maximum threshold to 400 and the minimum threshold to 200 on queue 0 of interface ge-1/1/3;
- Set the drop probability to 50% on queue 0 of interface ge-1/1/3;
- Enable ECN (Explicit Congestion Notification) on queue 0 of interface ge-1/1/3.

```
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 wred queue 0 enable true
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 wred queue 0 max_thresh 400
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 wred queue 0 min_thresh 200
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 wred queue 0 drop_probability 50
admin@PICOS# set interface gigabit-ethernet ge-1/1/3 wred queue 0 ecn_thresh 1
admin@PICOS# commit
```

Show the WRED information of the specified interface.

```
admin@PICOS# run show interface gigabit-ethernet ge-1/1/3 wred
Queue Num    Min Thresh   Max Thresh   Drop Probability    ECN Thresh      Status
----------   ----------   ----------   ----------------    -----------     ----------
0              200            400            50%             Enabled        Enabled
1              0              0              0%              Disabled       Disabled
2              0              0              0%              Disabled       Disabled
3              0              0              0%              Disabled       Disabled
4              0              0              0%              Disabled       Disabled
5              0              0              0%              Disabled       Disabled
6              0              0              0%              Disabled       Disabled
7              0              0              0%              Disabled       Disabled
```

Test Recommended Configuration

Configuring ECN thresholds properly is crucial for ensuring optimal network performance, which helps in managing congestion proactively, leading to improved network performance, reduced packet loss, and lower latency.Testing recommended configurations involves setting specific parameters for ECN to manage congestion effectively and then evaluating the performance outcomes.

In the Lab, we use network simulation tools to create a controlled environment for testing. Simulate various traffic patterns and congestion scenarios to test how the network handles congestion. The table below provides recommended configuration values to prevent packet loss and avoid triggering the PFC threshold.

Test Method	Switch Port MTU	Switch Egress Port Link Bandwidth	ECN Min Threshold (Bytes)	ECN Max Threshold (Bytes)	Probability
 Three Ingress Port to One Egress Port	9000	99.75G	80000	8000000	80
 Three Ingress Port to One Egress Port	4096	97.68G	1000000	30000000	50
 Three Ingress Port to One Egress Port	9000	99.75G	1000000	32000000	50

Users have to continuously monitor network performance and ECN marking rates. Make dynamic adjustments to the ECN thresholds as needed to respond to changing network conditions.

Configuring Easy ECN

- Overview
- Configuration Notes and Constraints
- Configuring Easy ECN
  - Example

Overview

The Easy ECN feature streamlines the traditionally complex configuration of Explicit Congestion Notification (ECN) by eliminating the need for manual setup of interface queues, WRED (Weighted Random Early Detection) policies, thresholds, and drop probabilities. In standard ECN configurations, users need to configure multiple parameters, such as:

- **Enabling ECN** on specific interface queues, ensuring that the network is aware of which traffic classes should use ECN.
- **Setting WRED thresholds**, which determine at what point packets will be marked or dropped based on queue depth.
- **Configuring the maximum packet drop probability**, dictating how likely a packet is to be dropped when congestion is high.

Easy ECN simplifies all of these by allowing users to configure ECN with just a single command, focusing on the network's traffic optimization strategy.

By using the command **set class-of-service easy-ecn mode <throughput-first | latency-first>**, network administrators can efficiently configure ECN with a focus on either throughput or latency globally for all the interface queues, without needing to manually set all the individual parameters for each interface queue. This simplified approach not only saves time but also ensures more consistent and effective congestion management.

1. **Throughput-first Mode:** This mode prioritizes maximizing the amount of data transferred across the network, making it ideal for use cases such as bulk data transfers or content delivery systems. It dynamically adjusts traffic flow to ensure that congestion management does not overly restrict throughput, while still using ECN to prevent excessive congestion.

   In this mode, the threshold for marking packets is set relatively high. This allows for larger buffers to accumulate before marking occurs, reducing the chances of packet drops and enabling more traffic to be handled.

2. **Latency-first Mode:** This mode prioritizes minimizing latency, ensuring that packets experience the least possible delay. This is particularly important for real-time applications such as VoIP, video conferencing, or online gaming, where even small delays can negatively impact performance.

   In this mode, the ECN marking threshold is set lower, meaning packets will be marked sooner when congestion starts to build up. This results in less buffer buildup, thus reducing queuing delays and minimizing latency.

Table 1 below shows ECN threshold and marking probability values for throughput-first and latency-first modes.

Table 1. ECN Threshold and Marking Probability: Throughput-First vs. Latency-First

Easy ECN Mode	ECN Threshold and Marking Probability	Tomahawk3	Trident3-X5/Trident3-X7	Tomahawk5
throughput-first	min_thresh (Bytes)	5,080,000	2,560,000	2,540,000
	max_thresh (Bytes)	25,400,000	12,800,000	12,700,000
	drop_probability	20%	20%	20%
latency-first	min_thresh (Bytes)	508,000	256,000	254,000
	max_thresh (Bytes)	2,540,000	1,280,000	1,270,000

	drop_probability	20%	20%	20%

To simplify the configuration, users can enable Easy ECN for global congestion management. However, if the global configuration does not fully address the specific needs of queue-level congestion management, standard ECN can be fine-tuned for individual interface queues.

> **NOTE**:
>
> When both global configuration and user-specified interface queue settings are applied, the settings for the user-specified interface queue will take effect.

Configuration Notes and Constraints

When configuring Easy ECN, consider the following points:

- Easy ECN is only supported on **Trident3-X5**, **Trident3-X7**, **Tomahawk3** and **Tomahawk5** platforms.
- **Throughput-First** mode prioritizes high data transfer rates. It is ideal for environments where bulk data transmission is critical. **Latency-First** mode focuses on minimizing delays in packet transmission, making it suitable for real-time applications (e.g., VoIP, video streaming).
- Easy ECN provides a simplified, global configuration for congestion management. If more granular control is required, standard ECN can be configured on specific interface queues. In such cases, interface-specific ECN configurations override global settings.

Configuring Easy ECN

To simplify the configuration, users can enable Easy ECN for global congestion management. However, if the global configuration does not fully address the specific needs of queue-level congestion management, standard ECN can be fine-tuned for individual interface queues.

The following command can be used to enable easy ECN globally.

set class-of-service easy-ecn mode <**throughput-first** | **latency-first**>

Example

- Configure easy ECN mode to **latency-first**.

```
admin@PICOS# set class-of-service easy-ecn mode latency-first
admin@PICOS# commit
```

- Configure easy ECN mode to **throughput-first**.

```
admin@PICOS# set class-of-service easy-ecn mode throughput-first
admin@PICOS# commit
```

PFC and ECN Statistical Reporting through gRPC

In modern network systems, efficient congestion management and data flow control are crucial to maintain high-performance levels, especially in data centers and cloud environments. PFC (Priority Flow Control) and ECN (Explicit Congestion Notification) are two complementary mechanisms that help manage traffic and congestion, while **gRPC** (Google Remote Procedure Call) facilitates real-time communication and reporting between network components.

PFC and ECN work together to handle congestion in a network. PFC ensures that critical traffic continues to flow by pausing lower-priority traffic, while ECN marks packets to indicate congestion. This cooperation minimizes packet loss and optimizes network performance.

As PFC and ECN manage traffic, they generate valuable statistics such as the number of paused frames (PFC) and the number of ECN-marked packets. These statistics are essential for understanding network health and congestion levels.

gRPC is used to gather and transmit these statistics to a central server. Because gRPC is designed for high-performance, low-latency communication, it is well-suited to handle the real-time transmission of PFC and ECN data. The statistical data can be analyzed to adjust network policies, improve performance, and prevent future congestion.

PFC and ECN Statistics

PFC and ECN, in conjunction with gRPC, can provide PFC pause frame counts, PFC deadlock monitoring and ECN-marked packet counts for statistical queries.

The statistics that PFC supports reporting include:

- Number of PFC pause frames sent
- Number of PFC pause frames received
- Number of PFC deadlock monitoring instances
- Number of PFC deadlock recovery instances
- Rate of PFC pause frames received
- Rate of PFC pause frames sent

The statistics that ECN supports reporting include:

- Number of ECN marked packets
- Rate of ECN marked packets

Configuration Procedure

1. Configure PFC on your network devices. Refer to Configuring Priority-based Flow Control (PFC) for details about how to configure PFC.
2. Enable ECN to help manage congestion. Refer to Configuring Explicit Congestion Notification (ECN) for details about how to enable ECN.
3. Deploy gRPC servers and clients to handle the statistical query requests. Refer to Configuring gNMI-gRPC Based Telemetry Technology for details about how to deploy gRPC.

This setup ensures you have real-time monitoring and statistical analysis capabilities for PFC and ECN, which can significantly aid in preventing network performance issues due to congestion and deadlocks.

Configuring Dynamic Load Balancing

- Overview
- Implementation Principle
  - Normal Mode
  - Optimal Mode
  - Assigned Mode
- Restrictions and Guidelines
- Configuring Dynamic Load Balancing
  - Procedure
  - Configuration Example
  - Verify the Configuration

Overview

Traditional static load balancing does not consider the utilization of each member link within the load-balancing group, leading to uneven load distribution among the member links. This issue becomes more pronounced with the appearance of large data flows, exacerbating congestion on the selected member link and potentially causing packet loss.

By enabling dynamic load balancing, the traffic of Equal-Cost Multi-Path (ECMP) routing can be distributed across different member links through dynamic load balancing, maximizing load balancing among the member links.

Implementation Principle

PICOS supports three modes of Dynamic load balancing: **Normal Mode**, **Optimal Mode** and **Assigned Mode**.

Normal Mode

There is link transmission delay between two directly connected devices. If the time interval between two data packets to be sent is greater than the maximum link transmission delay of the member links in the load-balancing group, these two packets can be forwarded using different member links without causing out-of-order delivery at the receiving end. Normal mode dynamic load balancing is based on this principle.

In Normal mode, the device determines the time interval between the packet to be forwarded and the previous packet in its flow. If the interval is greater than the maximum link transmission delay of the member links, the packet to be forwarded is considered the first packet of a new flowset. If the interval is less than the maximum link transmission delay, the packet is considered part of the same flowset as the previous packet.

The device forwards the packets based on the flowset, selecting the member link with the lighter load for forwarding. Packets within the same flowset are forwarded using the same member link.

Optimal Mode

The Optimal mode of dynamic load balancing operates on a per-packet distribution system, where each packet is forwarded independently based on the real-time load conditions of the available links. This mechanism allows the device to select the least congested or lightly loaded link at any given moment, distributing the packets dynamically to optimize network performance. However, this method introduces a potential issue when packets belonging to the same flow are forwarded through different links. If the time interval between two consecutively sent packets is shorter than the maximum transmission delay across the links, the packets may arrive out of order at the receiving end. This happens because different links may have varying transmission delays, causing later-sent packets to arrive before earlier ones.

For this reason, Optimal mode can lead to out-of-order packet delivery, particularly in scenarios where flows are split across multiple paths. Out-of-order packets can disrupt certain types of network traffic, especially those that rely on sequence consistency, such as real-time voice or video communication. To mitigate this, it is crucial that the receiving device or terminal has the capability to reorder packets properly. Devices must be equipped with reassembly buffers or out-of-order packet handling mechanisms to ensure the integrity of the flow, allowing the receiving system to reorder the packets correctly before processing them. Optimal mode, while improving load distribution and avoiding bottlenecks, requires robust support on the receiving end to handle these potential sequencing issues effectively.

Assigned Mode

In Assigned mode dynamic load balancing, the system ensures that each packet within a specific flow follows a consistent path by using the same forwarding link as the previous packet in that flow. This approach minimizes the risk of out-of-order packet delivery by keeping the traffic for the flow on the same route. However, when a flow starts and the first packet is sent, the system cannot rely on a previous packet's path. In this case, a static load balancing mechanism comes into play, where a hash-based algorithm determines the member link to forward the packet. The hash function typically considers factors such as source and destination IP addresses or port numbers to ensure an even distribution of traffic across the available links while maintaining flow consistency. Once the path is set for the first packet, subsequent packets in the same flow will continue to follow that route until the flow is completed.

Restrictions and Guidelines

When you configure Dynamic Load Balancing, follow these restrictions and guidelines:

- Dynamic Load Balancing for ECMP is only supported on **Trident3**, **Tomahawk3** and **Tomahawk5** platforms.
- When the ECMP hash-mapping mode configuration (set/delete) changes, a system restart is required for the configuration to take effect.
- ECMP hash-mapping modes (**round-robin-load-balancing**, **randomized-load-balancing**, **symmetric, resilient-load-balancing, dlb-optimal**, **dlb-assigned** and **dlb-normal**) are mutually exclusive. To switch between modes, you must first delete the configured mode before setting up the new one. Then, restart the system for the configuration to take effect.

Configuring Dynamic Load Balancing

Procedure

Step 1 Enable one of the three modes of Dynamic load balancing for ECMP: **Normal mode**, **Optimal mode** and **Assigned mode**.

set interface ecmp hash-mapping dlb-normal [**flowset-time** <*flowset-time*>]

set interface ecmp hash-mapping dlb-optimal

set interface ecmp hash-mapping dlb-assigned

By default, Dynamic Load Balancing for ECMP is disabled.

Step 2 Commit the configuration.

commit

Step 3 Under CLI operational mode (prompted with ">"), run the following command to restart the system for the configuration to take effect.

request system reboot

Configuration Example

- The following commands enable normal mode of Dynamic Load Balancing for ECMP.

```
admin@PICOS# set interface ecmp hash-mapping dlb-normal
admin@PICOS# commit
```

```
admin@PICOS# exit
admin@PICOS> request system reboot
```

- The following commands change Dynamic Load Balancing normal mode to optimal mode for ECMP.

```
admin@PICOS# delete interface ecmp hash-mapping dlb-normal
admin@PICOS# commit
admin@PICOS# set interface ecmp hash-mapping dlb-optimal
admin@PICOS# commit
admin@PICOS# exit
admin@PICOS> request system reboot
```

Verify the Configuration

- Use the command **run show route ipv4** to view the ECMP routes. In the following show result, we can see that the destination address 10.20.51.0/24 is reached via three different next hops: 192.168.0.1, 192.168.1.1, and 192.168.2.1, forming ECMP routes.

```
admin@PICOS# run show route ipv4
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, T - Table, D - SHARP,
       F - PBR,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure

K * 0.0.0.0/0 [255/8192] unreachable (blackhole), 23:42:36
K>* 0.0.0.0/0 [0/2] via 10.10.51.1, eth0, 23:42:36
C>* 10.10.51.0/24 is directly connected, eth0, 23:42:36
S>* 10.20.51.0/24 [1/0] via 192.168.0.1, vlan10, weight 1, 00:09:06
  *                     via 192.168.1.1, vlan20, weight 1, 00:09:06
  *                     via 192.168.2.1, vlan30, weight 1, 00:09:06
C>* 192.168.0.0/24 is directly connected, vlan10, 00:09:09
C>* 192.168.1.0/24 is directly connected, vlan20, 00:09:09
C>* 192.168.2.0/24 is directly connected, vlan30, 00:09:09
```

- Use the command **run show interface gigabit-ethernet** <*interface-name*> to view the traffic distribution for each interface. Here is an example:

```
admin@PICOS# run show interface gigabit-ethernet ge-1/1/5
Physical interface: ge-1/1/5, Enabled, error-discard False, Physical link is Up
Interface index: 5, Mac Learning Enabled
Port mode: trunk
Description:
Link-level type: Ethernet, MTU: 1518, Speed: 2.5Gb/s, Duplex: Full
Source filtering: Disabled, Flow control: Disabled
Auto-negotiation: Enabled, Advertised speed modes: 10M,100M,1G,2.5G
Interface flags: SNMP-Traps Internal: 0x0
Interface rate limit  ingress: unlimited, egress: unlimited
Interface burst limit ingress: unlimited, egress: unlimited
Precision Time Protocol mode: none
Current address: 1c:72:1d:c9:1b:e1, Hardware address: 1c:72:1d:c9:1b:e1
Traffic statistics:
  5 sec input rate 5440 bits/sec, 1 packets/sec

Typical Configuration Example of Lossless Network

Networking Requirements

Procedure

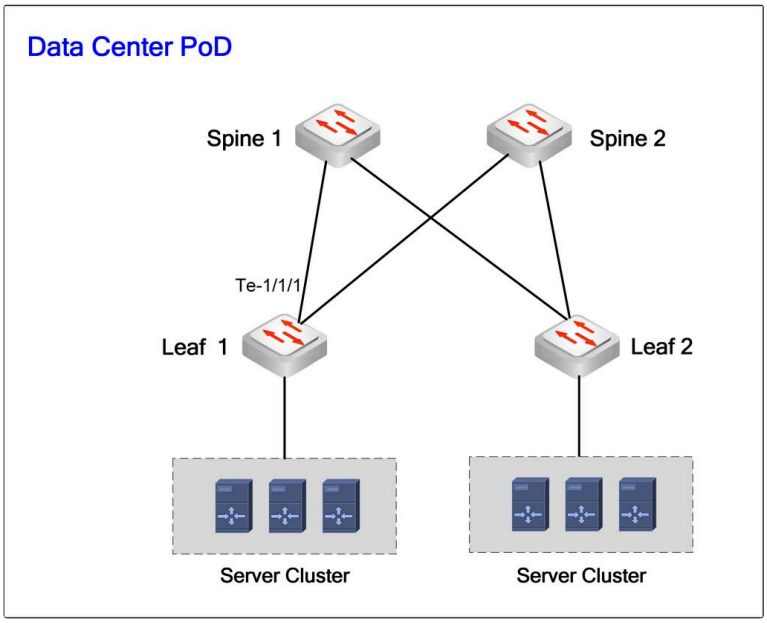
Networking Requirements

In **Figure 1**, in the following data center network PoD, two Server Clusters are connected to the network through devices Leaf 1, Leaf 2, Spine 1 and Spine 2. A lossless network is required to apply in the network devices to prevent packet loss during data transmission, ensuring high reliability and performance, especially for applications that are sensitive to latency and data integrity.

Setting up a lossless network involves careful planning, consistent configuration across all devices, and continuous monitoring and management. Follow the configuration roadmap below to ensure all components are correctly configured:

- Configure **PFC** on all relevant ports to prevent packet loss by pausing traffic during congestion.
- Employ a **PFC watchdog** mechanism to detect and mitigate PFC deadlocks.
- Enable Explicit Congestion Notification (ECN) on all switches and endpoints to signal congestion without dropping packets. Configure ECN thresholds to detect and mark packets early before severe congestion occurs.
- Enable dynamic load balancing, the traffic of Equal-Cost Multi-Path (ECMP) routing can be distributed across different member links through dynamic load balancing.

Figure 1. Typical Configuration Example of Lossless Network



Procedure

The following configuration steps are for Leaf 1. The configurations for Leaf 2, Spine 1 and Spine 2 are similar to Leaf 1 and will not be repeated.

Step 1 On Leaf 1, configure **PFC** on all relevant ports to prevent packet loss by pausing traffic during congestion.

The following commands complete the configurations:

- Configure PFC profile `pfc1`.
- Apply PFC profile to the port `te-1/1/1`.

```
admin@PICOS# set class-of-service pfc-profile pfc1
admin@PICOS#set class-of-service interface te-1/1/1 pfc-profile pfc1
admin@PICOS# commit
```

- Show the class of service statistics information on specified interface.

The class 0~7 in PFC frame corresponds to the following "802.1P" item. The value of ”RxPFC“ item will be incremented by 1 if te-1/1/1 receives a PFC frame. The value of ”TxPFC“ item will be incremented by 1 if te-1/1/1 sends out a PFC frame.

```
admin@PICOS# run show class-of-service interface te-1/1/1
Interface : te-1/1/1
802.1P         Priority Flow Control    RxPFC              TxPFC
-----------    ---------------------    ---------------    ---------------
0              true                     0                  500
1              true                     0                  0
2              true                     0                  71
3              true                     0                  0
4              true                     0                  0
5              true                    0                  0
6              true                     0                  102
7              true                     0                  0
trust mode : ieee-802.1
Default ieee-802.1 : 0
Default dscp : 0
Default inet-precedence : 0
Local-priority   Queue-Schedule               Code-points
--------------   --------------------------   ------------------------
0                SP,0kbps
1                SP,0kbps
2                SP,0kbps
3                SP,0kbps
4                SP,0kbps
5                SP,0kbps
6                SP,0kbps
7                SP,0kbps
```

Step 2 (Optional) Configure the PFC buffer.

After the PFC function is enabled, the default storage space is available for priority queues. You can flexibly make good use of the storage space through configuring buffer thresholds based on certain queues as needed.

The following commands complete the configurations:

- Set the upper threshold of guaranteed buffer for PFC queue 3 on the ingress interface te-1/1/1 as 24000 cells.
- Set the static threshold of shared buffer for PFC queue 1 on the ingress interface te-1/1/1 as 10000 cells.
- Set the offset value of shared buffer for PFC queue 1 on the ingress interface te-1/1/1 as 3000 cells.

```
admin@PICOS# set interface gigabit-ethernet te-1/1/1 ethernet-switching-options buffer ingress-queue 3
guaranteed 24000
admin@PICOS# set interface gigabit-ethernet te-1/1/1 ethernet-switching-options buffer ingress-queue 1
threshold 10000
admin@PICOS# set interface gigabit-ethernet te-1/1/1 ethernet-switching-options buffer ingress-queue 1 reset-
offset 3000
admin@PICOS# commit
```

Step 3 Configure PFC watchdog.

The following commands complete the configurations:

- Enable PFC watchdog on queue5 of interface te-1/1/1.

- Configure the time interval of PFC deadlock detection to 10 x 100ms, where 100ms is the default value of PFC deadlock detection timer granularity.
- Configure the restore time to 10 x 100ms when PFC deadlock occurs, where 100ms is the default value of PFC deadlock restore timer granularity.

```
admin@PICOS# set class-of-service interface te-1/1/1 pfc-watchdog code-point 5 enable true
admin@PICOS# set class-of-service pfc-watchdog code-point 5 detect-interval 10
admin@PICOS# set class-of-service pfc-watchdog code-point 5 restore-interval 10
admin@PICOS# commit
```

After the configuration, use command **run show pfc-watchdog config** to view the configuration information about PFC watchdog.

```
admin@PICOS# run show pfc-watchdog config
      PORT         ACTION          QUEUE    DETECTION TIME    RESTORATION TIME
----------    -----------   ------------  ----------------  ------------------
te-1/1/1          forward            5              1000                1000
```

Use command **run show pfc-watchdog stats** to view the statistics information about PFC watchdog, including the number of PFC pause storms that have been detected and restored, as well as the number of packets that have been dropped, on the PFC queues on an interface.

```
admin@PICOS# run show pfc-watchdog stats
       QUEUE       STATUS    STORM DETECTED/RESTORED        TX OK/DROP    TX LAST OK/DROP
------------  -----------  -------------------------  ----------------  -----------------
te-1/1/1:5       stormed                      9/8      82072626556/0      32053822365/0
```

Step 4 Configure ECN.

Users have to continuously monitor network performance and ECN marking rates. Make dynamic adjustments to the ECN thresholds as needed to respond to changing network conditions.

The following commands complete the configurations:

- Enable WRED on queue 0 of interface te-1/1/1;
- Set the maximum threshold to 400 and the minimum threshold to 200 on queue 0 of interface te-1/1/1;
- Set the drop probability to 50% on queue 0 of interface te-1/1/1;
- Enable ECN (Explicit Congestion Notification) on queue 0 of interface te-1/1/1.

```
admin@PICOS# set interface gigabit-ethernet te-1/1/3 wred queue 0 enable true
admin@PICOS# set interface gigabit-ethernet te-1/1/3 wred queue 0 max_thresh 400
admin@PICOS# set interface gigabit-ethernet te-1/1/3 wred queue 0 min_thresh 200
admin@PICOS# set interface gigabit-ethernet te-1/1/3 wred queue 0 drop_probability 50
admin@PICOS# set interface gigabit-ethernet te-1/1/3 wred queue 0 ecn_thresh 1
admin@PICOS# commit
```

Show the WRED information of the specified interface.

```
admin@PICOS# run show interface gigabit-ethernet te-1/1/1 wred
Queue Num    Min Thresh   Max Thresh   Drop Probability    ECN Thresh      Status
----------   ----------   ----------   ----------------    -----------     ----------
0              200            400            50%             Enabled        Enabled
1              0              0              0%              Disabled       Disabled
2              0              0              0%              Disabled       Disabled
3              0              0              0%              Disabled       Disabled
4              0              0              0%              Disabled       Disabled
5              0              0              0%              Disabled       Disabled
6              0              0              0%              Disabled       Disabled
7              0              0              0%              Disabled       Disabled
```

Step 5 Enable normal mode of Dynamic Load Balancing for ECMP.

By enabling dynamic load balancing, the traffic of Equal-Cost Multi-Path (ECMP) routing can be distributed across different member links through dynamic load balancing, maximizing load balancing among the member links.

```
admin@PICOS# set interface ecmp hash-mapping dlb-normal
admin@PICOS# commit
```

OpenFlow in Crossflow Mode

- Crossflow Mode Introduction
- CrossFlow Mode Known Limitations
- Crossflow Basic Configuration
- Configuration Example1 in Crossflow Mode
- Configuration Example2 in Crossflow Mode
- Example for Configuring STM Resource Allocation
- Multi-action in crossflow mode

Crossflow Mode Introduction

This chapter describes the details of OpenFlow via CrossFlow mode. CrossFlow mode allows traditional L2/L3 and OpenFlow protocols to run simultaneously on the same physical switch.

Warning:
On FS S5810 Series and S5860 Series switches, run "save_config" command when set Crossflow commands. Otherwise, the Crossflow configuration will be lost after PicOS reboot. For detail, please refer to Configuration Saving Guide.

CrossFlow mode has been greatly improved starting in PicOS 2.6.2. Now, most of the OVS mode commands are available in CrossFlow mode.

OVS features that are available in the CrossFlow mode:

- controller (test ok)
- egress-mode (test ok)
- combinated-mode (test ok)
- multi-table (test ok)
- max-ecmp-ports (test ok)
- loopback-enable (test ok)
- flow-counter-mode (test ok)
- GRE (test ok)
- meter (test ok)
- group (test ok)
- Q-in-Q (test ok)
- udf-mode(test ok)
- manager(test ok)
- mpls flow entries(test ok)

OVS features that need to be configured in Xorplus mode:

- qos (test ok)
- qe-port-mode (test ok)
- lag-advance-hash-mapping-fields (test ok)
- LACP (test ok)

The OVS features which are unavailable in CrossFlow mode:

- proxy-arp
- proxy-icmpv6
- pbb flow entries
- VxLAN
- L2MPLS
- L2GRE
- match-mode

Configuration Notes:

- Only Openflow ports can be added to an Openflow lag as members, and only Crossflow ports can be added to a Crossflow lag as members. All lag's members are configured in Switching CLI.
- All LACP packets are handled by Switching.
- Besides LACP, all other protocol packets received from Openflow ports will be sent to OVS. For the packets received from Crossflow ports, user can configure either Switching or OVS to handle the packets. By default, these packets are handled by Switching.
- All port speed, mtu, VLAN members, and other information is configured in Switching CLI as usual, and these configurations in OVS CLI will not take effect.
- When add flow with matching mpls,mpls_label cannot be configured as 0-15.

The Switch Hardware Architecture page describes the meaning of some terms used here, such as TCAM or FIB.

CrossFlow Mode Introduction

In CrossFlow mode, switches can achieve most of the functions that exist in OVS mode, including: basic flow function, meter, group, multi-table, Q-in Q and so on.

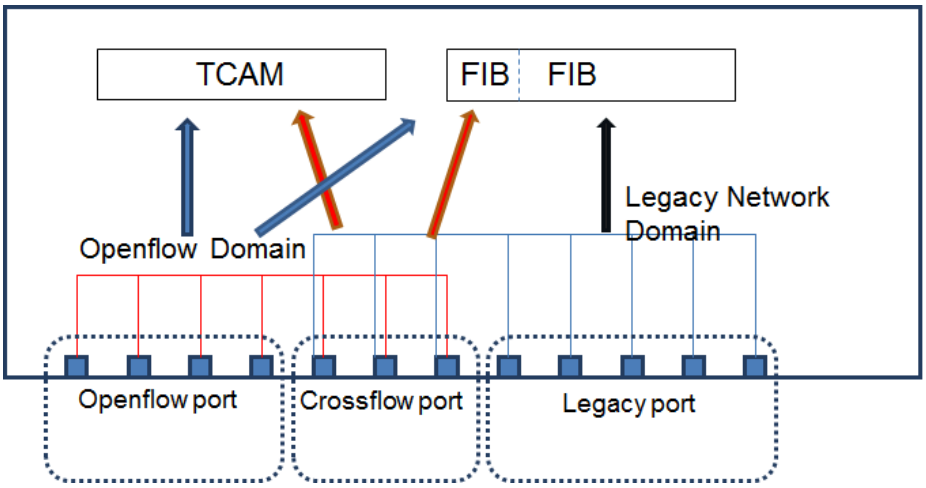
- Like in PicOS OVS mode, in CrossFlow mode, OpenFlow 1.0, OpenFlow 1.1, OpenFlow 1.2, OpenFlow 1.3, and OpenFlow 1.4 are supported. User can configure any supported version in the CLI.
- After PicOS 2.6.2, ports in the switch can be configured in any one of these three modes: Legacy, Crossflow or Openflow. The difference in configuration is:

  Legacy port: disable crossflow

  Crossflow port: enable crossflow and enable local-control

  Openflow port: enable crossflow and disable local-control

- After PicOS 2.4, Openflow can also support the multiple-table control, which means that Openflow can configure some flows in FIB (mac address table and routing table). The flow should match some conditions to install them in FIB. Please refer to the manual in the PicOS Openflow Configuration documentation.



As the figure above shows, the switch ports working status in Crossflow mode is shown. The Openflow flow can look up two tables including TCAM and FIB (multiple tables). The ports in Crossflow mode can be summarized as follows:

Enable Crossflow mode and local-control disable (Openflow port):

1. The port is completely controlled by Openflow
2. All broadcast turned off and auto learning turned off
3. Packet forwarded by looking up the TCAM table default
4. Packet forwarded by looking up the FIB once enable multi-table and configure L2/L3 flow table

Enable Crossflow mode and local-control enable (Crossflow port):

1. The port is controlled by both local legacy stack and Openflow.
2. All broadcast is turned on and auto learning is turned on
3. Packet is forwarded by looking up the FIB (FDB/routing table) and TCAM table
4. No matter if multi-table is enabled or not, packets all can forward by looking up the FIB

Disable Crossflow mode (Legacy port):

1. The port is controlled by local legacy stacks.
2. All broadcast is turned on and auto learning is turned on.
3. Packet is forwarded by looking up the FIB (FDB/routing table).

In Crossflow mode, user can enable L2/L3 mode as a PicOS OVS multi-table function. If the L2/L3 mode is enabled, the FIB table resource will be shared by legacy ports and Crossflow ports, and data traffic cannot mix between the different type ports. User can allocate the resource for special ports as the following command shows.

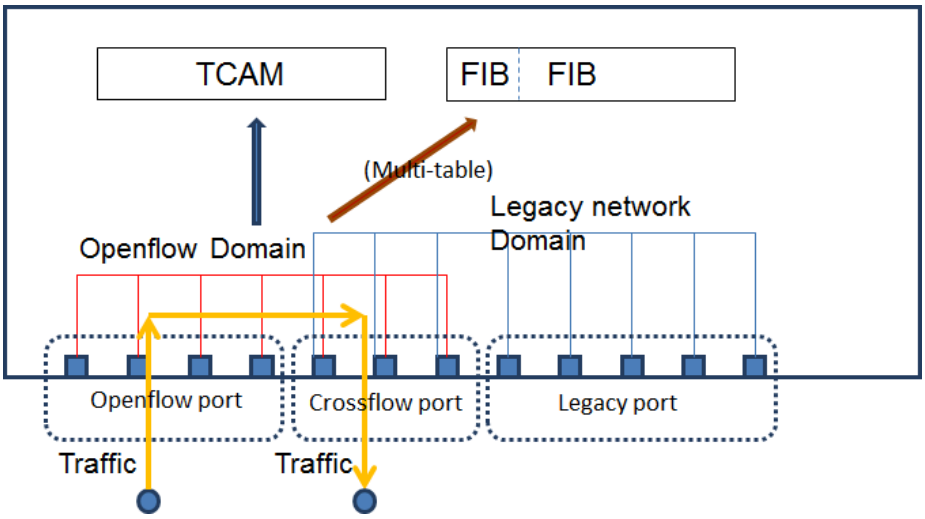
```
set interface stm firewall-table ingress 100
set interface stm mac-table 20000
set interface stm ipv4-route 6000
set interface stm ipv6-route 1000
```

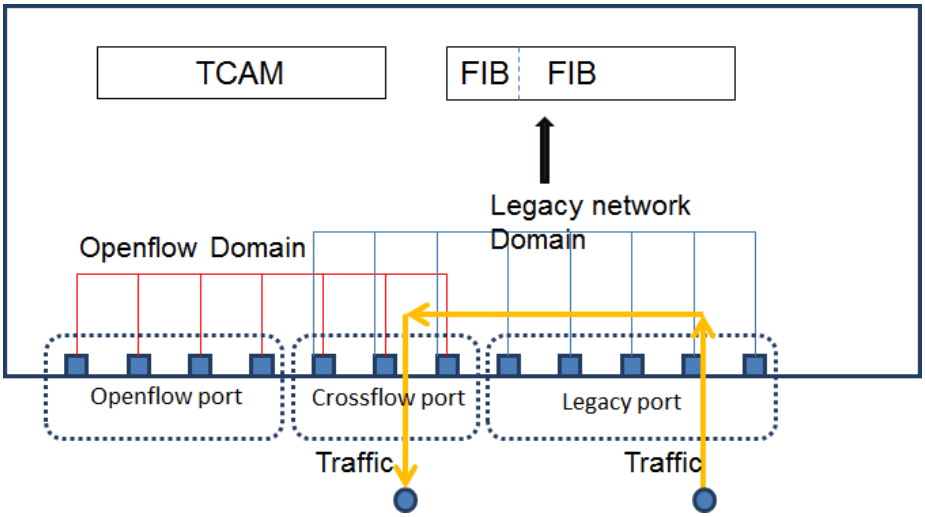
The first command, **set interface stm firewall-table ingress 100**, means allocate the TCAM resource for ingress ACL rule, and part of the rest of resource for Crossflow port and Openflow port;

The second command, **set interface stm mac-table 20000**, means allocate the FDB table resource for legacy port, and the rest of resource for Crossflow port and Openflow port.

The last two commands, **set interface stm ipv4-route 6000,** and **set interface stm ipv6-route 1000**, means allocate the route table resource for legacy port, and the rest of resources for Crossflow port and Openflow port.

In Crossflow mode, traffic can only be forwarded in the OpenFlow or Legacy network domain (as shown in the following figures). The traffic between Openflow port and Crossflow port forwarded by Tcam flow table default, if user wants to forward by FIB, enable multi-table and configure L2/L3 flow entries. The traffic between Crossflow port and Legacy port is forwarded by FIB.





Install a flow with action "NORMAL":

1. By default, the traffic output port will be replaced by the TCAM flow's action after packets are switched and routed. e.g. A packet matches a route and decides the output port (ge-1/1/10) by a route, then it also matches a TCAM flow which has the output port ge-1/1/12, Then, the packet will be forwarded to ge-1/1/12 because the TCAM flow action will replace the original route output port.
2. When a flow in TCAM has an action "NORMAL", the packet which has decided the output port after route table, will still be forwarded to route output port. "NORMAL" means there is no change to the packet output port.
3. When a route packet will not match any flows in TCAM, the output port also will not be changed.

CrossFlow Mode Known Limitations

Conflict Management between OpenFlow and CLI Configurations

The physical configurations of the FDB table and routing table of Openflow should not conflict with the CLI configurations. This means that Openflow can install a flow in the routing table at the same time that legacy network installs a flow in routing table without conflicts. If these configurations conflict, the later configuration will fail.

set firewall filter description and OpenFlow TCAM Flows may conflict. For instance, the OpenFlow rule could be dropping a specific type of packet when the Firewall filters are forwarding them. In this case, both rules are performed concurrently and independently, and the results of the matches are merged. When there are no conflicting results, all results are applied. When there are overlapping and conflicting results, the conflicted parts of the result are selected based on priorities. DROP action has the highest priority, followed by REDIRECT, REPLACE, and TCAM slice number. (OpenFlow rules and Firewall rules are places in different TCAM Slices.)

In CrossFlow mode, the ACL filter has a higher priority than that of Openflow flow entry.

Because arp works in different group with ip,so if there is one or more openflow ports, the arp packets will be dropped because drop actions has the highest priority.And you can add a flow like this:ovs-ofctl add-flow br0 priority=1,actions=normal

Default Drop In OpenFlow

There is a default drop flow in the system when user enables Crossflow mode, and this drop flow only applies to the Openflow ports.

Other Limitations

From PicOS-2.6, some ports can work within both the legacy network domain and the Openflow domain. We call these ports Crossflow ports.

If user enables multi-table and configures L2/L3 flow entry on the Openflow port, traffic from the legacy port can also match the L2/L3 flow entry and be forward on the Openflow port.

If packets can match TCAM flow entry and route table at the same time, the TCAM flow entry has the higher priority. Because the packets must go through FIB table, if there is no mod-src-mac in the TCAM flow entry, the packets will be modified by the src-mac in FIB table then go out as a TCAM flow entry.

If a packet needs match to a Crossflow port, it must have in_port in match field when adding flow.

Crossflow Basic Configuration

OpenFlow is supported in PicOS, and user can configure PicOS switches with both legacy network protocol and Openflow, which will provide extreme flexibility in network deployment.

Configure ovsdb-server Locally

Check the ovsdb-server state on the switch. By default, the ovsdb-server listens to the local switch, and the ovs-vswitchd can only be configured by the local switch.

```
admin@XorPlus$ps aux|grep ovs
root      5174  0.5  0.7  46716  3900 ?        S<l  01:41   0:07 /xorplus/bin/system/tools/xorplus_monitor -c 80 -r
root      5205  0.0  0.1   6288   624 ?        Ss   01:42   0:00 ovsdb-server: monitoring pid 5206 (healthy)
root      5206  0.0  0.4   6432  2124 ?        S    01:42   0:00 /ovs/sbin/ovsdb-server --pidfile --log-file --deta
root      5208  0.0  1.0  49580  5388 ?        Sl   01:42   0:00 /ovs/sbin/ovs-vswitchd --enable-shared-lcmgr
admin     5219  0.0  0.1   2128   684 ttyS0    S+   02:01   0:00 grep --color=auto ovs
```

Configure ovs-vswitchd Locally

```
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
admin@XorPlus$ovs-vsctl add-port br0 ge-1/1/21 -- set interface ge-1/1/21 type=pica8
admin@XorPlus$ovs-vsctl set-controller br0 tcp:10.10.51.59:6633
```

Configure ovsdb-server Remotely

Modify the ovsdb-server state on the switch. Configure the ovsdb-server listening switch management-ethernet interface IP 10.10.51.138 and PORT 6640.

```
admin@XorPlus$ps aux|grep ovs
root      5174  0.6  0.7  46716  3900 ?        S<l  01:41   0:10 /xorplus/bin/system/tools/xorplus_monitor -c 80 -r
root      5205  0.0  0.1   6288   624 ?        Ss   01:42   0:00 ovsdb-server: monitoring pid 5206 (healthy)
root      5206  0.0  0.4   6432  2136 ?        S    01:42   0:00 /ovs/sbin/ovsdb-server --pidfile --log-file --deta
root      5208  0.3  1.2  75456  6520 ?        Sl   01:42   0:05 /ovs/sbin/ovs-vswitchd --enable-shared-lcmgr
admin     5262  0.0  0.1   2128   684 ttyS0    S+   02:09   0:00 grep --color=auto ovs
admin@XorPlus$
admin@XorPlus$sudo kill -9 5206
admin@XorPlus$
admin@XorPlus$sudo /ovs/sbin/ovsdb-server --pidfile --log-file --detach --monit
or --remote=ptcp:6640:10.10.51.144 --remote=punix:/ovs/var/run/openvswitch/db.s

admin@XorPlus$
admin@XorPlus$ps aux|grep ovs
root      5174  0.5  0.7  46716  3900 ?        S<l  01:41   0:12 /xorplus/bin/system/tools/xorplus_monitor -c 80 -r
root      5208  0.2  1.2  75456  6520 ?        Sl   01:42   0:05 /ovs/sbin/ovs-vswitchd --enable-shared-lcmgr
root      5267  0.0  0.1   6288   628 ?        Ss   02:15   0:00 ovsdb-server: monitoring pid 5268 (healthy)
root      5268  0.5  0.4   6432  2124 ?        S    02:15   0:00 /ovs/sbin/ovsdb-server --pidfile --log-file --deta
admin     5270  0.0  0.1   2128   684 ttyS0    S+   02:15   0:00 grep --color=auto ovs
admin@XorPlus$
```

Configure ovs-vswitchd by Remote Server 10.10.50.42

```
root@dev-42:~# ovs-vsctl --db=tcp:10.10.51.144:6640 add-br br0 -- set bridge br0 datapath_type=pica8
root@dev-42:~# ovs-vsctl --db=tcp:10.10.51.144:6640 add-port br0 ge-1/1/21 -- set interface ge-1/1/21 type=pica8
root@dev-42:~# ovs-vsctl --db=tcp:10.10.51.144:6640 set-controller br0 tcp:10.10.51.59:6633
```

Configuration Example1 in Crossflow Mode

Configure the OpenFlow Port in CrossFlow Mode

Commands:

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 crossflow local-control false
admin@XorPlus# set vlans vlan-id 2,2000,4094
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 2000
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 family ethernet-switching vlan members 4094
admin@XorPlus# commit
```

Commands in Linux:

```
admin@XorPlus$ovs-vsctl list pica8
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
admin@XorPlus$ovs-vsctl add-port br0 ge-1/1/1 -- set Interface ge-1/1/1 type=pica8
```

Configure the Hybrid Port in CrossFlow Mode

Commands:

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 crossflow enable true
admin@XorPlus# set vlans vlan-id 2,2000,4094
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 2
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 2000
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 family ethernet-switching vlan members 4094
admin@XorPlus# commit
```

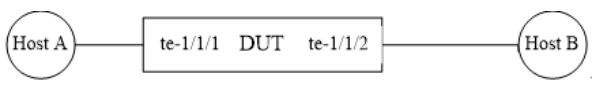
Commands in Linux:

```
admin@XorPlus$ovs-vsctl list pica8
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
admin@XorPlus$ovs-vsctl add-port br0 ge-1/1/2 -- set Interface ge-1/1/2 type=crossflow
```

Examples

Basic Configurations

topology



Step 1: Configure port te-1/1/1 as OpenFlow port and te-1/1/2 as CrossFlow port

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow enable true
```

```
admin@XorPlus# set vlans vlan-id 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 2,10,20
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 speed 1000
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 speed 1000
admin@XorPlus# commit
```

Step 2: Exit the Xorplus system, then enter Linux system

```
admin@XorPlus#exit
admin@XorPlus>exit
admin@XorPlus$
```

Step 3: Create a new bridge named br0

```
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
```

Step 4: Add ports to br0

```
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/1 -- set Interface te-1/1/1 type=pica8
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/2 -- set Interface te-1/1/2 type=crossflow
```

Step 5: Add a flow

```
admin@XorPlus$ovs-ofctl  add-flow br0 in_port=1,actions=output:2
```

Step 6: Send packets to te-1/1/1

Send untagged packets to te-1/1/1 that match this flow. Then, te-1/1/2 will forward the packets (with no vlan). Send packets with vlan 2 to te-1/1/1. Then, te-1/1/2 will forward the packets (with vlan 2).

Lag Configurations

Step 1: Set lag interface (Only Openflow ports can be added to an openflow lag as members, and only Crossflow ports can be added to a Crossflow lag as members.)

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow enable true
admin@XorPlus# commit
admin@XorPlus#set interface aggregate-ethernet ae1 crossflow enable true
admin@XorPlus#set interface aggregate-ethernet ae1 crossflow local-control false
admin@XorPlus#set interface aggregate-ethernet ae2 crossflow enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 speed 1000
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 speed 1000
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 ether-options 802.3ad ae1
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 ether-options 802.3ad ae2
admin@XorPlus# commit
admin@XorPlus#set vlans vlan-id 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface aggregate-ethernet ae1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface aggregate-ethernet ae1 family ethernet-switching vlan members 2,10,20
admin@XorPlus# set interface aggregate-ethernet ae2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface aggregate-ethernet ae2 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
```

Step 2: Exit the Xorplus system, then enter Linux system

```
admin@XorPlus#exit
admin@XorPlus>exit
```

```
admin@XorPlus$
```

Step 3: Create a new bridge named br0.

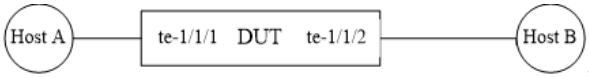
```
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
```

Step 4: Add ports to br0.

```
admin@XorPlus$ovs-vsctl add-port br0 ae1 -- set Interface ae1 type=pica8_lag
admin@XorPlus$ovs-vsctl add-port br0 ae2 -- set Interface ae2 type=pica8_lag
```

Flow Priority Configurations

topology



Step 1: Configure two ports as Openflow ports

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow local-control false
admin@XorPlus# set vlans vlan-id 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
```

Step 2: Exit the Xorplus system, then enter Linux system

```
admin@XorPlus#exit
admin@XorPlus>exit
admin@XorPlus$
```

Step 3: Create a new bridge named br0.

```
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
```

Step 4: Add ports to br0.

```
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/1 -- set Interface te-1/1/1 type=pica8
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/2 -- set Interface te-1/1/2 type=pica8
```

Step 5: Add two flows

```
admin@XorPlus$ovs-ofctl  add-flow br0 in_port=1,dl_src=22:11:11:11:11:11,actions=output:2
admin@XorPlus$ovs-ofctl  add-flow br0 in_port=1,priority=50000,dl_src=22:11:11:11:11:11,actions=mod_dl_src:22:22:2
```

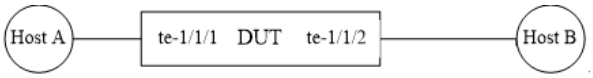
Step 6: Send packets to te-1/1/1

Send untagged packets to te-1/1/1 that match this flow, then te-1/1/2 will forward the packets (with no vlan), and the packets' source mac address is modified to 22:22:22:22:22:22, because the priority of the second flow is higher than that of the first flow.

Send packets with vlan 2 to te-1/1/1, then te-1/1/2 will forward the packets with vlan 2 and the packets' source mac address is modified to 22:22:22:22:22:22.

FDB Configurations

topology



Step 1: Configure two ports as Openflow ports

Step 2: Exit the Xorplus system, then enter Linux system

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow local-control false
admin@XorPlus#set vlans vlan-id 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
admin@XorPlus#exit
admin@XorPlus>exit
admin@XorPlus$
```

Step 3: Create a new bridge named br0.

```
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
```

Step 4: Add ports to br0.

```
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/1 -- set Interface te-1/1/1 type=pica8
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/2 -- set Interface te-1/1/2 type=pica8
```

Step 5: Set table 1 to FDB table

```
admin@XorPlus$ovs-vsctl set-l2-mode true 1
```

Step 6: Add a flow

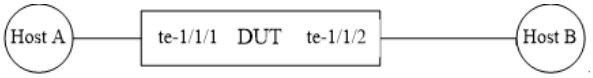
```
admin@XorPlus$ovs-ofctl  add-flow br0 table=1,dl_dst=22:22:22:22:22:22,dl_vlan=10,actions=output:2
```

Flows must match dl_dst,dl_vlan and output port if they want to be stored in FDB table. Table number of FDB table is 251 by default. User can specify another table as the FDB table instead of the 251 by using this command: ***ovs-vsctl set-l2-mode true [table number].***

If you want flows to be stored in ROUTE table, flows must match dl_dst,dl_vlan,dl_type,nw_dst, and mod_dl_dst in action, and the default table number of ROUTE is 252. Use command ***ovs-vsctl set-l3-mode true [table number]*** to set route table.

Route Configurations

topology



Step 1: Configure two ports as Openflow ports

Step 2: Exit the Xorplus system, then enter Linux system

```
admin@XorPlus# set xovs enable true
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 crossflow local-control false
admin@XorPlus#set vlans vlan-id 2,10,20
admin@XorPlus# commit
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
```

```
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching port-mode trunk
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching vlan members 2,10,20
admin@XorPlus# commit
admin@XorPlus#exit
admin@XorPlus>exit
admin@XorPlus$
```

Step 3: Create a new bridge named br0.

```
admin@XorPlus$ovs-vsctl add-br br0 -- set bridge br0 datapath_type=pica8
```

Step 4: Add ports to br0.

```
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/1 -- set Interface te-1/1/1 type=pica8
admin@XorPlus$ovs-vsctl add-port br0 te-1/1/2 -- set Interface te-1/1/2 type=pica8
```

Step 5: enable L3-mode and the default table is 252

```
admin@XorPlus$ovs-vsctl set-l3-mode true
```

Step 6: Add a route flow

```
admin@XorPlus$ovs-ofctl add-flow br0 table=252,dl_vlan=1,dl_dst=22:00:00:00:00:00,ip,nw_dst=1.1.1.100/24,actions=se
```

Configuration Example2 in Crossflow Mode

In the following topology, we build a server network in a datacenter. The following requirements should be met:
● Servers should not be able to communicate with each other, which means traffic from a server can only be forwarded in the upstream direction.
●The network should be scalable, and the configuration of the switch should be simple (e.g., isolating the traffic between servers by ACLs or VLANs is too complex of a configuration). You can configure a ToR switch manually or by a controller—it's up to you.

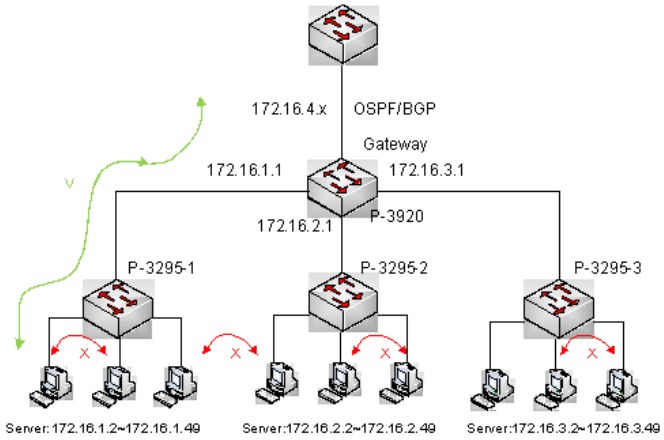


Figure 8-5. Crossflow network.

Configuring theP3295-1 switch

For P3295-1, configure ports ge-1/1/1~ge-1/1/48 in crossflow mode. Create 48 flows that will make traffic from the servers be forwarded only upstream, and be sure to configure flows that will forward the downstream traffic to the corresponding server.

```
admin@XorPlus# set interface stm firewall-table ingress  400
admin@XorPlus# set interface stm ipv4-route 6000
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.
Save done.
admin@XorPlus#
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet ge-1/1/1 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet ge-1/1/2 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet ge-1/1/3 crossflow local-control false
admin@XorPlus# set interface gigabit-ethernet te-1/1/49 crossflow enable true
admin@XorPlus# set interface gigabit-ethernet te-1/1/49 crossflow local-control false
admin@XorPlus# commit
Waiting for merging configuration.
Commit OK.

admin@XorPlus#
```

Create br0 and add ports to bridge.

```
ovs-vsctl add-br br0
ovs-vsctl add-port br0 ge-1/1/1
ovs-vsctl add-port br0 ge-1/1/2
ovs-vsctl add-port br0 ge-1/1/3
ovs-vsctl add-port br0 te-1/1/49
```

Add flows.

```
ovs-ofctl add-flow br0 in_port=1,actions=49
```

```
ovs-ofctl add-flow br0 in_port=49,nw_dst=172.16.1.2/32,actions=1
ovs-ofctl add-flow br0 in_port=2,actions=49
ovs-ofctl add-flow br0 in_port=49,nw_dst=172.16.1.3/32,actions=2
ovs-ofctl add-flow br0 in_port=3,actions=49
ovs-ofctl add-flow br0 in_port=49,nw_dst=172.16.1.4/32,actions=3
```

Configuring P3295-2 and P3295-3 switches

You can configure P3295-2 and P3295-3 using the instructions for configuring P3295-1.

Configuring the P3920 switch

For P3920, configure ports te-1/1/1~te-1/1/48 as a Layer 3 interfaces and enable the OSPF interface in xe-1/1/1. The interface xe-1/1/1 will join the OSPF network to the outside.

```
admin@XorPlus# set vlans vlan-id 100 l3-interface vlan100
admin@XorPlus# set vlans vlan-id 200 l3-interface vlan200
admin@XorPlus# set vlans vlan-id 300 l3-interface vlan300
admin@XorPlus# set vlans vlan-id 400 l3-interface vlan400
admin@XorPlus# set interface gigabit-ethernet te-1/1/1 family ethernet-switching native-vlan-id 100
admin@XorPlus# set interface gigabit-ethernet te-1/1/2 family ethernet-switching native-vlan-id 200
admin@XorPlus# set interface gigabit-ethernet te-1/1/3 family ethernet-switching native-vlan-id 300
admin@XorPlus# set interface gigabit-ethernet xe-1/1/1 family ethernet-switching native-vlan-id 400
admin@XorPlus# commit
Commit OK.

```

Be sure to configure the OSPF interface to work with the OSPF Layer 3 network.

```
admin@Xorplus# set protocols ospf interface vlan400 area 0.0.0.0
admin@XorPlus# set protocols ospf router-id 1.1.1.1
admin@XorPlus# set protocols ospf redistribute connected
admin@XorPlus# commit
Commit OK.
Save done.
admin@XorPlus#
```

Create br0 and add ports to br0

```
ovs-vsctl add-br br0
ovs-vsctl add-port br0 te-1/1/1 - set interface te-1/1/1 type=crossflow
ovs-vsctl add-port br0 te-1/1/2 - set interface te-1/1/2 type=crossflow
ovs-vsctl add-port br0 te-1/1/3 - set interface te-1/1/1 type=crossflow
ovs-vsctl add-port br0 xe-1/1/1 - set interface xe-1/1/1 type=crossflow
```

Add flows.

```
ovs-ofctl add-flow br0 in_port=1,actions=set_field:22:22:22:22:22:22-\>dl_dst,49
ovs-ofctl add-flow br0 in_port=2,actions=set_field:22:22:22:22:22:22-\>dl_dst,49
```

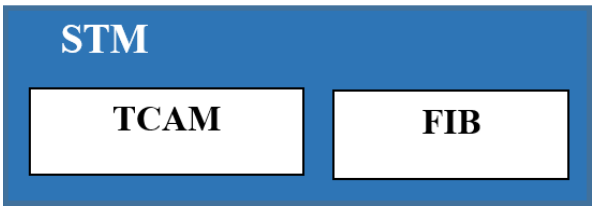
```
ovs-ofctl add-flow br0 in_port=3,actions=set_field:22:22:22:22:22:22-\>dl_dst,49
```

Example for Configuring STM Resource Allocation

Shared Table Memory (STM), is a feature designed to allow sharing a common resource across several table memories. This provides a large number of shared resources that can be allocated depending on the intended user application. It allows allocating resources to tables as needed instead of in fixed proportions, enabling large tables to receive more resources.

As shown in Figure 1, STM resource space includes two parts: TCAM and FIB. TCAM and FIB resources were separate entities of fixed size. If a given system application did not utilize one of these resources, then the entries remained unused and could not be reclaimed for other purpose. This document describes an example of how to configure TCAM and FIB resource allocation.

Figure 1. Shared Table Memory



TCAM

The TCAM resource is used to configure ACL entries and OpenFlow entries which contain the following parts:

- User defined firewall tables including ingress and egress tables, which occupy the TCAM resource.
- Resources reserved for the ACL entries for the Control Plane Policing (CoPP) and MAC Authentication Bypass (MAB).
- OpenFlow flow table resources.

You can use the CLI command to configure the maximum number of entries in the user-defined firewall tables that are allocated in TCAM. The remaining TCAM system resources are used for OpenFlow flow tables and the system reserved TCAM resource for ACL entries of COPP. In the result of this is that after the resources reserved by the system for the COPP and MAB are exhausted, it will go onto to allocate more memory resource from the free OpenFlow resources. But the space allocated through CLI for the user-defined firewall tables remains unaffected even if there is free space in it in case space runs out for CoPP and MAB or the OpenFlow tables.

NOTE :

CoPP firewall table occupies the egress firewall table resource.

In CrossFlow mode, by default, the system allocates all TCAM resources to the L2/L3 firewall tables except the resources reserved for COPP and the MAB. Take AS5812_54T switch (ASIC is Trident2+) as an example.

```
admin@Xorplus# set interface stm firewall-table egress
Possible completions:
  [0..512]                       Max Egress ACL Counter
admin@Xorplus# set interface stm firewall-table ingress
Possible completions:
  [0..768]                       Max Ingress ACL Counter
```

We can see that the total number of TCAM resource is 512+768=1280 entries (which do not include the resources reserved for CoPP and MAB), are all allocated to L2/L3 firewall tables by default. In this case, there is no resource left to configure OpenFlow flow tables. If you want to configure OpenFlow flow tables, you need to modify the number of resources allocated to the firewall tables. For example, we can commit the following configurations:

```
admin@Xorplus# set interface stm firewall-table ingress 100
admin@Xorplus# set interface stm firewall-table egress 300
admin@Xorplus# commit
```

The above configurations have allocated up to 100 ingress ACL entries and 300 egress ACL entries in TCAM. The remaining system resources in TCAM are 1280-100-300=880, which is the maximum resource that can be used for OpenFlow flow entries.

FIB Table Resources

The L2/L3 entry tables are allocated in the FIB of the dedicated memory space in STM. The MAC table occupies the FDB resource; the IPv4 route table and IPv6 route table occupy the routing table resource. The STM share mode, can be set by using **set interface stm share-mode** command. It determines the fixed resource size for these L2/L3 entry tables in the FIB.

Taking the Trident2+ switch as an example, we can see that under different share modes, the dedicated resource allocation of each L2/host-route/route entries in the STM is different.

```
admin@Xorplus# set interface stm share-mode
Possible completions:
  0                              l2-size 294912, host-route 12000, route 12000
  1                              l2-size 229376, host-route 44800, route 12000
  2                              l2-size 163840, host-route 70400, route 12000
  3                              l2-size 98304,  host-route 96000, route 12000
  4                              l2-size 32768,  host-route 12000, route 115200
```

```
  5                              l2-size 32768,  host-route 12000, route 12000
```

In CrossFlow mode, user can enable L2/L3 mode as a PICOS OVS multi-table function. If the L2/L3 mode is enabled, the FIB table resource will be shared by legacy ports and CrossFlow ports (see description in Crossflow Mode Introduction), in a way that will prevent mixing of data traffic between the different types of ports.

User can allocate the FIB resource for special ports as the following command shows.

```
admin@Xorplus# set interface stm share-mode 3
admin@Xorplus# set interface stm mac-table 20000
admin@Xorplus# set interface stm ipv4-route 6000
admin@Xorplus# set interface stm ipv6-route 1000
admin@Xorplus# commit
```

The second command, **set interface stm mac-table 20000**, allocates the FDB table resource for legacy ports, and the rest of the resource for CrossFlow ports and OpenFlow ports.

The last two commands, **set interface stm ipv4-route 6000**, and **set interface stm ipv6-route 1000**, allocates the route table resource for legacy ports, and the rest of resources for CrossFlow ports and OpenFlow ports.

After the configurations are committed, we can use the **run show interface stm** command line to view the STM resource allocation:

```
admin@Xorplus# run show interface stm
Total stm resource:
  Share-mode: 3
  number of host routes: 96000
  number of mac unicast addresses: 20000
  number of firewall ingress tables: 100
  number of firewall egress tables: 300
  number of IPv4 unicast routes: 6000
  number of IPv6 unicast routes: 1000
Stm resource in use:
  number of firewall ingress tables: 0
  number of firewall egress tables: 21
```

The item **number of firewall egress tables** is used for describing STM resources for CoPP. By default, the value of number of firewall egress tables in STM resource in use: is 21 as have been used by the default CoPP configurations.

Multi-action in crossflow mode

From version 4.1.1,pica8 switch support multi-action in crossflow mode. Before supporting this ,there is a issue. When the host forward the packet to others, first packet is forwarded to SDN Controller. This is caused “ONE” packet loss every time when the host forward the packet, and without OF rule, the SDN Controller can not update the device information (IP/MAC).That is why we want to support when the packet is forwarded to PicOS, the action should be supported both “go to Controller” and “Normal” at the same time

Command

ovs-ofctl add-flow br0 in_port=5,actions=normal,controller

Example

prerequisites

xorplus configurations:

```
admin@Xorplus# show|display set

set interface gigabit-ethernet ge-1/1/5 crossflow enable true

set interface gigabit-ethernet ge-1/1/5 family ethernet-switching port-mode "trunk"

set interface gigabit-ethernet ge-1/1/5 family ethernet-switching vlan members 200

set interface gigabit-ethernet ge-1/1/6 crossflow enable true

set interface gigabit-ethernet ge-1/1/6 family ethernet-switching port-mode "trunk"

set interface gigabit-ethernet ge-1/1/6 family ethernet-switching vlan members 200

set interface gigabit-ethernet ge-1/1/7 crossflow enable true

set interface gigabit-ethernet ge-1/1/7 family ethernet-switching port-mode "trunk"

set interface gigabit-ethernet ge-1/1/7 family ethernet-switching vlan members 200

set protocols spanning-tree enable false

set system log-level "trace"

set vlans vlan-id 200

set xovs enable true

set xovs special-packets-options sequence 123 match destination-mac-address 22:22:22:22:22:22

set xovs special-packets-options sequence 123 match ether-type 2048

set xovs special-packets-options sequence 123 handler "both"
```

ovs configurations:

```
ovs-vsctl set-controller br0 tcp:10.10.51.42:6633

ovs-vsctl add-port br0 ge-1/1/5 -- set interface ge-1/1/5 type=crossflow

ovs-vsctl add-port br0 ge-1/1/6 -- set interface ge-1/1/6 type=crossflow

ovs-vsctl add-port br0 ge-1/1/7 -- set interface ge-1/1/7 type=crossflow
```

start controller

ryu-manager ….py

add flow with normal and controller

step1,configurations are the same with prerequisites

step2,add flow

ovs-ofctl add-flow br0 in_port=5,actions=normal,controller

step3:send packets

send ip packets with dst mac 22:22:22:22:22:22,type is 0x0800,vlan is 200,src ip 1.1.1.200,dst ip is 5.5.5.200 to ge-1/1/5.

Result:ge-1/1/6 and ge-1/1/7 will transmit packets.And the packets are sending to cpu(500pps). Packet-in packets' data is the same with the original packets from ge-1/1/5

PICOS Routing and Switching Command Reference

Command-Line Interface Commands

- copy running-config startup-config
- set cli idle-timeout
- set cli screen-length
- set cli terminal
- syslog monitor
- syslog notify
- hwclock
- rollback

System Management Commands

- NAC Configuration Commands
  - set protocols dot1x aaa radius authentication server-ip
  - set protocols dot1x aaa radius authentication server-ip priority
  - set protocols dot1x aaa radius authentication server-ip retry-num
  - set protocols dot1x aaa radius authentication server-ip retry-interval
