WARRANTY ITEMS

Particular parts and/or equipment covered by warranty are specifically stated as such in the warranty or contract given to the customer at the time of sale. The warranty or contract also stipulates the conditions under which the warranty may be exercised.

To obtain a new replacement for such warranty items, contact your local RCA sales office and please supply Product Identification (including the Original Invoice Number, MI Number, Type Number, Model Number, and Serial Number) and Replacement Part Identification (including Stock Number and Description). Requests for warranty replacements may be unduly delayed if all this information is not supplied.

EQUIPMENT LOST OR DAMAGED IN TRANSIT

When delivering the equipment to you, the truck driver or carrier's agent will present a receipt for your signature. Do not sign it until you have (a) inspected the containers for visible signs of damage and (b) counted the containers and compared with the amount shown on the shipping papers. If a shortage or if evidence of damage is noted, insist that notation to that effect be made on the shipping papers before you sign them.

Further, after receiving the equipment, unpack it and inspect thoroughly for concealed damage. If concealed damage is discovered, immediately notify the carrier, confirming the notification in writing, and secure an inspection report. This item should be unpacked and inspected for damage WITHIN 15 DAYS after receipt. Report all shortages and damages to RCA, Communication Systems Division — Camden, New Jersey 08102.

RCA will file all claims for loss and damage on this equipment so long as the inspection report is obtained. Disposition of the damaged item will be furnished by RCA.

FIELD ENGINEERING SERVICE

RCA Field Engineering Service is available at current rates. Requests for field engineering service may be addressed to your RCA Broadcast Field Representative or the RCA Service Company, Incorporated — Broadcast Service Division — Camden, New Jersey 08102. Telephone 609-963-8000.

OPERATING HAZARDS

This equipment is designed to fully safeguard all personnel from operating hazards. Labels and warning notices on the equipment and warning and caution notices in the Instruction Book clearly point out these potential hazards and hazards that necessarily exist.

Before operating this equipment, read the following comments and take the necessary precautions to protect operating personnel. Safe operating practices are the responsibility of the station personnel.

HIGH VOLTAGE

High Voltages are present in this equipment which can cause serious injury or loss of life. High voltage circuits are enclosed to prevent accidental contact by personnel and have interlock switch circuits which open the primaries of power supply transformers and discharge high voltage capacitors whenever access to the equipment is required.

MICROWAVE RADIATION

Exposure of the human body to microwave radiation in excess of 10 mW/cm^2 (See Ref. A) may be unsafe and can result in blindness or other injury. Personnel must be fully protected from the microwave energy which may radiate from tubes or transmission line connections. All input and output R F connections, gaskets, and flanges must be leakproof and properly installed. Unless connected to an antenna, NEVER OPERATE MICROWAVE RADIATING EQUIPMENT WITHOUT A RADIATION ENERGY ABSORBING LOAD ATTACHED. Personnel must be prevented from looking into an open antenna while the equipment is operating.

X-RAYS

X-Ray radiation may be produced by energized VHF and UHF equipment. Personnel must be protected by appropriate shielding. Adequate shielding on all sides of the tubes and equipment is provided as well as on the auxiliary equipment. X-Ray Warning signs or labels are permanently attached to the equipment (where necessary) directing personnel not to operate the equipment without proper X-Ray shielding.

DESCRIPTION

GENERAL

The RCA Model BTR-15B Remote Control System is designed to provide remote control and metering of standard AM and FM broadcast transmitters. The BTR-15B offers a total of 15 metering channels and 15 bi-directional control functions. Metering and control signals may be conveyed between studio and transmitter over a single voice-grade telephone circuit using the RCA Type BTR-15BW, or by radio link using the Type BTR-15BR.

The radio Type BTR-15BR generates a subcarrier which is multiplexed on the station STL link to send control signals to the transmitter. Transmitter metering signals are returned to the studio via a subcarrier multiplexed on the FM broadcast carrier signal, or in the case of AM, by subaudible modulation of the main broadcast carrier. A selection of control signal subcarrier frequencies is available as standard equipment, but any specified frequency of from 26 kHz to 185 kHz can be

supplied on custom order. The standard 26 kHz system is recommended for AM radio and the 110 kHz system is recommended for FM.

In accordance with FCC regulations governing remote control systems, fail-safe provisions are incorporated in the BTR-15B that will operate to take the transmitter off the air in the event of failure of the remote control system or link.

EQUIPMENT

The BTR-15B comprises a studio unit and a transmitter unit. Each requires 5-1/4 inches of vertical 19-inch rack space. Pushbuttons on the studio unit permit selection of the desired control and metering channel. In each position, raise and lower (on or off) commands may be sent while return telemetry signals are simultaneously observed on the front panel meter. A simple strapping operation permits wiring of the signal

Figure 1. Basic BTR-15BW Wireline Remote Control System

to as many as four external meters. Certain of the plug-in circuit modules are used in both the wireline and radio systems.

Wireline AM and FM

The BTR-15BW for wireline operation, shown in the block diagram of figure 1, is the basic remote control system. Major modules of the studio unit are the control signal generator and metering signal demodulator. The transmitter unit contains a metering signal generator module and control demodulator module.

The studio unit sends control tones in the region of 300 to 400 Hz to the transmitter site. At the transmitter, the audible metering generator in the transmitter unit returns metering tones of 800 to 1200 Hz over the telephone line back to the studio unit.

Wireless FM

If the link is by radio rather than by telephone line, the BTR-15BR system for wireless operation is used. The basic BTR-15BR system is applicable to the FM station equipped with SCA facilities at the trans-

Figure 2. Basic BTR-15BR Wireless FM Remote Control System

mitter and an FM/SCA receiver at the studio. This system is shown in the block diagram of figure 2. The studio unit contains a subcarrier generator which is modulated by the control signals in the range of 300 to 400 Hz from the control generator. The output of the subcarrier generator is applied to the subcarrier input of an STL microwave link. The multiplexed subcarrier signal is then detected at the transmitter site by a subcarrier demodulator in the transmitter unit to provide the same control tone which originated at the studio.

Wireless AM

The BTR-15BR system for wireless remote control and metering of an AM broadcast transmitter is shown in the block diagram of figure 3. The studio unit sends

control signals to the transmitter site on a subcarrier of the STL link, as in the FM transmitter system, but the metering tone is returned to the studio on the AM broadcast carrier. The metering signal is in the subaudible 20 to 30 Hz range and is applied directly to the AM carrier through use of the RCA MIU-1 Metering Insertion Unit, MI-561458. Modulation of the AM carrier is set to about 5%, 6% being the maximum allowed by FCC rules.

The return path for the metering signals in this system is also by subcarrier. The subaudible metering generator (20 to 30 Hz) in the transmitter unit frequency modulates subcarrier generator which is a part of the FM transmitter. The metering signal is multiplexed on the FM carrier as an SCA signal which is received and demodulated by an SCA receiver at the studio.

Figure 3. Basic BTR-15BR Wireless AM Remote Control System

When the metering signal is returned to the studio in this manner, it is customary to use the frequency range of 20 to 30 Hz for the metering signal. In this way, program material may also be broadcast on the SCA. The subaudible metering signal is usually adjusted to modulate the SCA subcarrier at about 14 dB below program level. Low pass filtering in the BTR-15BR keeps normal program material above 40 Hz out of the metering circuit.

If the FM station equipment does not include an SCA generator, an accessory 67 kHz (or other optional frequency) special telemetering (frequency response limited) subcarrier generator module can be plugged into the BTR-15B transmitter and studio units to provide the metering function of the transmitter at the studio.

CIRCUITS, STUDIO UNIT

The BTR-15B Remote Control System may be

functionally divided into control circuits and metering circuits. Control signal flow is from the studio unit to the transmitter unit, and metering signal flow is from the transmitter unit to the studio unit.

The modules of the BTR-15B that perform the control and metering functions are described in the following paragraphs with reference to individual block diagrams and schematics.

Control Generator

The control generator module in the studio unit develops a control tone which is frequency shifted by control commands. The unit is shown in the block diagram of figure 4 and the schematic of figure 40.

The control generator idling frequency of the FM oscillator is 300 Hz. Any of four different commands shifts the frequency upward to about 400 Hz. Com-

Figure 4. Control Generator, Block Diagram.

mands are in the form of pulses of different widths. One of these pulses is a channel advance or counting pulse (approximately 0.033 second duration) that determines which metering channel is selected, and enables selection of a specific raise/lower output terminal pair. Two other commands pulses operate the raise (0.066 sec.) and lower relays (0.133 sec.) in the transmitter unit. The longest pulse, (about 0.3 seconds) is a reset pulse. This is a single reset pulse triggered by pushing the front panel RECYCLE button.

The reset pulse returns the channel selecting electronics at the studio and transmitter sites to the start or calibrate positions, and resets the channel-counter at the studio.

To select a specific channel, the channel button is pushed where upon the advance provides a series of pulses which drive the advance counter unit until it develops a binary number which agrees with the number selected by the front panel pushbutton deck. When this occurs the advance generator stops, and the transmitter and studio units will be locked on the same channel.

The raise or lower commands may be applied only

when the system is not resetting or advancing to a new channel.

The remaining digital circuitry on the control generator board separates the commands by appropriate time delays to electronically lock out simultaneous transmission of commands.

There are two adjustments on the module: the FREQUENCY control, R27, sets the idling frequency of the FM oscillator; and the CONTROL TONE AMPLITUDE control, R41, adjusts the level of the control tone to the telephone line. A second output is available for application to a subcarrier generator if a radio link is used.

Subcarrier Generator

The subcarrier generator is used in both the control and transmitter units of the BTR-15BR when metering signals are to be returned by broadcast carrier. However, if the system provides for programming, the operation may use the subcarrier in service with the FM Transmitter. Circuits are shown in the block diagram of figures 5, and in the schematic diagram of figure 41.

Figure 5. Subcarrier Generator, Block Diagram

Modulation, which can be 300 to 400 Hz control tones, or 20 to 30 Hz metering tones, is applied via a deviation adjustment to the modulated oscillator, which is a free running multivibrator with temperature compensation and voltage regulation. Typical frequency deviation is about 5 to 6% of carrier frequency for control purposes, and about 1% (or more) for metering. Output of the modulated oscillator is applied to a buffer amplifier, which can be keyed on or off by a 3.3 volt signal applied to a metering input terminal. This signal, if used, is normally supplied by the control demodulator module. By removing the keyer transistor, the subcarrier will always remain on. The output of the buffer is applied to a low pass filter for removal of the unwanted harmonics of the subcarrier, and amplified for application to an STL at the studio, or to an FM exciter for return of metering signals by broadcast carrier.

There are three controls on the subcarrier generator board: The **DEVIATION** frequency control, R1, permits adjustment of modulation (frequency deviation); the **FREQUENCY** control, R4, permits adjustment of oscillator center frequency; and the **OUTPUT LEVEL** control, R31, sets the output level of the subcarrier generator. If the subcarrier generator board is

not required, a subcarrier generator jumper board must be installed in its place.

Subcarrier Demodulator

The subcarrier demodulator is used in the studio and transmitter units of systems where control signals are sent by an STL link and metering signals are returned by a broadcast carrier. Its purpose is to demodulate an RF subcarrier to extract control or metering signals. Circuits are shown in the block diagram of figure 6 and the schematic of figure 42.

The input to this module is derived either from the multiplex output of an STL receiver, or the composite output of an FM monitor or receiver. The subcarrier signal and its important sidebands are passed by the input bandpass filter, while program material and other unwanted components are rejected. Output of the bandpass filter is applied to a limiter where amplitude variations are removed and the subcarrier signal is turned into a square wave. This signal is then applied to a pulse counting demodulator circuit. The output of the demodulator is applied to a 4000 Hz low pass filter where

Figure 6. Subcarrier Demodulator, Block Diagram

Figure 7. Audible Metering Demodulator, Block Diagram.

the subcarrier and possible high frequency beat notes are rejected. Metering signals in the 20 to 30 Hz range, and control signals in the 300 to 400 Hz range are passed by this filter. Output of the filter is amplified by the linear amplifier, IC1.

Adjustments on this module are the DEMODULATOR TUNING control, R9, and the OUTPUT LEVEL control, R17. Adjustment of the subcarrier bandpass filter, which is tunable, is covered in the TUNING section. If the subcarrier demodulator board is not required, a subcarrier demodulator jumper board must be installed in its place.

Audible Metering Demodulator

The audible metering demodulator is located in the studio unit, and processes the metering tone into a direct current suitable for application to the studio unit meter. Circuits are shown in the block diagram of figure 7 and the schematic of figure 43.

An on-board strapping option allows selection of metering recovery from either the telephone line or a subcarrier demodulator. The selected signal is applied to a bandpass filter which extracts the 800 to 1200 Hz tone and applies it to limiter and level sensing circuits. The latter allows the front panel metering-read lamp to be energized. The limiter drives a pulse-counting demodula-

tor employing a Schmitt trigger and monostable multivibrator. The output of this demodulator is applied to a dc amplifier which is arranged so as to provide considerable control over the meter ballistics. In addition, the input level sensor is connected to a muting system so that the meter comes to rest near zero when the metering tone is of insufficient amplitude.

Adjustment of the ACCELERATION control, R42, and the OVERSHOOT control, R45, are given in the TUNING section. Two more controls, electrically connected but located on the front panel (figure 39, studio unit) are the ZERO SET control, R3, for adjusting meter zero position (tone at 800 Hz), and the CALIBRATE control, R4, for adjusting meter deflection in the calibrate mode (tone at 1000 Hz).

Subaudible Metering Demodulator

The subaudible metering demodulator is located in the BTR-15BR studio unit. This module converts the subaudible metering signal into a direct current suitable for application to the studio meter. Circuits are shown in the block diagram of figure 8 and in the schematic of figure 44.

The signal applied to this board possibly could have program material on it as well as the subaudible

Figure 8. Subaudible Metering Demodulator, Block Diagram.

metering signal. The active low pass filter rejects the program material and passes only the subaudible signal.

This filter significantly outperforms a conventional L-C filter at the frequencies involved (20 to 30 Hz). Following the filter, the signal is amplified for application to a Schmitt trigger which shapes the sinusoidal signal into a square wave as required to trigger a monostable multivibrator. The monostable and associated circuitry form the last stage of the pulse-counting demodulator. The output of this demodulator is applied to a dc amplifier which has a frequency cutoff of about 5 Hz. In this way, the 20 to 30 Hz signal is kept from causing "dither" or quivering of the meter pointer, while still maintaining a reasonable rate of response for the meter movement. The output of the Schmitt trigger is connected to a muting system to cause the meter to come to rest near zero when the metering tone is of insufficient amplitude.

The only adjustment on this board is an INPUT LEVEL control, R1 (figure 39, studio unit). The ZERO SET (R3) and CALIBRATE (R4) controls are on the front panel.

Power Supply

Power input of 120/240 volts 50/60 Hz is applied to the studio unit through an ac line filter and a 1/4 ampere slo-blo fuse. The power supply is normally shipped connected for 120 volt ac input. To verify or to change the power input connections, refer to the schematic diagram, figure 39. Power supply resistors and diodes are mounted on a printed circuit board. Output is

15 Vdc regulated and 5 Vdc regulated. A 17 volt rms sine wave is also supplied to the control generator for sync purposes.

CIRCUITS, TRANSMITTER UNIT

Circuits of the transmitter unit are shown in the schematic of figure 45. This unit of the BTR-15BR employs subcarrier generator and subcarrier demodulator modules which are described under CIRCUITS, STUDIO UNIT.

Control Bandpass Filter

Output from the subcarrier demodulator in the BTR-15B, or the telephone line in the case of the BTR-15BW, is fed to the control bandpass filter. A jumper or resistor is installed on this board, depending upon whether the BTR-15B is a radio or wireline version. Refer to the schematic diagram of figure 46.

Control Demodulator

This module in the transmitter unit receives and processes the 300 Hz frequency modulated control tone originating in the studio unit. Circuits are shown in the block diagram of figure 9 and in the schematic of figure 47.

Control tones are extracted by a bandpass filter followed by an amplifier and limiter which provide a constant-amplitude signal for the FM demodulator. The demodulated pulses are then separated by four pulse-

Figure 9. Control Demodulator, Block Diagram

width detectors into reset pulses, channel advance pulses, and raise or lower relay pulses. The control tone level sensor deenergizes fail safe relay K19, if the control tone should fail. Other circuitry permits local control of the unit by means of the front panel buttons, and to interlock circuits for proper sequencing.

The DEMOD TUNING control R27, sets the operating point of the pulse counter, and the RAMP control R41, allows the various pulses to be correctly separated according to width. For proper adjustment procedures, refer to the TUNING section.

Audible Metering Generator

This module is used in the BTR-15BW transmitter unit to convert the dc metering sample into an audible tone of 800 to 1200 Hz for transmission back to the studio on a telephone line. Circuits are shown in the block diagram of figure 10 and in the schematic diagram of figure 48.

The metering sample is applied to an adjustable gain dc amplifier which shapes the output to audible frequencies and applies them to a voltage-controlled

Figure 10. Audible Metering Generator, Block Diagram

oscillator. This oscillator, with no metering input, idles at a frequency of 800 Hz. This frequency is shifted upward in direct proportion to the amplitude of the applied metering signal. Its upper limit of 1200 Hz, representing full scale deflection of the studio meter, is reached upon application of a one-volt dc sample.

The entire module, including power supply and regulators, floats with no connection to ground. To translate the output of the voltage-controlled oscillator to ground, an optical isolator is used. The output of this device is a square wave which is applied to a low pass filter for conversion to a sine wave. This is applied to an output amplifier to drive the telephone line. An output is also available for application to a subcarrier generator, should a radio return link, such as with the BTR-15BR, be used.

Adjustments on this module include: an idling FREQUENCY control, R11, for tuning the voltage-controlled oscillator; SENSITIVITY control, R4, for adjusting the gain of the dc amplifier for full scale sensitivity; and a LINE LEVEL control, R33, for adjusting the level of the metering signal applied to the telephone line.

Subaudible Metering Generator

This module is located in the transmitter unit of the BTR-15BR system. It converts the dc metering sample into a 20 to 30 Hz signal which may be sent back to the studio unit on a subcarrier or other return link capable of passing 20 Hz. Circuits are shown in the block diagram of figure 11 and in the schematic diagram of figure 49.

Figure 11. Subaudible Metering Generator, Block Diagram.

The metering sample is applied to a dc amplifier which has a roll-off to reduce its response above 30 Hz. Its output is applied to a voltage-controlled oscillator. This oscillator, with no metering input, idles at a frequency of 800 Hz. Frequency is shifted upwards in direct proportion to the amplitude of the applied metering signal. Its upper limit of 1200 Hz, representing full-scale deflection of the studio meter, is reached upon application of a one-volt dc sample.

The entire module, including power supply and regulators, floats electrically with no connection to ground. To translate the output of the voltage-controlled oscillator down to ground, an optical isolator is used. The output of this device is applied to an integrated circuit divider chain for frequency scaling down to the 20 to 30 Hz region. The output of this divider chain is a square wave which is applied to a low pass filter for conversion to a sine wave. This sine wave is applied to an adjustable-gain amplifier which drives either the internal metering return SCA subcarrier generator or an external subcarrier system.

Adjustments on this board include: an idling

FREQUENCY control, R11, for tuning of the voltage-controlled oscillator; SENSITIVITY control, R4, for adjusting the gain of the dc amplifier for full scale sensitivity; and an OUTPUT LEVEL control, R32, for adjusting the level of the metering signal applied to the subcarrier generator.

Power Supply

Power input of 120/240 volts 50/60 Hz is applied to the transmitter unit through an ac line filter and a 1/2 ampere slo-blo fuse. The power supply is normally shipped connected for 120 Vac input. To verify or to change the power input connections, refer to the schematic diagram of figure 45.

The power supply printed circuit board holds most of the power supply resistors and diodes. Output of the power supply is 15 Vdc and 5 Vdc regulated, 22 Vdc, -15 Vdc and a -15 Vdc auxiliary unregulated. Also included is a floating unregulated power supply providing 15 Vdc, -15 Vdc with floating common.

PRE-INSTALLATION CHECK

It is recommended that the front panels be pulled forward for a brief superficial inspection. Be sure the various printed circuit boards are secure, the integrated circuits and transistors are seated in their sockets, and that the fuse-holder caps are installed. The rear door of the transmitter unit should be swung down and the relays and fuses confirmed as being in place.

Check the subcarrier generator frequency deter-

mining parts for installation and correct value, as presented in table 1. See figure 41. Check the subcarrier demodulator frequency determining parts for installation and correct value, as presented in table 2. Refer to figure 42.

One Studio Unit, one Transmitter Unit, and two instruction manuals are shipped with each system as standard items.

INSTALLATION

GENERAL

Appropriate locations should be selected in rack cabinets for the studio and transmitter units of the BTR-15B. Both units should be mounted at heights that are convenient for use and for observation of meter readings. Since the studio unit will receive frequent operator attention during the routine controlling and logging operation, its location at the studio should receive careful attention. Since the transmitter unit may require occasional adjustment of front panel controls, its location is also important. It is suggested that the transmitter unit be located so as to provide easy access for weekly calibration. In each case, rack cabinets should be well bonded to a good ground system.

NOTE: It is highly recommended that no connections be made to the BTR-15B by installing personnel until the basic concepts of system operation are understood. The reader is referred to these concepts as they

are presented in the preceding chapter, under DESCRIPTION, and with particular reference to the system block diagrams of figures 1, 2 and 3.

BTR-15B SYSTEM INTERCONNECTIONS

Installation of studio and transmitter units may proceed as soon as installation personnel are thoroughly familiar with the principles involved in the particular BTR-15B system to be used.

The first stage of installation will involve the studio and transmitter units only; no connections will be made to the transmitting equipment. After the units are installed and operation is confirmed, the remainder of the installation may be accomplished.

The control path to the transmitter site, and the metering path to the studio should be completed.

Figure 12. Telephone Line Interconnections

BTR-15BW Studio-Transmitter Units

In the case of the BTR-15BW, the interconnecting link is simply a telephone line to carry control tones of 300 Hz to 400 Hz produced at the studio unit and metering tones of 800 to 1200 Hz produced at the transmitter unit. Figure 12 illustrates the telephone line connections to the rear of these units. Make these connections. Then with reference to figures 39 and 45, verify the power transformer primary connections in each unit for the power source to be used.

The next step is to check that control signals originating at the studio are received correctly at the transmitter. For this test, make no connections to the control terminals or metering terminals of the transmitter unit (figure 23). The test for return of metering signals is described later.

With power applied to both units, press the RAISE button on the studio unit. This should make the raise relay, K17, pull in. Pressing the LOWER button should make the lower relay, K18, pull in. Pressing a numbered button on the studio unit should energize the correspondingly numbered relay at the transmitter unit.

Should there be a problem at this point, check interconnections between studio and transmitter units to be sure each line is carrying the correct signal. To assist in initial setup, recommended standards are given in

table 3. The first three measurements involving the telephone line are made at the telephone line terminals. Refrain from making internal adjustments unless a reading is definitely unsatisfactory.

BTR-15BR Studio Unit

Figure 13 illustrates subcarrier and radio equipment connections to the studio and transmitter units of the BTR-15BR wireless systems shown in figures 2 and 3. At the rear of the studio unit, the CONTROL OUTPUT jack normally delivers a subcarrier signal which is frequency-modulated by the control tone (300 to 400 Hz). This signal is to be routed to the STL transmitter multiplex or subcarrier input. If an external subcarrier generator is to be used, the internal generator is removed and replaced with a jumper/terminating board (figure 18). The connector will then deliver the control tone itself.

Metering input to the studio unit is normally applied from the output of a telemetry receiver, or any receiver capable of extracting the metering tone from the AM or FM broadcast carrier. For FM, an SCA receiver modified for telemetry purposes is customarily used. For AM, any receiver with a 1.5 volt peak-to-peak subaudible output may be used. (The studio unit of the BTR-15B can be easily modified to increase its sensitivity by as much as 20 dB above this figure).

Figure 13. Wireline Interconnections

TABLE 3. RECOMMENDED CONTROL AND METERING STANDARDS

Control or Signal	Level
Control tone leaving studio	0 dBm
Metering tone leaving transmitter	0 dBm
Maximum telephone line loss, 300 Hz to 1200 Hz (with 0 dBm send level at each end of line)	30 dB
Subcarrier generator output at studio site (used for control; connects to STL transmitter)	1.5 volts peak-to-peak
Subcarrier demodulator input at transmitter site (used for control; driven by STL receiver)	1.5 volts peak-to-peak of subcarrier
Subcarrier generator output at transmitter site (used for metering return to studio; connects to FM transmitter)	Adjustable up to 6 volts peak-to-peak
Subcarrier demodulator input at studio site (used for metering; driven by FM receiver)	1.5 volts peak-to-peak of subcarrier
Control signal direct output at studio (connects to external subcarrier generator)	1.5 volts peak-to-peak
Control signal direct input at transmitter site (driven from STL via external subcarrier demodulator)	1.5 volts peak-to-peak
Metering signal direct output at transmitter site (connects to AM transmitter or to external subcarrier generator)	Subaudible: up to 6 volts peak-to-peak, adjustable. Audible: approximately 1.5 volts peak-to-peak, fixed
Metering signal direct input at studio site (driven from AM or SCA receiver)	1.5 volts peak-to-peak of metering signal
Modulation of AM transmitter by metering signal	5% (6% maximum)
Deviation of SCA subcarrier at FM transmitter site by metering signal	800 Hz

Make connections that link the studio and transmitter units as indicated in figure 13, but do not connect control terminals or metering terminals of the transmitter unit (figure 23) to the broadcast transmitter equipment at this time. With reference to figures 39 and 45, verify the power transformer primary connections in each unit is for the power source that is to be used.

Next check that control signals are received correctly by the transmitter unit. The test for return of metering signals will be made later.

With power applied to both units, press the RAISE button on the studio unit. This should make the raise relay, K17, on the transmitter unit pull in. Pressing the LOWER button should make the lower relay, K18, pull in. Pressing a numbered button on the studio unit should energize the correspondingly numbered relay at the transmitter unit.

Should there be a problem at this point, check interconnections between studio and transmitter units to be sure each line is carrying the correct signal. To assist in initial setup, recommended standards are given in table 3. The measurements applicable to wireless systems are made at the type BNC connectors. Refrain from making internal adjustments unless a reading is definitely unsatisfactory.

If the metering signal to be fed to the studio unit is a sample of the undemodulated subcarrier as radiated from the FM transmitter, then an optional internal subcarrier demodulator is substituted (figure 18) for the jumper/terminating board in the studio unit.

BTR-15BR Transmitter Unit

The CONTROL INPUT connector of the transmitter unit is generally connected to the multiplex or subcarrier output of the STL receiver, and the internal subcarrier demodulator extracts from the subcarrier a replica of the control tones originating at the studio. If the signal to be fed into the CONTROL INPUT connector is in the form of an audible tone, as supplied by an external subcarrier demodulator, then the internal subcarrier generator must be replaced by a jumper/terminating board (figure 22).

The METERING OUTPUT jack of the BTR-15BR transmitter unit normally delivers 20 to 30 Hz metering tones. These may be applied to the subcarrier generator in the FM transmitter, or for AM, to the RCA accessory MIU-1 Metering Insertion Unit, MI-561458. If the FM transmitter is not equipped with a subcarrier generator, an accessory subcarrier generator board for telemetry is available to plug into the BTR-15BR transmitter unit in place of the existing jumper/terminating board (figure

22). The METERING OUTPUT jack will then deliver a tone-modulated subcarrier signal which may be applied directly to the transmitter multiplex input. If program service is to be accommodated along with the telemetry signal, the RCA BTX-1A Subcarrier Generator is recommended and no modification of the BTR-15BR will be necessary.

Telemetry SCA Generator (Optional)

As previously mentioned, an accessory plug-in subcarrier (SCA) generator board, MI-561181-1, (67 kHz) is available for telemetry use with the BTR-15B transmitter unit when the FM transmitter is not equipped with a subcarrier generator. This will of course require use of the optional plug-in subcarrier demodulator board at the studio unit. This accessory generator is for telemetry use only and will not carry program material.

The normal operating frequency of the accessory generator is 67 kHz, but other frequencies from 26 kHz to 185 kHz are available on special order. Subcarrier signal from the METERING OUTPUT jack may be fed conveniently into one of the telemetry input jacks J104 or J105 on the main frame of the RCA BTE-15 FM Exciter. When using either of these inputs, it will be necessary to jumper pin 4 to pin 1 on whichever jack is used. In this way, subcarrier input will be fed directly to input terminals 12 or 13 of the FM exciter. (See figure 50, IB-8027524 or 8027524-1).

BTX-1B Subcarrier Generator (Optional)

If program service is to accompany the telemetry signal, the RCA BTX-1B Subcarrier Generator is recommended for use with the BTE-15 FM exciter in the FM transmitter. In this case, the optional subcarrier generator will not be needed at the BTR-15B transmitter unit, and the telemetry tones from the METERING OUTPUT jack may be fed directly to the SCA input jacks J104 or J105 on the main frame. The optional demodulator board, however, will still be required at the studio unit.

METERING CONNECTIONS

NOTE: Before any metering connections are made to the BTR-15B, it is recommended that the installer read the following instructions so that the metering requirements of the system will be understood.

Voltage Samples

Obviously, metering signals applied to the BTR-15B metering terminals are not the same voltages

and currents that are indicated on the transmitter panel meters. They are "metering samples," derived independently and in such a manner that they represent the meter readings without interfering with the meters.

Whatever the source of the metering voltage sample, it should measure in the vicinity of 2 volts dc when a 22 k resistor is connected across it, and it should not measure more than 10 volts when the resistor is disconnected. It must be no more than 350 volts peak, or dc referenced to ground, or damage may result to the BTR-15B. It should not be more than 50 volts above or below ground unless wiring is protected and all terminals and points where it is exposed, covered. The use of shielded wire, conduit, and other techniques to keep rf out of the metering samples is encouraged.

RCA offers a variety of kits designed for several sampling functions, the principles of which are described in the following paragraphs.

Plate Voltage and Plate Current Sampling

The RCA sampling unit for one of these functions is available as PVK-1 or PVK-2 Plate Voltage Sample Resistor Kit, MI-561482-* or MI-561483, respectively.

This method of plate voltage sampling is illustrated in figure 14A, where resistors R1, R2 and R3 have been added to develop an output voltage representative of plate voltage. R1 and R2 are typically stable metal-oxide resistors of several megohms, with power ratings of 10 to 20 watts. R3 is in the vicinity of 10 k to 100 k ohms and serves to keep the output sample terminals at a reasonable voltage should the load (transmitter unit) be removed. The target output voltage is 2 Vdc with 1 volt minimum and 10 volts maximum. Less than 1 volt may not produce full-scale deflection of the studio meter, and more than 4 volts may make setting of the calibration controls difficult.

Figure 14B shows the addition of a shunt resistor, R4, to the cathode circuit. This resistor of about 1.5 ohms develops a plate current sample at a point of safe potential in the circuit. The value of this resistor is calculated to develop 2 volts with normal plate current flowing. Two resistors in parallel are recommended for safety, in which case two resistors of three (3) ohms each would provide the proper voltage.

WARNING

Connections to this resistor must be secure. A poor connection or open resistor will result in excessive voltage appearing at the output sample terminals. It is for this reason that paralleled resistors are preferred.

2P091

Figure 14. Deriving Metering Samples.

AC Sampling

Since metering inputs to the BTR-15B must be dc, ac voltages such as filament and line voltages must be rectified to be sampled. Filament voltages must also be near ground potential with either a center tap or one side grounded. RCA offers the LVK-1 Filament Voltage Rectifier Kit, MI-561463, 120 to 240 VAC, as an optional accessory for this purpose. A simple method of sampling ac filament or line voltages is shown in figure 14C.

RF Sampling

Since the AM tower is a linear device, antenna base current may be measured by connecting a capacitive voltage divider from antenna to ground and measuring the voltage as shown in figure 14D. An RCA Antenna Voltage Kit, RFK-1, MI-561193-1 is available as an accessory for this purpose. The 10 pf capacitor may be a short piece of coaxial cable or transmitting mica capacitor. The divider provides about 50 volts peak which is rectified by a 200 volt high-speed type diode and smoothed by an .01 μ f capacitor. For high base voltage installations, reduce the value of the 10 pf capacitor to lower the voltage at the junction of the capacitors. The same system may be used to measure transmission line or common point current.

FM systems may use the method illustrated in figure 14E, although it must be constructed carefully to avoid damage to transmitting equipment, therefore purchase from a manufacturer is recommended. An optional FM Antenna Voltage Kit is available from RCA as RFK-2, MI-561193-2 or RFK-3, MI-561193-3.

Monitor Sampling

Outputs from reflectometers and frequency monitors are generally as low as 25 μ A, and in the case of the frequency monitor, an offset adjustment may be required (no input results in half-scale deflection). Both these disadvantages are solved by use of a dc amplifier, such as the RCA Type CSA-3, MI-561461, connected between the reflectometer or frequency monitor and the BTR-15B.

CONTROL CONNECTIONS

NOTE: Before any control connections are made to the transmitter unit of the BTR-15B, it is recommended that the installer read the following paragraphs so that control requirements of the system will be thoroughly understood.

Figure 15 is a simplified schematic showing the "Raise" control section of the BTR-15B transmitter unit. A series of relays, identified as "1" through "15" and actuated by the CHANNEL SELECTOR push-buttons on the studio unit, allows 15 terminal pairs to be selected, one at a time. After a pair has been selected, the circuit between terminals of the pair is completed by energizing the Raise relay. With selection of any one channel, all other channels are locked out. This circuitry is duplicated for the Lower terminal pairs, and there is no connection between Raise and Lower circuits. A third set of contacts on each channel relay selects the metering sample for that channel.

Figure 15. Control Connections, Simplified Schematic

Figure 16. Control Circuitry, Simplified Schematic

Figure 16 illustrates simple control circuits and how they may be connected to the Raise and Lower pairs of the BTR-15B transmitter unit. When Channel 1 is selected, the 24 volt dc relay will be energized by pressing the RAISE button. Selecting Channel 2 and pressing and LOWER button will energize the 12 Vac relay coil. Going to Channel 4 and pressing the LOWER button will close the pushbutton circuit.

Control Contact Loads

Current through the control contacts of the BTR-15B should never exceed 1 ampere, even of a transient nature; a lesser value is preferred. External ac loads must be bypassed by a series RC network. Values of 0.1 μ f and 100 ohms are suggested for small loads. Voltages should not exceed 250 volts dc or peak ac. Use

of interface relays, as described in the following paragraph is to be encouraged.

Use of Interface Relays

Channels are isolated from each other, that is, there are no connections between channels inside the unit. This allows great flexibility, since various voltages, ac and dc, can be used with the control system. Nevertheless, it is considered wise to use a repeating or interface relay between the BTR-15B and outside loads. These relays have important advantages. They prevent serious control transients from entering the circuitry of the BTR-15B. They provide a form of power gain, handling loads up to several amperes without ill effect to the BTR-15B. They also provide a means for opening, instead of closing circuits, where necessary, by use of

relays with normally closed contacts (figure 16, Channel 15). It is suggested that these relays be operated from a simple dc supply, and with their coils shunted by a diode to suppress transients. Connect the diode as shown in figure 16 so that it will not conduct coil energizing current.

RCA provides a series of plug-in relays that can be mounted on a rack panel so installer can interface high current/voltage transmitter circuits with the BTR-15B Transmitter unit. Contact your RCA representative for information on various types of relays available.

Fail Safe Circuits

FCC regulations require that the remote control system be fail-safe, meaning that a control system or link failure will take the transmitter off the air. This is accomplished in the BTR-15B by means of the fail safe circuitry in the transmitter unit. The fail-safe output is

in the form of a single-pole, double-throw relay contact. When the control system is operational the fail-safe relay is energized and a pair of terminals on the rear of the transmitter unit is closed. When a failure occurs in the control system, or in the link carrying control system signals, the normally-closed fail-safe contacts are opened. Terminals of these contacts must be connected to transmitter control in a manner that will take the transmitter off the air should the contacts open. A commonly used method is to connect these contacts in series with the transmitter door interlock system.

Auxiliary Power Circuits

The terminals labeled AUX POWER on the rear of the BTR-15B transmitter unit are intended to supply power to RCA accessory kits. Available at the terminals is 15 Vdc at up to 100 mA. Use of this power for miscellaneous non-remote control purposes is not recommended.

OPERATION

Connections to the units should be made permanent, with power applied continuously, so that controls are operational at all times. If a wireless system is used, of course the radio subcarrier links must be operating properly before control or metering can be accomplished.

The LOCAL/REMOTE switch on the transmitter unit must be in the REMOTE position for the studio unit to assume control. Operation is simple. Going, for example, to Channel 1, pressing the RAISE button will actuate the device connected to the Raise/1 terminals at the transmitter, such as a relay to turn on the filaments. Other channels may be selected and operated as well as monitored.

Operation of the system from the transmitter site is accomplished after depressing the LOCAL switch on the transmitter unit. This disconnects the studio unit from the system. RAISE and LOWER switches control the respective relays just as if they were controlled from the studio. The selected channel can be determined by observing the front panel readout lamps.

Before using the BTR-15B, return transmitter control to the studio by pressing the REMOTE COMMAND switch, and make the following routine tests and adjustments to assure proper calibration of the system.

ROUTINE ADJUSTMENTS

The controls to be checked initially as well as routinely are the meter ZERO SET and CALIBRATE controls on the studio unit, and the channel CALIBRATE controls on the transmitter unit.

Adjustments are made with the help of a voice link between studio and transmitter locations. With the LOCAL/REMOTE switch on the transmitter unit in REMOTE, select the CAL channel by pressing the CAL button on the studio unit. Now press the RAISE button. The meter should show a deflection to mid scale. If it does not, adjust the CALIBRATE control until it does. Release the RAISE button. The meter pointer should drop to zero. If it does not, adjust the ZERO SET control. Recheck mid-scale deflection by pressing the RAISE button. Readjust CALIBRATE control if necessary.

At the transmitter site, adjust the channel CALIBRATE controls to make the studio meter readings coincide with the transmitter meter readings. Check these controls as often as required or deemed necessary, probably weekly.

INTERNAL ADJUSTMENTS

The various modules in the BTR-15B have adjustable controls that provide a means to compensate for manufacturing tolerances and offer operational flexibility. The settings of these controls should not be altered unless it has been determined that a problem exists which will be corrected by readjustment of the control. For the location of these controls, refer to the component diagram for the particular module. When making measurements involving a test point, the common lead of the test equipment is connected to the chassis, except for TP1 through TP4 on the Audible Metering Generator and Subaudible Metering Generator, where the common side of the equipment is connected to the floating common point.

Control Generator

The quiescent frequency of the Control Generator should be within the limits of 280 to 320 Hz and is frequency-shift-keyed upward to about 400 Hz. Refer to the schematic diagram, figure 40. Observe TP7, the violet test point on the Control Generator board, and adjust the CONTROL TONE FREQUENCY control, R27, to an indicated 300 Hz. Use a frequency counter, compare the tone with an accurately calibrated audio oscillator, or use an oscilloscope to set the tone to the fifth or sixth harmonic of the power line, depending on the input frequency.

The amplitude of the control tone output is set by the CONTROL TONE AMPLITUDE control, R41, and is normally adjusted to a level of 0 dBm into the telephone line. Use a VTVM calibrated directly in dBm for this adjustment, or an ac VOM as an alternate. Should excessive RF or noise appear on the line, use TP8, the gray test point on the control generator board.

If this is done, set for an indication of +6 dBm. The drop in an internal resistor will reduce this to 0 dBm on the telephone line. There is no adjustment provided for the control-tone-output level as applied to the subcarrier generator; this is fixed by internal resistor values to a suitable value.

Control Demodulator

The DEMODULATOR TUNING control, R27, sets the operating point of the pulse counter. Refer to the Control Demodulator Schematic Diagram, figure 47. It may be set by observing TP "E", the green test point on the Control Demodulator board. While observing this test point, press the RAISE button on the studio unit to send a continuous pulse train. Then set the demodulator tuning control for zero volts dc as read on an ordinary dc voltmeter connected between ground and test point "E" (green) on the Control Demodulator. When the button at the studio is released, test point "E" will show a negative voltage reading. When the RAISE, LOWER, or RECYCLE buttons are held down, the reading will go to zero and will show "dither" or low-frequency variation due to the presence of the low-frequency train.

The RAMP control, R41, allows the various pulses to be correctly separated according to their width. If misadjusted one control command could be misinterpreted by the comparators, IC12 through IC15 as being another. For example, pressing the studio RAISE button might result in the Lower relay being energized, or perhaps the other way around. Prior to resetting the RAMP adjustment, be sure that the Control Generator and the DEMODULATOR TUNING controls are both correctly set. To adjust the RAMP control, press the studio RAISE button. When the RAMP control is turned, a point will be reached where the Lower relay will be energized instead of the Raise relay. Turning the

control the other way, the Raise relay will become de-energized. The correct setting for this control is midway between these two settings. After resetting this control, confirm that all other functions are satisfactory. Minor readjustment may be necessary.

Audible Metering Generator

The FREQUENCY control, R11, sets the "no input" frequency of the metering oscillator. Refer to the schematic diagram, figure 48. To set this control, go to an unused telemetry input or the CAL position. Connect a frequency counter or other measurement device (see the suggestions listed under "Control Generator") to TP6, the gray test point on the Audible Metering Generator board. Set the FREQUENCY control for an indication of 800 Hz. The acceptable limits are 780 Hz to 830 Hz.

The SENSITIVITY control, R4, sets the sensitivity of the voltage-controlled metering oscillator. When the calibration voltage is applied to the unit, this control is adjusted for a metering oscillator frequency of 1000 Hz. To set the SENSITIVITY control, go to the CAL position and press the RAISE button. This applies the calibration voltage from the Audible Metering Generator board terminal 3, through contacts on raise relay K17 and calibrate relay K16, to terminal 1 of the Audible Metering Generator board. Refer to the Transmitter Unit Schematic Diagram, figure 45. This applies the calibration voltage to the dc amplifier. Set the SENSITIVITY control for an indication of 1000 Hz at TP6, the gray test point, using the same procedure recommended in the preceding paragraph. Acceptable limits are 980 Hz to 1020 Hz.

The LINE LEVEL control, R33, sets the amplitude of the metering tone applied to the telephone line. This will normally be set to a level of 0 dBm into the line. Use a VTVM calibrated in dBm for this adjustment, or an ac VOM as an alternate. Should the line have RF or noise on it, use TP7, the white test point, on the Audible Metering Generator board. If this is done, set for an indication of +6 dBm. The drop in an internal resistor will reduce this to 0 dBm on the telephone line. There is no adjustment provided for the metering tone level applied to the Subcarrier Generator; this is fixed by internal resistor values to a suitable value.

Subaudible Metering Generator

The FREQUENCY control, R11, sets the "no input" frequency of the metering oscillator. Refer to the schematic diagram, figure 49. To set this control, go to an unused telemetry input or the CAL position. Connect a frequency counter or other measurement device (see Control Generator equipment suggestions, above) to TP6, the gray test point on the Subaudible Metering Generator board. Set the FREQUENCY control for an indication of 20 Hz $\pm$ 1/2-Hz.

The SENSITIVITY control, R4, sets the sensitivity of the voltage-controlled metering oscillator. When the calibration voltage is applied to the unit, this control is adjusted for a metering oscillator frequency of 25 Hz. To set the SENSITIVITY control, go to the CAL position and press the RAISE button. This applies the calibration voltage from the Subaudible Metering Generator board terminal 3, through contacts on raise relay K17 and calibrate relay K16, to terminal 1 of the Subaudible Metering Generator board. Refer to the Transmitter Unit, Schematic Diagram, figure 45. This applies the calibration voltage to the dc amplifier. Set the SENSITIVITY control for an indication of $25 \text{ Hz} \pm 1/2\text{-Hz}$ at TP6, the gray test point, using the same procedure recommended in the preceding paragraph.

THE OUTPUT LEVEL control, R32, sets the amplitude of the metering tone applied to the Subcarrier Generator. This will normally be set to a level of 0 dBm output. Use a VTVM calibrated in dBm for this adjustment, or an ac VOM as an alternate. Should the line have RF or noise on it, use TP7, the white test point, on the Subaudible Metering Generator board. If this is done, set for an indication of +6 dBm.

Audible Metering Demodulator

The OVERSHOOT control, R45, sets the effective damping of the meter movement. Refer to the Audible Metering Demodulator Schematic Diagram, figure 43. First, set both controls on this board fully counterclockwise. Then adjust the OVERSHOOT control so that the meter nearly overshoots when a step voltage is applied to the metering system. A convenient step for adjustment is the calibrate signal. Merely select the calibrate channel, and alternately press and release the RAISE button for a step input to the metering system from the internal calibration voltage at the transmitter site.

The ACCELERATION control, R42, sets the amplitude of the "speedup" applied to the meter movement. After the OVERSHOOT adjustment is made, the ACCELERATION is adjusted. As it is advanced from the counterclockwise position, it will be noticed that the meter movement is more and more responsive. Finally, the meter overshoots, and the control may be backed off somewhat. The meter-movement rise time is quickened if a small overshoot is permitted.

Subaudible Metering Demodulator

The INPUT LEVEL control, R1, is the only control on this board. Refer to the schematic diagram, figure 44. With a signal containing subaudible metering information applied to this module, adjust the INPUT LEVEL control for a reading of -6 Vdc at TP "E", the violet test point, using an ordinary voltmeter. Should the input signal be of very low amplitude, the sensitivity of the amplifier, IC4, can be increased by installing a

resistor in parallel with R15. A value of 2200 ohms installed in the holes provided will give an increase in gain of about five times (14 dB). A 470 ohm resistor will provide a gain increase of about twenty times (26 dB).

Subcarrier Generator

The FREQUENCY control, R4, adjusts the center frequency of the Subcarrier Generator. The Subcarrier Generator Schematic Diagram is presented in figure 41. Observe TP2, the yellow test point, with a counter or oscilloscope and adjust the FREQUENCY control for the correct frequency. For a list of frequency-determining (FD) parts, refer to table 1. It may be advisable if a counter is used, and will be necessary if an oscilloscope is used, to first remove any modulation on the subcarrier prior to setting the frequency. This can be done by turning the DEVIATION control, R1, fully counterclockwise.

The DEVIATION control, R1, is set by using an SCA modulation monitor, an oscilloscope, or by observing the subcarrier demodulator. Adjust the deviation control for a subcarrier deviation of about 5% of its center frequency for control purposes or 800 Hz for metering service. If the subcarrier demodulator is used to measure the subcarrier deviation, refer to the section on that module for instruction.

The OUTPUT LEVEL control, R31, is set for about 20% injection of subcarrier into an aural STL, or 1.5 volts peak-to-peak at the output of the Subcarrier Generator (green test point 3). If the Subcarrier Generator is used to modulate an FM exciter, the OUTPUT LEVEL control is adjusted for 9% modulation of the FM carrier. Notice that the word deviation as used in this section means modulation of the subcarrier by the control or metering signal, and the word injection means modulation of the main carrier by the subcarrier.

Subcarrier Demodulator

With 1.5 volts peak-to-peak of subcarrier signal applied to the Subcarrier Demodulator, figure 42, adjust the four inductors, LA through LD, for maximum subcarrier amplitude coincident with minimum ripple or modulation as observed with an oscilloscope connected to TP1, the orange test point. This filter realignment should not be necessary unless a component has been replaced.

The DEMODULATOR TUNING control, R9, is used to set the operating point of the pulse-counting discriminator. Connect voltmeter to TP2, the yellow test point, and adjust the DEMODULATOR TUNING control for a reading of 5 volts dc. This reading should be within the range of 4 volts to 6 volts dc and must not exceed 7 volts dc. Be sure the subcarrier Generator is on frequency and of the correct amplitude before this adjustment is made.

The OUTPUT LEVEL control, R17, is used to set the output level from the Subcarrier Demodulator. This control is set for 1.5 volts peak-to-peak output from the demodulator as observed at TP3, the green test point. Should a particular unit yield higher than this figure, the DEMODULATOR TUNING control may be adjusted

counterclockwise for a vernier adjustment. The subcarrier is being deviated correctly for control purposes (studio-to-transmitter link) when 0.2 volts rms is measured at TP2, the yellow test point, of the Subcarrier demodulator when the DEMODULATOR TUNING control is set for 5 volts dc at TP2.

MAINTENANCE

GENERAL

The transmitter should be visited periodically as specified by FCC regulations and the remote meter readings checked against the transmitter site meter readings using the routine adjustment procedure given under OPERATION.

In case of a failure of the BTR-15B Remote Control System, the following comments may prove helpful:

1. If possible, remove nearby sources of RF when the electronic circuitry is exposed. Strong RF fields tend to re-bias amplifiers and saturate IC's, making operation unpredictable.

2. Try to isolate the problem to a specific area. To assist in this, voltages and waveforms are shown on the schematics at key points. By comparing the suspected unit with the measurements given on the schematics, the difficulty can usually be localized quickly.

3. If an integrated circuit is suspected, carefully remove the original and plug in the new one, observing polarity. These devices may be inadvertently installed backwards and improper installation may damage the new IC. The "key" on these IC's is a small dot at pin 1, or an indentation at one end, or (for round IC's only) a tab extending out from the highest numbered pin. Correct orientation of the IC's is shown on the component diagrams.

4. Repairs may be effected by replacing the defective component, replacing the defective sub-assembly, or RCA Field Engineering Service may be utilized.

5. When replacing fuses, replace only with a fuse of the type and current rating called for in the REPLACEMENT PARTS list.

6. Upon completion of repairs, be certain correct polarity is observed for telephone lines and that any other connections that were removed are correctly and securely reconnected.

CARE AND SERVICE OF RELAYS AND SWITCHES

Trouble free relay and switch operation depends upon keeping contacts clean and free of dust, lint, grease, paint, oil or similar materials. Contamination from sources such as these is the most common cause of contacts arcing, pitting and burning.

Relays and switches should be inspected periodically, and at such times contacts should be cleaned and adjusted as necessary. Relay contacts should be cleaned with Chlorothene applied with a soft brush after which they should be burnished with a tool such as the RCA Stock No. 22963 Contact Cleaning Tool. Finally, contacts should be wiped with a clean piece of bond paper.

The following is a list of conditions to watch for when making routine relay maintenance checks.

- Improperly adjusted residual screws on relays.
- Arcing contacts caused by a defective spark suppressor.
- Spring and contact assemblies which show evidence of tampering.
- Contacts out of alignment more than 1/3 of their diameter at the base of the contact points.
- Loose screws and nuts.
- Insecurely mounted coils, contacts, and other parts.
- Mutilated or defective screws, nuts, or other parts.
- Sharp bends or kinks in springs. The free length of relay spring can have only a normal bow.
- Bushings not in the approximate center of the springs they strike.

PARTS ORDERING INFORMATION

REPLACEMENT PARTS

When ordering replacement parts, please give Stock or Master Item (MI) Number, Description, and Symbol of each item ordered.

The part which will be supplied against an order for a replacement item may not be an exact duplicate of the original part. However, it will be a satisfactory

replacement differing only in minor mechanical or electrical characteristics. Such differences will in no way impair the operation of the equipment.

EMERGENCY SERVICE

For emergency service after working hours, contact RCA Parts and Accessories, Telephone 609-963-8000 or 609-848-5900.

LOCATION	ORDERING INSTRUCTIONS
Continental United States, including Alaska and Hawaii	Replacement Parts bearing a STOCK NUMBER should be ordered from RCA Parts and Accessories – 2000 Clements Bridge Road – Deptford, New Jersey 08096. Replacement Parts bearing a MASTER ITEM (MI) NUMBER should be ordered from RCA, Commercial Electronics Systems Division – Attention Commercial Service – Camden, New Jersey 08102 or your nearest RCA Regional Office. Replacement Parts with NO STOCK or MASTER ITEM (MI) NUMBER are standard components. They are not stocked by RCA and should be obtained from your local electronics distributor.
Dominion of Canada	Order from your local RCA Sales Representative or his office or from: RCA Victor Company Limited, 1001 Lenoir Street, Montreal, Quebec.
Outside of Continental United States, Alaska, Hawaii, and the Dominion of Canada	Order from your local RCA Sales Representative or from: RCA International Division, Clark, New Jersey – U.S.A. – Wire: RADIOINTER Emergency: Cable RADIOPARTS, DEPTFORD, N.J.
