E0: Outdoor unit communication error

Reason: The communication between the slave unit and the master unit is lost, and the slave show error.

- 1. Check whether the connection wire between the main board of the master and slave unit to the communication terminal is normal and whether the connection is firm;
- 2. Check whether the communication line H1H2E of the master and slave unit is connected correctly, connect the corresponding letters hand in hand, prohibit star connection, use a multimeter to measure whether the communication line is open current/short current;
- 3. If there is no problem with the above steps, replace the communication board or main control board.

E1: Phase sequence malfunction

Reason: Three-phase power supply phase sequence error or lack of phase (This fault is only reflected when phase B is missing, phase A is missing, the main control board is out of power, phase C is missing, and the fan module is out of power)

- 1. Use a multimeter to measure the phase voltage, whether it is between 220-240V, to ensure that there is no lack of phase;
- 2. Check whether the power supply of the filter board is normal, the line voltage is 380V, if it is not normal, replace the filter board;
- 3. The above steps are normal, replace the main control board;

E2: Communication failure between indoor unit and outdoor unit;

Reason: Communication failure between indoor unit and outdoor unit

- 1. Check whether the communication wire between the communication board and the main control board is normal, confirm that the wiring is firm and the wiring harness is not damaged, then proceed to the next step;
- 2. Check whether the communication wire PQE uses 2-core shielded wire and connect it correctly. Star connection is forbidden. It must be P to P, Q to Q, E to E;
- 3. Check whether there is an open circuit/short circuit in the communication wire. Use a multimeter to measure the resistance between PQ to see if there is a short circuit; if there is no short circuit, short circuit PQ, and measure whether there is open circuit from the PQ terminal of outdoor unit;
- 4. Confirm that there is no problem with the communication wire, then check whether all the indoor unit are powered on, whether the indoor unit have addresses, make sure that the indoor unit are powered on and have addresses, if there is no address, please refer to the internal machine FE troubleshooting;
- 5. If there is no problem with the above steps, it may be communication interference. Connect a 100Ω resistance between the PQ of the last indoor unit of system. If it still cannot be solved, check the interference source and eliminate it. If it still does not solve the problem, replace the communication board/main board;

E3/E4/E5/E6/E7/EA: Exhaust gas temperature sensor TP/ambient temperature sensor T4/plate exchange inlet T6A sensor/condenser temperature T3 sensor/plate exchange outlet T6B sensor failure/refrigerant heat dissipation copper pipe sensor T8

Reason: Sensor reading error or sensor is damaged

- 1. Confirm whether the sensor is firmly connected to the main board, reconnect it firmly, or if it is faulty, proceed to the next step;
- 2. Unplug the sensor, measure the resistance of the sensor, whether it is open/short, if yes, replace the sensor group, otherwise replace the main board;
- 3. E3 exhaust sensor failure may be inaccurate resistance (After running for 10 minutes, Pc \geq 3.0MPa, TP \leq 15 $^{\circ}$ C)

E8: Outdoor unit address error

Reason: Outdoor unit address dialing error

Solution:

1. Check the dialing codes of the master and slave unit, perform the dialing according to the SW6 dialing introduction, and power on again

SW6 Outdoor address setting							
1 2 3 4 5 6 7 8 8 P E D C B A	1 2 3 4 5 6 7 8 9 9 A	2 3 4 5 6 7 8 8 P A A	1 0 6 7 8 9 P D C B A				
0	1	2	3				
Master	Slave 1	Slave 2	Slave 3				

E9: AC voltage protection

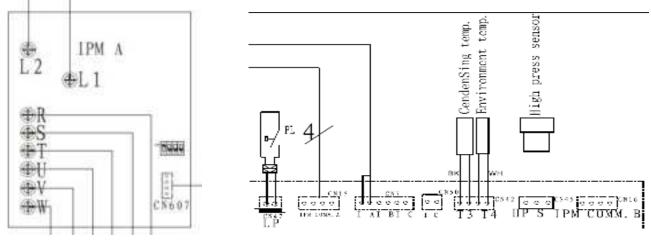

Reason: AC supply voltage problem

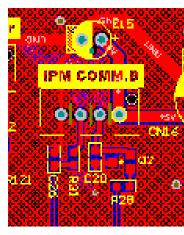

- 1. Use a multimeter to measure the voltage of the power supply phase to confirm the supply voltage (below 165V or higher than 265V);
- 2. If the power supply voltage is no problem, replace the main board;

XHO: Communication failure between main control chip and DSP module board

Reason: Communication failure between main control board chip and module

- 1. Use a multimeter to measure the RST voltage to confirm whether the voltage is 380V, if not, check the power supply and the power supply voltage of the filter board, otherwise proceed to the next step;
- 2. Check whether the connection wire of the module board and the main control board is open current/short current, confirm that it is normal and connect firmly;
- 3. Determine the reference voltage between the middle port and the GND or 5V on both sides. If there are fluctuations on both ends of the multimeter's DC gear, or there is no fluctuation at both ends, then the motherboard is faulty: if one end has fluctuations and the other end has no fluctuations, the module board is faulty.

H1: Communication error between master chip and slave chip

Reason: The internal chip communication problem of the main control board

Solution:

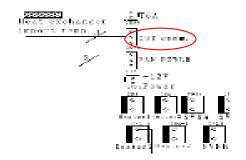

1. Replace the outdoor unit main board;

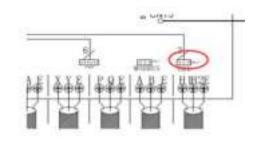

H2: Outdoor units decrease

Reason: Slave unit communication lost on parallel system

- 1. Check if any slave unit is powered off, and confirm that all outdoor unit are powered on;
- 2. Check whether the slave dialing code is wrong, refer to the introduction of SW6 dialing code, correct the dialing code and power on again;
- 3. Check whether the connection wire from the main board to the communication terminal is normal and whether it is firmly connected;
- 4. Check whether the slave communication line H1H2E is connected correctly, hand in hand connection, star connection is prohibited, use a multimeter to measure whether the communication line is open current/short current;
- 5. If there is no problem with the above steps, replace the communication board or main control board.

23.240	23.4.24	12-64	22-4
000	000		1
0	1	2	3
Manter	Slave 1	Slave 2	Slave 3

H3: Outdoor units increase

Reason: Master unit read slave unit quantity increase

- 1. Check whether the number of master unit and slave unit is correct, and whether other system slave unit communication is incorrectly connected to this system;
- 2. Confirm that the actual number of outdoor unit in the system is correct, then power on again;

XH4: There are 3 times P6 protection in 60 minutes

Solution: Refer to P6

H5: There are 3 times P2 protection in 60 minutes

Solution: Refer to P2

H6: There are 3 times P4 protection in 100 minutes

Solution: Refer to P4

H7: Indoor unit quantities decreasing malfunction over 3 minutes

Reason: Part of the indoor unit communication is lost

Solution:

1. Refer to the indoor unit error code FE&E1;

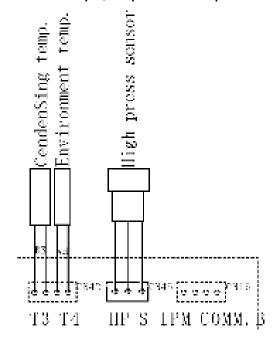

H8: Pressure sensor error

Reason: The main control board detects exhaust pressure \leq 0.3MPa

Solution:

1. Check whether the pressure sensor is firmly connected, and confirm that the connection is secure;

2. There is no problem with the above steps, replace the pressure sensor/main control board.

XH9: There are 3 times P9 protection in 30 minutes

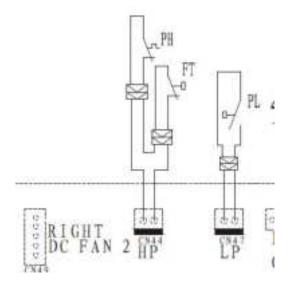

Solution: Refer to P9

P0: Reserved

P1: High pressure protection

Reason: The open circuit state is detected at the high pressure switch detection port

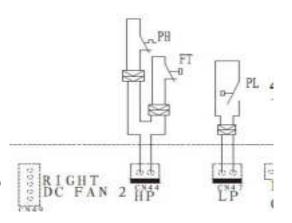

- 1. Check whether the wiring of the high pressure switch is firm and confirm that the wiring is normal;
- 2. Check whether the condenser has poor heat dissipation and ensure that there is no problem with heat dissipation;
- 3. Check parameter item 23/24 exhaust temperature to see if it is less than 120°C, if yes, short-circuit the exhaust thermostat, if the fault disappears, replace the exhaust thermostat; if the exhaust is ≥120°C, refer to P4 fault; otherwise Go to the next step;
- 4. Connect the pressure gauge, run the unit, check the high and low pressure, if the pressure is normal, remove the pressure switch to measure the resistance, if it is infinite, replace the pressure switch; if the pressure switch resistance is 0, replace the main board;
- 5. Connecting the pressure gauge to test, if the pressure of the pressure gauge is too high, it is the system Reason, and it is necessary to troubleshoot problems such as system blockage, vacuum, and excessive refrigerant;

P2: Low pressure protection

Reason: The open circuit state is detected at the low pressure switch detection port

- 1. Check whether the wiring of the low pressure switch is firm and confirm that the wiring is normal;
- 2. Check whether the evaporator has poor heat dissipation and ensure that there is no problem with heat dissipation;
- 3. Connect the pressure gauge, run the unit, check the high and low pressure, if the pressure is normal, remove the pressure switch to measure the resistance, if it is infinite, replace the pressure switch; if the pressure switch resistance is 0, replace the main board;
- 4. Connecting the pressure gauge to test, if the pressure of the pressure gauge is too low, it is the system Reason, and it is necessary to troubleshoot problems such as system blockage, leakage, and lack refrigerant;

XP3: Inverter compressor over current protection

Reason: The main board detects that the operating current is too large

Solution:

1. Check whether the wiring of the motor and compressor is tight and confirm that the wiring is normal;

2. Check whether the current transformer is firmly connected;

3. Use the clamp meter to check the primary side AC current and the secondary side compressor DC current, and check items 32/33/34/35, compare the difference between the check value and the clamp meter, if the difference is large, it means there is a problem with the current transformer or the main control board. Try to use a normal transformer, if not resolved, replace the main control board;

4. If the difference between the clamp meter and the check value is not large, the compressor problem or the system problem.

P4: Discharge temperature sensor protection

Reason: Exhaust temperature sensor reads that the temperature is too high

- 1. Connect a pressure gauge to measure whether the low pressure pressure is too low (normally 0.7-0.9MPa). If the pressure is too low, add refrigerant. At the same time, check whether the SV5 spray cooling valve on the main control board has output 220V before the failure. If there is no output, replace the main board. If the output valve does not act, replace the SV5 coil;
- 2. Measure the resistance of the temperature sensor, If it is inaccurate, replace the sensor;
- 3. If the temperature sensor reading is accurate, check the exhaust temperature of item 11 and compare it. If the temperature of the main control board is unreasonable, replace the main control board;
- 4. If the above steps are normal, check whether the refrigerant system is normal, such as blockage of the air return pipe, poor evaporation, wear of the compressor, etc.

P5: Heat exchanger high temperature protection

Reason: The condenser temperature sensor reads that the temperature is too high

- 1. Check whether the heat dissipation of the condenser is normal, to ensure that there is no dirty block, poor return air, etc.
- 2. Measure the resistance of the temperature sensor, If it is inaccurate, replace the sensor;
- 3. If the temperature sensor reading is accurate, Check the middle and outlet temperature of the condenser for items 8 & 9 and compare it, If the temperature of the main control board is unreasonable, replace the main control board.
- 4. The above steps are all normal, check whether the system is normal, such as the indoor unit load is too large, the vacuum problem.

XP6: IPM module protection

Reason: Compressor drive module abnormal

- 1. Check whether the power supply is normal, the power supply phase voltage is 220-240V, and confirm that the power supply is normal;
- 2. Check whether the heat dissipation of the condenser is normal, to ensure that there is no dirty blockage, poor return air, etc.
- 3. Measure the resistance between compressor UWV (normally within 20Ω) and UVW resistance to ground (normally infinite, $M\Omega$ level), if the compressor resistance is abnormal, replace the compressor, otherwise proceed to the next step;
- 4. Check whether the module heat dissipation silicone grease is applied evenly and normally, if abnormal, apply silicone grease again, otherwise proceed to the next step;
- 5. The above steps are normal, then run the unit and observe whether the compressor is abnormal, such as abnormal noise, excessive current, etc., otherwise replace the compressor;
- 6. Observe whether the system has poor heat dissipation or module overheating and overcurrent caused by mixing with difficult-to-compress gas, otherwise replace the main control board;

P7: Insufficient exhaust gas overheat protection

Reason: Too much refrigerant in the system, liquid back in the compressor, problems with the refrigerant system

- 1. Check whether the exhaust temperature sensor is inaccurate, replace it if it is inaccurate, otherwise it is a refrigerant system problem;
- 2. Connect the pressure gauge to check the high and low pressures, and check items 15/23/24 to see if there is too much refrigerant. If there is too much refrigerant, release the refrigerant;
- 3. Check whether the indoor unit is poorly evaporated and other problems.

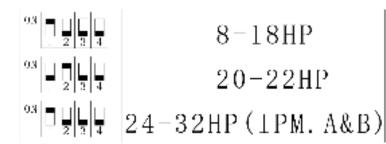

XP8: The outdoor unit capacity dial code does not match the compressor drive model protection

Reason: Dial code problem, fan module detection is abnormal

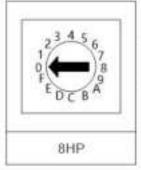

Solution:

- 1. Check whether the SW11 capability dialing code of the main control board is correct, correct it if it is incorrect;
- 2. Check whether the dialing code of the IPM module board is correct, correct it if it is incorrect;
- 3. After correcting the dialing code, power on again, if the problem is not resolved, replace the main control board.

DIP switch on IPM:

Sw11 setting for outdoor unit capacity:

Set	0	1	2	3	4	5	6	7	8	.9
Capacity	8НР	10HP	12HP	14HP	16HP	18HP	20HP	22HP	24HP	26HP
Set	Α	В	С	D	E	F				
Capacity	28HP	30HP	32HP	Reserved	Reserved	Reserved				

XP9: DC fan module protection

Reason: Fan drive module abnormal

- 1. Check whether the power supply is normal, the power supply phase voltage is 220-240V, and confirm that the power supply is normal;
- 2. Check whether the input voltage of the rectifier bridge is 220V, if not, replace the filter board;
- 3. Check whether the output of the rectifier bridge is 310V, otherwise replace the rectifier bridge, if yes, proceed to the next step;
- 4. Check if the DC+/DC- of the fan module board is 310V, otherwise replace the filter board, if yes, proceed to the next step.

XP9: DC fan module protection

Reason: Fan drive module abnormal

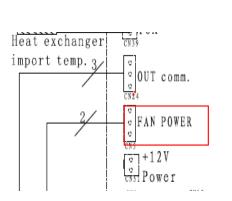

- 5. Check whether the FAN POWER interface of the main control board is DC12V, otherwise replace the main control board, if yes, proceed to the next step;
- 6. Check whether the communication line between the main control board and the fan module is firmly connected, whether it is open/short, otherwise replace the communication line and proceed to the next step normally;
- 7. Use a multimeter to measure the resistance between the UVW of the motor, whether it is open/short, within 20Ω ; measure the resistance of UVW to ground, and it is normal infinity (M Ω level), otherwise the motor is damaged, replace the motor;

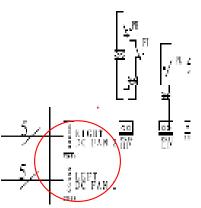

XP9: DC fan module protection

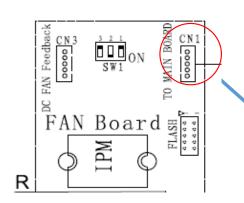

Reason: Fan drive module abnormal

Solution:

- 8. Measure the voltage between VCC and COM, it is normally DC5V, otherwise replace the main control board;
- 9. Measure PWM-COM, DCOV is off, normal DC2.5V voltage fluctuates, otherwise replace the main control board;
- 10. If the voltages of VCC-COM and PWM-COM are normal, replace the module board. If it still cannot be solved, replace the motor.

Communication port with main board,
Power ground COM;
Fan start signal Ctrl;
OV start, 5V close;
Fan speed feedback FG.

XPA: Module temperature sensor over-temperature protection

Reason: IPM module board temperature is too high

- 1. Check whether the heat dissipation of the condenser is normal, to ensure that there is no dirty block, short circuit of the return air, etc.
- 2. Check whether the module heat dissipation silicone grease is applied evenly and normally, if it is abnormal, apply silicone grease again, otherwise proceed to the next step;
- 3. Check whether the system has poor heat dissipation or module overheating and overcurrent caused by mixing with difficult-to-compress gas, otherwise replace the IPM module board;
