Legal Notice

The use of Aruba Networks, Inc. switching platforms and software, by all individuals or corporations, to terminate other vendors' VPN client devices constitutes complete acceptance of liability by that individual or corporation for this action and indemnifies, in full, Aruba Networks, Inc. from any and all legal actions that might be taken against it with respect to infringement of copyright on behalf of those vendors.

The Dell Networking W-Series ArubaOS 6.4.x command-line interface (CLI) allows you to configure and manage Dell controllers. The CLI is accessible from a local console connected to the serial port on the controllers or through a Telnet or Secure Shell (SSH) session from a remote management console or workstation.

Telnet access is disabled by default. To enable Telnet access, enter the **telnet** CLI command from a serial connection or an SSH session, or in the WebUI navigate to the **Configuration > Management > General** page.

What's New In ArubaOS 6.4.x

This section lists the commands introduced, modified, or deprecated in ArubaOS 6.4.x.

Commands in ArubaOS 6.4.3.0

New Commands

The following commands are introduced in ArubaOS 6.4.3.0:

Command	Description
aaa auth-survivability	This command configures authentication survivability on a controller.
amon msg-buffer-size	This command modifies the AMON packet size on the controller.
clear aaa auth-survivability-cache	This command, introduced with this release, allows you to clear the data stored in the local Survival Server cache
crypto local isakmp disable-ipcomp	This command disables IP compression on the master controller.
disable-whitelist-sync	This command disables whitelist synchronization with local or Cloud Services Controller on the master controller.
ip access-list route	This command configures an access control list (ACL) for policy-based packet routing.
ip nexthop-list	A next hop IP is the IP address of an adjacent router or device with layer-2 connectivity to the controller. Use this command to configure a next hop list, providing redundancy for the next hop devices by forwarding the traffic to a backup next hop device in case of failures.
ip probe	This command configures WAN health-check ping-probes for measuring WAN availability and latency.
pan-options	This command configures options to integrate a branch controller with a Palo Alto Networks (PAN) firewall

Command	Description
routing-policy-map	This command associates a routing access control list (ACL) with a user role.
show ap debug radar-logs	Displays the latest four RADAR event logs from the AP.
show ap debug radio-info	Displays the Wi-Fi radio debug logs from the AP driver.
show auth-survivability	This command displays the auth-survivability parameters that are configured in the local controller.
show branch	Shows configuration and DHCP address settings on a branch controller.
show branch-config-group	The output of this command shows configuration settings for a branch config group.
show branch-dhcp-pool	The output of this command shows a summary of DHCP pool information for branch controllers.
show ip nexthop-list	Display nexthop list settings for policy-based routing.
show local-userdb-branch	The output of this command lists the MAC address and assigned branch config group for branch controllers associated with that master.
show log arm-user-debug	This command displays a user's ARM debug logs.
show pan-gp	This command displays Palo Alto Networks portal or gateway settings on a branch or local controller.
show pan-options	This command displays configured options to integrate a branch controller with a Palo Alto Networks (PAN) firewall.
show wlan anyspot-profile	The output of this command displays configuration settings for a WLAN anyspot profile.
wlan anyspot-profile	This command configures the anyspot client probe suppression feature, which decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.

Modified Commands

The following commands are modified in ArubaOS 6.4.3.0:

Command	Description
aaa profile	The max-ip parameter is introduced.
aaa authentication-server radius	The following parameters are introduced: • c ppm • enable-radsec • radsec-client-cert-name • radsec-port • radsec-trusted-cacert-name • radsec-trusted-servercert-name
activate	The sync parameter is introduced.
airgroup	The policy parameter is introduced.
airgroupservice	The autoassociate parameter is introduced.
ap system-profile	The following new parameters are introduced: • ap-arp-attack-protection • mcast-aggr • mcast-aggr-allowed-vlan • ap-usb-power-override • shell-passwd • bkup-band • bkup-mode • bkup-password • ble-token • ble-url
clear	• The clear counter tunnel interface limit was changed from 2147483647 to 16777215. • The cli-policy all sub-parameter is introduced under the airgroup parameter. • The global-credits statistics parameter is introduced. • The port-channel sub-parameter is introduced under the counters parameter.
cp-bandwidth-contract	The unit of bandwidth contract traffic rate changed from Mbps or Kbps to pps. The range for pps is 1–64000.
interface fastethernet gigabitethernet	• The bw-contract parameter is introduced • The bpduguard, point-to-point, and vlan parameters are introduced as part of spanning-tree.

Command	Description
interface port-channel	The description parameter is introduced.
interface tunnel	- The tunnel interface limit is changed from 2147483647 to 16777215. - The <remote-node-master-ip> option is introduced as part of the tunnel destination parameter. - The <cisco> option is introduced as part of the tunnel keepalive parameter.
interface vlan	- The access-group <name> parameter is introduced to associate the interface with an ACL. - For the option-82 parameter, the ap-name [essid] sub-parameter is introduced.
ip route	The <nexthop> [<cost>] parameters is introduced, which supports routing using a next-hop list.
show aaa authentication-server radius	The following parameters are introduced: enable-radsec radsec-client-cert-name radsec-port radsec-trusted-cacert-name radsec-trusted-servercert-name
show aaa debug	The following parameters are introduced: age role The dev-id-cache sub-parameter is moved under the age parameter.
show ap active	The Q flag is introduced in the output of this command.
show ap arm client-match history	The following parameters are introduced as part of this command output: Station Status/Roam Time/Mode Signal Band Radio BSSID AP Name Additionally, the advanced parameter is introduced.
show ap arm client-match summary	The following parameters are introduced as part of this command output:

Command	Description
	• VHT Steer Moves • Moves • 11v Moves
<u>show ap arm client-match unsupported</u>	The following parameters are introduced as part of this command output: • Unsteerable Flags • Expiry Time • Total steers/successful
<u>show ap arm neighbors</u>	CLI Help text is introduced before the output table.
<u>show ap arm scan-times</u>	The following parameters are introduced under Group Scan Times: • channels • assign-time (ms) • scans-attempted • scans-rejected • scan-deferred • group-width • timer-tick
<u>show ap arm virtual-beacon-report</u>	The following parameters are introduced as part of this command output: • Active Voice • Steerable • Dual-Network Capable • VHT-Capable • EIRP
<u>show ap bss-table</u>	The n-anyspot forwarding-mode flag is introduced.
<u>show ap virtual-beacon-report</u>	The following parameters are introduced as part of this command output: • Steer attempts/success • Consecutive (Fails/BTM Rej/BTM Timeouts) • Client Device Type • Current State • Client Supported Channels • ESSID • Add Time

Command	Description
	• EIRP • Flag • Active Media Sessions Additionally, the all parameter is introduced.
show ap wired stats	This command now displays results for both campus and Remote access points.
show cp-bwcontracts	The CP bw contracts table now lists the traffic rate in packets/second instead of bits/second.
show datapath	The following changes were introduced: • The compression parameter displays datapath compression statistics. By default, the combined statistics for all CPUs are shown. • The output of the show datapath session command now supports the r flag, which indicates that the session was routed through a nexthop device defined by a nexthop-list. For more information, see ip nexthop-list. • The output of the show datapath cp-bwm command now displays the rate in pps.
show ip ospf	The tunnel ID limit is changed from 2147483647 to 16777215.
show interface vlan	The DHCP Option-82 AP name and ESSID are configured on this Interface parameter is introduced.
show port stats	The PC # (port-channel) value is introduced under the Port column.
show port status	Following values are introduced: • The PC# (port-channel) value is introduced under the PortMode column. • The PC (port-channel) value is introduced under the PortType column. • Speed and Duplex columns are introduced.
show spantree	The BpduGuard field is introduced as part of this command output.
show ucc call-info cdrs	The UCC-Band, MOS, and MOS-Band fields are introduced as part of the show ucc call-info cdrs command output. Following changes are made as part of the show ucc call-info cdrs cid <cid> command output: • Moved the UCC Score, Client Health, MOS parameters from the CDR-Basic section to the Call Samples section heading. • Added a new Call Sample(per 60 secs) section heading. This section displays the properties of media session like IP, port,

Command	Description
	codec, DSCP, and WMM values. - Renamed the CDRS-Detail section heading to WLAN Quality-Details. - Added a new End-to-End Quality-Details section heading. This section displays the MOS, MOS band, delay, jitter, packet loss values. - Under the Call Samples section heading, added the MOS, MOS-Band, End-to-End Delay(ms)/Jitter(ms)/PktLoss(%) fields. Following changes are made as part of the show ucc call-info cdrs detail command output: - Removed the Src Port, Dest Port, Codec, DSCP, Orig DSCP, WMM-AC, Orig WMM-AC fields. - Merged the Delay(msec), Jitter(msec), and Packet Loss (%) fields to WLAN Delay(ms)/Jitter(ms)/PktLoss(%). - Added the MOS, MOS-Band, End-to-End Delay(ms)/Jitter(ms)/PktLoss(%) fields.
show ucc client-info	Following changes are made as part of the show ucc client-info details command output: - Renamed the Client Status Details section heading to Client Status Details(Average) and removed the Avg word from all field headings. - Added the Client Name field. - Merged the Avg Delay(msec), Avg Jitter(msec), and Avg Packet Loss (%) fields to WLAN Delay(ms)/Jitter(ms)/PktLoss(%). - Added the End-to-End Delay(ms)/Jitter(ms)/PktLoss(%) field. - Renamed the Num CAC Denied field to CAC Denied. Following changes are made as part of the show ucc client-info sta <mac> command output: - Under the Station Report section heading, added the Client Name field. Removed the UCC-Score and Client Health fields. - Under the Active Calls section heading, added the UCC-Band, MOS, and MOS-Band fields. - Under the Call History section heading, added the UCC-Band, MOS, and MOS-Band fields.
show ucc trace-buffer	The InCallQuality Update value is added under the Call Status field.
show user-table	The detail sub-parameter is introduced as part of the ip parameter.
show vrrp	The holdtime parameter is introduced.
show whitelist-db cpsec	The ap-group and ap-name parameters were introduced as part of this command output.

Command	Description
show whitelist-db cpsec-status	The Whitelist-sync is enabled parameter is introduced as part of the command output.
tunnel-group	The tunnel ID limit is changed from 2147483647 to 16777215.
voice real-time-config	The default value is changed to enabled .
vrrp	The holdtime parameter is introduced.
whitelist-db cpsec add	The ap-group and ap-name parameters are introduced.
whitelist-db cpsec modify	The ap-group and ap-name parameters are introduced.
wlan virtual-ap	The wan-operation parameter is introduced.

Commands in ArubaOS 6.4.2.5

Modified Commands

The following commands are modified in ArubaOS 6.4.2.5:

Command	Description
aaa authentication-server radius	The cppm parameter is introduced.
firewall	The optimize-dad-frames parameter is introduced.
show aaa authentication-server radius	The CPPM credentials parameter is introduced.
show firewall	The Optimize Duplicate Address Detection frames parameter is introduced.
show running-config	The default dot1x high-watermark and dot1x low-watermark values were removed from the show running-config command.
show web-server	The Enable bypass captive portal landing page parameter is introduced.
tar	The show dot1x watermark history is added as part of the techsupport.log file.
web-server profile	The bypass-cp-landing-page parameter is introduced.

Commands in ArubaOS 6.4.2.4

Modified Commands

The following commands are modified in ArubaOS 6.4.2.4:

Command	Description
show dot1x watermark	The table parameter is introduced.

Commands in ArubaOS 6.4.2.3

Modified Commands

The following commands are modified in ArubaOS 6.4.2.3:

Command	Description
ids general-profile	The following parameters are introduced: • packet-snr-threshold • frame-types-for-rssi • max-monitored-stations • max-unassociated-stations
rf arm-profile	The cm-dot11v parameter is introduced.
show ids general-profile	The following parameters are introduced as part of this command output: • Packet SNR Threshold • Frame Types for RSSI calculation • Max Monitored Stations • Max Unassociated Stations
show tunnel-group	The Type parameter is introduced as part of this command output.
show web-server	The profile and statistics parameters were introduced.
tunnel-group	The mode parameter is introduced.
web-server profile	The web-server command is renamed to web-server profile . The following parameters are introduced: • tls1.1 • tls1.2

Deprecated Commands

The following commands are deprecated in ArubaOS 6.4.2.3:

Command	Description
web-server profile	The ssl3 sub-parameter is deprecated.

Commands in ArubaOS 6.4.2.0

New Commands

The following commands are introduced in ArubaOS 6.4.2.0:

Command	Description
ap-lacp-striping-ip	This command defines an AP LACP LMS map information profile that maps a GRE striping IP address to an existing LMS-IP address, allowing W-AP220 Series and W-AP270 Series AP to form a tunnel to a backup controller in the event of a controller failover.
kernel coredump	This command enables the controller to capture the snapshot of the working memory of the control plane when the control plane has terminated abnormally.
show web-cc	This command display information about web content (web-cc) classification settings, category and reputation types, classification statistics and bandwidth contracts.
web-cc	This command defines global bandwidth contracts for HTTP traffic matching a predefined web content category or reputation type.

Modified Commands

The following commands are modified in ArubaOS 6.4.2.0:

Command	Description
ap-rename	The service-tag parameter is introduced to identify an AP with its service tag.
ap-regroup	The service-tag parameter is introduced to identify an AP with its service tag.
ap system-profile	- The gre-striping-ip parameter is deprecated. GRE striping IP settings are defined using the ap-lacp-striping-ip command. - The system-message-frequency parameter now accepts a value in the range of 1-3600 seconds.
clear	- The web-cc cache and web-cc stats parameters are introduced, to clear the web content classification category cache and statistics. - The datapath web-cc parameter is introduced, to clear datapath web content classification statistics.

Command	Description
firewall	- The web-cc parameter is introduced. This parameter enables web content classification for all HTTP traffic. Once enabled, ArubaOS enforces ACLs and bandwidth policies associated with web content categories or reputation levels. - The web-cc-cache-miss-drop parameter is introduced. Issue this command to allow the controller to drop any packets that do not match any web content category or reputation levels in the controller's internal web content cache.
ip access-list session	The web-cc-category and web-cc-reputation parameters are introduced. Use these parameters to define a session ACL for traffic matching a web content category or reputation level.
provision-ap	The service-tag parameter was introduced under reprovision parameter.
rf dot11g-radio-profile	The very-high-throughput-rates-enable parameter is introduced. This command enables very high throughput (VHT) rates on the 2.4 GHz band through the addition of VHT Modulation and Coding Scheme values 8 and 9, providing 256-QAM modulation and encoding that allows for 600 Mbit/sec performance over 802.11n networks. VHT rates are supported on W-AP220 Series access points on both 20 and 40 MHz channels.
show ap database	The output of this command can display: - an s flag to indicate that the AP is enabled with a striping IP address. - the service tag of an AP.
show ap debug lacp	If a GRE striping IP address is configured in the ap-lacp-striping-ip profile, the output of this command displays the GRE striping IP address.
show ap debug system-status	The format of the System Status Script output is changed to the following: function-name(line-num): new-total-drops/total-drops new-priority-drops/total-priority-drops Example: wlc_dotxstatus(40576): 5034/3231117 4272/1907873 This change helps to determine if priority (voice or video) frames are dropped from the AP Wi-Fi driver drop-list. NOTE: The System Status Script is displayed for W-AP200 Series and W-AP220 Series access points only.
show ap details	The output of this command can display the service tag of an AP.
show datapath	- The session web-cc parameter is introduced. This command displays web-content category information about the session. - The web-cc parameter is introduced. This command parameter displays web-content classification table information, including the

Command	Description
	web content category ID, reputation score, and URL.
show firewall	The following parameters are introduced as part of this command output: • Web Content Classification • Web Content Cache Miss Drop
show provisioning-ap-list	The output of this command can display the service tag of an AP.
user-role	• The web-cc-category and web-cc-reputation parameters are introduced. Use these parameters to create a user role that applies a bandwidth contract to the specified web content category or reputation level. • The web-cc disable parameter is introduced to disable web content classification for this particular user-role.
wlan ssid-profile	The description of the multicast-rate parameter is changed to denote the rate for video multicast frames.

Deprecated Commands

The following commands are deprecated in ArubaOS 6.4.2.0:

Command	Description
ap system-profile	The gre-striping-ip parameter is deprecated. GRE striping IP settings are defined using the ap-lacp-striping-ip command.

Commands in ArubaOS 6.4.1.0

New Commands

The following commands are introduced in ArubaOS 6.4.1.0:

Command	Description
ap regulatory activate	This command activates a specified Regulatory Cert and pushes it to APs associated to the controller.
ap regulatory reset	This command deactivates and clears the currently activated Regulatory Cert from APs associated to the controller.
file syncing profile	This command is used to configure the file syncing profile on the controller.
show ap regulatory	This command displays the currently active Regulatory Cert on the controller.

Command	Description
show file syncing profile	This command displays the file syncing configuration on the controller.

Modified Commands

The following commands are modified in ArubaOS 6.4.1.0:

Command	Description
aaa profile	The user-idle-timeout parameter now accepts a value of 0.
airgroup	- The Chromecast service is renamed to DIAL. - The googlecast service is introduced.
firewall	The following new sub-parameters are introduced: arp grat-arp
ipv6 firewall	The valid range for the following parameters is changed to <1-16384>: ping session tcp-syn
rf arm-profile	The default values for the following parameters are changed: cm-band-g-max-signal cm-sticky-snr cm-sticky-min-signal cm-lb-client-thresh
show aigroup status	- The Chromecast service is renamed to DIAL. - The googlecast service is introduced.
show aigroupservice	- The Chromecast service is renamed to DIAL. - The googlecast service is introduced.
show ap arm client-match restriction-table	Following parameters are introduced as part of this command output: PS deauth Probe(home/scan/bc_ssid) Auth(home/scan) Radio Bssid

Command	Description
	The following parameters are modified as part of this command output: • Time last restricted • Restricted(Cur/Last) • Time since last restricted
show ap blacklist-clients	The following reason codes are introduced: • ARP-attack • gratuitous-ARP-attack
show datapath	The following parameters are introduced as part of the show datapath frame command output: • Excessive ARP Requests • Excessive Gratuitous ARP Requests The acl id <ACL-id> parameter has been added. This command displays acl-id related information. The acl {[ap-name <ap-name> ip-addr <ip-address>] name <acl-name> type <acl-type>} command retrieves ACL related details from an access point using the access point's name or ip-address.
show firewall	The following parameters are introduced as part of this command output: • Blacklist Grat ARP attack client • Blacklist ARP attack client • Monitor ARP attack • Monitor Gratuitous ARP attack
show switches	The regulatory parameter was added.
show whitelist-db cpsec	The following new parameters are introduced as part of this command output: • cert-type • page • start • state
show whitelist-db rap	The following new parameters are introduced as part of this command output: • apgroup • apname • fullname
user-role	The check-for-accounting parameter is introduced as part of this command output.

Commands in ArubaOS 6.4.0.0

New Commands

The following commands are introduced in the ArubaOS 6.4.0.0:

Command	Description
<u>airgroup static mdns-record</u>	This command enables an administrator to add mDNS static records to cache using the following methods: Group mDNS static records Individual mDNS static records
<u>app lync traffic-control</u>	This command creates a traffic control profile that allows the controller to recognize and prioritize a specific type of Lync traffic in order to apply QoS through the Lync Application Layer Gateway (ALG).
<u>dpi</u>	This command configures Deep-Packet Inspection and the global bandwidth contract for an application or application category for the AppRF feature.
<u>iap trusted-branch-db</u>	This command configures an IAP-VPN branch as trusted.
<u>pan active-profile</u>	This command activates a configured PAN profile.
<u>pan profile</u>	This command is used to configure a PAN profile.
<u>show aaa load-balance statistics</u>	This command displays the load balancing statistics for RADIUS servers.
<u>show lldp interface</u>	This command displays the LLDP interfaces information.
<u>show lldp neighbor</u>	This command displays information about LLDP peers.
<u>show lldp statistics</u>	This command displays the LLDP statistics information.
<u>show iap detailed-table</u>	This command displays the details of all the branches terminating at the controller.
<u>show pan active-profile</u>	This command displays the currently active PAN profile.
<u>show pan-options</u>	This command displays all configured PAN profiles.
<u>show pan state</u>	This command displays the current status of associated PAN firewalls.
<u>show pan statistics</u>	This command displays PAN profile statistics.
<u>show sso idp-profile</u>	This command displays the configured SSO IDP profiles.

Command	Description
<u>show ucc call-info cdrs</u>	This command displays the Call Detailed Report (CDR) statistics for Unified Communication and Collaboration (UCC).
<u>show ucc client-info</u>	This command displays the UCC client status and CDR statistics.
<u>show ucc configuration</u>	This command displays the UCC configuration in the controller.
<u>show ucc statistics</u>	This command displays the UCC call statistics in the controller.
<u>show ucc trace-buffer</u>	This command displays the UCC call message trace buffer for Lync, SCCP, and SIP ALGs. Events such as establishing voice, video, desktop sharing, and file transfer are recorded.
<u>sso idp-profile</u>	This command creates an SSO profile.
<u>wlan hotspot advertisement-profile</u>	This command configures a WLAN advertisement profile for an 802.11u public access service provider.
<u>wlan hotspot anqp-3gpp-nwk-profile</u>	This profile defines information for a 3rd Generation Partnership Project (3GPP) Cellular Network for hotspots that have roaming relationships with cellular operators.
<u>wlan hotspot anqp-domain-name-profile</u>	This command defines the domain name to be sent in an Access Network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.
<u>wlan hotspot anqp-ip-addr-avail-profile</u>	This command defines available IP address types to be sent in a Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.
<u>wlan hotspot anqp-nai-realm-profile</u>	This command defines a Network Access Identifier (NAI) realm whose information can be sent as an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.
<u>wlan hotspot anqp-nwk-auth-profile</u>	This command configures an ANQP Network Authentication profile to define authentication type being used by the hotspot network.
<u>wlan hotspot anqp-roam-cons-profile</u>	This command configures the Roaming Consortium OI information to be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.
<u>wlan hotspot anqp-venue-name-profile</u>	This command defines venue information be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.
<u>wlan hotspot h2qp-conn-capability-profile</u>	This command defines a Hotspot 2.0 Query Protocol (H2QP) profile that advertises hotspot protocol and port capabilities.

Command	Description
wlan hotspot h2qp-op-cl-profile	This command defines a Hotspot 2.0 Query Protocol (H2QP) profile that defines the Operating Class to be sent in the ANQP IE.
wlan hotspot h2qp-operator-friendly-name-profile	This command defines a Hotspot 2.0 Query Protocol (H2QP) operator-friendly name profile. The operator-friendly name configured in this profile is a free-form text field that can identify the operator and also something about the location.
wlan hotspot h2qp-wan-metrics-profile	This command creates a Hotspot 2.0 Query Protocol (H2QP) profile that specifies the hotspot WAN status and link metrics.
wlan hotspot hs2-profile	This command configures a hotspot profile for an 802.11u public access service provider.

Modified Commands

The following commands are modified in ArubaOS 6.4.0.0:

Command	Description
airgroup	The dlina and mdns parameters are introduced.
aaa authentication captive-portal	The url-hash-key parameter is introduced.
aaa authentication-server radius	The called-station-id parameter is introduced.
aaa authentication via auth-profile	The pan-integration parameter is introduced.
aaa authentication vpn	The pan-integration parameter is introduced.
aaa profile	The multiple-server-accounting and download-role parameters are introduced. The pan-integration parameter is introduced.
aaa server-group	The load-balance parameter is introduced.
clear	The lldp parameter is introduced. The Server and User options are introduced under airgroup parameter.
crypto dynamic-map	The disable/enable parameters are introduced.
crypto isakmp policy	The disable/enable and no parameters are introduced.
firewall	The following parameters are added:

Command	Description
	• allow-stun • dpi • stall-crash
ha	The following parameters are introduced to support the high availability inter-controller heartbeat, controller oversubscription and state synchronization features. • heartbeat: • heartbeat-interval • heartbeat-threshold • over-subscription • pre-shared-key • state-sync
interface fastethernet gigabitethernet	The lldp parameter is introduced.
interface vlan	The dhcp parameter for configuring dynamic host configuration protocol for IPv6 is introduced.
interface tunnel	Tunnel destination ipv6 , tunnel mode gre ipv6 , tunnel source ipv6 , parameters are introduced.
ip access-list session	The redirect parameter is introduced under action. The app , and appcategory parameters are introduced under service.
ip igmp	The ssm-range parameter is introduced.
ipv6 mld	The ssm-range parameter is introduced.
ipv6 route	The vlan parameter is introduced.
ntp server	The IPv6 parameter is introduced.
show aaa authentication-server radius	The called-station-id parameter is introduced as part of this command output.
show airgroup	The dlina and mdns parameters are introduced as part of the following command outputs: • show airgroup blocked-queries • show airgroup blocked-service-id • show airgroup internal-state statistics The dlina, mdns, and verbose parameters are introduced as part of the following command outputs:

Command	Description
	• show airgroupservice • show airgroup servers • show airgroup users The dlina, mdns, and static parameters are introduced as part of the show airgroup cache entries command output.
show airgroupservice	The dlina , mdns , and verbose parameters are introduced as part of this command output.
show app lync traffic-control	The profile-name parameter is introduced as part of this command output.
show datapath	The following parameters are introduced as part of this command output: • dpi • session dpi • session ipv6 dpi • session session-id dpi
show ipv6 interface	The tunnel parameter is introduced as part of this command output.
show ipv6 mld config	The ssm-range parameter is introduced as part of this command output.
show ipv6 mld group	The mode and age parameters are introduced.
show ntp peer	The IPv6 parameter is introduced.
show ntp servers	Flags indicating the status of the server, are introduced.
show ntp status	The following parameters are introduced as part of this command output: • time since restart • packets received • packets processed • current version • previous version • declined • access denied • bad length or format • bad authentication • rate exceeded

Command	Description
show voice real-time-analysis	The following new parameters are introduced as part of this command output: • Jitter(D)(usec) • UCC Score
show vrrp	The ipv6 , stats , and summary parameters are introduced as part of this command output.
snmp-server	The IPv6 parameter is introduced.
user-role	The following parameters are introduced: • bandwidth-contract app • bandwidth-contract appcategory • bandwidth-contract exclude • traffic-control-profile • sso
vrrp	The IPv6 parameter is introduced.
web-server profile	The idp-certificate parameter is introduced.
wlan ssid-profile	• The mfp-capable and mfp-required parameters are added. • The eapol-rate-opt parameter is enabled by default.

Deprecated Commands

The following commands are deprecated in ArubaOS 6.4.0.0:

Command	Description
app lync traffic-control (deprecated)	This command is deprecated and replaced by app lync traffic-control <profile-name> .
interface tunnel	The checksum parameter is deprecated.
show voice real-time-analysis	The following parameters are deprecated as part of this command output: • Jitter(U)(msec) • rvalue(U) • Pkt-loss(U)(%) • Delay(U)(usec) • Jitter(D)(msec) • rvalue(D)

About this Guide

This guide describes the Dell Networking W-Series ArubaOS 6.4.x command syntax. The commands in this guide are listed alphabetically.

The following information is provided for each command:

- Command Syntax—The complete syntax of the command.
- Description—A brief description of the command.
- Syntax—A description of the command parameters, including license requirements for specific parameters if needed. The applicable ranges and default values, if any, are also included.
- Usage Guidelines—Information to help you use the command, including: prerequisites, prohibitions, and related commands.
- Example—An example of how to use the command.
- Command History—The version of ArubaOS in which the command was first introduced. Modifications and changes to the command are also noted.
- Command Information—This table describes any licensing requirements, command modes and platforms for which this command is applicable. For more information about available licenses, see the Licenses chapter of the *Dell Networking W-Series ArubaOS 6.4.x User Guide*.

Connecting to the Controller

This section describes how to connect to the controller to use the CLI.

Serial Port Connection

The serial port is located on the front panel of the controller. Connect a terminal or PC/workstation running a terminal emulation program to the serial port on the controller to use the CLI. Configure your terminal or terminal emulation program to use the following communication settings.

Baud Rate	Data Bits	Parity	Stop Bits	Flow Control
9600	8	None	1	None

The Dell W-7200 Series controller supports baud rates between 9600 and 115200.

Telnet or SSH Connection

Telnet or SSH access requires that you configure an IP address and a default gateway on the controller and connect the controller to your network. This is typically performed when you run the Initial Setup on the controller, as described in the *Dell Networking W-Series ArubaOS 6.4.x Quick Start Guide*. In certain deployments, you can also configure a loopback address for the controller; see [interface loopback on page 473](#) for more information.

Configuration changes on Master Controllers

Some commands can only be issued when connected to a master controller. If you make a configuration change on a master controller, all connected local controllers will subsequently update their configurations as well. You can manually synchronize all of the controllers at any time by saving the configuration on the master controller.

CLI Access

When you connect to the controller using the CLI, the system displays its host name followed by the login prompt. Log in using the admin user account and the password you entered during the Initial Setup on the controller (the password displays as asterisks). For example:

```
(host)
User: admin
Password: *****
```

When you are logged in, the *user* mode CLI prompt displays. For example:

```
(host) >
```

User mode provides only limited access for basic operational testing such as running **ping** and **traceroute**.

Certain management functions are available in enable (also called “privileged”) mode. To move from user mode to enable mode requires you to enter an additional password that you entered during the Initial Setup (the password displays as asterisks). For example:

```
(host) > enable
Password: *****
```

When you are in enable mode, the > prompt changes to a pound sign (#):

```
(host) #
```

Configuration commands are available in *config* mode. Move from enable mode to config mode by entering **configure terminal** at the # prompt:

```
(host) # configure terminal
Enter Configuration commands, one per line. End with CNTL/Z
```

When you are in basic config mode, (config) appears before the # prompt:

```
(host) (config) #
```

There are several other sub-command modes that allow users to configure individual interfaces, subinterfaces, loopback addresses, GRE tunnels and cellular profiles. For details on the prompts and the available commands for each of these modes, see [Appendix A: Command Modes on page 2370](#).

Command Help

You can use the question mark (?) to view various types of command help.

When typed at the beginning of a line, the question mark lists all the commands available in your current mode or sub-mode. A brief explanation follows each command. For example:

```
(host) > ?
```

enable	Turn on Privileged commands
logout	Exit this session. Any unsaved changes are lost.
ping	Send ICMP echo packets to a specified IP address.
traceroute	Trace route to specified IP address.

When typed at the end of a possible command or abbreviation, the question mark lists the commands that match (if any). For example:

```
(host) > c?
```

clear	Clear configuration
clock	Configure the system clock
configure	Configuration Commands
copy	Copy Files

If more than one item is shown, type more of the keyword characters to distinguish your choice. However, if only one item is listed, the keyword or abbreviation is valid and you can press tab or the spacebar to advance to the next keyword.

When typed in place of a parameter, the question mark lists the available options. For example:

```
(host) # write ?
erase                Erase and start from scratch
file                 Write to a file in the file system
memory              Write to memory
terminal            Write to terminal
<cr>
```

The <cr> indicates that the command can be entered without additional parameters. Any other parameters are optional.

Command Completion

To make command input easier, you can usually abbreviate each key word in the command. You need type only enough of each keyword to distinguish it from similar commands. For example:

```
(host) # configure terminal
```

could also be entered as:

```
(host) # con t
```

Three characters (**con**) represent the shortest abbreviation allowed for **configure**. Typing only **c** or **co** would not work because there are other commands (like **copy**) which also begin with those letters. The configure command is the only one that begins with **con**.

As you type, you can press the spacebar or tab to move to the next keyword. The system then attempts to expand the abbreviation for you. If there is only one command keyword that matches the abbreviation, it is filled in for you automatically. If the abbreviation is too vague (too few characters), the cursor does not advance and you must type more characters or use the help feature to list the matching commands.

Deleting Configuration Settings

Use the **no** command to delete or negate previously-entered configurations or parameters.

- To view a list of no commands, type **no** at the enable or config prompt followed by the question mark. For example:

```
(host) (config) # no?
```

- To delete a configuration, use the **no** form of a configuration command. For example, the following command removes a configured user role:

```
(host) (config) # no user-role <name>
```

- To negate a specific configured parameter, use the **no** parameter within the command. For example, the following commands delete the DSCP priority map for a priority map configuration:

```
(host) (config) # priority-map <name>
(host) (config-priority-map) # no dscp priority high
```

Saving Configuration Changes

Each Dell controller contains two different types of configuration images.

- The *running-config* holds the current controller configuration, including all pending changes which have yet to be saved. To view the running-config, use the following command:

```
(host) # show running-config
```

- The *startup config* holds the configuration which will be used the next time the controller is rebooted. It contains all the options last saved using the **write memory** command. To view the startup-config, use the following command:

```
(host) # show startup-config
```

When you make configuration changes via the CLI, those changes affect the current running configuration only. If the changes are not saved, they will be lost after the controller reboots. To save your configuration changes so they are retained in the startup configuration after the controller reboots, use the following command in enable mode:

```
(host) # write memory
Saving Configuration...
Saved Configuration
```

Both the startup and running configurations can also be saved to a file or sent to a TFTP server for backup or transfer to another system.

Commands That Reset the Controller or AP

If you use the CLI to modify a currently provisioned and running radio profile, those changes take place immediately; you do not reboot the controller or the AP for the changes to affect the current running configuration. Certain commands, however, automatically force the controller or AP to reboot. You may want to consider current network loads and conditions before issuing these commands, as they may cause a momentary disruption in service as the unit resets. Note also that changing the **lms-ip** parameter in an AP system profile associated with an AP group will cause all APs in that AP group to reboot.

Table 1: *Reset Commands*

Commands that Reset an AP	Commands that Reset a Controller
• ap-regroup • ap-rename • apboot • provision-ap • ap wired-ap-profile <profile> forward-mode {bridge split-tunnel tunnel} • wlan virtual-ap <profile-name> {aaa-profile <profile-name> forward-mode {tunnel bridge split-tunnel decrypt-tunnel} ssid-profile <profile-name> vlan <vlan>...} • ap system-profile <profile> {bootstrap-threshold <number> lms-ip <ipaddr> } • wlan ssid-profile <profile-name> {battery-boost deny-bcast essid opmode strict-svp wepkey1 <key> wepkey2 <key> wepkey3 <key> wepkey4 <key> weptxkey <index> wmm wmm-be-dscp <best-effort> wmm-bk-dscp <background> wmm-ts-min-inact-int <milliseconds> wmm-vi-dscp <video> wmm-vo-dscp <voice> wpa-hexkey <psk> wpa-passphrase <string> } • wlan dot11k <profile-name> {bcn-measurement-mode dot11k-enable force-dissasoc}	• reload

Typographic Conventions

The following conventions are used throughout this manual to emphasize important concepts:

Table 2: *Text Conventions*

Type Style	Description
<i>Italics</i>	This style is used to emphasize important terms and to mark the titles of books.
Boldface	This style is used to emphasize command names and parameter options when mentioned in the text.
Commands	This fixed-width font depicts command syntax and examples of commands and command output.
<angle brackets>	In the command syntax, text within angle brackets represents items that you should replace with information appropriate to your specific situation. For example: <pre>ping <ipaddr></pre> In this example, you would type “ping” at the system prompt exactly as shown, followed by the IP address of the system to which ICMP echo packets are to be sent. Do not type the angle brackets.
[square brackets]	In the command syntax, items enclosed in brackets are optional. Do not type the brackets.
{Item_A Item_B}	In the command examples, single items within curled braces and separated by a vertical bar represent the available choices. Enter only one choice. Do not type the braces or bars.
{ap-name <ap-name>} {ipaddr <ip-addr>}	Two items within curled braces indicate that both parameters must be entered together. If two or more sets of curled braces are separated by a vertical bar, like in the example to the left, enter only one choice. Do not type the braces or bars.

Command Line Editing

The system records your most recently entered commands. You can review the history of your actions, or reissue a recent command easily, without having to retype it.

To view items in the command history, use the *up* arrow key to move back through the list and the *down* arrow key to move forward. To reissue a specific command, press **Enter** when the command appears in the command history. You can even use the command line editing feature to make changes to the command prior to entering it. The command line editing feature allows you to make corrections or changes to a command without retyping. [Table 1](#) lists the editing controls. To use key shortcuts, press and hold the **Ctrl** button while you press a letter key.

Table 3: *Line Editing Keys*

Key	Effect	Description
Ctrl A	Home	Move the cursor to the beginning of the line.
Ctrl B or the left arrow	Back	Move the cursor one character left.
Ctrl D	Delete Right	Delete the character to the right of the cursor.
Ctrl E	End	Move the cursor to the end of the line.
Ctrl F or the right arrow	Forward	Move the cursor one character right.
Ctrl K	Delete Right	Delete all characters to the right of the cursor.
Ctrl N or the down arrow	Next	Display the next command in the command history.
Ctrl P or up arrow	Previous	Display the previous command in the command history.
Ctrl T	Transpose	Swap the character to the left of the cursor with the character to the right of the cursor.
Ctrl U	Clear	Clear the line.
Ctrl W	Delete Word	Delete the characters from the cursor up to and including the first space encountered.
Ctrl X	Delete Left	Delete all characters to the left of the cursor.

Specifying Addresses and Identifiers in Commands

This section describes addresses and other identifiers that you can reference in CLI commands.

Table 4: Addresses and Identifiers

Address/Identifier	Description
IP address	For any command that requires entry of an IP address to specify a network entity, use IPv4 network address format in the conventional dotted decimal notation (for example, 10.4.1.258).
Netmask address	For subnet addresses, specify a netmask in dotted decimal notation (for example, 255.255.255.0).
Media Access Control (MAC) address	For any command that requires entry of a device's hardware address, use the hexadecimal format (for example, 00:05:4e:50:14:aa).
Service Set Identifier (SSID)	A unique character string (sometimes referred to as a network name), consisting of no more than 32 characters. The SSID is case-sensitive (for example, WLAN-01).
Basic Service Set Identifier (BSSID)	This entry is the unique hard-wireless MAC address of the AP. A unique BSSID applies to each frequency— 802.11a and 802.11g—used from the AP. Use the same format as for a MAC address.
Extended Service Set Identifier (ESSID)	Typically the unique logical name of a wireless network. If the ESSID includes spaces, you must enclose the name in quotation marks.
Fast Ethernet or Gigabit Ethernet interface	Any command that references a Fast Ethernet or Gigabit Ethernet interface requires that you specify the corresponding port on the controller in the format <code><slot>/<port></code>: <slot> is always 1, except when referring to interfaces on the W-6000 controller(slots 0-3). The <port> parameter refers to the network interfaces that are embedded in the front panel of the W-3000 Series controller, or a W-6000M3 controller module installed in a W-6000 controller chassis. Port numbers start at 0 from the left-most position. Use the show port status command to obtain the interface information currently available from a controller.

aaa alias-group (deprecated)

```
aaa alias-group
  clone <group>
  no ...
  set vlan condition essid|location equals <operand> set-value <set-value-string>
```

Description

This command configured an aaa alias with set of VLAN derivation rules that could speed up user rule derivation processing for deployments with a very large number of user derivation rules.

Command History

Version	Description
ArubaOS 6.3	Command introduced.
ArubaOS 6.4	Command deprecated.

aaa auth-survivability

```
aaa auth-survivability
  cache-lifetime
  enable
  server-cert
```

Description

This command configures Authentication Survivability on a controller.

Syntax

Parameter	Description	Default
cache-lifetime <hrs>	This parameter specifies the lifetime in hours for the cached access credential in the local Survival Server. When the specified cache-lifetime expires, the cached access credential is deleted from the controller. The valid range is from 1 to 72 hours.	24 hours
enable	This parameter controls whether to use the Survival Server when no other servers in the server group are in-service. This parameter also controls whether to store the user access credential in the Survival Server when it is authenticated by an external RADIUS or LDAP server in the server group. Authentication Survivability is enabled or disabled on each controller. NOTE: Authentication survivability will not activate if the Authentication Server Dead Time is configured as 0	Disabled
server-cert	This parameter allows you to view the name of the server certificate used by the local Survival Server. The local Survival Server is provided with a default server certificate from AOS. The customer server certificate must be imported into the controller first, and then you can assign the server certificate to the local Survival Server. NOTE: In the deployment environment, it is recommended that you switch to a customer server certificate.	—

Usage Guidelines

Use this command to configure authentication survivability on a standalone, local, or master controller.

To configure authentication survivability on a branch controller, you must use the Smart Config WebUI. On the branch controller, navigate to **Configuration > BRANCH > Smart Config**.

Command History

Version	Description
ArubaOS 6.4.3.0	Command introduced.

aaa authentication captive-portal

```
aaa authentication captive-portal <profile>
  apple-cna-bypass
  auth-protocol mschapv2|pap|chap
  black-list <black-list>
  clone <source-profile>
  default-guest-role <role>
  default-role <role>
  enable-welcome-page
  guest-logon
  ip-addr-in-redirect <ipaddr>
  login-page <url>
  logon-wait {cpu-threshold <percent>}{maximum-delay <seconds>}{minimum-delay <seconds>}
  logout-popup-window
  max-authentication-failures <number>
  no ...
  protocol-http
  redirect-pause <seconds>
  redirect-url <url>
  server-group <group-name>
  show-acceptable-use-policy
  show-fqdn
  single-session
  switchip-in-redirect-url <ipaddr>
  url-hash-key <key>
  user-idle-timeout
  user-logon
  user-vlan-in-redirect-url <vlan>
  welcome-page <url>
  white-list <white-list>
```

Description

This command configures a Captive Portal authentication profile.

Syntax

Parameter	Description	Range	Default
apple-cna-bypass	Enable this knob to bypass Apple CNA on iOS devices such as iPad, iPhone, and iPod. You need to perform Captive Portal authentication from browser.	—	
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	"default"
authentication-protocol mschapv2 pap chap	This parameter specifies the type of authentication required by this profile, PAP is the default authentication type.	mschap v2 pap chap	pap

Parameter	Description	Range	Default
<code>black-list</code>	Name of an existing black list on an IPv4 or IPv6 network destination. The black list contains websites (unauthenticated) that a guest cannot access. Specify a netdestination host or subnet to add that netdestination to the captive portal blacklist. If you have not yet defined a netdestination, use the CLI command netdestination to define a destination host or subnet before you add it to the blacklist.	—	—
<code>clone</code>	Name of an existing Captive Portal profile from which parameter values are copied.	—	—
<code>default-guest-role</code>	Role assigned to guest.	—	guest
<code>default-role <role></code>	Role assigned to the Captive Portal user when that user logs in. When both user and guest logons are enabled, the default role applies to the user logon; users logging in using the guest interface are assigned the guest role.	—	guest
<code>enable-welcome-page</code>	Displays the configured welcome page before the user is redirected to their original URL. If this option is disabled, redirection to the web URL happens immediately after the user logs in.	enabled/ disabled	enabled
<code>guest-logon</code>	Enables Captive Portal logon without authentication.	enabled/ disabled	disabled
<code>ipaddr-in-redirection-url <ipaddr></code>	Sends the controller's interface IP address in the redirection URL when external captive portal servers are used. An external captive portal server can determine the controller from which a request originated by parsing the 'switchip' variable in the URL. This parameter requires the Public Access license.	—	—
<code>login-page <url></code>	URL of the page that appears for the user logon. This can be set to any URL.	—	/auth/index.html

Parameter	Description	Range	Default
logon-wait	Configure parameters for the logon wait interval.	1-100	60%
cpu-threshold <percent>	CPU utilization percentage above which the logon wait interval is applied when presenting the user with the logon page.	1-100	60%
maximum-delay <seconds>	Maximum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high. This works in conjunction with the Logon wait CPU utilization threshold parameter.	1-10	10 seconds
minimum-delay <seconds>	Minimum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high. This works in conjunction with the Logon wait CPU utilization threshold parameter.	1-10	5 seconds
logout-popup-window	Enables a pop-up window with the Logout link that allows the user to log out. If this option is disabled, the user remains logged in until the user timeout period has elapsed or the station reloads.	enabled/ disabled	enabled
max-authentication-failures <number>	Maximum number of authentication failures before the user is blacklisted.	0-10	0
no	Negates any configured parameter.	—	—
protocol-http	Use HTTP protocol on redirection to the Captive Portal page. If you use this option, modify the captive portal policy to allow HTTP traffic.	enabled/ disabled	disabled (HTTPS is used)
redirect-pause <secs>	Time, in seconds, that the system remains in the initial welcome page before redirecting the user to the final web URL. If set to 0, the welcome page displays until the user clicks on the indicated link.	1-60	10 seconds
redirect-url <url>	URL to which an authenticated user will be directed. This parameter must be an absolute URL that begins with either http:// or https:// .	—	—

Parameter	Description	Range	Default
server-group <group-name>	Name of the group of servers used to authenticate Captive Portal users. See aaa server-group on page 125 .	—	—
show-fqdn	Allows the user to see and select the fully-qualified domain name (FQDN) on the login page. The FQDNs shown are specified when configuring individual servers for the server group used with captive portal authentication.	enabled disabled	disabled
show-acceptable-use-policy	Show the acceptable use policy page before the login page.	enabled disabled	disabled
single-session	Allows only one active user session at a time.	—	disabled
switchip-in-redirection-url	Sends the controller's IP address in the redirection URL when external captive portal servers are used. An external captive portal server can determine the controller from which a request originated by parsing the 'switchip' variable in the URL.	enabled disabled	disabled
url-hash-key <key>	Issue this command to hash the redirection URL using the specified key.	—	disabled
user-idle-timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.	—	disabled
user-logon	Enables Captive Portal with authentication of user credentials.	enabled disabled	enabled
user-vlan-in-redirection-url <ipaddr>	Add the user VLAN in the redirection URL. This parameter requires the Public Access license.	enabled disabled	disabled
user-vlan-redirection-url	Sends the user's VLAN ID in the redirection URL when external captive portal servers are used.	—	—

Parameter	Description	Range	Default
welcome-page <url>	URL of the page that appears after logon and before redirection to the web URL. This can be set to any URL.	—	/auth/welcome.html
white-list <white-list>	Name of an existing white list on an IPv4 or IPv6 network destination. The white list contains authenticated websites that a guest can access. If you have not yet defined a netdestination, use the CLI command netdestination to define a destination host or subnet before you add it to the whitelist.	—	—

Usage Guidelines

You can configure the Captive Portal authentication profile in the base operating system or with the Next Generation Policy Enforcement Firewall (PEFNG) license installed. When you configure the profile in the base operating system, the name of the profile must be entered for the initial role in the AAA profile. Also, when you configure the profile in the base operating system, you cannot define the default-role.

Example

The following example configures a Captive Portal authentication profile that authenticates users against the controller's internal database. Users who are successfully authenticated are assigned the auth-guest role.

To create the auth-guest user role shown in this example, the PEFNG license must be installed in the controller.

```
aaa authentication captive-portal guestnet
    default-role auth-guest
    user-logon
    no guest-logon
    server-group internal
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 6.0	The max-authentication-failures parameter no longer requires a license.
ArubaOS 6.1	The sygate-on-demand , black-list and white-list parameters were added.
ArubaOS 6.2	the auth-protocol parameter was added, and the user-chap parameter was deprecated.
ArubaOS 6.3	The user-idle-timeout parameter was introduced.
ArubaOS 6.4	The url-hash-key parameter was introduced.

Description

This command configures the 802.1X authentication profile.

Syntax

Parameter	Description	Range	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	"default"
clear	Clear the Cached PMK, Role and VLAN entries. This command is available in enable mode only.	—	—
countermeasures	Scans for message integrity code (MIC) failures in traffic received from clients. If there are more than 2 MIC failures within 60 seconds, the AP is shut down for 60 seconds. This option is intended to slow down an attacker who is making a large number of forgery attempts in a short time.	—	disabled
ca-cert <certificate>	CA certificate for client authentication. The CA certificate needs to be loaded in the controller.	—	—
cert-cn-lookup	If you use client certificates for user authentication, enable this option to verify that the certificate's common name exists in the server. This parameter is disabled by default.	—	—
delete-keycache	Delete the key cache entry when the user entry is deleted.	—	disabled
eapol-logoff	Enables handling of EAPOL-LOGOFF messages.	—	disabled
enforce-suite-b-128	Configure Suite-B 128 bit or more security level authentication enforcement		disabled
enforce-suite-b-192	Configure Suite-B 192 bit or more security level authentication enforcement		disabled

Parameter	Description	Range	Default
framed-mtu <MTU>	Sets the framed MTU attribute sent to the authentication server.	500-1500	1100
heldstate-bypass-counter <number>	(This parameter is applicable when 802.1X authentication is terminated on the controller, also known as AAA FastConnect.) Number of consecutive authentication failures which, when reached, causes the controller to not respond to authentication requests from a client while the controller is in a held state after the authentication failure. Until this number is reached, the controller responds to authentication requests from the client even while the controller is in its held state.	0-3	0
ignore-eap-id-match	Ignore EAP ID during negotiation.	—	disabled
ignore-eapol-start-afterauthentication	Ignores EAPOL-START messages after authentication.	—	disabled
machine-authentication	(For Windows environments only) These parameters set machine authentication: NOTE: This parameter requires the PEFNG license.		
blacklist-on-failure	Blacklists the client if machine authentication fails.	—	disabled
cache-timeout <hours>	The timeout, in hours, for machine authentication.	1-1000	24 hours (1 day)
enable	Select this option to enforce machine authentication before user authentication. If selected, either the machine-default-role or the user-default-role is assigned to the user, depending on which authentication is successful.	—	disabled
machine-default-role <role>	Default role assigned to the user after completing only machine authentication.	—	guest

Parameter	Description	Range	Default
<code>user-default-role <role></code>	Default role assigned to the user after 802.1X authentication.	—	guest
<code>max-authentication-failures <number></code>	Number of times a user can try to login with wrong credentials after which the user is blacklisted as a security threat. Set to 0 to disable blacklisting, otherwise enter a non-zero integer to blacklist the user after the specified number of failures.	0-5	0 (disabled)
<code>max-requests <number></code>	Maximum number of times ID requests are sent to the client.	1-10	5
<code>multicast-key rotation</code>	Enables multicast key rotation	—	disabled
<code>no</code>	Negates any configured parameter.	—	—
<code>opp-key-caching</code>	Enables a cached pairwise master key (PMK) derived with a client and an associated AP to be used when the client roams to a new AP. This allows clients faster roaming without a full 802.1X authentication. NOTE: Make sure that the wireless client (the 802.1X supplicant) supports this feature. If the client does not support this feature, the client will attempt to renegotiate the key whenever it roams to a new AP. As a result, the key cached on the controller can be out of sync with the key used by the client.	—	enabled
<code>reauth-max <number></code>	Maximum number of reauthentication attempts.	1-10	3
<code>reauth-server-termination-action</code>	Specifies the termination-action attribute from the server.		

Parameter	Description	Range	Default
reauthentication	Select this option to force the client to do a 802.1X reauthentication after the expiration of the default timer for reauthentication. (The default value of the timer is 24 hours.) If the user fails to reauthenticate with valid credentials, the state of the user is cleared. If derivation rules are used to classify 802.1X-authenticated users, then the reauthentication timer per role overrides this setting.	—	disabled
reload-cert	Reload Certificate for 802.1X termination. This command is available in enable mode only.	—	—
server	Sets options for sending authentication requests to the authentication server group.		
server-retry <number>	Maximum number of authentication requests that are sent to server group.	0-3	3
server-retry-period <seconds>	Server group retry interval, in seconds.	5-65535	5 seconds
server-cert <certificate>	Server certificate used by the controller to authenticate itself to the client.	—	—
termination	Sets options for terminating 802.1X authentication on the controller.		
eap-type <type>	The Extensible Authentication Protocol (EAP) method, either EAP-PEAP or EAP-TLS.	eap-peap/ eap-tls	eap-peap
enable	Enables 802.1X termination on the controller.	—	disabled

Parameter	Description	Range	Default
enable-token -caching	If you select EAP-GTC as the inner EAP method, you can enable the controller to cache the username and password of each authenticated user. The controller continues to reauthenticate users with the remote authentication server, however, if the authentication server is not available, the controller will inspect its cached credentials to reauthenticate users.	—	disabled
inner-eap-type eap-gtc eap-mschapv2	When EAP-PEAP is the EAP method, one of the following inner EAP types is used: EAP-Generic Token Card (GTC): Described in RFC 2284, this EAP method permits the transfer of unencrypted usernames and passwords from client to server. The main uses for EAP-GTC are one-time token cards such as SecureID and the use of LDAP or RADIUS as the user authentication server. You can also enable caching of user credentials on the controller as a backup to an external authentication server. EAP-Microsoft Challenge Authentication Protocol version 2 (MS-CHAPv2): Described in RFC 2759, this EAP method is widely supported by Microsoft clients.	eap-gtc/eap-mschap v2	eap-mschap v2
token-caching-period <hours>	If you select EAP-GTC as the inner EAP method, you can specify the timeout period, in hours, for the cached information.	(any)	24 hours
timer	Sets timer options for 802.1X authentication:		
idrequest-period <seconds>	Interval, in seconds, between identity request retries.	1-65535	5 seconds
mkey-rotation-period <seconds>	Interval, in seconds, between multicast key rotation.	60-864000	1800 seconds

Parameter	Description	Range	Default
quiet-period <seconds>	Interval, in seconds, following failed authentication.	1-65535	30 seconds
reauth-period <seconds>	Interval, in seconds, between reauthentication attempts, or specify server to use the server-provided reauthentication period.	60-864000	86400 seconds (1 day)
ukey-rotation-period <seconds>	Interval, in seconds, between unicast key rotation.	60-864000	900 seconds
wpa-groupkey-delay <milliseconds>	Interval, in milliseconds, between unicast and multicast key exchanges.	0-2000	0 ms (no delay)
wpa-key-period <milliseconds>	Interval, in milliseconds, between each WPA key exchange.	1000-5000	1000 ms
wpa2-key-delay <milliseconds>	Set the delay between EAP-Success and unicast key exchange.	1-2000	0 ms (no delay)
tls-guest-access	Enables guest access for EAP-TLS users with valid certificates.	—	disabled
tls-guest-role <role>	User role assigned to EAP-TLS guest. NOTE: This parameter requires the PEFNG license.	—	guest
unicast-keyrotation	Enables unicast key rotation.	—	disabled
use-session-key	Use RADIUS session key as the unicast WEP key.	—	disabled
use-static-key	Use static key as the unicast/multicast WEP key.	—	disabled

Parameter	Description	Range	Default
validate-pmkid	This parameter instructs the controller to check the pairwise master key (PMK) ID sent by the client. When this option is enabled, the client must send a PMKID in the associate or reassociate frame to indicate that it supports OKC or PMK caching; otherwise, full 802.1X authentication takes place. (This feature is optional, since most clients that support OKC and PMK caching do not send the PMKID in their association request.)	—	disabled
voice-aware	Enables rekey and reauthentication for VoWLAN clients. NOTE: The Next Generation Policy Enforced Firewall license must be installed.	—	enabled
wep-key-retries <number>	Number of times WPA/WPA2 key messages are retried.	1-5	3
wep-key-size	Dynamic WEP key size, either 40 or 128 bits.	40 or 128	128 bits
wpa-fast-handover	Enables WPA-fast-handover. This is only applicable for phones that support WPA and fast handover.	—	disabled
wpa-key-retries	Set the number of times WPA/WPA2 Key Messages are retried. The supported range is 1-10 retries, and the default value is 3.	1-10	3
xSec-mtu <mtu>	Sets the size of the MTU for xSec.	1024-1500	1300 bytes

Usage Guidelines

The 802.1X authentication profile allows you to enable and configure machine authentication and 802.1X termination on the controller (also called “AAA FastConnect”).

In the AAA profile, specify the 802.1X authentication profile, the default role for authenticated users, and the server group for the authentication.

Examples

The following example enables authentication of the user's client device before user authentication. If machine authentication fails but user authentication succeeds, the user is assigned the restricted "guest" role:

```
aaa authentication dot1x dot1x
  machine-authentication enable
  machine-authentication machine-default-role computer
  machine-authentication user-default-role guest
```

The following example configures an 802.1X profile that terminates authentication on the controller, where the user authentication is performed with the controller's internal database or to a "backend" non-802.1X server:

```
aaa authentication dot1x dot1x
  termination enable
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The cert-cn-lookup , enforce-suite-b-128 and enforce-suite-b-192 parameters were introduced.
ArubaOS 6.3.1.2	The delete-keycache parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system. The voice-aware parameter requires the PEFNG license	Config mode on master controllers

aaa authentication mac

```
aaa authentication mac <profile>
  case upper|lower
  clone <profile>
  delimiter {colon|dash|none}
  max-authentication-failures <number>
  no ...
  reauthentication
  timer reauth period {<ra-period>|server}
```

Description

This command configures the MAC authentication profile.

Syntax

Parameter	Description	Range	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	“default”
case	The case (upper or lower) used in the MAC string sent in the authentication request. If there is no delimiter configured, the MAC address in lower case is sent in the format xxxxxxxxxxxx, while the MAC address in upper case is sent in the format XXXXXXXXXXXX.	upper lower	lower
clone <profile>	Name of an existing MAC profile from which parameter values are copied.	—	—
delimiter	Delimiter (colon, dash, or none) used in the MAC string.	colon dash none	none
max-authentication-failures <number>	Number of times a client can fail to authenticate before it is blacklisted. A value of 0 disables blacklisting.	0-10	0 (disabled)
no	Negates any configured parameter.	—	—
reauthentication	Use this parameter to enable or disable reauthentication.		Disabled
timer reauth period <ra-period> server	<ra-period> specifies the period between reauthentication attempts in seconds. The server parameter specifies the server-provided reauthentication interval.	60- 864000 seconds	86400 seconds (1 day)

Usage Guidelines

MAC authentication profile configures authentication of devices based on their physical MAC address. MAC-based authentication is often used to authenticate and allow network access through certain devices while

denying access to all other devices. Users may be required to authenticate themselves using other methods, depending upon the network privileges.

Example

The following example configures a MAC authentication profile to blacklist client devices that fail to authenticate.

```
aaa authentication mac mac-blacklist
    max-authentication-failures 3
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3.1.8	The max-authentication-failures parameter was allowed in the base operating system. In earlier versions of ArubaOS, the max-authentication-failures parameter required the Wireless Intrusion Protection license
ArubaOS 6.3	The reauthentication and timer reauth period parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication mgmt

aaa authentication mgmt

```
default-role {guest-provisioning|location-api-mgmt|network-operations|no-access|read-only|root}  
enable  
no ...  
server-group <group>
```

Description

This command configures authentication for administrative users.

Syntax

Parameter	Description	Range	Default
default-role	Select a predefined management role to assign to authenticated administrative users:	—	default
default	Default superuser role	—	—
guest-provisioning	Guest provisioning role	—	—
location-api-mgmt	Location API role	—	—
network-operations	Network operations role	—	—
no-access	No commands are accessible for this role	—	—
read-only	Read-only role	—	—
enable	Enables authentication for administrative users.	enabled disabled	disabled
mchapv2	Enable MSCHAPv2	enabled disabled	disabled
no	Negates any configured parameter.	—	—
server-group <group>	Name of the group of servers used to authenticate administrative users. See aaa server-group on page 125 .	—	default

Usage Guidelines

If you enable authentication with this command, users configured with the **mgmt-user** command must be authenticated using the specified server-group.

You can configure the management authentication profile in the base operating system or with the PEFNG license installed.

Example

The following example configures a management authentication profile that authenticates users against the controller's internal database. Users who are successfully authenticated are assigned the read-only role.

```
aaa authentication mgmt
  default-role read-only
  server-group internal
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.2	The network-operations role was introduced.
ArubaOS 3.3	The location-api-mgmt role was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication-server internal

aaa authentication-server internal use-local-switch

Description

This command specifies that the internal database on a local controller be used for authenticating clients.

Usage Guidelines

By default, the internal database in the master controller is used for authentication. This command directs authentication to the internal database on the local controller where you run the command.

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

aaa authentication-server ldap

```
aaa authentication-server ldap <server>
  admin-dn <name>
  admin-passwd <string>
  allow-clear-text
  authport <port>
  base-dn <name>
  clone <server>
  enable
  filter <filter>
  host <ipaddr>
  key-attribute <string>
  max-connection <number>
  no ...
  preferred-conn-type ldap-s|start-tls|clear-text
  timeout <seconds>
```

Description

This command configures an LDAP server.

Starting from ArubaOS 6.4, a maximum of 128 LDAP servers can be configured on the controller.

Syntax

Parameter	Description	Range	Default
<server>	Name that identifies the server.	—	—
admin-dn <name>	Distinguished name for the admin user who has read/search privileges across all of the entries in the LDAP database (the user does not need write privileges but should be able to search the database and read attributes of other users in the database).	—	—
admin-passwd <string>	Password for the admin user.	—	—
allow-clear-text	Allows clear-text (unencrypted) communication with the LDAP server.	enable d disable d	disabled
authport <port>	Port number used for authentication. Port 636 will be attempted for LDAP over SSL, while port 389 will be attempted for SSL over LDAP, Start TLS operation and clear text.	1- 65535	389
base-dn <name>	Distinguished Name of the node which contains the entire user database to use.	—	—

Parameter	Description	Range	Default
clone <server>	Name of an existing LDAP server configuration from which parameter values are copied.	—	—
enable	Enables the LDAP server.	—	
filter <filter>	Filter that should be applied to search of the user in the LDAP database. The default filter string is (objectclass=*)	—	(objectclass=*)
host <ip-addr>	IP address of the LDAP server, in dotted-decimal format.	—	—
key-attribute <string>	Attribute that should be used as a key in search for the LDAP server. For Active Directory, the value is sAMAccountName.	—	sAMAccountName
max-connection	Maximum number of simultaneous non-admin connections to an LDAP server.	—	—
no	Negates any configured parameter.	—	—
preferred-conn-type	Preferred connection type. The default order of connection type is: 1. ldap-s 2. start-tls 3. clear-text The controller will first try to contact the LDAP server using the preferred connection type, and will only attempt to use a lower-priority connection type if the first attempt is not successful. NOTE: You enable the allow-clear-text option before you select clear-text as the preferred connection type. If you set clear-text as the preferred connection type but do not allow clear-text, the controller will only use ldap-s or start-tls to contact the LDAP server.	ldap-s start-tls clear-text	ldap-s
timeout <seconds>	Timeout period of a LDAP request, in seconds.	1-30	20 seconds

Usage Guidelines

You configure a server before you can add it to one or more server groups. You create a server group for a specific type of authentication (see [aaa server-group on page 125](#)).

Example

The following command configures and enables an LDAP server:

```
aaa authentication-server ldap ldap1
  host 10.1.1.243
```

```
base-dn cn=Users,dc=1m,dc=corp,dc=com
admin-dn cn=corp,cn=Users,dc=1m,dc=corp,dc=com
admin-passwd abc10
key-attribute sAMAccountName
filter (objectclass=*)
enable
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication-server radius

```
aaa authentication-server radius <rad_server_name>
  acctport <port>
  authport <port>
  called-station-id type
    {ap-group | ap-macaddr | ap-name | ipaddr | macaddr | vlan-id}
    [delimiter {colon | dash | none}] [include-ssid {enable | disable}]
  clone <server>
  cppm username <username> password <password>
  enable
  enable-ipv6
  enable-radsec
  host <ipaddr>|<FQDN>
  key <psk>
  mac-delimiter [colon | dash | none | oui-nic]
  mac-lowercase
  nas-identifier <string>
  nas-ip <ipaddr>
  nas-ip6 <ipv6-address>
  no
  radsec-client-cert-name <name>
  radsec-port <radsec-port>
  radsec-trusted-cacert-name <radsec-trusted-ca>
  radsec-trusted-servercert-name <name>
  retransmit <number>
  service-type-framed-user
  source-interface vlan <vlan> ip6addr <ip6addr>
  timeout <seconds>
  use-ip-for-calling-station
  use-md5
```

Description

This command configures a RADIUS server.

Starting from ArubaOS 6.4, a maximum of 128 RADIUS servers can be configured on the controller.

Syntax

Parameter	Description	Range	Default
<rad_server_name>	Name that identifies the server.	—	—
acctport <port>	Accounting port on the server.	1-65535	1813
authport <port>	Authentication port on the server	1-65535	1812

Parameter	Description	Range	Default
called-station-id type {ap-group ap-macaddr ap-name ipaddr macaddr vlan-id}	Configure this parameter to be sent with the RADIUS attribute Called Station ID for authentication and accounting requests. The called-station-id parameter can be configured to include AP group, AP MAC address, AP name, controller IP, controller MAC address, or user vlan. The default value is controller MAC address.	—	macaddr
clone <server>	Name of an existing RADIUS server configuration from which parameter values are copied.	—	—
c ppm username <username> password <password>	Configure the CPPM username and password. The controller authenticating to CPPM is enhanced to use configurable username and password instead of support password. The support password is vulnerable to attacks as the server certificate presented by CPPM server is not validated.	—	—
enable	Enables the RADIUS server.	—	—
enable-ipv6	Enables the RADIUS server in IPv6 mode.	—	—
enable-radsec	Enables RadSec for RADIUS data transport over TCP and TLS.	—	—

Parameter	Description	Range	Default
host	Identify the RADIUS server either by its IP address or fully qualified domain name.	—	—
<ipaddr>	IPv4 or IPv6 address of the RADIUS server.	—	—
<FQDN>	Fully qualified domain name (FQDN) of the RADIUS server. The maximum supported length is 63 characters.	—	—
key <psk>	Shared secret between the controller and the authentication server. The maximum length is 128 characters.	—	—
mac-delimiter [colon dash none oui-nic]	Send MAC address with user-defined delimiter.	—	none
mac-lowercase	Send MAC addresses as lowercase.	—	—
nas-identifier <string>	Network Access Server (NAS) identifier to use in RADIUS packets.	—	—
nas-ip <ip-addr>	NAS IP address to send in RADIUS packets.	—	—

Parameter	Description	Range	Default
	You can configure a "global" NAS IP address that the controller uses for communications with all RADIUS servers. If you do not configure a server-specific NAS IP, the global NAS IP is used. To set the global NAS IP, enter the <code>ip radius nas-ip <ipaddr></code> command.		
<code>nas-ip6 <ipv6-address></code>	NAS IPv6 address to send in RADIUS packets. You can configure a "global" NAS IPv6 address that the controller uses for communications with all RADIUS servers. If you do not configure a server-specific NAS IPv6, the global NAS IPv6 is used. To set the global NAS IPv6, enter the <code>ipv6 radius nas-ip6 <ipv6-address></code> command.		
<code>no</code>	Negates any configured parameter.	—	—
<code>radsec-client-cert <radsec-client-cert></code>	Configures a RadSec client certificate on the RADIUS server to identify and authenticate clients.	—	—
<code>radsec-port <radsec-port></code>	Designates a RadSec port for RADIUS data transport.	1-65535	2083
<code>radsec-trusted-cacert-name <radsec-trusted-ca></code>	Designates a Certificate Authority to sign RadSec certificates.	—	—
<code>radsec-trusted-servercert-name <radsec-trusted-ca></code>	Designates a trusted RadSec server certificate.	—	—

Parameter	Description	Range	Default
<code>retransmit <number></code>	Maximum number of retries sent to the server by the controller before the server is marked as down.	0-3	3
<code>service-type-framed-user</code>	Send the service-type as FRAMED-USER instead of LOGIN-USER. This option is disabled by default	—	disabled
<code>source-interface vlan <vlan> ip6addr <ip6addr></code>	This option associates a VLAN interface with the RADIUS server to allow the server-specific source interface to override the global configuration. • If you associate a Source Interface (by entering a VLAN number) with a configured server, then the source IP address of the packet will be that interface's IP address. • If you do not associate the Source Interface with a configured server (leave the field blank), then the IP address of the global Source Interface will be used. • If you want to configure an IPv6 address for the Source Interface, specify the IPv6 address for the ip6addr parameter.	—	—

Parameter	Description	Range	Default
timeout <seconds>	Maximum time, in seconds, that the controller waits before timing out the request and resending it.	1-30	5 seconds
use-ip-for-calling-station	Use an IP address instead of a MAC address for calling station IDs. This option is disabled by default.	—	disabled
use-md5	Use MD5 hash of cleartext password.	—	disabled

Usage Guidelines

You configure a server before you can add it to one or more server groups. You create a server group for a specific type of authentication (see [aaa server-group on page 125](#)).

Example

The following command configures and enables a RADIUS server:

```
aaa authentication-server radius radius1
    host 10.1.1.244
    key qwERTyuIOp
    enable
```

Command History

Version	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.0	RADIUS server can be identified by its qualified domain name (FQDN).
ArubaOS 6.1	The source-interface parameter was added.
ArubaOS 6.3	- The mac-delimiter parameter was introduced. - The enable-ipv6 and nas-ip6 parameters were introduced. An IPv6 host address can be specified for the host parameter. - The ipv6 addr parameter was added.

Version	Modification
ArubaOS 6.4	The called-station-id parameter was introduced.
ArubaOS 6.4.2.5	The cppm parameter was introduced.
ArubaOS 6.4.3.0	• The enable-radsec parameter was introduced. • The radsec-client-cert, radsec-port, and radsec-trusted-ca parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication-server tacacs

```
aaa authentication-server tacacs <server>
  clone <server>
  enable
  host <host>
  key <psk>
  no ...
  retransmit <number>
  session-authorization
  tcp-port <port>
  timeout <seconds>
```

Description

This command configures a TACACS+ server.

Starting from ArubaOS 6.4, a maximum of 128 TACACS servers can be configured on the controller.

Syntax

Parameter	Description	Range	Default
<server>	Name that identifies the server.	—	—
clone <server>	Name of an existing TACACS server configuration from which parameter values are copied.	—	—
enable	Enables the TACACS server.	—	
host <host>	IPv4 or IPv6 address of the TACACS server.	—	—
key	Shared secret to authenticate communication between the TACACS+ client and server.	—	—
no	Negates any configured parameter.	—	—
retransmit <number>	Maximum number of times a request is retried.	0-3	3
session-authorization	Enables TACACS+ authorization. Session-authorization turns on the optional authorization session for admin users.	—	disabled
tcp-port <port>	TCP port used by the server.	1-65535	49
timeout <timeout>	Timeout period of a TACACS request, in seconds.	1-30	20 seconds

Usage Guidelines

You configure a server before you can add it to one or more server groups. You create a server group for a specific type of authentication (see [aaa server-group on page 125](#)).

Example

The following command configures, enables a TACACS+ server and enables session authorization:

```
aaa authentication-server tacacs tacacs1
  clone default
  host 10.1.1.245
  key qwERTyuIOp
  enable
  session-authorization
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 6.0	session-authorization parameter was introduced.
ArubaOS 6.3	IPv6 support was added for TACACS server. You can now specify an IPv6 host address for the host parameter.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication-server windows

```
aaa authentication-server windows <windows_server_name>
  clone <source>
  domain <domain>
  enable
  host <ipaddr>
  no
```

Description

This command configures a windows server for stateful-NTLM authentication.

Syntax

Parameter	Description
<windows_server_name>	Name of the windows server. You will use this name when you add the windows server to a server group.
clone <source>	Name of a Windows Server from which you want to make a copy.
domain <domain>	The Windows domain for the authentication server.
enable	Enables the Windows server.
host <ipaddr>	IP address of the Windows server.
no	Delete command.

Usage Guidelines

You must define a Windows server before you can add it to one or more server groups. You create a server group for a specific type of authentication (see [aaa server-group on page 125](#)). Windows servers are used for stateful-NTLM authentication.

Example

The following command configures and enables a windows server:

```
aaa authentication-server windows IAS_1
  host 10.1.1.245
  enable
```

Command History

This command was available in ArubaOS 3.4.1

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication stateful-dot1x

```
aaa authentication stateful-dot1x
  default-role <role>
  enable
  no ...
  server-group <group>
  timeout <seconds>
```

Description

This command configures 802.1X authentication for clients on non-Dell APs.

Syntax

Parameter	Description	Range	Default
default-role <role>	Role assigned to the 802.1X user upon login. NOTE: The PEFNG license must be installed.	—	guest
enable	Enables 802.1X authentication for clients on non-Dell APs. Use no enable to disable stateful 802.1X authentication.	—	enabled
no	Negates any configured parameter.	—	—
server-group <group>	Name of the group of RADIUS servers used to authenticate the 802.1X users. See aaa server-group on page 125 .	—	—
timeout <seconds>	Timeout period, in seconds.	1-20	10 seconds

Usage Guidelines

This command configures 802.1X authentication for clients on non-Dell APs. The controller maintains user session state information for these clients.

Example

The following command assigns the employee user role to clients who successfully authenticate with the server group corp-rad:

```
aaa authentication stateful-dot1x
  default-role employee
  server-group corp-rad
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication stateful-dot1x clear

aaa authentication stateful-dot1x clear

Description

This command clears automatically-created control path entries for 802.1X users on non-Dell APs.

Syntax

No parameters.

Usage Guidelines

Run this command after changing the configuration of a RADIUS server in the server group configured with the **aaa authentication stateful-dot1x** command. This causes entries for the users to be created in the control path with the updated configuration information.

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa authentication stateful-kerberos

```
aaa authentication stateful-kerberos <profile-name>
  clone
  default-role <role>
  enable
  server-group <server-group>
  timeout <timeout>
```

Description

This command configures stateful Kerberos authentication.

Syntax

Parameter	Description	Range	Default
clone	Create a copy of an existing stateful Kerberos profile	—	—
default-role	Select an existing role to assign to authenticated users.	—	guest
server-group <server-group>	Name of a server group.	—	default
timeout <timeout>	Amount of time, in seconds, before the request times out.	1-20 seconds	10 seconds

Example

```
(host)(config) # aaa authentication stateful-kerberos default
  default-role guest
  timeout 10
  server-group internal
```

Command History

Command introduced in ArubaOS 3.4.3

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication stateful-ntlm

```
aaa authentication stateful-ntlm <profile-name>
  clone
  default-role <role>
  enable
  server-group <server-group>
  timeout <timeout>
```

Description

This command configures stateful NT LAN Manager (NTLM) authentication.

Syntax

Parameter	Description	Range	Default
clone	Create a copy of an existing stateful NTLM profile	—	—
default-role	Select an existing role to assign to authenticated users.	—	guest
no	Negates any configured parameter.	—	—
server-group <server-group>	Name of a server group.	—	default
timeout <timeout>	Amount of time, in seconds, before the request times out.	1-20 seconds	10 seconds

Usage Guidelines

NT LAN Manager (NTLM) is a suite of Microsoft authentication and session security protocols. You can use a stateful NTLM authentication profile to configure a controller to monitor the NTLM authentication messages between clients and an authentication server. The controller can then use the information in the Server Message Block (SMB) headers to determine the client's username and IP address, the server IP address and the client's current authentication status. If the client successfully authenticates via an NTLM authentication server, the controller can recognize that the client has been authenticated and assign that client a specified user role. When the user logs off or shuts down the client machine, the user will remain in the authenticated role until the user's authentication is aged out.

The Stateful NTLM Authentication profile requires that you specify a server group which includes the servers performing NTLM authentication, and a default role to be assigned to authenticated users. For details on defining a windows server used for NTLM authentication, see [aaa authentication-server windows](#).

Example

The following example configures a stateful NTLM authentication profile that authenticates clients via the server group "Windows1." Users who are successfully authenticated are assigned the "guest2" role.

```
aaa authentication stateful-ntlm
  default-role guest2
  server-group Windows1
```

Command History

Command introduced in ArubaOS 3.4.1

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication via auth-profile

```
aaa authentication via auth-profile <profile>
  auth-protocol {mschapv2|pap}
  cert-cn-lookup
  clone <source>
  default-role <default-role>
  desc <description>
  max-authentication-failures <max-authentication-failures>
  no
  pan-integration
  radius-accounting <server_group_name>
  rfc-3576-server <rfc-server>
  server-group <server-group>
```

Description

This command configures the VIA authentication profile.

Syntax

Parameter	Description	Default
auth-protocol {mschapv2 pap}	Authentication protocol support for VIA authentication; MSCHAPv2 or PAP	PAP
cert-cn-lookup	Check certificate common name against AAA server.	Enabled
clone <source>	Name of an existing profile from which configuration values are copied.	-
default-role <default-role>	Name of the default VIA authentication profile.	-
desc <description>	Description of this profile for reference.	-

Parameter	Description	Default
<code>max-authentication-failures <max-authentication-failures></code>	Number of times VIA will prompt user to login due to incorrect credentials. After the maximum authentication attempts failures VIA will exit.	3
<code>pan-integration</code>	Requires IP mapping at Palo Alto Network.	-
<code>radius-accounting <server_group_name></code>	Server group for RADIUS accounting.	-
<code>rfc-3576-server <rfc-server></code>	Configures the RFC 3576 server.	-
<code>server-group <server-group></code>	Server group against which the user is authenticated.	-

Usage Guidelines

Use this command to create VIA authentication profiles and associate user roles to the authentication profile.

Example

```
(host) (config) #aaa authentication via auth-profile default
(host) (VIA Authentication Profile "default") #auth-protocol mschapv2
(host) (VIA Authentication Profile "default") #default-role example-via-role
(host) (VIA Authentication Profile "default") #desc "Default VIA Authentication Profile"
(host) (VIA Authentication Profile "default") #server-group "via-server-group"
```

Command History

Version	Description
ArubaOS 5.0	Command introduced.
ArubaOS 6.3	The auth-protocol parameter was added.

Command Information

Platforms	Licensing	Command Mode

aaa authentication via connection-profile

```
aaa authentication via connection-profile <profile>
  admin-logout-script
  admin-logon-script
  allow-user-disconnect
  allow-whitelist-traffic
  auth_domain_suffix
  auth-profile <auth-profile>
  auth_doman_suffix
  auto-launch-supPLICANT
  auto-login
  auto-upgrade
  banner-message-reappear-timeout <mins>
  client-logging
  client-netmask <client-netmask>
  client-wlan-profile <client-wlan-profile> position <position>
  clone
  controllers-load-balance
  csec-gateway-url <URL>
  csec-http-ports <comma separated port numbers>
  dns-suffix-list <dns-suffix-list>
  domain-pre-connect
  enable-csec
  enable-fips
  enable-supPLICANT
  ext-download-url <ext-download-url>
  ike-policy <ike-policy>
  ikev2-policy
  ikev2-proto
  ikev2auth
  ipsec-cryptomap map <map> number <number>
  ipsecv2-cryptomap
  lockdown-all-settings
  max-reconnect-attempts <max-reconnect-attempts>
  minimized
  max-timeout <value>
  minimized
  no
  save-passwords
  server
  split-tunneling
  suiteb-crypto
  support-email
  tunnel
  user-idle-timeout
  validate-server-cert
  whitelist
  windows-credentials
```

Description

This command configures the VIA connection profile.

Syntax

Parameter	Description	Default
<code>admin-logoff-script</code>	Enables VIA logoff script.	Disabled
<code>admin-logon-script</code>	Enables VIA logon script.	Disabled
<code>allow-user-disconnect</code>	Enable or disable users to disconnect their VIA sessions.	Enabled
<code>allow-whitelist-traffic</code>	If enabled, this feature will block network access until the VIA VPN connection is established.	Disabled
<code>auth_domain_suffix</code>	Enables a domain suffix on VIA Authentication, so client credentials are sent as <i>domainnameusername</i> instead of just <i>username</i> .	—
<code>auto-launch-supPLICANT</code>	Allows you to connect automatically to a configured WLAN network.	Disabled
<code>auth-profile <auth-profile></code>	This is the list of VIA authentication profiles that will be displayed to users in the VIA client.	—
<code>admin-logoff-script</code>	Specify the name of the script that must be executed when the VIA connection is disconnected. The script must reside on the user / client system.	—
<code>admin-logon-script</code>	Specify the name of the script that must be executed when the VIA connection is established. The script must reside on the user / client system.	—
<code>auto-login</code>	Enable or disable VIA client to auto login and establish a secure connection to the controller.	Enabled

Parameter	Description	Default
auto-upgrade	Enable or disable VIA client to automatically upgrade when an updated version of the client is available on the controller.	Enabled
banner-message-reappear-timeout	Timeout value, in minutes, after which the user session will end and the VIA Login banner message reappears.	1440 minutes
client-logging	Enable or disable VIA client to auto login and establish a secure connection to the controller.	Enabled
client-netmask <client-netmask>	The network mask that has to be set on the client after the VPN connection is established.	255.255.255.255
client-wlan-profile <client-wlan-profile>	A list of VIA client WLAN profiles that needs to be pushed to the client machines that use Windows Zero Config (WZC) to configure or manage their wireless networks.	—
position <position>		—
clone	Create a copy of connection profile from an another VIA connection profile.	—
controllers-load-balance	Enable this option to allow the VIA client to failover to the next available selected randomly from the list as configured in the VIA Servers option. If disabled, VIA will failover to the next in the sequence of ordered list of VIA Servers.	Disabled

Parameter	Description	Default
server	Address: This is the public IP address or the DNS hostname of the VIA controller. Users will connect to remote server using this IP address or the hostname. Internal IP Address: This is the IP address of any of the VLAN interface IP addresses belongs to this controller. Description: This is a human-readable description of the controller.	—
addr <addr>		—
<internal-ip <internal-ip>		—
desc <description>		—
csec-gateway-url	Specify the content security service providers URL here. You must provide a fully qualified domain name.	—
csec-http-ports	Specify the ports (separated by comma) that will be monitored by the content security service provider. Do not add space before or after the comma.	—
domain-preconnect	Enable this option to allow users with lost or expired passwords to establish a VIA connection to corporate network. This option authenticates the user's device and establishes a VIA connection that allows users to reset credentials and continue with corporate access.	Enabled
dns-suffix-list <dns-suffix-list>	The DNS suffix list (comma separated) that has be set on the client once the VPN connection is established. .	None
enable-csec	Use this option to enable the content security service.	—

Parameter	Description	Default
enable-fips	Enable the VIA (Federal Information Processing Standard) FIPS module so VIA checks for FIPS compliance during startup.	Disabled
enable-supPLICant	If enabled, VIA starts in bSec mode using L2 suite-b cryptography. This option is disabled by default.	Disabled
ext-download-url <ext-download-url>	End users will use this URL to download VIA on their computers.	—
ike-policy <ike-policy>	List of IKE policies that the VIA Client has to use to connect to the controller.	—
ikev2-policy	List of IKE V2 policies that the VIA Client has to use to connect to the controller	—
ikev2-proto	Enable this to use IKEv2 protocol to establish VIA sessions.	Disabled
ikev2auth	Use this option to set the IKEv2 authentication method. By default user certificate is used for authentication. The other supported methods are EAP-MSCHAPv2, EAP-TLS. The EAP authentication is done on an external RADIUS server.	User Certificates
ipsec-cryptomap	List of IPsec crypto maps that the VIA client uses to connect to the controller. These IPsec Crypto Maps are configured in the CLI using the <code>crypto-local ipsec-map <ipsec-map-name> command</code> .	—
map <map>		—
number <number>		—
ipsecv2-cryptomap	List of IPSec V2 crypto maps that the VIA client uses to connect to the controller.	—
lockdown-all-settings	Allows you to lockdown all user configured settings.	Disabled.

Parameter	Description	Default
<code>max-reconnect-attempts <max-reconnect-attempts></code>	The maximum number of re-connection attempts by the VIA client due to authentication failures.	3
<code>max-timeout value <value></code>	The maximum time (minutes) allowed before the VIA session is disconnected.	1440 min
<code>minimized</code>	Use this option to keep the VIA client on a Microsoft Windows operating system minimized to system tray.	—
<code>save-passwords</code>	Enable or disable users to save passwords entered in VIA.	Enabled
<code>server</code>	Configure VIA servers.	
<code>split-tunneling</code>	Enable or disable split tunneling. • If enabled, all traffic to the VIA tunneled networks will go through the controller and the rest is just bridged directly on the client. • If disabled, all traffic will flow through the controller.	off
<code>suiteb-crypto</code>	Use this option to enable Suite-B cryptography. See RFC 4869 for more information about Suite-B cryptography.	Disabled
<code>support-email</code>	The support e-mail address to which VIA users will send client logs.	None

Parameter	Description	Default
tunnel address <address>	A list of network destination (IP address and netmask) that the VIA client will tunnel through the controller. All other network destinations will be reachable directly by the VIA client. Enter tunneled IP address and its netmask.	—
address <address>		—
netmask <netmask>		—
user-idle-timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.	disabled
validate-server-cert	Enable or disable VIA from validating the server certificate presented by the controller.	Enabled
whitelist addr	Specify a hostname or IP address and network mask to define a whitelist of users allowed to access the network if the allow-whitelist-traffic option is enabled	—
addr <addr>	Host name of IP address of a client	—
netmask <netmask>	Netmask, in dotted decimal format	—
description <description>	(Optional) description of the client	—
windows-credentials	Enable or disable the use of the Windows credentials to login to VIA. If enabled, the SSO (Single Sign-on) feature can be utilized by remote users to connect to internal resources.	Enabled

Usage Guidelines

Issue this command to create a VIA connection profile. A VIA connection profile contains settings required by VIA to establish a secure connection to the controller. You can configure multiple VIA connection profiles. A VIA

connection profile is always associated to a user role and all users belonging to that role will use the configured settings. If you do not assign a VIA connection profile to a user role, the default connection profile is used.

Example

The following example shows a simple VIA connection profile:

```
(host) (config) #aaa authentication via connection-profile "via"
(host) (VIA Connection Profile "via") #server addr 202.100.10.100 internal-ip 10.11.12.13 desc
"VIA Primary" position 0
(host) (VIA Connection Profile "via") #auth-profile "default" position 0
(host) (VIA Connection Profile "via") #tunnel address 10.0.0.0 netmask 255.255.255.0
(host) (VIA Connection Profile "via") #split-tunneling
(host) (VIA Connection Profile "via") #windows-credentials
(host) (VIA Connection Profile "via") #client-netmask 255.0.0.0
(host) (VIA Connection Profile "via") #dns-suffix-list mycorp.com
(host) (VIA Connection Profile "via") #dns-suffix-list example.com
(host) (VIA Connection Profile "via") #support-email via-support@example.com
```

Command History

Release	Modification
ArubaOS 5.0	Command introduced
ArubaOS 6.1	The following commands were introduced: • admin-logon-script • admin-logoff-script • ikev2-policy • ikev2-proto • ikev2-auth • ipsecv2-crypto • minimized • suiteb-crypto
ArubaOS 6.1.3.2	The auth_domain_suffix parameter was introduced.
ArubaOS 6.2	The following commands were introduced: • allow-whitelist-traffic • banner-message-reappear-timeout • controllers-load-balancing • enable-fips • enable-suppliant • whitelist
ArubaOS 6.3	The user-idle-timeout parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

aaa authentication via global-config

```
aaa authentication via global-config
no
ssl-fallback-enable
```

Description

The global config option allows to you to enable SSL fallback mode. If the SSL fallback mode is enabled the VIA client will use SSL to create a secure connection.

Syntax

Parameter	Description	Default
no	Disable SSL fallback option	—
ssl-fallback-enable	Use this option to enable an SSL fallback connection.	Disabled

Example

```
(host) (config) #aaa authentication via global-config
```

Command History

Command introduced in 5.0

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

aaa authentication via web-auth

```
aaa authentication via web-auth default
  auth-profile <auth-profile> position <position>
  clone <source>
no
```

Description

A VIA web authentication profile contains an ordered list of VIA authentication profiles. The web authentication profile is used by end users to login to the VIA download page (<https://<server-IP-address>/via>) for downloading the VIA client. Only one VIA web authentication profile is available. If more than one VIA authentication profile is configured, users can view this list and select one during the client login.

Syntax

Parameter	Description	Default
auth-profile <auth-profile>	The name of the VIA authentication profile	—
position <position>	The position of the profile to specify the order of selection.	—
clone <source>	Duplicate an existing authentication profile.	—

Example

```
(host) (config) #aaa authentication via web-auth default
(host) (VIA Web Authentication "default") #auth-profile default position 0
```

Command History

Command introduced in 5.0

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

aaa authentication vpn

```
aaa authentication vpn <profile-name>
  cert-cn-lookup
  clone <source>
  default-role <guest>
  export-route
  max-authentication-failures <number>
  no ...
  pan-integration
  radius-accounting
  server-group <group>
  user-idle-timeout
```

Description

This command configures VPN authentication settings.

Syntax

Parameter	Description	Default
<profile-name>	There are three VPN profiles: default , default-rap or default-cap . This allows users to use different AAA servers for VPN, RAP and CAP clients. NOTE: The default and default-rap profiles are configurable. The default-cap profile is not configurable and is predefined with the default settings.	—
cert-cn-lookup	If you use client certificates for user authentication, enable this option to verify that the certificate's common name exists in the server. This parameter is enabled by default in the default-cap and default-rap VPN profiles, and disabled by default on all other VPN profiles.	—
clone <source>	Copies data from another VPN authentication profile. Source is the profile name from which the data is copied.	—
default-role <role>	Role assigned to the VPN user upon login. NOTE: This parameter requires the Policy Enforcement Firewall for VPN Users (PEFV) license.	guest
export-route	Exports a VPN IP address as a route to the external world. See the show ip ospf command to view the link-state advertisement (LSA) types that are generated.	enabled

Parameter	Description	Default
<code>max-authentication-failures <number></code>	Maximum number of authentication failures before the user is blacklisted. The supported range is 1-10 failures. A value of 0 disables blacklisting. NOTE: This parameter requires the RFPProtect license.	0 (disabled)
<code>no</code>	Negates any configured parameter.	—
<code>pan-integration</code>	Require IP mapping at Palo Alto Networks firewalls.	disabled
<code>radius-accounting <</code>	Configure server group for RADIUS accounting	—
<code>server-group <group></code>	Name of the group of servers used to authenticate VPN users. See aaa server-group on page 125 .	internal
<code>user-idle-timeout</code>	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.	—

Usage Guidelines

This command configures VPN authentication settings for VPN, RAP and CAP clients. Use the **vpdn group** command to configure Layer-2 Tunneling Protocol and Internet Protocol Security (L2TP/IPsec) or a Point-to-Point Tunneling Protocol (PPTP) VPN connection. (See [vpdn group l2tp on page 2213](#).)

Example

The following command configures VPN authentication settings for the default-rap profile:

```
aaa authentication vpn default-rap
  default-role guest
  clone default
  max-authentication-failures 0
  server-group vpn-server-group
```

The following message appears when a user tries to configure the non-configurable default-cap profile:

```
(host) (config) #aaa authentication vpn default-cap
Predefined VPN Authentication Profile "default-cap" is not editable
```

The following example describes the steps to use the CLI to configure a VPN for Cisco Smart Card Clients using certificate authentication and IKEv1, where the client is authenticated against user entries added to the internal database:

```
(host) (config) #aaa authentication vpn default
  server-group internal

(host) (config) #no crypto-local isakmp xauth
```

```
(host)(config) #vpdn group l2tp
    enable
    client dns 101.1.1.245

(host)(config) #ip local pool sc-clients 10.1.1.1 10.1.1.250

(host)(config) #crypto-local isakmp server-certificate MyServerCert
(host)(config) #crypto-local isakmp ca-certificate TrustedCA

(host)(config) #crypto isakmp policy 1
    authentication rsa-sig
```

The following command configures client entries in the internal database in enable mode:

```
(host)(config) #local-userdb add username <name> password <password>
```

The following example configures a VPN for XAuth IKEv1 clients in config mode using a username and password:

```
(host)(config) #aaa authentication vpn default
    server-group internal

crypto-local isakmp xauth

(host)(config) #vpdn group l2tp
    enable
    client dns 101.1.1.245

(host)(config) #ip local pool pw-clients 10.1.1.1 10.1.1.250

(host)(config) #crypto isakmp key 0987654 address 0.0.0.0 netmask 0.0.0.0

(host)(config) #crypto isakmp policy 1
    authentication pre-share
```

Enter the following command in enable mode to configure client entries in the internal database:

```
(host)(config) #local-userdb add username <name> password <password>
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 5.0	The default-cap and default-rap profiles were introduced.
ArubaOS 6.1	The cert-cn-lookup parameter was introduced.
ArubaOS 6.3	The user-idle-timeout parameter was introduced.
ArubaOS 6.3.1	The export-route parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system, except for noted parameters. The default-role parameter requires the Policy Enforcement Firewall for VPN Users (PEFV) license.	Config mode on master controllers

aaa authentication wired

```
aaa authentication wired
no ...
profile <aaa-profile>
```

Description

This command configures authentication for a client device that is directly connected to a port on the controller.

Syntax

Parameter	Description
no	Negates any configured parameter.
profile <aaa-profile>	Name of the AAA profile that applies to wired authentication. This profile must be configured for a Layer-2 authentication, either 802.1X or MAC. See aaa profile on page 114 .

Usage Guidelines

This command references an AAA profile that is configured for MAC or 802.1X authentication. The port on the controller to which the device is connected must be configured as untrusted.

Example

The following commands configure an AAA profile for dot1x authentication and a wired profile that references the AAA profile:

```
aaa profile sec-wired
    dot1x-default-role employee
    dot1x-server-group sec-svrs
aaa authentication wired
    profile sec-wired
```

Related Commands

Command	Description
vlan	Assign an AAA profile to an individual VLAN to enable role-based access for wired clients connected to an untrusted VLAN or port on the controller.

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa authentication wispr

```
aaa authentication wispr
  agent string
  clone
  default-role <role>
  logon-wait {cpu-threshold <cpu-threshold>}|{maximum-delay <maximum-delay>}|{minimum-delay <minimum-delay>}
  no ...
  max-authentication-failures
  server-group <server-group>
  wispr-location-id-ac <wispr-location-id-ac>
  wispr-location-id-cc <wispr-location-id-cc>
  wispr-location-id-isocc <wispr-location-id-isocc>
  wispr-location-id-network <wispr-location-id-network>
  wispr-location-name-location <wispr-location-name-location>
  wispr-location-name-operator-name <wispr-location-name-operator>
```

Description

This command configures WISPr authentication with an ISP's WISPr RADIUS server.

Syntax

Parameter	Description
agent string	User Agent String to be registered for use in WISPR Profile. Max User Agent String len: 32 characters.Max number of User Agent string: 32.
clone	Copy data from another WISPr Authentication Profile.
default-role	Default role assigned to users that complete WISPr authentication.
logon-wait	Configure the CPU utilization threshold that will trigger logon wait maximum and minimum times
CPU-threshold <cpu-threshold>	Percentage of CPU utilization at which the maximum and minimum login wait times are enforced. Range: 1-100%.Default: 60%.
max-authentication-failures	Maximum auth failures before user is blacklisted. Range: 0-10. Default: 0.

Parameter	Description
<code>maximum-delay <maximum-delay></code>	If the controller's CPU utilization has surpassed the CPU-threshold value, the maximum-delay parameter defines the minimum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 10 seconds.
<code>minimum-delay <minimum-delay></code>	If the controller's CPU utilization has surpassed the CPU-threshold value, the minimum-delay parameter defines the minimum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 5 seconds.
<code>wispr-location-id-ac <wispr-location-id-ac></code>	The E.164 Area Code in the WISPr Location ID.
<code>wispr-location-id-cc <wispr-location-id-cc></code>	The 1-3 digit E.164 Country Code in the WISPr Location ID.
<code>wispr-location-id-isocc <wispr-location-id-isocc></code>	The ISO Country Code in the WISPr Location ID.
<code>wispr-location-id-network <wispr-location-id-network></code>	The SSID/network name in the WISPr Location ID.
<code>wispr-location-name-location <wispr-location-name-location></code>	A name identifying the hotspot location. If no name is defined, the default ap-name is used.
<code>wispr-location-name-operator-name <wispr-location-name-operator></code>	A name identifying the hotspot operator.

Usage Guidelines

WISPr authentication allows a "smart client" to remain authenticated on the network when they roam between Wireless Internet Service Providers, even if the wireless hotspot uses an ISP for which the client may not have an account.

If you are hotspot operator using WISPr authentication, and a client that has an account with your ISP attempts to access the Internet at your hotspot, then your ISP's WISPr AAA server authenticates that client directly, and allows the client access on the network. If, however, the client only has an account with a *partner* ISP, then your ISP's WISPr AAA server will forward that client's credentials to the partner ISP's WISPr AAA server for authentication. Once the client has been authenticated on the partner ISP, it will be authenticated on your hotspot's own ISP, as per their service agreements. Once your ISP sends an authentication message to the controller, the controller assigns the default WISPr user role to that client.

ArubaOS supports the following smart clients, which enable client authentication and roaming between hotspots by embedding iPass Generic Interface Specification (GIS) *redirect*, *proxy*, *authentication* and *logoff* messages within HTML messages to the controller.

- iPass
- Bongo
- Trustive
- weRoam
- AT&T

A WISPr authentication profile includes parameters to define RADIUS attributes, the default role for authenticated WISPr users, maximum numbers of authenticated failures and logon wait times. The WISPr-Location-ID sent from the controller to the WISPr RADIUS server will be the concatenation of the ISO Country Code, E.164 Country Code, E.164 Area Code and SSID/Zone parameters configured in this profile.

The parameters to define WISPr RADIUS attributes are specific to the RADIUS server your ISP uses for WISPr authentication; contact your ISP to determine these values. You can find a list of ISO and ITU country and area codes at the ISO and ITU websites www.iso.org and <http://www.itu.int>.

A Boingo smart client uses a NAS identifier in the format <CarrierID>_<VenueID> for location identification. To support Boingo clients, you must also configure the **NAS identifier** parameter in the Radius server profile for the WISPr server

Example

The following commands configure an WISPr authentication profile:

```
aaa authentication wispr
  default-role authuser
  max-authentication-failures 5
  server-group wispr1
  wispr-location-id-ac 408
  wispr-location-id-cc 1
  wispr-location-id-isocc us
  wispr-location-id-network <wispr-location-id-network>
  wispr-location-name-location <wispr-location-name-location>
  wispr-location-name-operator-name <wispr-location-name-location>
```

Command History

This command was available in ArubaOS 3.4.1.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

aaa bandwidth-contract

```
aaa bandwidth-contract <name> {kbits <kbits>|mbits <mbits>}
```

Description

This command configures a bandwidth contract.

Syntax

Parameter	Description	Range
<name>	Name that identifies this bandwidth contract.	—
kbits <bits>	Limit the traffic rate for this bandwidth contract to a specified number of kilobits per second.	256-2000000
mbits <bits>	Limit the traffic rate for this bandwidth contract to a specified number of megabits per second.	1-2000

Usage Guidelines

You can apply a configured bandwidth contract to a user role or to a VLAN. When you apply a bandwidth contract to a user role (see [user-role on page 2190](#)), you specify whether the contract applies to upstream traffic (from the client to the controller) or downstream traffic (from the controller to the client). You can also specify whether the contract applies to all users in a specified user role or per-user in a user role.

When you apply a bandwidth contract to a VLAN (see [interface vlan on page 490](#)), the contract limits multicast traffic and does not affect other data. This is useful because an AP can only send multicast traffic at the rate of the slowest associated client. Thus excessive multicast traffic will fill the buffers of the AP, causing frame loss and poor voice quality. Generally, every system should have a bandwidth contract of 1 Mbps or even 700 Kbps and it should be applied to all VLANs with which users are associated, especially those VLANs that pass through the upstream router. The exception are VLANs that are used for high speed multicasts, where the SSID is configured without low data rates.

Example

The following commands configure a set of bandwidth contracts, then apply those contracts to all upstream and downstream traffic *except* for the echo, icmp, iperf, icmp6, and synflood applications, and the web, streaming, peer-to-peer, unified-communication, and tunneling application categories.

```
(host) (config) #aaa bandwidth-contract up-256k-1 kbits 256
(host) (config) #aaa bandwidth-contract up-512k-1 kbits 512
(host) (config) #aaa bandwidth-contract up-1m-1 mbits 1
(host) (config) #aaa bandwidth-contract up-5m-1 mbits 5
(host) (config) #aaa bandwidth-contract up-10m-1 mbits 10
(host) (config) #aaa bandwidth-contract up-20m-1 mbits 20
(host) (config) #aaa bandwidth-contract up-50m-1 mbits 50
(host) (config) #aaa bandwidth-contract up-100m-1 mbits 100
(host) (config) #aaa bandwidth-contract up-500m-1 mbits 500
(host) (config) #aaa bandwidth-contract up-1000m-1 mbits 1000
(host) (config) #aaa bandwidth-contract dw-256k-1 kbits 256
(host) (config) #aaa bandwidth-contract dw-512k-1 kbits 512
(host) (config) #aaa bandwidth-contract dw-1m-1 mbits 1
(host) (config) #aaa bandwidth-contract dw-5m-1 mbits 5
```

```

(host) (config) #aaa bandwidth-contract dw-10m-1 mbits 10
(host) (config) #aaa bandwidth-contract dw-20m-1 mbits 20

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa derivation-rules

```
aaa derivation-rules user <name>
no ...
set {aaa-profile|role|vlan} condition <rule-type> <attribute> <value> set-value
{<role>|<vlan>} [description <rule description>] [position <number>]
```

Description

This command configures rules which assigns a AAA profile, user role or VLAN to a client based upon the client's association with an AP.

A user role cannot be assigned by an AAA derivation rule unless the controller has an installed PEFNG license.

Syntax

Parameter	Description
<name>	Name that identifies this set of user derivation rules.
no	Negates a configured rule.
set {role vlan}	Specify whether the action of the rule is to set the role or the VLAN.
condition	Condition that should be checked to derive role/VLAN
<rule-type>	For a rule that sets an AAA profile, use the user-vlan rule type. For a role or VLAN user derivation rule, select one of the following rules: • bssid: BSSID of access point. • dhcp-option: Use DHCP signature matching to assign a role or VLAN. • dhcp-option-77: Enable DHCP packet processing. • encryption-type: Encryption method used by station. • essid: ESSID of access point. • location: user location (ap name). • macaddr: MAC address of user. NOTE: If you use the dhcp-option rule type, best practices are to enable the enforce-dhcp option in the AAA profile referenced by AP group's Virtual AP profile.
<attribute><value>	Specify one of the following conditions: • contains: Check if attribute <i>contains</i> the string in the <value> parameter. • ends-with: Check if attribute <i>ends with</i> the string in the <value> parameter. • equals: Check if attribute <i>equals</i> the string in the <value> parameter. • not-equals: Check if attribute <i>is not equal</i> to the string in the <value> parameter. • starts-with: Check if attribute <i>starts with</i> the string in the <value>

Parameter	Description
	parameter.
set-value <role> <vlan>	Specify the user role or VLAN ID to be assigned to the client if the above condition is met.
description	Describes the user derivation rule. This parameter is optional and has a 128 character maximum.
position	Position of this rule relative to other rules that are configured.

Usage Guidelines

The user role can be derived from attributes from the client's association with an AP. User-derivation rules are executed *before* the client is authenticated.

You configure the user role to be derived by specifying condition rules; when a condition is met, the specified user role is assigned to the client. You can specify more than one condition rule; the order of rules is important as the first matching condition is applied. You can also add a description of the rule.

The table below describes the conditions for which you can specify a user role or VLAN.

Rule Type	Condition	Value
bssid: Assign client to a role or VLAN based upon the BSSID of AP to which client is associating.	One of the following: - contains - ends with - equals - does not equal - starts with	MAC address (xx:xx:xx:xx:xx:xx)
dhcp-option: Assign client to a role or VLAN based upon the DHCP signature ID.	One of the following: - equals - starts with	DHCP signature ID. Note: This string is <i>not</i> case sensitive.
dhcp-option-77: Assign client to a role or VLAN based upon the user class identifier returned by DHCP server.	equals	string
encryption-type: Assign client to a role or VLAN based upon the encryption type used by the client.	One of the following: - equals - does not equal	- Open (no encryption) - WPA/WPA2 AES - WPA-TKIP (static or dynamic) - Dynamic WEP - WPA/WPA2 AES PSK - Static WEP - xSec

Rule Type	Condition	Value
ssid: Assign client to a role or VLAN based upon the ESSID to which the client is associated	One of the following: - contains - ends with - equals - does not equal - starts with - value of (does not take <i>string</i>; attribute value is used as role)	string
location: Assign client to a role or VLAN based upon the ESSID to which the client is associated	One of the following: - equals - does not equal	string
macaddr: MAC address of the client	One of the following: - contains - ends with - equals - does not equal - starts with	MAC address (xx:xx:xx:xx:xx:xx)

The device identification feature allows you to assign a user role or VLAN to a specific device type by identifying a DHCP option and signature for that device. If you create a user rule with the **DHCP-Option** rule type, the first two characters in the **Value** field must represent the hexadecimal value of the DHCP option that this rule should match, while the rest of the characters in the **Value** field indicate the DHCP signature the rule should match. To create a rule that matches DHCP option 12 (host name), the first two characters of the in the **Value** field must be the hexadecimal value of 12, which is 0C. To create a rule that matches DHCP option 55, the first two characters in the **Value** field must be the hexadecimal value of 55, which is 37.

The following table describes some of the DHCP options that are useful for assigning a user role or VLAN.

DHCP Option	Description	Hexidecimal Equivalent
12	Host name	0C
55	Parameter Request List	37
60	Vendor Class Identifier	3C
81	Client FQDN	51

To identify DHCP strings used by an individual device, access the command-line interface in config mode and issue the following command to include DHCP option values for DHCP-DISCOVER and DHCP-REQUEST frames in the controller's log files:

logging level debugging network process dhcpd

Now, connect the device you want to identify to the network, and issue the CLI command **show log network**. The sample below is an example of the output that may be generated by this command.

Be aware that each device type may not have a unique DHCP fingerprint signature. For example, devices from different manufacturers may use vendor class identifiers that begin with similar strings. If you create a DHCP-Option rule that uses the starts-with condition instead of the equals condition, the rule may assign a role or VLAN to more than one device type.

37:010f03062c2e2f1f21f92b 2b:dc0100
```

Examples

The following command sets the client's user role to "guest" if the client associates to the "Guest" ESSID. The rule description indicates that it was created for special customers.

```
aaa derivation-rules user derive1
  set role condition essid equals Guest set-value guest description
  createdforspecialcustomers
```

The example rule shown below sets a user role for clients whose host name (DHCP option 12) has a value of 6C6170746F70, which is the hexadecimal equivalent of the ASCII string "laptop". The first two digits in the Value field are the hexadecimal value of 12 (which is 0C), followed by the specific signature to be matched

```
aaa derivation-rules user device-role
  set role condition dhcp-option equals 0C6C6170746F70 set-value laptop_role
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 6.0	Description parameter was introduced.
ArubaOS 6.1	DHCP-Option rule type was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system. The PEFNG license must be installed for a user role to be assigned.	Config mode on master controllers

aaa dns-query-interval

aaa dns-query-interval <minutes>

Description

Configure how often the controller should generate a DNS request to cache the IP address for a RADIUS server identified via its fully qualified domain name (FQDN).

Syntax

Parameter	Description
<minutes>	Specify, in minutes, the interval between DNS requests sent from the controller to the DNS server. By default, DNS requests are sent every 15 minutes. Range: 1-1440 minutes

Usage Guidelines

If you define a RADIUS server using the FQDN of the server rather than its IP address, the controller will periodically generate a DNS request and cache the IP address returned in the DNS response. Issue this command to configure the frequency of these requests.

Example

This command configures a DNS query interval of 30 minutes.

```
(host) # aaa dns-query-interval 30
```

Related Commands

To view the current DNS query interval, issue the command [show aaa dns-query-interval](#).

Command History

This command was available in ArubaOS 6.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on local and master controllers

aaa inservice

```
aaa inservice <server-group> <server>
```

Description

This command designates an “out of service” authentication server to be “in service”.

Syntax

Parameter	Description
<server-group>	Server group to which this server is assigned.
<server>	Name of the configured authentication server.

Usage Guidelines

By default, the controller marks an unresponsive authentication server as “out of service” for a period of 10 minutes (you can set a different time limit with the **aaa timers dead-time** command). The **aaa inservice** command is useful when you become aware that an “out of service” authentication server is again available before the dead-time period has elapsed. You can use the **aaa test-server** command to test the availability and response of a configured authentication server.

Example

The following command sets an authentication server to be in service:

```
aaa inservice corp-rad rad1
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa ipv6 user add

```
aaa ipv6 user add <ipv6addr>
  authentication-method {dot1x|stateful-dot1x}
  mac <macaddr>
  name <username>
  profile <aaa-profile>
  role <role>
```

Description

This command manually assigns a user role or other values to a specified IPv6 client.

Syntax

Parameter	Description
<ipv6addr>	IPv6 address of the user to be added.
authentication-method	Authentication method for the client.
dot1x	802.1X authentication.
stateful-dot1x	Stateful 802.1X authentication.
mac <macaddr>	MAC address of the client.
name <username>	Name of the client.
profile <aaa-profile>	AAA profile for the client.
role <role>	User role for the client.

Usage Guidelines

This command should only be used for troubleshooting issues with a specific IPv6 client. This command allows you to manually assign a client to a role. For example, you can create a role “debugging” that includes a policy to mirror session packets to a specified destination for further examination, then use this command to assign the “debugging” role to a specific client. Use the **aaa ipv6 user delete** command to remove the client or device from the role.

Note that issuing this command does not affect ongoing sessions that the client may already have. For example, if a client is in the “employee” role when you assign them to the “debugging” role, the client continues any sessions allowed with the “employee” role. Use the **aaa ipv6 user clear-sessions** command to clear ongoing sessions.

Example

The following commands create a role that logs HTTPS traffic, then assign the role to a specific IPv6 client:

```
ip access-list session ipv6-log-https
  any any svc-https permit log
user-role ipv6-web-debug
```

```
session-acl ipv6-log-https
```

In enable mode:

```
aaa ipv6 user add 2002:d81f:f9f0:1000:e409:9331:1d27:ef44 role ipv6-web-debug
```

Command History

This command was available in ArubaOS 3.3.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa ipv6 user clear-sessions

```
aaa ipv6 user clear-sessions <ipaddr>
```

Description

This command clears ongoing sessions for the specified IPv6 client.

Syntax

Parameter	Description
<ipaddr>	IPv6 address of the client.

Usage Guidelines

This command clears any ongoing sessions that the client already had before being assigned a role with the **aaa ipv6 user add** command.

Example

The following command clears ongoing sessions for an IPv6 client:

```
aaa user clear-sessions 2002:d81f:f9f0:1000:e409:9331:1d27:ef44
```

Command History

This command was available in ArubaOS 3.3.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa ipv6 user delete

```
aaa ipv6 user delete {<ipaddr>|all|mac <macaddr>|name <username>|role <role>}
```

Description

This command deletes IPv6 clients, users, or roles.

Syntax

Parameter	Description
<ipv6addr>	IPv6 address of the client to be deleted.
all	Deletes all connected IPv6 clients.
mac	MAC address of the IPv6 client to be deleted.
name	Name of the IPv6 client to be deleted.
role	Role of the IPv6 client to be deleted.

Usage Guidelines

This command allows you to manually delete clients, users, or roles. For example, if you used to the **aaa ipv6 user add** command to assign a user role to an IPv6 client, you can use this command to remove the role assignment.

Example

The following command a role:

```
aaa ipv6 user delete role web-debug
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa ipv6 user logout

aaa ipv6 user logout <ipaddr>

Description

This command logs out an IPv6 client.

Syntax

Parameter	Description
<ipv6addr>	IPv6 address of the client to be logged out.

Usage Guidelines

This command logs out an authenticated IPv6 client. The client must reauthenticate.

Example

The following command logs out an IPv6 client:

```
aaa user logout 2002:d81f:f9f0:1000:e409:9331:1d27:ef44
```

Command History

This command was available in ArubaOS 3.3.

Command Information

All platforms	Base operating system	Enable mode on master controllers

aaa log

[no] aaa log

Description

Enable per-user log files for AAA events.

Syntax

No parameters

Usage Guidelines

By default, logging is always enabled. Issue the **no aaa log** command to disable per-user logging and reenable it again using the command **aaa log**. The W-7200 Series controllers support 1 KB of log files per user for up to 32,000 users, and W-6000 and W-3600 controllers support 1 KB of log files per user for up to 16,000 users.

Example

The example below enables per-user AAA log files.

```
(host) (config) #aaa log
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

Platforms	Licensing	Command Mode
W-6000, W-3600 and W-7200 Series controllers	Base operating system	Enable or Config mode on master or local controllers

aaa password-policy mgmt

```
aaa password-policy mgmt
  enable
  no
  password-lock-out
  password-lock-out-time
  password-max-character-repeat.
  password-min-digit
  password-min-length
  password-min-lowercase-characters
  password-min-special-character
  password-min-special-character
  password-min-uppercase-characters
  password-not-username
```

Description

Define a policy for creating management user passwords.

Syntax

Parameter	Description
enable	enable the password management policy
password-lock-out	The number of failed attempts within a 3 minute window that causes the user to be locked out for the period of time specified by the password-lock-out-time parameter. Range: 0-10 attempts. By default, the password lockout feature is disabled, and the default value of this parameter is 0 attempts.
password-lock-out-time	The number of minutes a user who has exceeded the maximum number of failed password attempts is locked out of the network. After this period has passed, the lockout is cleared without administrator intervention. Range: 1 min to 1440 min (24 hrs). Default: 3. NOTE: When a management user gets locked out, that event is logged in the controller log file. The management user lockout warning message can have any one of the following warning IDs. • 125060 = Password policy locked out a management user created via the mgmt-user command in the serial console CLI. • 125061 = Password policy locked out a management user created via the WebUI or the mgmt-user command in the Telnet/SSH CLI. • 133109 = Password policy locked out a management user created via the local-userdb command in the CLI.
password-max-character-repeat	The maximum number of consecutive repeating characters allowed in a management user password. Range: 0-10 characters. By default, there is no limitation on the numbers of character that can repeat within a password, and the parameter has a default value of 0 characters.

Parameter	Description
password-min-digit	The minimum number of numeric digits required in a management user password. Range: 0-10 digits. By default, there is no requirement for numerical digits in a password, and the parameter has a default value of 0.
password-min-length	The minimum number of characters required for a management user password Range: 6-64 characters. Default: 6.
password-min-lowercase-characters	The minimum number of lowercase characters required in a management user password. Range: 0-10 characters. By default, there is no requirement for lowercase letters in a password, and the parameter has a default value of 0.
password-min-special-characters	The minimum number of special characters (!, @, #, \$, %, ^, &, *, <, >, {, }, [,], :, ., comma, , +, ~, `) in password. Range: 0-10 special characters. Default: 0 (minimum number of special character required is disabled by default, The following ('), ' (' ; , ~, space, =, /, ?) are dis-allowed).
password-min-special-character	The minimum number of special characters required in a management user password. Range: 0-10 characters. By default, there is no requirement for special characters in a password, and the parameter has a default value of 0. See Usage Guidelines below for a list of allowed and disallowed special characters
password-min-uppercase-characters	The minimum number of uppercase characters required in a management user password. Range: 0-10 characters. By default, there is no requirement for uppercase letters in a password, and the parameter has a default value of 0.
password-not-username	Password cannot be the management users' current username or the username spelled backwards.

Usage Guidelines

By default, the password for a management user has no requirements other than a minimum length of 6 alphanumeric or special characters. You do not need to configure a different management user password policy unless your company enforces a best practices password policy for management users with root access to network equipment.

The table below lists the special characters allowed and not allowed in any management

Example

The following command sets a management password policy that requires the password to have a minimum of nine characters, including one numerical digit and one special character:

```
aaa password-policy mgmt
  enable
  password-min-digit 1
  password-min-length 9
  password-min-special-characters 1
```

Related Commands

```

Description

This command configures the authentication for a WLAN.

Syntax

Parameter	Description	Default
<profile>	Name that identifies this instance of the profile. The name must be 1-63 characters.	"default"
authentication-dot1x <dot1x-profile>	Name of the 802.1X authentication profile associated with the WLAN. See aaa authentication dot1x on page 40 .	—
authentication-mac <mac-profile>	Name of the MAC authentication profile associated with the WLAN. See aaa authentication mac on page 49 .	—
clone <profile>	Name of an existing AAA profile configuration from which parameter values are copied.	—

Parameter	Description	Default
devtype-classification	The device identification feature can automatically identify different client device types and operating systems by parsing the User-Agent strings in a client's HTTP packets. When the devtype-classification parameter is enabled, the output of the show user and show user-table commands shows each client's device type, if that client device can be identified.	enabled
dot1x-default-role <role>	Configured role assigned to the client after 802.1X authentication. If derivation rules are present, the role assigned to the client through these rules take precedence over the default role. NOTE: This parameter requires the PEFNG license.	guest
dot1x-server-group <group>	Name of the server group used for 802.1X authentication. See aaa server-group on page 125 .	—
enforce-dhcp	When you enable this option, clients must complete a DHCP exchange to obtain an IP address. Best practices are to enable this option, when you use the aaa derivation-rules command to create a rule with the DHCP-Option rule type. This parameter is disabled by default.	disabled
download-role	Enables role download from ClearPass Policy Manager (CPPM) if not defined.	disabled
initial-role <role>	Role for unauthenticated users.	logon
l2-auth-fail-through	To select different authentication method if one fails	disabled
mac-default-role <role>	Configured role assigned to the user when the device is MAC authenticated. If derivation rules are present, the role assigned to the client through these rules take precedence over the default role. NOTE: This parameter requires the PEFNG license.	guest
mac-server-group group	Name of the server group used for MAC authentication. See aaa server-group on page 125 .	—
max-ip ipv4 wireless <max_ipv4_users>	Control the number of IPv4 addresses that can be associated to single wireless user. Range: 1-32	2

Parameter	Description	Default
	WARNING: Increasing the max-ip limit may prevent the system from scaling to maximum users on all master/local controllers. For more information, refer to Usage Guidelines for max-ip ipv4 wireless on page 118 .	
multiple-server-accounting	If enabled, the controller sends RADIUS accounting to all servers in RADIUS accounting server group.	disabled
no	Negates any configured parameter.	—
pan-integration	The profile requires mapping at a Palo Alto Networks (PAN) firewall	disabled
radius-accounting <group>	Name of the server group used for RADIUS accounting. See aaa server-group on page 125 .	—
radius-interim-accounting	By default, the RADIUS accounting feature sends only start and stop messages to the RADIUS accounting server. Issue the interim-radius-accounting command to allow the controller to send Interim-Update messages with current user statistics to the server at regular intervals.	disabled
rfc-3576-server <ip-addr>	IP address of a RADIUS server that can send user disconnect, session timeout and change-of-authorization messages, as described in RFC 3576, "Dynamic Authorization Extensions to Remote Dial In User Service (RADIUS)". See aaa rfc-3576-server on page 123 . NOTE: This parameter requires the PEFNG license.	—
sip-authentication-role <role>	Configured role assigned to a session initiation protocol (SIP) client upon registration. NOTE: This parameter requires the PEFNG license.	guest
user-derivation-rules <profile>	User attribute profile from which the user role or VLAN is derived.	—

Parameter	Description	Default
user-idle-timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. A value of 0, deletes the user immediately after disassociation from the wireless network. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.	disabled
wired-to-wireless-roam	Keeps user authenticated when roaming from the wired side of the network.	enabled
xml-api-server <ip-addr>	IP address of a configured XML API server. See aaa xml-api on page 145 . NOTE: This parameter requires the PEFNG license.	—

Usage Guidelines

The AAA profile defines the user role for unauthenticated users, the default user role for MAC or 802.1X authentication, and user derivation rules. The AAA profile contains the authentication profile and authentication server group.

There are predefined AAA profiles available, default-dot1x, default-mac-auth, and default-open. These profiles have the parameter values shown in the following table.

Parameter	default-dot1x	default-mac-auth	default-open
authentication-dot1x	default	N/A	N/A
authentication-mac	N/A	default	N/A
dot1x-default-role	authenticated	guest	guest
dot1x-server-group	N/A	N/A	N/A
initial-role	logon	logon	logon
mac-default-role	guest	authenticated	guest
mac-server-group	default	default	default
radius-accounting	N/A	N/A	N/A
rfc-3576-server	N/A	N/A	N/A

Parameter	default-dot1x	default-mac-auth	default-open
user-derivation-rules	N/A	N/A	N/A
wired-to-wireless roam	enabled	enabled	enabled

Usage Guidelines for max-ip ipv4 wireless

Changing the **max-ip ipv4 wireless** parameter from the default value is recommended for special deployments. If your WLAN has multiple device IP associated to single MAC address, you can increase the this value from the default value of 2.

The default value is 2 IPv4 users per wireless user. Total number of IPv4 users created can be a maximum of two times the license. If you configure 32 max-ip IPv4 users, total number of IPv4 users is 32 times the license. This can prevent the controller from scaling to the maximum limit of IP users. Total number of IPv4 users should be scaled down to offset this issue.

Increasing the value of the **max-ip ipv4 wireless** parameter may increase the look-up time due to an increase in the creation and deletion of IPv4 users on the controller. In a deployment where there is Captive Portal and 802.1X authentication implemented, increasing the number of IPv4 users can further deplete performance.

Example

The following command configures an AAA profile that assigns the “employee” role to clients after they are authenticated using the 802.1X server group “radiusnet”.

```
aaa profile corpnet
    dot1x-default-role employee
    dot1x-server-group radiusnet
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 3.4.1	License requirements changed in ArubaOS 3.4.1, so the sip-authentication-role parameter required the Policy Enforcement Firewall license instead of the Voice Services Module license required in earlier versions.
ArubaOS 6.1	The radius-interim-accounting , devtype-classification and enforce-dhcp parameters were introduced.
ArubaOS 6.3	The user-idle-timeout parameter was introduced.
ArubaOS 6.4	The multiple-server-accounting and download-role parameters were introduced.
ArubaOS 6.4.1.0	The user-idle-timeout parameter now accepts a value of 0.
ArubaOS 6.4.3.0	The max-ip parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system, except for noted parameters	Config mode on master controllers

aaa query-user

aaa query-user <ldap-server-name> <user-name>

Description

Troubleshoot an LDAP authentication failure by verifying that the user exists in the ldap server database.

Syntax

Parameter	Description
<ldap-server-name>	Name of an LDAP server.
<user-name>	Name of a user whose LDAP record you want to view.

Usage Guidelines

If the Admin-DN binds successfully but the wireless user fails to authenticate, issue this command to troubleshoot whether the problem is with the wireless network, the controller, or the ldap server. The **aaa query-user <ldap_server_name> <username>** command makes the controller send a search query to find the user. If that search fails in spite of the user being in the LDAP database, it is most probable that the base DN where the search was started was not correct. In such case, it is advisable to make the base DN at the root of the ldap tree.

Example

The example below shows part of the output for an LDAP record for the username JDOE.

```
(host) #aaa query-user eng JDOE
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: user
cn: John Doe
sn: Doe
userCertificate: 0\202\005\2240\202\004|\240\003\002\001\002\002\012H\011\333K
userCertificate: 0\202\005\2240\202\004|\240\003\002\001\002\002\012J\350\346F
userCertificate: 0\202\005\2240\202\004|\240\003\002\001\002\002\012\023\001\017\240
userCertificate: 0\202\005\2240\202\004|\240\003\002\001\002\002\012\031\224\030
userCertificate: 0\202\005~0\202\004f\240\003\002\001\002\002\012\031\223\246\022

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa radius-attributes

```
aaa radius-attributes add <attribute> <attribute-id> {date|integer|ipaddr|string} [vendor <name> <vendor-id>]
```

Description

This command configures RADIUS attributes for use with server derivation rules.

Syntax

Parameter	Description
add <attribute> <attribute-id>	Adds the specified attribute name (alphanumeric string), associated attribute ID (integer), and type (date, integer, IP address, or string).
date	Adds a date attribute.
integer	Adds a integer attribute.
ipaddr	Adds a IP address attribute.
string	Adds a string attribute.
vendor	(Optional) Display attributes for a specific vendor name and vendor ID.

Usage Guidelines

Add RADIUS attributes for use in server derivation rules. Use the **show aaa radius-attributes** command to display a list of the current RADIUS attributes recognized by the controller. To add a RADIUS attribute to the list, use the **aaa radius-attributes** command.

Example

The following command adds the VSA “Dell-User-Role”:

```
aaa radius-attributes add Dell-User-Role 1 string vendor Dells 14823
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode

aaa rfc-3576-server

```
aaa rfc-3576-server <ipaddr>
    clone <source>
    key <psk>
    no ...
```

Description

This command configures a RADIUS server that can send user disconnect, session timeout, and change-of-authorization (CoA) messages, as described in RFC 3576, "Dynamic Authorization Extensions to Remote Dial In User Service (RADIUS)".

Syntax

Parameter	Description
<ipaddr>	IP address of the server.
clone <source>	Name of an existing RFC 3576 server configuration from which parameter values are copied.
key <psk>	Shared secret to authenticate communication between the RADIUS client and server.
no	Negates any configured parameter.

Usage Guidelines

The disconnect, session timeout and change-of-authorization messages sent from the server to the controller contains information to identify the user for which the message is sent. The controller supports the following attributes for identifying the users who authenticate with a RFC 3576 server:

- user-name: Name of the user to be authenticated
- framed-ip-address: User's IP address
- calling-station-id: Phone number of a station that originated a call
- accounting-session-id: Unique accounting ID for the user session.

If the authentication server sends both supported and unsupported attributes to the controller, the unknown or unsupported attributes will be ignored. If no matching user is found the controller will send a 503: Session Not Found error message back to the RFC 3576 server.

Example

The following command configures an RFC 3576 server:

```
aaa rfc-3576-server 10.1.1.245
    clone default
    key P@$$w0rD;
```

Related Commands

Command	Description
<code>aaa profilerfc-3576-server <ip-addr></code>	Associate an RFC-3576 server to a AAA profile.
<code>show aaa state user</code>	View information for a user whose session timeout is altered by a RFC 3576 server.

Command History

Version	Description
ArubaOS 3.0	Command introduced
ArubaOS 6.3	Introduced support for session timeout messages from the RFC 3576 server.

aaa server-group

```
aaa server-group <group>
  allow-fail-through
  auth-server <name> [match-authstring contains|equals|starts-with <string>] [match- fqdn
<string>] [position <number>] [trim-fqdn]
  clone <group>
  load-balance
  no ...
  set role|vlan condition <attribute> contains|ends-with|equals|not-equals|starts-with
    <string> set-value <set-value-str> [position <number>]
```

Description

This command allows you to add a configured authentication server to an ordered list in a server group, and configure server rules to derive a user role, VLAN ID or VLAN name from attributes returned by the server during authentication.

Syntax

Parameter	Description	Default
<group>	Name that identifies the server group. The name must be 32 characters or less.	—
allow-fail-through	When this option is configured, an authentication failure with the first server in the group causes the controller to attempt authentication with the next server in the list. The controller attempts authentication with each server in the ordered list until either there is a successful authentication or the list of servers in the group is exhausted.	disabled
auth-server <name>	Name of a configured authentication server.	—
match-authstring	This option associates the authentication server with a match rule that the controller can compare with the user/client information in the authentication request. With this option, the user/client information in the authentication request can be in any of the following formats: <domain>\<user> <user>@<domain> host/<pc-name>.<domain> An authentication request is sent to the server only if there is a match between the specified match rule and the user/client information. You can configure multiple match rules for an authentication server.	—
contains	contains: The rule matches if the user/client information contains the specified string.	—

Parameter	Description	Default
<code>equals</code>	The rule matches if the user/client information exactly matches the specified string.	—
<code>starts-with</code>	The rule matches if the user/client information starts with the specified string.	—
<code>match-fqdn <string></code>	This option associates the authentication server with a specified domain. An authentication request is sent to the server only if there is an exact match between the specified domain and the <domain> portion of the user information sent in the authentication request. With this option, the user information must be in one of the following formats: <domain>\<user> <user>@<domain>	—
<code>position <number></code>	Position of the server in the server list. 1 is the top.	(last)
<code>trim-fqdn</code>	This option causes the user information in an authentication request to be edited before the request is sent to the server. Specifically, this option: removes the <domain>\ portion for user information in the <domain>\<user> format removes the @<domain> portion for user information in the <user>@<domain> format	—
<code>clone</code>	Name of an existing server group from which parameter values are copied.	—
<code>load-balance</code>	Enables load-balancing functionality.	—
<code>no</code>	Negates any configured parameter.	—
<code>set role vlan</code>	Assigns the client a user role, VLAN ID or VLAN name based on attributes returned for the client by the authentication server. Rules are ordered: the first rule that matches the configured condition is applied. VLAN IDs and VLAN names cannot be listed together.	—
<code>condition</code>	Attribute returned by the authentication server.	—
<code>contains</code>	The rule is applied if and only if the attribute value contains the specified string.	—
<code>ends-with</code>	The rule is applied if and only if the attribute value ends with the specified string.	—
<code>equals</code>	The rule is applied if and only if the attribute value equals the specified string.	—

Parameter	Description	Default
not-equals	The rule is applied if and only if the attribute value is not equal to the specified string.	—
starts-with	The rule is applied if and only if the attribute value begins with the specified string.	—
set-value	User role or VLAN applied to the client when the rule is matched.	—
value-of	Sets the user role or VLAN to the value of the attribute returned. The user role or VLAN ID returned as the value of the attribute must already be configured on the controller when the rule is applied.	—

Usage Guidelines

You create a server group for a specific type of authentication or for accounting. The list of servers in a server group is an ordered list, which means that the first server in the group is always used unless it is unavailable (in which case, the next server in the list is used). You can configure servers of different types in a server group, for example, you can include the internal database as a backup to a RADIUS server. You can add the same server to multiple server groups. There is a predefined server group “internal” that contains the internal database.

Example

The following command configures a server group “corp-servers” with a RADIUS server as the main authentication server and the internal database as the backup. The command also sets the client’s user role to the value of the returned “Class” attribute.

```
aaa server-group corp-servers
  auth-server radius1 position 1
  auth-server internal position 2
  set role condition Class value-of
  load-balance
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.4	The load-balance parameter was added.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa sygate-on-demand (deprecated)

```
aaa sygate-on-demand remediation-failure-role <role>
```

Description

This command configures the user role assigned to clients that fail Sygate On-Demand Agent (SODA) remediation.

Command History

Version	Description
ArubaOS 3.0	Command introduced
ArubaOS 3.4	Command deprecated

aaa tacacs-accounting

```
aaa tacacs-accounting server-group <group>
    command {action|all|configuration|show}
    mode {enable|disable}
```

Description

This command configures reporting of commands issued on the controller to a TACACS+ server group.

Syntax

Parameter	Description	Range	Default
server-group <group>	The TACACS server group to which the reporting is sent.	—	—
command	The types of commands that are reported to the TACACS server group.	—	—
action	Reports action commands only.	—	—
all	Reports all commands.	—	—
configuration	Reports configuration commands only	—	—
show	Reports show commands only	—	—
mode	Enables accounting for the server group.	enable/ disable	disabled

Usage Guidelines

You must have previously configured the TACACS+ server and server group (see [aaa authentication-server tacacs on page 64](#) and [aaa server-group on page 125](#)).

Example

The following command enables accounting and reporting of configuration commands to the server-group "tacacs1":

```
aaa tacacs-accounting server-group tacacs1 mode enable command configuration
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa test-server

```
aaa test-server {mschapv2|pap} <server> <username> <passwd>
```

Description

This command tests a configured authentication server.

Syntax

Parameter	Description
mschapv2	Use MSCHAPv2 authentication protocol.
pap	Use PAP authentication protocol.
<server>	Name of the configured authentication server.
<username>	Username to use to test the authentication server.
<passwd>	Password to use to test the authentication server.

Usage Guidelines

This command allows you to check a configured RADIUS authentication server or the internal database. You can use this command to check for an “out of service” RADIUS server.

Example

The following commands adds a user in the internal database and verifies the configuration:

```
local-userdb add kgreen lkjHGfds  
aaa test-server pap internal kgreen lkjHGfds
```

```
Authentication successful
```

Command History

This command was available in ArubaOS 3.0.

Command Information

All platforms	Base operating system	Enable mode on master controllers

aaa timers

```
aaa timers
  dead-time <minutes>
  idle-timeout <time> [seconds]
  logon-lifetime <0-255>
  stats-timeout <time> [seconds]
```

Description

This command configures the timers that you can apply to clients and servers.

Syntax

Parameter	Description	Range	Default
dead-time <minutes>	Maximum period, in minutes, that the controller considers an unresponsive authentication server to be “out of service”. This timer is only applicable if there are two or more authentication servers configured on the controller. If there is only one authentication server configured, the server is never considered out of service and all requests are sent to the server. If one or more backup servers are configured and a server is unresponsive, it is marked as out of service for the dead time; subsequent requests are sent to the next server on the priority list for the duration of the dead time. If the server is responsive after the dead time has elapsed, it can take over servicing requests from a lower-priority server; if the server continues to be unresponsive, it is marked as down for the dead time.	0-50	10 minutes
idle-timeout <1-15300>	Maximum number of minutes after which a client is considered idle if there is no user traffic from the client. The timeout period is reset if there is a user traffic. If there is no IP traffic in the timeout period or there is no 802.11 traffic as indicated in the station ageout time that is set in the wlan ssid profile, the client is aged out. Once the timeout period has expired, the user is removed immediately and no ping request is sent. If the seconds parameter is not specified, the value defaults to minutes.	1 to 255 minutes (30 to 15300 seconds)	5 minutes (300 seconds)
logon-lifetime	Maximum time, in minutes, that unauthenticated clients are allowed to remain logged on.	0-255	5 minutes

Parameter	Description	Range	Default
stats-timeout	User Interim stats timeout value. If the seconds parameter is not specified, the value defaults to minutes.	5-10 minutes (300 to 600 seconds)	10 minutes (600 seconds)

Usage Guidelines

These parameters can be left at their default values for most implementations.

Example

The following command changes the idle time to 10 minutes:

```
aaa timers idle-timeout 10
```

Related Commands

```
(host) (config) #show aaa timers
(host) (config) #show datapath user table
```

Command History

Version	Description
ArubaOS 3.0	Command introduced
ArubaOS 3.4	Idle timeout values and defaults changed

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa trusted-ap

```
aaa trusted-ap <macaddr>
```

Description

This command configures a trusted non-Dell AP.

Syntax

Parameter	Description
<macaddr>	MAC address of the AP

Usage Guidelines

This command configures a non-Dell AP as a trusted AP.

Example

The following command configures a trusted non-Dell AP:

```
aaa trusted-ap 00:40:96:4d:07:6e
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa user add

```
aaa user add <ipaddr> [<nusers>] [authentication-method {dot1x|mac|stateful-dot1x|vpn|web}] [mac-addr <macaddr>] [name <username>] [profile <aaa_profile>] [role <role>]
```

Description

This command manually assigns a user role or other values to a specified client or device.

Syntax

Parameter	Description
<ipaddr>	IP address of the user to be added.
<nusers>	Number of users to create starting with <ipaddr>.
authentication-method	Authentication method for the user.
dot1x	802.1X authentication.
mac-addr	MAC authentication.
stateful-dot1x	Stateful 802.1X authentication.
vpn	VPN authentication.
web	Captive portal authentication.
mac <macaddr>	MAC address of the user.
name <username>	Name for the user.
profile <aaa_profile>	AAA profile for the user.
role <role>	Role for the user.

Usage Guidelines

This command should only be used for troubleshooting issues with a specific client or device. This command allows you to manually assign a client or device to a role. For example, you can create a role “debugging” that includes a policy to mirror session packets to a specified destination for further examination, then use this command to assign the “debugging” role to a specific client. Use the **aaa user delete** command to remove the client or device from the role.

Note that issuing this command does not affect ongoing sessions that the client may already have. For example, if a client is in the “employee” role when you assign them to the “debugging” role, the client continues any sessions allowed with the “employee” role. Use the **aaa user clear-sessions** command to clear ongoing sessions.

Example

The following commands create a role that logs HTTPS traffic, then assign the role to a specific client:

```
ip access-list session log-https
  any any svc-https permit log
user-role web-debug
  session-acl log-https
```

In enable mode:

```
aaa user add 10.1.1.236 role web-debug
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa user clear-sessions

```
aaa user clear-sessions <ipaddr>
```

Description

This command clears ongoing sessions for the specified client.

Syntax

Parameter	Description
<ip-addr>	IP address of the user.

Usage Guidelines

This command clears any ongoing sessions that the client already had before being assigned a role with the **aaa user add** command.

Example

The following command clears ongoing sessions for a client:

```
aaa user clear-sessions 10.1.1.236
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa user delete

```
aaa user delete {<ipaddr>|all|mac <macaddr>|name <username>|role <role>}
```

Description

This command deletes clients, users, or roles.

Syntax

Parameter	Description
<ipaddr>	IP address of the client to be deleted.
all	Deletes all connected clients.
mac	MAC address of the client to be deleted.
name	Name of the client to be deleted.
role	Role of the client to be deleted.

Usage Guidelines

This command allows you to manually delete clients, users, or roles. For example, if you used to the **aaa user add** command to assign a user role to a client, you can use this command to remove the role assignment.

Example

The following command a role:

```
aaa user delete role web-debug
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa user fast-age

aaa user fast-age

Description

This command enables fast aging of user table entries.

Syntax

No parameters.

Usage Guidelines

When this feature is enabled, the controller actively sends probe packets to all users with the same MAC address but different IP addresses. The users that fail to respond are purged from the system. This command enables quick detection of multiple instances of the same MAC address in the user table and removal of an “old” IP address. This can occur when a client (or an AP connected to an untrusted port on the controller) changes its IP address.

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa user logout

aaa user logout <ipaddr>

Description

This command logs out a client.

Syntax

Parameter	Description
<ipaddr>	IP address of the client to be logged out.

Usage Guidelines

This command logs out an authenticated client. The client must reauthenticate.

Example

The following command logs out a client:

```
aaa user logout 10.1.1.236
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa user monitor

```
aaa user monitor <ipaddr>|off
```

Description

This command checks to see whether an authenticated user's attributes differ from those in the SOS.

Syntax

Parameter	Description
<ipaddr>	IP address of the user whose attributes are being checked.
off	Disable aaa user monitoring

Usage Guidelines

This command installs a timer that polls the SOS every 60 seconds and checks the following:

- L3 ACLs
- Upstream bandwidth contract
- Downstream bandwidth contract

Example

The following command checks user SOS attributes:

```
aaa user monitor 10.1.1.236
```

Command History

This command was introduced in ArubaOS 6.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa user purge-log

aaa user purge-log

Description

This clear aaa user log files

Syntax

No parameters

Usage Guidelines

Per-user log files for AAA events can be used for troubleshooting issues with a specific client or device. This command clears log information for deleted users.

Example

```
aaa user purge log
```

Command History

This command was available in ArubaOS 6.3

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

aaa user stats-poll

```
aaa user stats-poll <secs>
```

Description

This command enables user statistics polling. If enabled, ArubaOS will poll user data verify that user information in the controller datapath is in synchronization with the data in the controller's authentication module.

Syntax

Parameter	Description
<secs>	This command enables user statistics polling, and defines the time interval between polls. The supported range is 60-600 seconds.

Example

The following command enables user statistics polling with an interval of 10 minutes:

```
aaa user stats-poll 600
```

Command History

This command was introduced in ArubaOS 6.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

aaa xml-api

```
aaa xml-api server <ipaddr>  
    clone <server>  
    default-authentication-role <role>  
    key <key>  
    no ...
```

Description

This command configures an external XML API server.

Syntax

Parameter	Description
server	IP address of the external XML API server.
clone	Name of an existing XML API server configuration from which parameter values are copied.
key	Preshared key to authenticate communication between the controller and the XML API server.
default-authentication-role <role>	Name of the role to be assigned to users after completing XML server authorization.
no	Negates any configured parameter.

Usage Guidelines

XML API is used for authentication and subscriber management from external agents. This command configures an external XML API server. For example, an XML API server can send a blacklist request for a client to the controller. The server configured with this command is referenced in the AAA profile for the WLAN (see [aaa profile on page 114](#)). Contact your Dell representative for more information about using the XML API.

Example

The following configures an XML API server:

```
aaa xml-api server 10.210.1.245  
    key qwerTYuiOP
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	PEFNG license	Config mode on master controllers

activate

```
activate sync[{whitelist download}]
```

Description

This command synchronizes a branch controller whitelist or remote AP whitelist on the controller with the Activate whitelist database.

Syntax

Parameter	Description
sync	Execute the activate sync command to immediately synchronize the list of branch controllers on the Activate server with the branch controller whitelist on the master controller. By default, this list is synchronized every hour.
whitelist download	Issue this command to enable the synchronization the list of branch controllers on the Activate server with the branch controller whitelist on the master controller.

Usage Guidelines

Use this command to synchronize the controller's remote AP whitelist or branch controller whitelist with the cloud-based Activate service. The controller and the Activate server must have layer-3 connectivity to communicate.

Example

The following example synchronizes the Activate whitelist with the remote AP whitelist on the controller:

```
(host)(config)# activate whitelist download
```

Related Commands

Parameter	Description
activate-service-whitelist	This command configures the profile that allows the controller to synchronize its remote AP whitelist from the cloud-based Activate service.

Command History

Release	Modification
ArubaOS 6.4	Command introduced.
ArubaOS 6.4.3.0	The sync parameter is introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master or local controllers

activate-service-whitelist

```
activate-service-whitelist
  add-only
  interval <days>
  no ...
  password <password>
  username <username>
  whitelist-enable
```

Description

This command configures the profile that allows the controller to integrate with the Dell Activate cloud-based services to track, provision and update your remote APs.

Syntax

Parameter	Description
add-only	Allow only addition or modification of entries to the Activate remote AP whitelist database. This parameter is enabled by default. If this setting is disabled, the activate-whitelist-download command can both add and remove entries from the Activate database.
interval <days>	Number of days between the automatic synchronization of the controller remote AP whitelist entries with the Activate whitelist. The supported range is 1-7 days, and the default value is 1 day.
no	Removes or disables an existing parameter.
password <password>	Activate user password
username <username>	Activate username
whitelist-enable	Issue this command to enable secure AP whitelist synchronization with the Activate service. This feature is disabled by default.

Usage Guidelines

Use this command to configure the credentials to synchronize the remote AP whitelist with an Activate server. The controller and the Activate server must have layer-3 connectivity to communicate.

Example

The following example enables the Activate whitelist service on the controller:

```
(host) (config) # activate-service-whitelist
(host) (activate-service-whitelist) #username user2 password pA$$w0rd whitelist-enable
```

Related Commands

Parameter	Description
activate	This command synchronizes the remote AP whitelist on the controller from the cloud-based Activate service.

Command History

This command was introduced in ArubaOS 6.3

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

adp

```
adp discovery {disable|enable} igmp-join {disable|enable} igmp-vlan <vlan>
```

Description

This command configures the Aruba Discovery Protocol (ADP).

Syntax

Parameter	Description	Range	Default
discovery	Enables or disables ADP on the controller.	enabled/ disabled	enabled
igmp-join	Enables or disables sending of Internet Group Management Protocol (IGMP) join requests from the controllers.	enabled/ disabled	enabled
igmp-vlan	VLAN to which IGMP reports are sent.	—	0 (default route VLAN used)

Usage Guidelines

Dell APs send out periodic multicast and broadcast queries to locate the master controller. If the APs are in the same broadcast domain as the master controller and ADP is enabled on the controller, the controller automatically responds to the APs' queries with its IP address. If the APs are not in the same broadcast domain as the master controller, you need to enable multicast on the network. You also need to make sure that all routers are configured to listen for IGMP join requests from the controller and can route the multicast packets. Use the **show adp config** command to verify that ADP and IGMP join options are enabled on the controller.

Example

The following example enables ADP and the sending of IGMP join requests on the controller:

```
adp discovery enable igmp-join enable
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

airgroup

{STRING|add|remove}|userlist {STRING|add|remove}}
  service <STRING> {disable|enable}
  static <mdns-record>
  vlan <NUMBER>
```

Description

This command configures AirGroup global settings, domain, and active-domain parameters.

Syntax

Parameter	Description	Range	Default
server-refresh <mac>	Sends refresh packet to refresh the cache for a AirGroup server. <mac> is the MAC address of the AirGroup server.	—	—
test-server <name> <macaddr>	Tests the AirGroup RADIUS server. <name> is the name of the RADIUS server and <macaddr> is the MAC address of the RADIUS server.	—	—
active-domain <STRING>	Configures an AirGroup active-domain for an AirGroup cluster. NOTE: This parameter is available only in Config mode.	—	—
active-wireless- discovery {disable enable}	Disables/Enables wireless discovery. If wireless discovery is enabled, controller actively sends refresh requests to discover wireless servers.	—	disable

Parameter	Description	Range	Default
	If wireless discovery is disabled, the controller sends refresh requests to wired AirGroup servers only. This parameter is available on the master controller only. The master controller pushes this AirGroup configuration to all the applicable local controllers. NOTE: This parameter is available only in Config mode.		
<pre> cppm-server {aaa {no rfc-3576-server <rfc3576_server- > rfc3576_udp_port <rfc3576_udp_ port> server-dead-time <server-dead- time> server-group <server-group>} enforce- registration query-inter- val <1..24>} </pre>	Configures the following settings in the AirGroup AAA profile: no: Delete command. rfc-3576-server <rfc3576_server>: Configure RFC 3576 server IP address. rfc3576_udp_port <rfc3576_udp_port>: Configure the UDP port number. server-dead-time <server-dead-time>: Server dead time in minutes. To disable the server dead time, set the value to 0. server-group <server-group>: Name of the server group. This parameter is available on the master controller only. The master controller pushes this AirGroup configuration to all the applicable local controllers. enforce-registration: Forces the AirGroup servers to register with CPPM. This parameter is available on the master controller only. The master controller pushes this AirGroup configuration to all the applicable local controllers. query-interval <1..24>: Configures the CPPM query interval, in hours, with the controller. This parameter is available on the master controller only. The master controller pushes this AirGroup configuration to all the applicable local controllers. NOTE: This parameter is available only in Config mode.	—	server-dead-time: 10

Parameter	Description	Range	Default
		query-interval : 1 — 24 hours	
disable	Disables AirGroup on the controller. NOTE: This parameter is available only in Config mode.	—	—
dlna {disable enable}	Disables/Enables AirGroup DLNA support on the controller. NOTE: This parameter is available only in Config mode.	—	disable
domain <STRING>	Configures the AirGroup domain. This parameter is available on the master controller only. The master controller pushes this AirGroup configuration to all the applicable local controllers. NOTE: This parameter is available only in Config mode.	—	—
enable	Enables AirGroup on the controller. NOTE: This parameter is available only in Config mode.	—	—
global-credits <query packets> <response packets>	Configures the controller to restrict the excess mDNS query and response packets generated in an AirGroup network, by assigning tokens. The controller processes these mDNS packets based on the token value. The controller rejects the packets beyond the token limit. The token renews every 15 seconds. The renewal time is not a configurable parameter. NOTE: This parameter is available only in Config mode.	15 — 15000	150
ipv6	Disables/Enables IPv6 support for AirGroup. NOTE: This parameter is available only in Config mode.	—	disable
location-discovery {disable enable}	Disables/Enables location discovery.	—	enable

Parameter	Description	Range	Default
	If enabled, an AirGroup user can see shared devices based on the proximity of the user. This parameter is available on the master controller only. The master controller pushes this AirGroup configuration to all the applicable local controllers. NOTE: This parameter is available only in Config mode.		
mdns {disable enable}	Disables/Enables AirGroup mDNS support on the controller. NOTE: This parameter is available only in Config mode.	—	disable
policy <mac> {grouplist {STRING add remove} location{ap-fqln ap-group ap-name} no {grouplist location {ap-fqln ap-group ap-name} rolelist userlist} rolelist {STRING add remove} userlist {STRING add remove}}	Configures the following policy for an AirGroup server: grouplist {STRING add remove}: Configures shared group-name for the AirGroup server. location{ap-fqln ap-group ap-name}: Configures shared location for the AirGroup server. no {grouplist location {ap-fqln ap-group ap-name} rolelist userlist}: Delete command. rolelist {STRING add remove}: Configures shared role-name for the AirGroup server. userlist {STRING add remove}: Configures shared user-name for the AirGroup server. <mac>: MAC address of AirGroup server. NOTE: This parameter is available only in Config mode.	—	—
service <STRING> {disable enable}	Disables/Enables an AirGroup service on the controller. <STRING> is the name of the AirGroup service. NOTE: This parameter is available only in Config mode.	—	Services enabled by default: • AirPlay • AirPrint • DIAL Services disabled by default: • iTunes

Parameter	Description	Range	Default
			• RemoteMgmt • Sharing • Chat • googlecast • allowall • DLNA Media • DLNA Print
<code>static <mdns-record></code>	Configures static mDNS record. For more information, see airgroup static mdns-record on page 160 NOTE: This parameter is available only in Config mode.	—	—
<code>vlan <NUMBER> {allow disallow}</code>	Configures allowed/disallowed VLAN ID. NOTE: This parameter is available only in Config mode.	1 — 4049	—

Usage Guidelines

Starting from ArubaOS 6.4, AirGroup is disabled by default. For the remaining global parameters, see the command syntax.

Example

Access the controller's command-line interface and use the following command to enable the AirGroup **Global Setting**:

```
(host) #airgroup server-refresh <mac>
(host) #airgroup test-server <name> <macaddr>
(host) (config) #airgroup enable
(host) (config) #airgroup dlna enable
(host) (config) #airgroup mdns enable
(host) (config) #airgroup cppm-server enforce-registration
(host) (config) #airgroup query-interval 10
(host) (config) #airgroup location-discovery enable
(host) (config) #airgroup active-wireless-discovery enable
```

Use the following command to enable the allowall service:

```
(host) (config) #airgroup service allowall enable
```

Use the following command to enable AirGroup access to devices in a specific VLAN:

```
(host) (config) #airgroup vlan 5 disallow
```

Related Commands

Command	Description
show airgroup	This command displays AirGroup global settings, domain, active-domain, and more AirGroup configuration information on the controller.

Command History

Release	Modification
ArubaOS 6.3	Command introduced.
ArubaOS 6.4	The static <mdns-record> parameter was introduced.
ArubaOS 6.4.1.0	• The Chromecast service was renamed to DIAL. • The googlecast service was introduced.
ArubaOS 6.4.3.0	The policy parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	The following commands are available only in Enable mode: • (config) # airgroup server-refresh <mac> MAC-address • (config) # airgroup test-server <name> <mac> MAC-address Configuration mode on master and local controllers NOTE: Few configuration parameters are available on the master controller only. For more information, see Syntax table description.

airgroupservice

```
airgroupservice <STRING>
  autoassociate {apfqln|apgroup|apname}
  description <STRING>
  disallow-role <STRING>
  disallow-vlan <1..4094>
  id <STRING>
  no
```

Description

This command defines an AirGroup service on the master controller. The master controller pushes this AirGroup configuration to all the applicable local controllers.

Syntax

Parameter	Description	Range	Default
airgroupservice <STRING>	Name of the AirGroup service.	—	—
autoassociate {apfqln apgroup apname}	Auto associates AirGroup server to service	—	—
description <STRING>	Description of the AirGroup service.	—	—
disallow-role <STRING>	User Role restricted from accessing the service.	—	—
disallow-vlan <1..4094>	User VLAN restricted from accessing the service.	1 — 4094	—
id	An AirGroup service ID is the name of a Bonjour service offered by a Bonjour-enabled device or application. Bonjour defines service ID strings using the following format: _<i>servicename</i>_.<protocol>.local Example: _airplay_.tcp.local The service ID string is case sensitive and should be entered without any modification, with the exception of the .local portion of the service ID which is optional.	—	—
no	Use this command to delete or negate previously-entered configurations or parameters.	—	—

Example

The following example configures the **iPhoto** service with access to the **_dpap_.tcp** service ID to share photos across MacBooks:

```
(host) (config) #airgroupservice iPhoto
```

```
(host) (config-airgroupservice) #description "Share Photos"
(host) (config-airgroupservice) #id _dpap._tcp
```

Related Commands

Command	Description
show airgroupservice	This command displays the service details of all AirGroup services in the controller.

Command History:

Release	Modification
ArubaOS 6.3	Command introduced.
ArubaOS 6.4.3.0	The autoassociate parameter was introduced.

airgroup static mdns-record

airgroup static mdns-record

```
ptr <mac_addr> <mdns_id> <domain_name> [server_ipaddr]
srv <port> <priority> <weight> <host_name>
a <ipv4addr>
aaaa <ipv6addr>
txt <text>
no...
```

Description

This command configures group static mDNS records.

Syntax

Parameter	Description	Range	Default
ptr	Specifies the PTR (Pointer) record that is used for DNS-Service Discovery	—	—
Mac_addr	MAC address of the server.	—	—
mdns_id <STRING>	Specifies the AirGroup mDNS service ID, that is the name of a Bonjour service offered by a Bonjour-enabled device or application. Bonjour defines mDNS service ID strings using the following format: _<servicename>._protocol.local Example: _airplay._tcp.local	String can include the following characters: 0-9, a-z, A-Z, and '_'	—
Domain_name <STRING>	Specify the name of the domain.	1 to 128 characters	—
Server_ipaddr <STRING>	IP address of the server.	—	—
srv	Specifies the SRV (Service) record that is used for mapping a DNS domain name to a specified list of DNS host servers.	—	—
port	Port value of the static mDNS record.	0 to 65535	—
priority	Priority of the static mDNS record.	0 to 65535	—
weight	Weight of the static mDNS record.	0 to 65535	—
host_name <STRING>	Host name of the mDNS static record.	1 to 63 characters.	—
a	Specifies the A (Address) record that is used for mapping a	—	—

Parameter	Description	Range	Default
	Domain Name System (DNS) domain name to an IP address that is used by a host.		
ipv4addr	IPv4 address of the server.	—	—
aaaa	Specifies the AAAA (IPv6 address) record. This is used for mapping host names to an IP address of the host.	—	—
ipv6addr	IPv6 address of the server.	—	—
text	Specifies the TEXT record for human-readable text in a DNS record.	1-255 characters.	—
server_ipaddr	Specifies the IP address of the AirGroup server.	—	—
no	Negates any configured parameter.	—	—

Usage Guidelines

The Administrator can create the static records using the following methods:

- Group mDNS static records
- Individual mDNS static records

After creating a PTR record, the controller enters into the AirGroup record configuration mode, allowing you to add SRV, A, AAAA, and TXT records. After creating a PTR, SRV, TXT, A, and AAAA static record, use the **show airgroup cache entries** command to view and verify the records created. You can view only the static records in the output of the **show airgroup cache entries static** command.

Example

Group mDNS Static Records

You can create a group of mDNS records for a device. This section describes how to create static records of a server as a group using the CLI.

Creating a PTR Record

Use the following command to create a PTR record:

```
(config) # airgroup static mdns-record ptr <mac_addr> <mdns_id> <domain_name> [server_ipaddr]
(config-airgroup-record) #
```

After creating a PTR record, controller displays the **(config-airgroup-record) #** prompt and you can create SRV, A, AAAA, and TXT records under this prompt.

After creating a PTR, SRV, TXT, A, and AAAA static record, you can use the **show airgroup cache entries** command to view and verify the records created. You can view only the static records in the output of the **show airgroup cache entries static** command.

The following example creates a PTR record:

```
(host) (config) #airgroup static mdns-record ptr 9c:20:7b:cd:ec:41 "_airplay._tcp" "Apple TV (9)._airplay._tcp.local" 10.15.121.240
```

The following example shows the PTR record was created:

```
(host) (config-airgroup-record) #show airgroup cache entries
Cache Entries
-----
Name Type Class TTL Origin Expiry Last Update
-----
_ airplay._tcp.local PTR IN 4500 10.15.121.240 static N/A
Num Cache Entries:1
```

Creating an SRV Record

Use the following command to create an SRV record:

```
(config-airgroup-record) # srv <port> <priority> <weight> <host_name>
```

The following example creates an SRV record:

```
(host) (config-airgroup-record) #srv 7000 0 0 Apple-TV-mbabu-9.local
```

The following example shows the SRV record was created:

```
(host) (config-airgroup-record) #show airgroup cache entries
Cache Entries
-----
Name Type Class TTL Origin Expiry
-----
_ airplay._tcp.local PTR IN 4500 10.15.121.240 static
Apple TV (9)._airplay._tcp.local SRV/NBSTAT IN 120 10.15.121.240 static
Num Cache Entries:2
```

Creating an A Record

Use the following command to create an A record:

```
(config-airgroup-record) #a <ipv4addr>
```

You can create/delete an A record if a corresponding SRV record is available.

The following example creates an A record:

```
(host) (config-airgroup-record) #a 10.15.121.240
```

The following example shows the A record was created:

```
(host) (config-airgroup-record) #show airgroup cache entries
Cache Entries
-----
Name Type Class TTL Origin Expiry Last Update
-----
_ airplay._tcp.local PTR IN 4500 10.15.121.240 static N/A
Apple TV (9)._airplay._tcp.local SRV/NBSTAT IN 120 10.15.121.240 static N/A
Apple-TV-mbabu-9.local A IN 120 10.15.121.240 static N/A
Num Cache Entries:3
```

Creating an AAAA Record

Use the following command to create an AAAA record:

```
(config-airgroup-record) #aaaa <ipv6addr>
```

You can create/delete an AAAA record if a corresponding SRV record is available.

The following example creates an AAAA record:

```
(host) (config-airgroup-record) #aaaa fe80::9e20:7bff:fece:ec41
```

The following example shows the AAAA record was created:

```
(host) (config-airgroup-record) #show airgroup cache entries static
Cache Entries
-----
Name Type Data Origin
----
_ airplay._tcp.local PTR Apple\032TV\032\0409\041._airplay._tcp.local 10.15.121.240
Apple TV (9)._airplay._tcp.local SRV/NBSTAT Apple-TV-mbabu-9.local port:7000 10.15.121.240
Apple-TV-mbabu-9.local A 10.15.121.240 10.15.121.240
Apple-TV-mbabu-9.local AAAA fe80::9e20:7bff:fece:ec41 10.15.121.240
Num Cache Entries:4
```

Creating a Text Record

Use the following command to create a text record:

```
(config-airgroup-record) #txt <text>
```

The following example creates a text record:

```
(host) (config-airgroup-record) #txt "deviceid=9C:20:7B:CD:EC:41"
```

The following example shows the text record was created:

```
(host) (config-airgroup-record) #show airgroup cache entries static
Cache Entries
-----
Name Type Data Origin
----
_ airplay._tcp.local PTR Apple\032TV\032\0409\041._airplay._tcp.local 10.15.121.240
Apple TV (9)._airplay._tcp.local SRV/NBSTAT Apple-TV-mbabu-9.local port:7000 10.15.121.240
Apple-TV-mbabu-9.local A 10.15.121.240 10.15.121.240
Apple-TV-mbabu-9.local AAAA fe80::9e20:7bff:fece:ec41 10.15.121.240
Apple TV (9)._airplay._tcp.local TXT deviceid=9C:20:7B:CD:EC:41 10.15.121.240
Num Cache Entries:5
```

Individual Static mDNS Records

You can create individual static records independently for each record type.

Creating an Individual SRV Record

Use the following command to configure an individual SRV record:

```
airgroup static mdns-record srv <mac_addr> <domain_name> <port> <priority> <weight> <host_
name> [ server_ipaddr]
```

The following example creates an SRV record:

```
(host) (config) #airgroup static mdns-record srv 9c:20:7b:cd:ec:41 "9C207BCDEC41@Apple TV mbab
u._raop._tcp.local" 5000 0 0 Apple-TV-mbabu-4.local 10.15.121.240
```

The following example shows the SRV record created:

```
(host) (config) #show airgroup cache entries
Cache Entries
-----
Name Type Class TTL Origin Expiry Last Update
----
_ airplay._tcp.local PTR IN 4500 10.15.121.240 static N/A
```

```
9C207BCDEC41@Apple TV mbabu._raop._tcp.local SRV/NBSTAT IN 120 10.15.121.240 static N/A
Num Cache Entries:2
```

Creating an Individual Text Record

Use the following command to configure an individual TEXT record:

```
airgroup static mdns-record txt <mac_addr> <domain_name> <text> [server_ipaddr]
```

The following example creates a TEXT record:

```
(host) (config) #airgroup static mdns-record txt 9c:20:7b:cd:ec:41 "Apple TV mbabu (4)._airplay._tcp.local" "features=0x5a7ffff7" 10.15.121.240
```

The following example shows the TEXT record was created:

```
Cache Entries
-----
Name Type Class TTL Origin Expiry Last Update
-----
_airplay._tcp.local PTR IN 4500 10.15.121.240 static N/A
9C207BCDEC41@Apple TV mbabu._raop._tcp.local SRV/NBSTAT IN 120 10.15.121.240 static N/A
Apple TV mbabu (4)._airplay._tcp.local TXT IN 4500 10.15.121.240 static N/A
Num Cache Entries:3
```

Creating an Individual A Record

Use the following command to configure an individual A record:

```
airgroup static mdns-record a <mac_addr> <host_name> <ipv4addr> [server_ipaddr]
```

The following example creates an A record:

```
(host) (config) #airgroup static mdns-record a 9c:20:7b:cd:ec:41 Apple-TV-mbabu-4.local 10.15.121.240
```

The following example shows the A record was created:

```
Cache Entries
-----
Name Type Class TTL Origin Expiry Last Update
-----
_airplay._tcp.local PTR IN 4500 10.15.121.240 static N/A
9C207BCDEC41@Apple TV mbabu._raop._tcp.local SRV/NBSTAT IN 120 10.15.121.240 static N/A
Apple TV mbabu (4)._airplay._tcp.local TXT IN 4500 10.15.121.240 static N/A
Apple-TV-mbabu-4.local A IN 120 10.15.121.240 static N/A
Num Cache Entries:4
```

Creating an Individual AAAA Record

Use the following command to configure an individual AAAA record:

```
airgroup static mdns-record aaaa <mac_addr> <host_name> <ipv6addr> [server_ipaddr]
```

The following example creates an individual AAAA record:

```
(host) (config) #airgroup static mdns-record aaaa 9c:20:7b:cd:ec:41 Apple-TV-mbabu-4.local fe80::9e20:7bff:fece:ec41
```

The following example shows the AAAA record created:

```
Cache Entries
-----
Name Type Class TTL Origin Expiry Last Update
-----
_airplay._tcp.local PTR IN 4500 10.15.121.240 static N/A
9C207BCDEC41@Apple TV mbabu._raop._tcp.local SRV/NBSTAT IN 120 10.15.121.240 static N/A
Apple TV mbabu (4)._airplay._tcp.local TXT IN 4500 10.15.121.240 static N/A
Apple-TV-mbabu-4.local A IN 120 10.15.121.240 static N/A
Apple-TV-mbabu-4.local AAAA IN 120 10.15.121.240 static N/A
Num Cache Entries:5
```

You can delete the mDNS records by appending `no` at the beginning of the command. Ensure that the **[server_ipaddr]** parameter is not added while deleting mDNS records.

am scan <ipaddr> <channel> [bssid <bssid>]  
am test <ipaddr> {suspect-rap bssid <bssid> match-type <match-type> match-method  
<method>|wired-mac {add|remove {bssid <bssid>|enet-mac <enet-mac>} mac <mac>}}
```

Description

These commands enable channel scanning or testing for the specified air monitor.

Syntax

Parameter	Description	Range
scan	IP address of the air monitor to be scanned.	—
<channel>	Channel to which the scanning is tuned. Set to 0 to enable scanning of all channels.	—
bssid	BSSID of the air monitor.	—
test	IP address of the air monitor to be tested.	—
suspect-rap	Tests suspect-rap feature.	—
match-type	Match type.	eth-wm ap-wm eth-gw-wm
match-method	Match method.	equal plus-one minus-one
wired-mac	Tests the rogue AP classification feature. Specifies the Wired MAC table.	—
enet-mac	Specifies the Ethernet MAC table.	—
mac	Specifies the MAC entry to add/remove from either the Wired MAC table or the Ethernet MAC table.	—

Usage Guidelines

These commands are intended to be used with an AP that is configured as an air monitor. You should not use the **am test** command unless instructed to do so by a Dell representative.

Example

The following command sets the air monitor to scan all channels:

```
(host) (config) #am scan 10.1.1.244 0
```

Command History:

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3.1	Support for the wired-mac and associated parameters was introduced.

amon msg-buffer-size

amon msg-buffer-size <msg-buffer-size>

Description

This command modifies the size of AMON packets on the controller.

Syntax

Parameter	Description	Range	Default
<msg-buffer-size>	This command modifies the size of AMON packets on the controller.	1280-40960 bytes	1400 bytes

Example

The following command caps the AMON message size at 1500 bytes:

```
(host) (config) #amon msg-buffer-size 1500
```

ap authorization-profile

```
ap authorization-profile <profile>
  authorization-group <profile>
```

Description

This command defines a temporary configuration profile for remote APs that are not yet authorized on the network.

Syntax

Parameter	Description	Range	Default
authorization-profile <profile>	Name of this instance of the profile. The name must be 1-63 characters.	—	"default"
authorization-group <profile>	Name of a configuration profile to be assigned to the group unauthorized remote APs.	—	"NoAuthApGroup"

Usage Guidelines

The AP authorization-profile specifies which configuration should be assigned to a remote AP that has been provisioned but not yet authenticated at the remote site. By default, these yet-unauthorized APs are put into the temporary AP group **authorization-group** and assigned the predefined profile **NoAuthApGroup**. This configuration allows a user to connect to an unauthorized remote AP via a wired port then enter a corporate username and password. Once a valid user has authorized the remote AP, the AP will be permanently marked as authorized on the network and will then download the configuration assigned to that AP by its permanent AP group.

Example

The following command creates a new authorization profile with a non-default configuration for unauthorized remote APs:

```
ap authorization-profile default2
  authorization-group NoAuthApGroup2
```

Command History

ap debug advanced-stats

```
ap debug advanced-stats {ap-name <ap-name>} [{ ip-addr <ip-addr>}] [{ ip6-addr <ip-addr>}]  
{net80211} [{radio 1|0} enable|disable
```

Description

Issue this command under the supervision of Dell technical support to enable the collection and display of advanced AP debugging information.

Syntax

Parameter	Description
ap-name <ap-name>	Name of the AP for which you want to record advanced debugging information.
ip-addr <ip-addr>	IP address of the AP for which you want to record advanced debugging information.
ip6-addr <ip6-addr>	IPv6 address of the AP for which you want to record advanced debugging information.
net80211	Include this parameter to enable or disable the collection of advanced statistics for transmitted and received frames, and information about packets per second statistics for different frame types.
radio 1 0	Include this parameter to enable or disable the collection of advanced radio driver statistics for the specified radio.
enable	Enable the collection of advanced radio troubleshooting statistics.
disable	Disable the collection of advanced radio troubleshooting statistics.

Usage Guidelines

The additional information collected when advanced net80211 or radio statistics are enabled on an AP appears in the output of the [show ap debug radio-stats](#) command.

```
ap debug client-trace start
{ap-name <ap-name>}|{ip-addr <ip>}|{ip6-addr <ip6>} mac <client-mac>
[length-range <max>|[length-range <min>]
```

Description

Use this command to trace management packets from a client MAC address.

Syntax

Parameter	Description
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IPv4 address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
mac <client-mac>	MAC address of the client..
length-range <max>	data packet max length.
length-range <min>	data packet min length.

Usage Guidelines

This command should only be used under the guidance of Dell technical support.

ap debug dot 11r remove-key

```
ap debug dot 11r remove-key <sta-mac>
[ap-name <ap-name> | ip-addr <ip-addr>]
```

Description

This command removes the r1 key from an AP.

Syntax

Parameter	Description
<sta-mac>	MAC address of the client.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.

Usage Guidelines

Use this command to remove an r1 key from an AP when the AP does not have a cached r1 key during Fast BSS Transition roaming.

Examples

You can use the following command to remove an r1 key from an AP when the AP does not have a cached r1 key during Fast BSS Transition roaming.

```
(host) #ap debug dot11r remove-key <sta-mac> ap-name <ap-name> | ip-addr <ip-addr>
(host) #ap debug dot11r remove-key 00:50:43:21:01:b8 ap-name MACage-105-GL
```

Execute the following command to check if the r1 key is removed from the AP:

```
(host) #show ap debug dot11r state ap-name MACage-105-GL
Stored R1 Keys
-----
Station MAC  Mobility Domain ID  Validity Duration  R1 Key
-----
```

Related Commands

To check if the r1 key is removed from an AP, use the **show ap debug dot11r state** command:

Command History

ap debug radio-event-log

```
ap debug radio-event log [start|stop] [ap-name <name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]  
radio <0|1> size <size-of-log> events [all|ani|rcfind|rcupdate|rx|size|text|tx] [hex  
<hexformat>]
```

Description

Start and stops packet log capture of radio events for debugging purposes, and sends a log file of the events to a dump server when logging stops.

Syntax

Parameter	Description
start	Start Wi-Fi packet log capture
stop	Stop Wi-Fi packet log capture and send a log file of the events to a dump server.
ap-name <ap-name>	Name of the AP for which you want to capture packet log events.
ip-addr <ip-addr>	IPv4 address of the AP for which you want to capture packet log events.
ip6-addr <ip6-addr>	IPv6 address of the for which you want to capture packet log events.
radio 1 0	Include this parameter to start or stop packet log capture for the specified radio.
size <size-of-log>	Specify the maximum radio log size, in bytes. The supported range is 1024-10485760 bytes (1KB-10MB), and the default log size is 3145728 bytes (3MB).
events	Specify the type of radio events you want to capture in the log file. • all: Capture all of the following types of radio events. • ani Adaptive Noise Immunity control events • rcfind: Transmission (Tx) control event • rcupdate: Transmission (Tx) rate update event • rx: Received (Rx) status register event • text: Text record event • tx: Transmission (Tx) control and Tx status register event
hex <hexformat>	(Optional) Specify the radio event type in hexadecimal format • 0x10: Adaptive Noise Immunity control events • 0x4: Transmission (Tx) control event • 0x8: Transmission (Tx) rate update event • 0x2: Received (Rx) status register event • 0X20: Text record event • 0x1: Transmission (Tx) control and Tx status register event
hex	Specify the radio event type in hex format.

Parameter	Description
	- all: Capture all of the following types of radio events. - ani Adaptive Noise Immunity control events - rcfind: Transmission (Tx) control event - rcupdate Transmission (Tx) rate update event in radio - rx: Received (Rx) status register event in radio - tx: Transmission (Tx) control and Tx status register event in radio

Example

The following commands starts and stops a Wi-Fi radio event log:

```
(host)(config)#ap debug radio-event-log start ap-name 6c:f3:7f:c6:71:90 radio 0 events all
(host)(config)#ap debug radio-event-log stop ap-name 6c:f3:7f:c6:71:90 radio 0
```

ap debug radio-registers dump

```
ap debug radio-registers dump [ap-name <name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>] [filename <filename> {all|interrupt|qcu |radio}]
```

Description

This command allows you to collect all or specific radio register information into a separate file.

Syntax

Parameter	Description
ap-name	Name of Access Point
ip-addr	Collect radio register information for this specific AP radio.
ip6-addr	Collect radio register information for the AP assigned to this ipv6 address.
filename	Name of file where information is collected.
all	All registers interrupted.
interrupt	Interrupt related registers.
qcu	Collect QCU information.
radio	Radio ID (0 or 1)

Usage Guidelines

This command collects specified radio-register information for debugging purposes, dumps the registers into a local file, and will automatically transfer the file to the dump-server that is configured in 'ap-system-profile.'

Example

The following command collects all radio registers from **myap1** into a file called **myradioregfile.:**

```
#ap debug radio-registers dump ap-name myap1 filename myradioregfile all
```

Command History

Introduced in ArubaOS 6.2.

Command Information

802.11n-capable APs	Base operating system	Enable mode on master controllers

ap enet-link-profile

```
ap enet-link-profile <profile>
  clone <profile>
  dot3az
  duplex {auto|full|half}
  no ...
  speed {10|100|1000|auto}
```

Description

This command configures an AP Ethernet link profile.

Syntax

Parameter	Description	Range	Default
<profile>	Name of this instance of the profile. The name must be 1-63 characters.	—	"default"
clone	Name of an existing Ethernet Link profile from which parameter values are copied.	—	—
dot3az	Enable support for the 803.az Energy Efficient Ethernet (EEE) standard, which allows the APs to consume less power during periods of low data activity. Only W-AP130 Series APs support this feature. If this feature is enabled for an APs group, any APs in the group that do not support 803.az will ignore this setting.		disabled
duplex	The duplex mode of the Ethernet interface, either full, half, or auto-negotiated.	full/half/auto	auto
no	Negates any configured parameter.	—	—
speed	The speed of the Ethernet interface, either 10 Mbps, 100 Mbps, 1000 Mbps (1 Gbps), or auto-negotiated.	10/100/1000/auto	auto

Usage Guidelines

This command configures the duplex and speed of the Ethernet port on the AP. The configurable speed is dependent on the port type.

Example

The following command configures the Ethernet link profile for full-duplex and 100 Mbps:

```
ap enet-link-profile enet
  duplex full
  speed 100
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3	Support for 1000 Mbps (1 Gbps) Ethernet port speed was introduced.
ArubaOS 6.2	Support for the dot3az parameter was introduced.

ap flush-r1-on-new-r0

ap•flush-r1-on-new-r0 {enable|disable}

Description

Use this command to enable or disable flushing of R1 keys, when R0 is updated for d-tunnel or bridge mode.

Syntax

Parameter	Description
enable	Enable flushing of R1 keys.
disable	Disable flushing of R1 keys.

Example

The following example enables flushing of R1 keys.

```
(host) (config) #ap flush-r1-on-new-r0 enable
```

The following command displays the status of flushing of R1 keys.

```
(host) (config) #show flush-r1-on-new-r0
Fast Roaming flush-r1-on-new-r0:enable
```

Command History

ap image-preload

```
ap image-preload
  activate all-aps|specific-aps
  add {ap-group <ap-group> | ap-name <ap-name>}
  cancel
  clear-all
  delete {ap-group <ap-group> | ap-name <ap-name>}
  [partition <part-num>]
  [max-downloads <max-downloads>]
```

Description

Configure APs to preload a new software image from a W-3600 or W-6000M3 controller before the controller starts actively running the new image.

Syntax

Parameter	Description
activate	Issue the ap image-preload activate command to activate this feature, allowing APs in the preload list to start downloading their new image from the controller.
all-aps	All APs will be allowed to pre download the image.
specific-aps	Only APs in the preload list will be allowed to preload the image.
add	Add individual APs or AP groups to the list of APs allowed to preload the image.
ap-group <group>	Add a group of APs to the preload list.
ap-name <name>	Add an individual AP to the preload list.
cancel	Cancel the AP preload and clear the preload list. Any APs downloading a new image at the time this command is issued will continue to download the file.
clear-all	Clear all APs from the preload list.
delete	Delete an individual AP or AP group from the preload list. NOTE: This command may be issued before or after preloading is activated. If it is executed after preloading has already been activated, any APs downloading a new image at the time this command is issued will continue to download the file. APs that are still waiting to preload will be removed from the preload list.
ap-group <group>	Remove the specified group of APs from the preload list

Parameter	Description
<code>ap-name <name></code>	Remove an individual AP from the preload list
<code>partition <partition-num></code>	Specify the partition from which the APs should download their images. By default, the APs will preload images from the controller's default boot partition.
<code>max-downloads <max-downloads></code>	Specify the maximum number of APs that can simultaneously download their image from the controller. The default value is ten APs.

Usage Guidelines

The AP image preload feature minimizes the downtime required for a controller upgrade by allowing the APs associated to a W-3400, W-3600 or W-6000M3 controller to download the new images before the controller actually starts running the new version.

This feature allows you to select the maximum number of APs that are allowed to preload the new software image at any one time, thereby reducing the possibility that the controller may get overloaded or that network traffic may be impacted by all APs on the controller attempting to download a new image at once.

APs can continue normal operation while they are downloading their new software version. When the download completes, the AP sends a message to the controller, informing it that the AP has either successfully downloaded the new software version, or that the preload has failed for some reason. If the download fails, the AP will retry the download after a brief waiting period.

You can allow every AP on a controller to preload a new software version, or also create a custom list of AP groups or individual APs that can use this feature. If a new AP associates to the controller while the AP image download feature is active, the controller will check that AP's name and group to see if it appears in the preload list. If an AP is on the list, (and does not already have the specified image in its Flash memory) that AP will start preloading its image.

Example

The following command enables the image preload feature and adds the APs in the AP groups **corp1** and **corp2** to the preload list.

```
ap image-preload activate specific-aps
  add ap-group corp1
  add ap-group corp2
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

ap-lacp-striping-ip

```
ap-lacp-striping-ip
  aplacp-enable
  no
  striping-ip <ip-addr> lms <ip-addr>
```

Description

Define an AP LACP LMS map information profile that maps a GRE striping IP address to an existing LMS-IP address.

Syntax

Parameter	Description
aplacp-enable	Issue this command to enable LACP IP striping. This feature is disabled by default
no ...	Issue this command to negate any setting or return a configured parameter it to its default value.
striping-ip <ip>	Specify an IPv4 address for the 802.11g radio of the controller to allow LACP-enabled switches to send traffic for the two controller radios on different links. Recommended value for this parameter is lms <ip-addr>+1 . NOTE: In ArubaOS 6.3.1.0 - 6.4.1.0, LACP striping is configured using the ap system profile <profile> gre-striping-ip command.
lms <ip-addr>	The LMS IP address to which a GRE striping IP address is associated.

Usage Guidelines

The **AP LACP LMS map information** profile is a local profile that maps a LMS IP address (defined in the AP system profile) to a GRE striping IP address. If a W-AP220 Series or W-AP270 Series access point fails over to a standby or backup controller, the AP LACP LMS map information profile on the new controller defines the IP address that the AP uses to terminate 802.11g radio tunnels on the new controller. This feature allows W-AP220 Series or W-AP270 Series access points to form a 802.11g radio tunnel to a backup controller the event of a controller failover, even if the backup controller is in a different L3 network.

In ArubaOS 6.4.1 and previous releases, the GRE striping IP address was defined in the global AP system profile, which did not allow APs to maintain GRE striping tunnels if the AP failed over to a backup controller in a different L3 network.

If your topology includes a backup controller you must define GRE striping IP settings in the active and the backup controller.

Example

The following example enables this feature and maps a GRE striping IP address to the LMS-IP address 192.0.2.0:

```
(host) (config) # ap-lacp-striping-ip
(host) (AP LACP LMS map information)#aplacp-enable
(host) (AP LACP LMS map information)#striping-ip 192.0.2.2 lms 192.0.2.1
```

Related Commands

The following show commands display information about the settings defined in the AP LACP LMS map information profile:

- [show ap-lACP-striping-ip](#): displays all settings defined in AP LACP LMS map information profile.
- [show ap database](#): the output of this command displays an **s** flag to indicate that the AP is enabled with a striping IP address.
- [show ap debug lacp](#): the output of this command displays the AP's striping IP address, as defined in the AP LACP LMS map information profile.

ap lldp med-network-policy-profile

```
ap lldp med-network-policy-profile <profile>
  application-type guest-voice|guest-voice-signaling|softphone-voice|streaming-video|video-
  conferencing|video-signaling|voice|voice-signaling
  clone <profile>
  dscp <dscp>
  l2-priority <l2-priority>
  no ...
  tagged
  vlan <vlan>
```

Description

Define an LLDP MED network policy profile that defines DSCP values and L2 priority levels for a voice or video application.

Syntax

Parameter	Description	Range
application-type	Specify the type of application that this profile manages.	-
guest-voice	Use this application type if the AP services a separate voice network for guest users and visitors.	-
guest-voice-signaling	Use this application type if the AP is part of a network that requires a different policy for guest voice signaling than for guest voice media. Do not use this application type if both the same network policies apply to both guest voice and guest voice signaling traffic.	-
softphone-voice	Use this application type if the AP supports voice services using softphone software applications on devices such as PCs or laptops.	-
streaming-video	Use this application type if the AP supports broadcast or multicast video or other streaming video services that require specific network policy treatment. This application type is not recommended for video applications that rely on TCP with buffering.	-
video-conferencing	Use this application type of the AP supports video conferencing equipment that provides real-time, interactive video/audio services.	-

Parameter	Description	Range
video-signaling	Use this application type if the AP is part of a network that requires a different policy for video signaling than for the video media. Do not use this application type if both the same network policies apply to both video and video signaling traffic.	-
voice	Use this application type if the AP services IP telephones and other appliances that support interactive voice services. NOTE: This is the default application type.	-
voice-signaling	Use this application type if the AP is part of a network that requires a different policy for voice signaling than for the voice media. Do not use this application type if both the same network policies apply to both voice and voice signaling traffic.	-
clone <profile>	Make a copy of an existing profile by specifying that profile name.	-
dscp	Select a Differentiated Services Code Point (DSCP) priority value for the specified application type by specifying a value from 0-63, where 0 is the lowest priority level and 63 is the highest priority.	0-63 Default is 0
l2-priority <L2-priority>	Select a 802.1p priority level for the specified application type, by specifying a value from 0-7, where 0 is the lowest priority level and 7 is the highest priority.	0-7 Default is 0
no ...	Issue this command to negate any setting or return a configured parameter it to its default value.	-
tagged	Specifies if the policy applies to a to a VLAN that is tagged with a VLAN ID or untagged. The default value is untagged. NOTE: When an LLDP-MED network policy is defined for use with an untagged VLAN, then the L2 priority field is ignored and only the DSCP value is used.	Default is untagged
vlan <vlan>	Specify a VLAN by VLAN ID (0-4094) or VLAN name.	Default is 0

Usage Guidelines

LLDP-MED (media endpoint devices) is an extension to LLDP that supports interoperability between VoIP devices and other networking clients. LLDP-MED network policy discovery lets end-points and network devices advertise their VLAN IDs (e.g. voice VLAN), priority levels, and DSCP values. ArubaOS supports a maximum of eight LLDP -MED Network Policy profiles.

Creating an LLDP MED network policy profile does not apply the configuration to any AP or AP interface or interface group. To apply the LLDP-MED network policy profile, you must associate it to an LLDP profile, then apply that LLDP profile to an AP wired port profile.

Example

The following commands create a LLDP MED network policy profile for streaming video applications and marks streaming video as high-priority traffic.

```
(host) (config) ap lldp med-network-policy-profile vid-stream
(host) (AP LLDP-MED Network Policy Profile "vid-stream") dscp 48
(host) (AP LLDP-MED Network Policy Profile "vid-stream") l2-priority 6
(host) (AP LLDP-MED Network Policy Profile "vid-stream") tagged
(host) (AP LLDP-MED Network Policy Profile "vid-stream") vlan 10
(host) (AP LLDP-MED Network Policy Profile "vid-stream") !
```

Next, the LLDP MED network policy profile is assigned to an LLDP profile, and the LLDP profile is associated with an AP wired-port profile.

```
(host) (config) ap lldp profile video1
(host) (AP LLDP Profile "video1") lldp-med-network-policy-profile vid-stream
(host) (AP LLDP Profile "video1") !
(host) (config) ap wired-port-profile corp2
(host) (AP wired port profile "corp2") lldp-profile video1
```

Command History

This command was introduced in ArubaOS 6.2.

Command Information

Platforms	Licensing	Command Mode

ap lldp profile

```
ap lldp profile <profile>
  clone <profile>
  dot1-tlvs port-vlan|vlan-name
  dot3-tlvs link-aggregation|mac|mfs|power
  lldp-med-network-policy-profile <profile>
  lldp-med-tlvs capabilities|inventory|network-policy
  no ...
  optional-tlvs capabilities|management-address|port-description|system-description|system-
  name
  receive
  transmit
  transmit-hold <transmit-hold>
  transmit-interval <transmit-interval>
```

Description

Define an LLDP profile that specifies the type-length-value (TLV) elements to be sent in LLDP PDUs.

Syntax

Parameter	Description
clone <profile>	Make a copy of an existing LLDP profile.
dot1-tlvs	Specify which of the following 802.1 TLVs the AP will send in LLDP PDUs. By default, the AP will send all 802.1 TLVs.
port-vlan	Transmit the LLDP 802.1 port VLAN TLV. If the native VLAN is configured on the port, the port-vlan TLV will send that value, otherwise it will send a value of "0".
vlan-name	Transmit the LLDP 802.1 VLAN name TLV. The AP sends a value of "Unknown" for VLAN 0, or "VLAN <number>" for non-zero VLAN numbers.
dot3-tlvs	Specify which of the following 802.3 TLVs the AP will send in LLDP PDUs. By default, the AP will send all 802.3 TLVs.
link-aggregation	Transmit the 802.3 link aggregation TLV to indicate that link aggregation is not supported.
mac	Transmit the 802.3 MAC/PHY Configuration/Status TLV to indicate the AP interface's duplex and bit rate capacity and current duplex and bit rate settings.
mfs	Transmit the 802.3 Maximum Frame Size (MFS) TLV to show the AP's maximum frame size capability.

Parameter	Description
power	Transmit the 802.3 Power Via media dependent interface (MDI) TLV to show the power support capabilities of the AP interface. NOTE: This parameter is supported by the W-IAP3WNP and W-AP130 Series only.
lldp-med-network-policy-profile <profile>	Specify the LLDP MED Network Policy profile to be associated with this LLDP profile.
lldp-med-tlvs	Specify which of the following LLDP-MED TLVs the AP will send in LLDP PDUs. The AP will not send any LLDP-MED TLVs by default.
capabilities	Transmit the LLDP-MED capabilities TLV. The AP will automatically send this TLV if any of the other LLDP-MED TLVs are enabled.
inventory	Transmit the LLDP-MED inventory TLV. NOTE: An AP can't send this TLV unless it also sends the LLDP-MED capabilities TLV.
network-policy	Transmit the LLDP-MED network-policy TLV. NOTE: An AP can't send this TLV unless it also sends the LLDP-MED capabilities TLV.
optional-tlvs	Specify which of the following optional TLVs the AP will send in LLDP PDUs.
capabilities	Transmit the system capabilities TLV to indicate which capabilities are supported by the AP.
management-address	Transmit a TLV that indicates the AP's management IP address, in either IPv4 or IPV6 format.
port-description	Transmit a TLV that gives a description of the AP's wired port in an alphanumeric format.
system-description	Transmit a TLV that describes the AP's model number and software version
system-name	Transmit a TLV that sends the AP name or wired MAC address.
receive	Issue this command to enable LLDP PDU reception. This parameter is enabled by default.
transmit	Issue this command to enable LLDP PDU transmission. This parameter is enabled by default.

Parameter	Description
<code>transmit-hold <transmit-hold></code>	Enter a value from 1-100. This value is multiplied by the transmit interval to determine the number of seconds to cache learned LLDP information before that information is cleared. If the transmit-hold value is at the default value of 4, and the transmit interval is at its default value of 30 seconds, then learned LLDP information will be cached for 4 x 30 seconds, or 120 seconds.
<code>transmit-interval <transmit-interval></code>	The interval between LLDP TLV transmission seconds. The supported range is 1-3600 seconds and the default value is 30 seconds.

Usage Guidelines

Link Layer Discovery Protocol (LLDP), is a Layer-2 protocol that allows network devices to advertise their identity and capabilities on a LAN. Wired interfaces on Dell APs support LLDP by periodically transmitting LLDP Protocol Data Units (PDUs) comprised of type-length-value (TLV) elements. Use this command to specify which TLVs should be sent by the AP interface associated with the LLDP profile.

Example

The following command configures an LLDP profile allows the AP interface to send the port-vlan and vlan-name TLVs.

```
ap lldp profile 8021TLVs
  dot1-tlvs port-vlan
  dot1-tlvs vlan-name
```

Command History

This command was introduced in ArubaOS 6.2.

Command Information

Platforms	Licensing	Command Mode
Available on all platforms	Base operating system	Config mode on master controllers

ap mesh-cluster-profile

```
ap mesh-cluster-profile <profile>
  clone <profile>
  cluster <name>
  no ...
  opmode [opensystem | wpa2-psk-aes]
  rf-band {a | g}
  wpa-hexkey <wpa-hexkey>
  wpa-passphrase <wpa-passphrase>
```

Description

This command configures a mesh cluster profile used by mesh nodes.

Syntax

Parameter	Description	Range	Default
<profile>	Name of this instance of the profile. The name must be 1-63 characters.	—	"default"
clone	Name of an existing mesh cluster profile from which parameter values are copied.	—	—
cluster	Indicates the mesh cluster name. The name can have a maximum of 32 characters, and is used as the MSSID for the mesh cluster. When you first create a new mesh cluster profile, the profile uses the default cluster name "Dell-mesh". Use the cluster parameter to define a new, unique MSSID before you assign APs or AP groups to the mesh cluster profile. NOTE: If you want a mesh cluster to use WPA2-PSK-AES encryption, <i>do not use spaces in the mesh cluster name</i>, as this may cause errors in mesh points associated with that mesh cluster. To view existing mesh cluster profiles, use the CLI command show ap mesh-cluster-profile.	—	"Dell-mesh"
no	Negates any configured parameter.	—	—
opmode	Configures one of the following types of data encryption. • opensystem—No authentication or encryption. • wpa2-psk-aes—WPA2 with AES encryption using a pershared key. Best practices are to select wpa2-psk-aes and use the wpa-passphrase parameter to select a passphrase. Keep the passphrase in a safe place.	opensystem wpa2-psk-aes	opensystem

Parameter	Description	Range	Default
rf-band	Configures the RF band in which multiband mesh nodes should operate: a = 5 GHz g = 2.4 GHz Best practices are to use 802.11a radios for mesh deployments.	a g	a
wpa-hexkey	Configures a WPA pre-shared key.	—	—
wpa-passphrase	Sets the WPA password that generates the PSK.	—	—

Usage Guidelines

Mesh cluster profiles are specific to mesh nodes (APs configured for mesh) and provide the framework of the mesh network. You must define and configure the mesh cluster profile before configuring an AP to operate as a mesh node.

You can configure multiple mesh cluster profiles to be used within a mesh cluster. You must configure different priority levels for each mesh cluster profile. See [ap-group](#) or [ap-name](#) for more information about priorities.

Cluster profiles, including the “default” profile, are not applied until you provision your APs for mesh.

Example

The following command configures a mesh cluster profile named “cluster1” for the mesh cluster “headquarters:”

```
ap mesh-cluster-profile cluster1
  cluster headquarters
```

Related Commands

To view a complete list of mesh cluster profiles and their status, use the following command:

```

Description

This command configures a mesh high-throughput SSID profile used by mesh nodes.

Syntax

Parameter	Description	Range	Default
<profile-name>	Enter the name of an existing mesh high-throughput SSID profile to modify that profile, or enter a new name or create a new mesh high-throughput profile. The mesh high-throughput profile can have a maximum of 32 characters. To view existing high-throughput SSID radio profiles, use the command show ap mesh-radio-profile .		default
40MHz-enable	Enable or disable the use of 40 MHz channels. This parameter is enabled by default.		enabled
80MHz-enable	Enable or disable the use of 80 MHz channels.		enabled
ba-amsdu-enable	Enable/Disable Receive AMSDU in BA negotiation.		enabled

Parameter	Description	Range	Default
clone <source>	Copy configuration information from a source profile into the currently selected profile		
high-throughput-enable	Enable or disable high-throughput (802.11n) features on this SSID. This parameter is enabled by default.		enabled
ldpc	If enabled, the AP will advertise Low-density Parity Check (LDPC) support. LDPC improves data transmission over radio channels with high levels of background noise.		enabled
legacy-stations	Allow or disallow associations from legacy (non-HT) stations. By default, this parameter is enabled (legacy stations are allowed).		enabled
max-rx-a-mpdu-size	Maximum size of a received aggregate MPDU, in bytes.	8191, 16383, 32767, 65535	
max-tx-a-mpdu-size	Maximum size of a transmitted aggregate MPDU, in bytes.	1576 - 65535	
max-tx-a-msdu-count-be	Maximum number of MSDUs in a TX A-MSDU on best-effort AC. TX-AMSDU disabled if 0.	0 - 15	2
max-tx-a-msdu-count-bg	Maximum number of MSDUs in a TX A-MSDU on background. TX-AMSDU disabled if 0.	0 - 15	2
max-tx-a-msdu-count-vi	Maximum number of MSDUs in a TX A-MSDU on video AC. TX-AMSDU disabled if 0.	0 - 15	2
max-tx-a-msdu-count-vo	Maximum number of MSDUs in a TX A-MSDU on voice AC. TX-AMSDU disabled if 0.	0 - 15	0
max-vht-mpdu-size	Maximum size of a VHT MPDU.	3895, 7991, 11454	11454

Parameter	Description	Range	Default
min-mpdu-start-spacing	Minimum time between the start of adjacent MPDUs within an aggregate MPDU, in microseconds.	0 (No restriction on MDPU start spacing), .25 μ sec, .5 μ sec, 1 μ sec, 2 μ sec, 4 μ sec	0 μ sec
mpdu-agg	Enable or disable MAC protocol data unit (MPDU) aggregation. High-throughput mesh APs are able to send aggregated MAC protocol data units (MDPUs), which allow an AP to receive a single block acknowledgment instead of multiple ACK signals. This option, which is enabled by default, reduces network traffic overhead by effectively eliminating the need to initiate a new transfer for every MPDU.		enabled
short-guard-intvl-20Mhz	Enable or disable use of short (400ns) guard interval for W-AP130 Series APs in 20 MHz mode. A guard interval is a period of time between transmissions that allows reflections from the previous data transmission to settle before an AP transmits data again. An AP identifies any signal content received inside this interval as unwanted inter-symbol interference, and rejects that data. The 802.11n standard specifies two guard intervals: 400ns (short) and 800ns (long). Enabling a short guard interval can decrease network overhead by reducing unnecessary idle time on each AP. Some outdoor deployments, may, however require a longer guard interval. If the short guard interval does not allow enough time for reflections to settle in your mesh deployment, inter-symbol interference values may increase and degrade throughput. This parameter is enabled by default.		enabled
short-guard-intvl-40Mhz	Enable or disable use of short (400ns) guard interval in 40 MHz mode. A guard interval is a period of time between transmissions that allows reflections from the previous data transmission to settle before an AP transmits data again. An AP identifies any signal content received inside this interval as unwanted inter-symbol interference, and rejects that data.		enabled

Parameter	Description	Range	Default
	The 802.11n standard specifies two guard intervals: 400ns (short) and 800ns (long). Enabling a short guard interval can decrease network overhead by reducing unnecessary idle time on each AP. Some outdoor deployments, may, however require a longer guard interval. If the short guard interval does not allow enough time for reflections to settle in your mesh deployment, inter-symbol interference values may increase and degrade throughput. This parameter is enabled by default.		
short-guard-intvl-80Mhz	Enable or disable use of short (400ns) guard interval in 80 MHz mode. A guard interval is a period of time between transmissions that allows reflections from the previous data transmission to settle before an AP transmits data again. An AP identifies any signal content received inside this interval as unwanted inter-symbol interference, and rejects that data. The 802.11n standard specifies two guard intervals: 400ns (short) and 800ns (long). Enabling a short guard interval can decrease network overhead by reducing unnecessary idle time on each AP. Some outdoor deployments, may, however require a longer guard interval. If the short guard interval does not allow enough time for reflections to settle in your mesh deployment, inter-symbol interference values may increase and degrade throughput. This parameter is enabled by default.		enabled
stbc-rx-streams	Controls the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the W-AP90 series, W-AP130 Series, W-AP68, W-AP175 and W-AP105 only. The configured value will be adjusted based on AP capabilities.)	0-1	1
stbc-tx-streams	Controls the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on W-AP90 series, W-AP175, W-AP130 Series and W-AP105 only. The configured value will be adjusted based on AP capabilities.)	0-1	1

Parameter	Description	Range	Default
supported-mcs-set	A list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20MHz vs. 40MHz) and the number of spatial streams used by the mesh node. The default value is 1-15; the complete set of supported values. To specify a smaller range of values, enter a hyphen between the lower and upper values. To specify a series of different values, separate each value with a comma. Examples: 2-10 1,3,6,9,12 Range: 0-15.	1-15	1-15
temporal-diversity	Shows if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries.		disabled

Guidelines

The mesh high-throughput profile defines settings unique to 802.11 n-capable, high-throughput APs. If none of the APs in your mesh deployment are 802.11 n-capable APs, you do not need to configure a high-throughput SSID profile.

If you modify a currently provisioned and running high-throughput SSID profile, your changes take effect immediately. You do not reboot the controller or the AP.

Example

The following command configures a mesh high-throughput SSID profile named "HT1" and sets some non-default settings for MAC protocol data unit (MPDU) aggregation:

```
(host) (config) #ap mesh-ht-ssid-profile HT1
max-rx-a-mpdu-size 32767
max-tx-a-mpdu-size 32767
min-mpdu-start-spacing .25
```

Related Commands

To view a complete list of mesh high-throughput SSID profiles and their status, use the following command:

```
(host) (config) #show ap mesh-ht-ssid-profile
```

To view the settings of a specific mesh radio profile, use the following command:

```
(host) (config) #show ap mesh-ht-ssid-profile <name>
```

Command History

```

Description

This command configures a mesh radio profile used by mesh nodes.

Syntax

Parameter	Description	Range	Default
<profile>	Name of this instance of the profile. The name must be 1-63 characters.	—	"default"
allowed-vlans	Specify a list of VLAN IDs that can be used by a mesh link on APs associated with this mesh radio profile		
<vlan-list>	A comma-separated list of VLAN IDs. You can also specify a range of VLAN IDs using a dash (for example, 1-4095)		
a-tx rates	Indicates the transmit rates for the 802.11a radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.	6, 9, 12, 18, 24, 36, 48, 54 Mbps	6, 9, 12, 18, 24, 36, 48, 54 Mbps
children	Indicates the maximum number of children a mesh node can accept.	1-64	64

Parameter	Description	Range	Default
clone	Name of an existing mesh radio profile from which parameter values are copied.		
eapol-rate-opt	Use a more conservative rate for more reliable delivery of EAPOL frames.	enabled disabled	disabled
g-tx rates	Indicates the transmit rates for the 802.11b/g radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.	1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54	1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54 Mbps
heartbeat-threshold	Indicates the maximum number of heartbeat messages that can be lost between neighboring mesh nodes.	1-255	10
hop-count	Indicates the maximum hop count from the mesh portal.	1-32	8
link-threshold	Indicates the minimal RSSI value. If the RSSI value is below this threshold, the link may be considered a sub-threshold link. A sub-threshold link is a link whose average RSSI value falls below the configured threshold. If this occurs, the mesh node may try to find a better link on the same channel and cluster (only neighbors on the same channel are considered). The supported threshold is hardware dependent, with a practical range of 10-90.	hardware dependent	12
mesh-ht-ssid-profile	High-throughput SSID Profile for the mesh feature.		default
max-retries	Maximum number of times a mesh node can re-send a packet.	0-15	4 times
mesh-mcast-opt	Enables or disables scanning of all active stations currently associated to a mesh point to select the lowest transmission rate based on the slowest connected mesh child. When enabled, this setting dynamically adjusts the multicast rate to that of the slowest connected mesh child. Multicast frames are not sent if there are no mesh children.		enabled

Parameter	Description	Range	Default
	Best practices are to use the default value.		
mesh-survivability	Allow mesh points and portals to become active even if the controller cannot be reached by bridging LAN traffic. This is a beta feature that is disabled by default; it should not be enabled unless you are instructed to do so by Dell technical support.	—	distributed-tree-rssi
metric-algorithm	Specifies the algorithm used by a mesh node to select its parent. Best practices are to use the default value distributed-tree-rssi.	—	distributed-tree-rssi
best-link-rssi	Selects the parent with the strongest RSSI, regardless of the number of children a potential parent has.	—	—
distributed-tree-rssi	Selects the parent based on link-RSSI and node cost based on the number of children. This option evenly distributes the mesh points over high quality uplinks. Low quality uplinks are selected as a last resort.	—	—
mpv	This parameter is experimental and reserved for future use.	0-4094	0 (disabled)
no	Negates any configured parameter.	—	—
reselection-mode	Specifies the method used to find a better mesh link. Best practices are to use the default value startup-subthreshold.	(see below)	startup-subthreshold
reselect-anytime	Mesh points using the reselect-anytime reselection mode perform a single topology readjustment scan within 9 minutes of startup and 4 minutes after a link is formed. If no better parent is found, the mesh point returns to its original parent. This initial scan evaluates more distant mesh points before closer mesh points, and incurs a dropout of 5-8 seconds for each mesh point.	—	—

Parameter	Description	Range	Default
	After the initial startup scan is completed, connected mesh nodes evaluate mesh links every 30 seconds. If a mesh node finds a better uplink, the mesh node connects to the new parent to create an improved path to the mesh portal.		
reselect-never	Connected mesh nodes do not evaluate other mesh links to create an improved path to the mesh portal.	—	—
startup-subthreshold	Mesh points using the startup-subthreshold reselection mode perform a single topology readjustment scan within 9 minutes of startup and 4 minutes after a link is formed. If no better parent is found, the mesh point returns to its original parent. This initial startup scan evaluates more distant mesh points before closer mesh points, and incurs a dropout of 5-8 seconds for each mesh point. After that time, each mesh node evaluates alternative links if the existing uplink falls below the configured threshold level (the link becomes a sub-threshold link). Best practices are to use the default startup-subthreshold value. Starting with ArubaOS 3.4.1, if a mesh point using the startup-subthreshold mode reselects a more distant parent because its original, closer parent falls below the acceptable threshold, then as long as that mesh point is connected to that more distant parent, it will seek to reselect a parent at the earlier distance (or less) with good link quality. For example, if a mesh point disconnects from a mesh parent 2 hops away and subsequently reconnects to a mesh parent 3 hops away, then the mesh point will continue to seek a connection to a mesh parent with both an acceptable link quality and a distance of two hops or less, even if the more distant parent also has an acceptable link quality.	—	—
subthreshold-only	Connected mesh nodes evaluate alternative links only if the existing uplink becomes a sub-threshold link. NOTE: Starting with ArubaOS 3.4.1, if a mesh point using the subthreshold-only mode reselects a more distant parent because its original, closer parent falls below the acceptable threshold, then as long as that mesh point is connected to that more distant parent, it will seek to reselect a parent at the earlier distance (or less) with good link quality. For example, if a	—	—

Parameter	Description	Range	Default
	mesh point disconnects from a mesh parent 2 hops away and subsequently reconnects to a mesh parent 3 hops away, then the mesh point will continue to seek a connection to a mesh parent with both an acceptable link quality and a distance of two hops or less, even if the more distant parent also has an acceptable link quality.		
<code>rts-threshold</code>	Defines the packet size sent by mesh nodes. Mesh nodes transmitting frames larger than this threshold must issue request to send (RTS) and wait for other mesh nodes to respond with clear to send (CTS) to begin transmission. This helps prevent mid-air collisions.	256-2,346	2,333 bytes

Usage Guidelines

Mesh radio profiles are specific to mesh nodes (APs configured for mesh) and determine the radio frequency/channel used by mesh nodes to establish mesh links and the path to the mesh portal. You can configure multiple radio profiles; however, you select and deploy only one radio profile per mesh cluster.

Radio profiles, including the “default” profile, are not active until you provision your APs for mesh. If you modify a currently provisioned and running radio profile, your changes take place immediately. You do not reboot the controller or the AP.

Example

The following command creates a mesh radio profile named “radio2” and associates a mesh high-throughput profile named meshHT1:

```
(host) (config) #ap mesh-radio-profile radio2
mesh-ht-ssid-profile meshHT1
```

Related Commands

To view a complete list of mesh radio profiles and their status, use the following command:

```
(host) (config) #show ap mesh-radio-profile
```

To view the settings of a specific mesh radio profile, use the following command:

```
(host) (config) #show ap mesh-radio-profile <name>
```

Command History

Release	Modification
ArubaOS 3.2	Command introduced.
ArubaOS 3.2.0.x, 3.3.1.x	The tx-power default increased from 14 to 30 dBm.
ArubaOS 3.3	The heartbeat-threshold default increased from 5 to 10 heartbeat messages.

Release	Modification
ArubaOS 3.3.2	The mesh-mcast-opt parameter was introduced.
ArubaOS 3.4	The mesh-ht-ssid-profile parameter was introduced The 11a-portal-channel , 11g-portal-channel , beacon-period and tx-power parameters were deprecated. These settings can now be configured via the rf dot11a-radio-profile and rf dot11g-radio-profile commands.
ArubaOS 6.1	The eapol-rate-opt parameter was introduced.

Description

This command defines a provisioning profile for an AP or group of APs.

Syntax

Parameter	Description	Default	Range
ap-poe-power-optimization	Enabling optimization minimizes the POE draw of the AP. Enabling optimization may disable some parts of the AP. Disabling ensures all features are enabled. • enabled: AP operates in normal mode. • disabled: USB and Ethernet port (eth1) are shut down on AP.	disabled	—
apdot1x-passwd	Password of the AP to authenticate to 802.1X using PEAP	—	—
apdot1x-username	Username of the AP to authenticate to 802.1X using PEAP	—	—
cellular_nw_preference g-only 4g-only advanced auto	The cellular network preference setting allows you to select how the modem should operate. • auto (default): In this mode, modem firmware will	auto	—

Parameter	Description	Default	Range
	control the cellular network service selection; so the cellular network service failover and fallback is not interrupted by the remote AP (RAP). 3g_only: Locks the modem to operate only in 3G. 4g_only: Locks the modem to operate only in 4G. advanced: The RAP controls the cellular network service selection based on an Received Signal Strength Indication (RSSI) threshold-based approach. Initially the modem is set to the default auto mode. This allows the modem firmware to select the available network. The RAP determines the RSSI value for the available network type (for example 4G), checks whether the RSSI is within required range, and if so, connects to that network. If the RSSI for the modem's selected network is not within the required range, the RAP will then check the RSSI limit of an alternate network (for example, 3G), and reconnect to that alternate network. The RAP will repeat the above steps each time it tries to connect using a 4G multimode modem in this mode. The RAP determines the RSSI value for the available network type (for example 4G), checks whether the RSSI is within required range, and if so, connects to that network.. If the RSSI for the modem's selected network is not within the required range, the RAP will then check the RSSI limit of an alternate network (for example, 3G), and reconnect to that alternate network. The RAP will repeat the above steps each time it tries to connect using a 4G multimode modem in this mode.		
<code>clone <source></code>	Clone an existing ap provisioning profile	—	—
<code>link-priority-cellular</code> <code><link-priority-cellular></code>	Set the priority of the cellular uplink. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link. Configuring the cellular link with a higher priority than your wired link priority will set your cellular link as the primary controller link.	0-255	0
<code>link-priority-ethernet</code> <code><link-priority-ethernet></code>	Set the priority of the wired uplink. Each uplink type has an associated priority; wired ports having the highest priority by default.	0-255	0
<code>master</code>	Change the FQDN or IP address for the master controller.	—	—
<code>set <masterstr></code>	Specify the or IP address or FQDN for the master controller.	—	—
<code>clear</code>	Clear the definition for the master controller in this profile.	—	—

Parameter	Description	Default	Range
no	Negates any configured parameter.	—	—
pppoe-passwd	Point-to-Point Protocol over Ethernet (PPPoE) password for the AP.	—	—
pppoe-service-name	PPPoE service name for the AP.	—	—
pppoe-user	PPPoE username for the AP.	—	—
remote-ap	Specifies that the profile is to be associated with a remote AP using certificates.	—	—
reprovision	Provisions one or more APs with the values in the provisioning profile.	—	—
reset-bootinfo	Restores factory default provisioning parameters to the specified AP. NOTE: This parameter can only be used on the master controller.	—	—
uplink-vlan <uplink-vlan>	If you configure an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink. By default, an AP has an uplink vlan of 0, which disables this feature. NOTE: If an AP is provisioned with an uplink VLAN, it must be connected to a trunk mode port or the AP's frames will be dropped.	0 (disabled) to 4095	0
usb-dev	The USB device identifier.	—	—
usb-dial	The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.	—	—
usb-init	The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct.	—	—
usb-modeswitch -v <default_vendor> -p <default_product> -V <target_vendor> -P <target_product> -M <message_content>	USB cellular devices on remote APs typically register as modems, but may occasionally register as a mass-storage device. If a remote AP cannot recognize its USB cellular modem, use the usb-modeswitch command to specify the parameters for the hardware model of the USB cellular data-card. NOTE: You must enclose the entire modeswitch parameter string in quotation marks.	—	—
usb-passwd	A PPP password, if provided by the cellular service provider	—	—
usb-power-mode auto	Set the USB power mode to control the power to the USB	—	—

Parameter	Description	Default	Range
enable disable	port.		
usb-tty	The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.	—	—
usb-tty-control	The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.	—	—
usb-type	Specify the USB driver type. • acm: Use ACM driver • airprime: Use Airprime driver • beceem-wimax: Use Beceem driver for 4G-WiMAX • ether: Use CDC Ether driver for direct IP 4G device • hso: Use HSO driver for newer Option • none: Disable 3G or 2G network on USB • option: Use Option driver • pantech-3g: Same as "pantech-uml290" - to support upgrade • pantech-uml290: Use Pantech USB driver for UML290 device • ptumlsbnet: Use Pantech USB driver for 4G device • rndis: Use a RNDIS driver for a 4G device • sierra-evdo: Use EVDO Sierra Wireless driver • sierra-gsm: Use GSM Sierra Wireless driver • sierrausbnet: Use SIERRA Direct IP driver for 4G device • storage: Use USB flash as storage device for storing RAP certificates	—	none
usb-user	The PPP username provided by the cellular service provider	—	—

Usage Guidelines

The AP provisioning profile allows you to define a set of provisioning parameters to an AP group. These settings can be saved or assigned to an AP group via the command **ap-group <group> provisioning-profile <profile>**.

In order to enable cellular uplink for a remote AP (RAP), the RAP must have the device driver for the USB data card and the correct configuration parameters. ArubaOS includes device drivers for the most common hardware types, but you can use the **usb** commands in this profile to configure a RAP to recognize and use an unknown USB modem type.

Release	Modification
ArubaOS 6.2.1.0	the cellular_nw_preference parameter was introduced for provisioning multi-mode modems, and the 4g-usb-type parameter was deprecated. Specify a 2/3G or 4G modem type using the usb-type parameter.
ArubaOS 6.3	The sierrausbnet and storage usb-type parameters were introduced.
ArubaOS 6.3.1	The rndis parameter was introduced.
ArubaOS 6.3.1.10	The ap-power-mode parameter was introduced.
ArubaOS 6.3.1.11	The ap-power-mode parameter was renamed to ap-poe-power-optimization .

```

```
show ap packet-capture status <ap-name|ip-addr|ip6-addr>
```

Description

These commands manage WiFi packet capture (PCAP) on Dell APs. The WiFi packets are encapsulated in a UDP header and sent to a client running a packet analyzer like Wildpacket's Airopeek, Omnippeek, or Wireshark.

Syntax

Parameter	Description
open-port	(CPSEC CAPs and RAPs only) Enable or allow access to this UDP port on the AP for packet capture purposes.
close-port	(CPSEC CAPs and RAPs only) Close or disallow access to this UDP port on the AP for packet capture purposes.
raw-start	Stream packets from the driver to a client running the packet analyzer.
<ipaddr>	IP address of the AP.
<target-ipaddr>	IP address of the client running the packet analyzer.
<target-port>	UDP port number on the client station where the captured packets are sent.
<format>	Specify a number to indicate one of the following formats for captured packets: • 0 : pcap • 1 : peek • 2 : airmagnet • 3 : pcap+radio header • 4 : ppi
channel	(Optional/Applicable only in Air Monitor mode) Number of a radio channel to tune into to capture packets.
maxlen	(Optional) Limit the length of 802.11 frames to include in the capture to a specified maximum.

Parameter	Description
<code>interactive</code>	Start an interactive packet capture session between an AP and a client running a packet analyzer.
<code><filter-spec></code>	Packet Capture filter specification. See Usage Guidelines for details.
<code>clear</code>	Clears the packet capture session.
<code>pause</code>	Pause a packet capture session.
<code>stop</code>	Stop a packet capture session.
<code>resume</code>	Resume a packet capture session.
<code><pcap-id></code>	ID of the PCAP session.

Usage Guidelines

These commands direct an AP to send WiFi packet captures to a client packet analyzer utility such as Airmagnet, Wireshark and so on, on a remote client.

Before using these commands, you need to start the packet analyzer utility on the client and open a capture window for the port from which you are capturing packets. The packet analyzer cannot be used to control the flow or type of packets sent from APs.

The packet analyzer processes all packets. However, you can apply display filters on the capture window to control the number and type of packets being displayed. In the capture window, the time stamp displayed corresponds to the time that the packet is received by the client and is not synchronized with the time on the AP.

Filter specification (used in `ap packet-capture interactive`) supports the following:

- type (beacon/rts/cts/data/ack/ctrl/mgmt/all)
- sta (mac address)
- bss (mac address)
- da (mac address)
- sa (mac address)
- dir (tods, fromds)
- retry (1, 0)
- frag (1, 0)
- wep (1, 0)

Filter spec examples:

```
(type eq beacon) or ((sta eq 000000010203) and (dir eq tods))
(type == data) && ((sta = 000000010203) || (sta == 000000010203))
(type != beacon)
(wep nq 1)
```

(type eq all)

Examples

The following command starts a raw packet capture session for the AP **ly115** on radio **0**, and sends the packets to the client at **10.64.102.4** on port **5000**.

```
(host) (config) #ap packet-capture raw-start ap-name ly115 10.64.102.4 5000 0 radio 0
Packet capture has started for pcap-id:1
```

The following commands start an interactive packet capture session for the AP **ap1**.

```
#ap packet-capture open-port 5555
```

```
#ap packet-capture interactive ap-name ap1 "type eq all" 192.168.0.3 5555 radio 0
```

The output of the command in the example below displays packet capture session statistics for the AP **ap1**. In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it will appear in a single, long table.

```
#show ap packet-capture status ap-name ap1
```

Packet Capture Sessions at ap1, IP 10.3.44.167

```
-----
pcap-id  filter      type      intf      channel  max-pkts
-----  -
1        type eq all  interactive 6c:f3:7f:ba:65:70 153      0
```

```
max-pkt-size  num-pkts  status      url target      Radio ID
-----
65536         3759     in-progress 192.168.0.3/5555 0
```

Related Commands

ap regulatory-domain-profile

```
ap regulatory-domain-profile <profile>
  clone <profile>
  country-code <code>
  no ...
  valid-11a-40mhz-channel-pair <valid-11a-40mhz-channel-pair>
  valid-11a-80mhz-channel-group <valid-11a-80mhz-channel-group>
  valid-11a-channel <num>
  valid-11g-40mhz-channel-pair <valid-11g-40mhz-channel-pair>
  valid-11g-channel <num>
```

Description

This command configures an AP regulatory domain profile.

Syntax

Parameter	Description	Default
<profile>	Name of this instance of the profile. The name must be 1-63 characters.	—
clone	Name of an existing regulatory domain profile from which parameter values are copied.	—
country-code	Code that represents the country in which the APs will operate. The country code determines the 802.11 wireless transmission spectrum. Improper country code assignment can disrupt wireless transmissions. Most countries impose penalties and sanctions for operators of wireless networks with devices set to improper country codes.	country code configured on the master controller during initial setup
no	Negates any configured parameter.	—
valid-11a-40mhz-channel-pair	Specify a channel pair valid for 40 MHz operation in the 802.11a frequency band for the specified regulatory domain. The two channels must be separated by a dash. Example: 36-40 44-48 52-56	country code determines supported channel pairs Note: Changing the country code causes the valid channel lists to be reset to the defaults for the country.
valid-11a-80mhz-channel-group	This parameter defines which 80MHz channels on the “a” band are available for assignment by ARM and for controller to randomly assign if the user has not specified a channel. The channel numbers	—

Parameter	Description	Default
	below correspond to channel center frequency.	
valid-11a-channel	Enter a single 802.11a channel number for 20 MHz operation within the specified regulatory domain.	country code determines supported channels Note: Changing the country code causes the valid channel lists to be reset to the defaults for the country.
valid-11g-40mhz-channel-pair	Specify a channel pair valid for 40 MHz operation in the 802.11g frequency band for the specified regulatory domain. The two channels must be separated by a dash. Example: 1-5 2-6 7-11	country code determines supported channel pairs Note: Changing the country code causes the valid channel lists to be reset to the defaults for the country.
valid-11g-channel	Enter a single 802.11g channel number for 20 MHz operation within the specified regulatory domain.	country code determines supported channels Note: Changing the country code causes the valid channel lists to be reset to the defaults for the country.

Usage Guidelines

This profile configures the country code and valid channels for operation of APs. The list of valid channels only affects the channels that may be selected by ARM or by the controller when no channel is configured. Channels that are specifically configured in the AP radio settings profile (see [rf dot11a-radio-profile](#) or [rf dot11g-radio-profile](#)) must be valid for the country and the AP model.

A controller shipped to certain countries, such as the U.S. and Israel, cannot terminate APs with regulatory domain profiles that specify different country codes from the controller. For example, if a controller is designated for the U.S., then only a regulatory domain profile with the "US" country code is valid; setting APs to a regulatory domain profile with a different country code will result in the radios not coming up. For controllers in other countries, you can mix regulatory domain profiles on the same controller; for example, one controller can support APs in Japan, Taiwan, China, and Singapore.

In order for an AP to boot correctly, the country code configured in the AP regulatory domain profile must match the country code of the LMS. If none of the channels supported by the AP have received regulatory approval by the country whose country code you selected, the AP will revert to Air Monitor mode.

Examples

The following command configures the regulatory domain profile for APs in Japan:

```
(host) (config) #ap regulatory-domain-profile rd1
country-code JP
```

The following command configures a regulatory domain profile for APs in the United States and specifies that the channel pair of 36 and 40, is allowed for 40 MHz mode of operation on the 5 GHz frequency band:

```
(host) (config) #ap regulatory-domain-profile usa1
country-code US
valid-11a-40mhz-channel-pair 36-40
```

The following command configures a regulatory domain profile for APs in the United States and specifies that the channel pair of 5 and 1, is allowed for 40 MHz mode of operation on the 2.4 GHz frequency band:

```
(host) (config) #ap regulatory-domain-profile usa1
country-code US
valid-11g-40mhz-channel-pair 1-5
```

Related Commands

To view the supported channels, use the **show ap allowed-channels** command.

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3	Support for the IEEE 802.11n standard, including channel pairs for 40 MHz mode of operation, was introduced.
ArubaOS 5.0	The valid-11a-40mhz-channel-pair and valid-11g-40mhz-channel-pair parameters no longer support the + and - parameters that allowed you to define a primary and backup channel within the channel pair.
ArubaOS 6.3	Support for the valid-11a-80mhz-channel-group parameter was introduced.

ap spectrum clear-webui-view-settings

ap spectrum clear-webui-view-settings

Description

Clear a saved spectrum dashboard view.

Syntax

no parameters

Usage Guidelines

Saved spectrum view preferences may not be backwards compatible with the spectrum analysis dashboard in earlier versions of ArubaOS. If you downgrade to an earlier version of ArubaOS and your client is unable to load a saved spectrum view in the spectrum dashboard, access the CLI in enable mode and issue this command to delete the saved spectrum views and display default view settings in the spectrum dashboard.

Command History

Introduced in ArubaOS 6.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	RF Protect license	Enable mode on master or local controllers

ap spectrum local-override

```
no
override ap-name <ap-name>
spectrum-band 2ghz|5ghz
```

Description

Convert an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.

Syntax

Parameter	Description	Range	Default
<code>override ap-name <ap-name></code>	name of an AP whose radio should be converted to a spectrum monitor radio	—	—
<code>spectrum band</code>	Spectrum band or portion of the band to be monitored by the spectrum monitor radio	2GHz (channels 1-14) 5GHz (channels 36-64, 100-140 and 149-165).	2Ghz

Usage Guidelines

There are two ways to change an AP that supports the spectrum monitor feature into a spectrum monitor. You can assign that AP to a 802.11 a and 802.11 g radio profile that is already set to spectrum mode, or you can temporarily change the AP into a spectrum monitor using a local spectrum override profile. When you use a local spectrum override profile to override an AP's mode setting, that AP will begin to operate as a spectrum monitor, but will remain associated with its previous 802.11 a and 802.11 g radio profiles. If you change any parameter (other than the overridden mode parameter) in the spectrum monitor's 802.11 a or 802.11 radio profiles, the spectrum monitor will immediately update with the change. When you remove the local spectrum override, the spectrum monitor will revert back to its previous mode, and remain assigned to the same 802.11 a and 802.11 radio profiles as before.

For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the Dell Networking W-Series ArubaOS 6.4.x User Guide.

Related Commands

Description

This command configures an AP system profile.

Syntax

Parameter	Description	Range	Default
<profile>	Name of this instance of the profile. The name must be 1-63 characters.	—	"default"
aeroscout-rtls-server	Enables the AP to send RFID tag information to an AeroScout real-time asset location (RTLS) server. RTLS station reporting includes information for APs and the clients that the AP has detected. If you include the include-unassoc-sta parameter, the station reports will also include information about clients not associated to any AP. By default, unassociated clients are not included in station reports.	—	—
am-scan-rf-band	Scanning band for multiple RF radios	a, g, all	all
a	Set the scanning band to 802.11a only	—	all
g	Set the scanning band to 802.11g only	—	all
all	Set the scanning band to apply to all bands	—	all
ap-arp-attack-protection	Drop ARP packets coming from wired or wireless clients with AP gateway IP address. In other words, disallow ARP attack from un-trusted ports.	—	enabled
mcast-aggr	Enable multicast aggregation at AP.	—	disabled
mcast-aggr-allowed-vlan <vlan-list>	Enable list of VLANs where AP multicast aggregation is allowed.	—	disabled

Parameter	Description	Range	Default
ap-usb-power-override	Enabling override enables the USB port of the AP with POE AT power. NOTE: This parameter is applicable for W-AP205H access point only.	—	disabled
ip-or-dns	IP address or the DNS of the AeroScout server to which location reports are sent.	—	—
port	Port number on the AeroScout server to which location reports are sent.	—	—
bkup-band a all g	Band on which the controller broadcasts the backup ESSID.	802.11a, all bands or 802.11g	all
bkup-lms-ip	In multi-controller networks, specifies the IP address of a <i>backup</i> to the IP address specified with the lms-ip parameter.	—	—
bkup-lms-ipv6	In multi-controller ipv6 networks, specifies the IPv6 address of a <i>backup</i> to the IPv6 address specified with the lms-ipv6 parameter.	—	—
bkup-mode dynamic off static	This parameter allows AP console access using a backup ESSID, allowing users to access an AP console after the AP has disconnected from the controller. When the AP advertises a backup ESSID in either static or dynamic mode, a user is able to access and debug the AP remotely through a virtual AP. Select dynamic or static to enable this feature and select the mode by which the controller broadcasts the backup ESSID. This feature is disabled by default.	dynamic off static	off
bkup-password <bkup-pass-word>	Allows client access to adjust the band and mode settings for the backup ESSID.	—	—
ble-token	The Bluetooth Low Energy (BLE) endpoint authorization token is a	—	—

Parameter	Description	Range	Default
	text string of 1-255 characters used by the BLE to authorize to and securely communicate with the Beacon Management Console. This token is unique for each deployment.		
ble-url	URL of the server to which the BLE sends monitoring data.	—	—
bootstrap-threshold	Number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots. On the controller, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.	1-65535	8
clone	Name of an existing AP system profile from which parameter values are copied.	—	—
dns-domain	Name of domain that is resolved by corporate DNS servers. Use this parameter when configuring split tunnel.	—	—
double-encrypt	This parameter applies only to remote APs. Use double encryption for traffic to and from a wireless client that is connected to a tunneled SSID. When enabled, all traffic is re-encrypted in the IPsec tunnel. When disabled, the wireless frame is only encapsulated inside the IPsec tunnel. All other types of data traffic between the controller and the AP (wired traffic and traffic from a split-tunneled SSID) are always encrypted in the IPsec tunnel.	—	disabled
dump-server	(For debugging purposes.) Specifies the server to receive a core dump generated when an AP process crashes.	—	—
gre-striping-ip	Specify an IPv4 address for the 802.11g radio of the controller to allow LACP enabled switches to	—	—

Parameter	Description	Range	Default
	send traffic for the two controller radios on different links. Recommended value for this parameter is <LMS-IP_addr>+1. NOTE: This parameter is deprecated in ArubaOS 6.4.2.0.		
heartbeat-dscp	Define the DSCP value of AP heartbeats. Use this feature to prioritize AP heartbeats and prevent the AP from losing connectivity with the controller over high-latency or low-bandwidth WAN connections.	0-63	0
heartbeat-in <secs>	Set the interval between heartbeat messages between a remote or campus AP and its associated controller. An increase in the heartbeat interval increases the time it will take for an AP to detect the loss in connectivity to the controller, but can reduce internet bandwidth consumed by a remote AP.	1-60 secs	1 sec
led-mode	The operating mode for the AP LEDs. This option is available on all 802.11n indoor AP platforms.		normal
normal	Display LEDs in normal mode.		
off	Turn off all LEDs.		
lms-hold-down-period	Time, in seconds, that the primary LMS must be available before an AP returns to that LMS after failover.	1-3600	600 seconds
lms-ip	In multi-controller networks, this parameter specifies the IP address of the local management switch (LMS)—the Dellcontroller—which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. This can be the IP address of the local or master controller.	—	—

Parameter	Description	Range	Default
	When using redundant controllers as the LMS, set this parameter to be the VRRP IP address to ensure that APs always have an active IP address with which to terminate sessions. NOTE: If the LMS-IP is blank, the access point will remain on the controller that it finds using methods like DNS or DHCP. If an IP address is configured for the LMS IP parameter, the AP will be immediately redirected to the controller at that address.		
lms-ipv6	In multi-controller ipv6 networks, specifies the IPv6 address of the local management switch (LMS)—the controller—which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. This can be the IP address of the local or master controller. When using redundant controllers as the LMS, set this parameter to be the VRRP IP address to ensure that APs always have an active IP address with which to terminate sessions.	—	—
lms-ping-interval	Specifies the interval at which application level ping needs to be sent to primary controller to check the reachability. Applicable only for RAP. NOTE: If this parameter is changed, UDP session timeout on an intermediate router which performs NATing should be set accordingly. The preferred timeout value is (lms-ping-interval + 30sec).	10-60 seconds	20 seconds
lms-preemption	Automatically reverts to the primary LMS IP address when it becomes available.	—	disabled
maintenance-mode	Enable or disable AP maintenance mode.		disabled

Parameter	Description	Range	Default
	This setting is useful when deploying, maintaining, or upgrading the network. If enabled, APs stop flooding unnecessary traps and syslog messages to network management systems or network operations centers when deploying, maintaining, or upgrading the network. The controller still generates debug syslog messages if debug logging is enabled.		
max-request-retries	Maximum number of times to retry AP-generated requests, including keepalive messages. After the maximum number of retries, the AP either tries the IP address specified by the bkup-lms-ip (if configured) or reboots.	1-65535	10
mtu	MTU, in bytes, on the wired link for the AP.	1024-1578	—
native-vlan-id	Native VLAN for bridge mode virtual APs (frames on the native VLAN are not tagged with 802.1q tags).	—	1
no	Negates any configured parameter.	—	—
number-ipsec-retries	The number of times the AP will attempt to recreate an IPsec tunnel with the master controller before the AP will reboot. A value of 0 disables the reboot.	1-1000	85
rap-bw-total	This is the total reserved uplink bandwidth (in Kilobits per second).	—	—
rap-bw-resv-1	Session ACLs with uplink bandwidth reservation in kilobits per second. You can specify up to three session ACLs to reserve uplink bandwidth. The sum of the three uplink bandwidths should not exceed the rap-bw-total value.	—	—
rap-bw-resv-2		—	—
rap-bw-resv-3		—	—

Parameter	Description	Range	Default
rap-dhcp-default-router	IP address for the default DHCP router.	—	192.168.11.1
rap-dhcp-dns-server	IP address of the DNS server.	—	192.168.11.1
rap-dhcp-lease	The amount of days that the assigned IP address is valid for the client. Specify the lease in <days>. 0 indicates the IP address is always valid; the lease does not expire.	0-30	0
rap-dhcp-pool-end	Configures a DHCP pool for remote APs. This is the last IP address of the DHCP pool.	—	192.168.11.254
rap-dhcp-pool-netmask	Configures a DHCP pool for remote APs. This is the netmask used for the DHCP pool.	—	255.255.255.0
rap-dhcp-pool-start	Configures a DHCP pool for remote APs. This is the first IP address of the DHCP pool.	—	192.168.11.2
rap-dhcp-server-id	IP address used as the DHCP server identifier.	—	192.168.11.1
rap-dhcp-server-vlan	VLAN ID of the remote AP DHCP server used if the controller is unavailable. This VLAN enables the DHCP server on the AP (also known as the remote AP DHCP server VLAN). If you enter the native VLAN ID, the DHCP server is unavailable.	—	—
rap-gre-mtu	Configures the maximum size of the GRE packets exchanged between a RAP and the controller.	1024-1578 bytes	1200 bytes
rap-local-network-access	Enable or disable local network access across VLANs in a Remote-AP.	—	disabled

Parameter	Description	Range	Default
request-retry-interval	Interval, in seconds, between the first and second retries of AP-generated requests. If the configured interval is less than 30 seconds, the interval for subsequent retries is increased up to 30 seconds.	1-65535	10 seconds
rf-band	For APs that support both a and b/g RF bands, RF band in which the AP should operate: - g = 2.4 GHz - a = 5 GHz	a/g	g
rtls-server	Enables the AP to send RFID tag information to an RTLS server.	—	—
ip-or-dns	IP address or the DNS of the RTLS server to which location reports are sent.	—	—
port	Port number on the server to which location reports are sent.	—	—
key	Shared secret key.	—	—
station-message-frequency	Indicates how often packets are sent to the server.	1-3600	30 seconds
include-unassoc-sta	RTLS station reporting includes information for APs and the clients that the AP has detected. If you include the <code>include-unassoc-sta</code> parameter, the station reports will also include information about clients not associated to any AP. By default, unassociated clients are not included in station reports.	—	disabled
session-acl	Session ACL configured with the <code>ip access-list session</code> command. NOTE: This parameter requires the PEFNG license.	—	—
shell-passwd	Sets a username and password for the AP console.	—	1500 bytes
spanning-tree	Enables the spanning-tree protocol.	—	disabled

Parameter	Description	Range	Default
syscontact	SNMP system contact information.	—	—
telnet	Enable or disable telnet to the AP.	—	disabled

Usage Guidelines

The AP system profile configures AP administrative operations, such as logging levels.

Example

For deployments running ArubaOS 6.3.1.x-6.4.1.x, execute the following commands to configure the LACP parameters (LMS IP and the GRE striping IP) on an AP system profile.

```
(host) (config) #ap system-profile LACP
(host) (AP system profile "LACP") #lms-ip 192.0.2.1
(host) (AP system profile "LACP") #gre-striping-ip 192.0.2.2
```

For deployments running ArubaOS 6.4.2.x and later, execute the following commands to configure LACP and AP LACP LMS map information settings.

```
(host) (config) #ap system-profile LACP
(host) (AP system profile "LACP") #lms-ip 192.0.2.1
(host) (AP system profile "LACP") #exit
(host) (config) #ap-lACP-striping-ip
(host) (AP LACP LMS map information) #striping-ip 192.0.2.2 lms 192.0.2.1
(host) (AP LACP LMS map information) #apLACP-enable
```

For more information on configuring LACP support, including important pre-deployment considerations and troubleshooting information, refer to the ArubaOS User Guide.

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.2	Support for additional RTLS servers and remote AP enhancements was introduced.
ArubaOS 3.3.2	• Maintenance-mode parameter was introduced. • Multiple remote AP DHCP server enhancements were introduced. • Support for RFprotect server and backup server configuration was introduced. • The mms-rtls-server parameter was deprecated in ArubaOS 3.3.2.
ArubaOS 5.0	The master-ip , rfprotect-server-ip and rfprotect-bkup-server parameters were deprecated.
ArubaOS 6.0	Added support for the option to set the RF scanning band (am-scan-rf-band).

Release	Modification
	The keepalive-interval parameter was deprecated.
ArubaOS 6.2	The default number of IPsec retries defined by number_ipsec_retries was reduced from 360 to 85.
ArubaOS 6.2.1.3	The root-ap parameter was deprecated. This parameter identifies the root AP in a hierarchy of Remote APs.
ArubaOS 6.3	- The aeroscout-rtls-server include-unassoc-sta parameter was introduced. - The spanning-tree and heartbeat-in parameters were introduced. - The rtls-serverip and aeroscout-rtls-server ip parameters were modified to rtls-server ip-or-dns and aeroscout-rtls-server ip-or-dns.
ArubaOS 6.3.1	The gre-striping-ip parameter was introduced.
ArubaOS 6.4.2.0	The gre-striping-ip parameter was deprecated. GRE striping IP settings are defined using the ap-lacp-striping-ip command. The system-message-frequency parameter now accepts a value in the range of 1-3600 seconds.
ArubaOS 6.4.3.0	The following new parameters were introduced: ap-arp-attack-protection mcast-aggr mcast-aggr-allowed-vlan ap-usb-power-override shell-passwd bkup-band bkup-mode bkup-password ble-token ble-url

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system, except for noted parameters	Config mode on master controllers

ap wipe out flash

```
ap wipe out flash
  ap-name <ap-name>
  ip-addr <ip-addr>
```

Description

Overwrite the entire AP compact flash, destroying its contents (including the current image file).

Syntax

Parameter	Description	Range	Default
ap-name	Wipe out the flash of the AP with the specified name.	—	—
ip-addr	Wipe out the flash of the AP with the specified IP address.	—	—

Usage Guidelines

Use this command only under the supervision of Dell technical support. If you delete the current image in the AP's flash memory, the AP will not function until you reload another image.

Command History

This command was introduced in ArubaOS 3.3.2.

Command Information

Platforms	Licensing	Command Mode
All platforms running ArubaOS 3.3.2.x-FIPS or later.	Base operating system	Config mode on master controllers

ap wired-ap-profile

```
ap wired-ap-profile <profile>
  broadcast
  clone <profile>
  forward-mode {bridge|split-tunnel|tunnel}
  no ...
  switchport access vlan <vlan> | {mode access|trunk} |trunk {allowed vlan <list>|
  add <list> | except <list> | remove <list>}| native vlan <vlan>
  trusted
  wired-ap-enable
```

Description

This command configures a wired AP profile.

Syntax

Parameter	Description
<profile>	Name of this instance of the profile. The name must be 1-63 characters.
broadcast	Forward broadcast traffic to this tunnel.
clone	Name of an existing wired AP profile from which parameter values are copied.
forward-mode	This parameter controls whether data is tunneled to the controller using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the controller, and Internet access remains local). All forwarding modes support band steering, TSPEC/TCLAS enforcement, 802.11k and station blacklisting.
tunnel	In this default forwarding mode, the AP handles all 802.11 association requests and responses, but sends all 802.11 data packets, action frames and EAPOL frames over a GRE tunnel to the controller for processing. The controller removes or adds the GRE headers, decrypts or encrypts 802.11 frames and applies firewall rules to the user traffic as usual.
bridge	802.11 frames are bridged into the local Ethernet LAN. When a remote AP or campus AP is in bridge mode, the AP handles all 802.11 association requests and responses, encryption/decryption processes, and firewall enforcement. The 802.11e and 802.11k action frames are also processed by the AP, which then sends out responses as needed. An AP in bridge mode supports only the 802.1X authentication type. NOTE: Virtual APs in bridge mode using static WEP should use key slots 2-4 on the controller. Key slot 1 should only be used with Virtual APs in tunnel mode.
split-tunnel	802.11 frames are either tunneled or bridged, depending on the destination (corporate traffic goes to the controller, and Internet access remains local). An AP in split-tunnel mode supports only the 802.1X authentication type. An AP in split-tunnel forwarding mode handles all 802.11 association requests and responses, encryption/decryption, and firewall enforcement. The 802.11e and 802.11k action frames are also processed by the AP, which then sends out responses as needed.

Parameter	Description
	NOTE: Virtual APs in split-tunnel mode using static WEP should use key slots 2-4 on the controller. Key slot 1 should only be used with Virtual APs in tunnel mode.
no	Negates any configured parameter.
switchport	Configures the switching mode characteristics for the port.
access	The VLAN to which the port belongs. The default is VLAN 1.
mode	The mode for the port, either access or trunk mode. The default is access mode.
trunk allowed	Allows multiple VLANs on the port interface. You must define this parameter using VLAN IDs or VLAN names VLAN IDs and VLAN names cannot be listed together.
trunk native	The native VLAN for the port (frames on the native VLAN are not tagged with 802.1q tags).
trusted	Sets port as either trusted or untrusted. The default setting is untrusted.
wired-ap-enable	Enables the wired AP. The wired AP is disabled by default.

Usage Guidelines

This command is only applicable to Dell APs that support a second Ethernet port. The wired AP profile configures the second Ethernet port (enet1) on the AP.

For mesh deployments, this command is applicable to all Dell APs configured as mesh nodes. If you are using mesh to join multiple Ethernet LANs, configure and enable bridging on the mesh point Ethernet port.

Mesh nodes only support bridge mode and tunnel mode on their wired ports (enet0 or enet1). Split tunnel mode is not supported.

Use the bridge mode to configure bridging on the mesh point Ethernet port. Use tunnel mode to configure secure jack operation on the mesh node Ethernet port.

When configuring the Ethernet ports on APs with multiple Ethernet ports, note the following requirements:

- If configured as a mesh portal, connect enet0 to the controller to obtain an IP address. The wired AP profile controls enet1. Only enet1 supports secure jack operation.
- If configured as a mesh point, the same wired AP profile will control both enet0 and enet1.

Example

The following command configures the enet1 port on a multi-port AP as a trunk port:

```
(host) (config) #ap wired-ap-profile wiredap1
switchport mode trunk
switchport trunk allowed 4,5
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.2	The split-tunnel forwarding mode was introduced.
ArubaOS 6.0	Wired ports on campus APs support bridge forwarding mode.

Platforms	Licensing	Command Mode
All platforms	Base operating system, except for noted parameters	Config mode on master controllers

ap wired-port-profile

```
ap wired-port-profile <profile>
  aaa-profile <profile>
  authentication-timeout <seconds>
  clone
  enet-link-profile <profile>
  lldp-profile <profile>
  no
  rap-backup
  shutdown
  spanning-tree
  wired-ap-profile <profile>
```

Description

This command configures a wired port profile.

Syntax

Parameter	Description
aaa-profile <profile>	Name of a AAA profile to be used by devices connecting to the AP's wired port.
authentication-timeout	Authentication timeout value, in seconds, for devices connecting the AP's wired port. The supported range is 1-65535 seconds, and the default value is 20 seconds.
clone <profile>	Create a new AP wired port profile based upon the values of an existing profile.
enet-link-profile <profile>	Specify an Ethernet link profile to be used by devices associated with this wired port profile. The Ethernet link profile defines the duplex value and speed to be used by the port.
lldp-profile <profile>	Specify an LLDP profile to be used by devices associated with this wired port profile. The LLDP profile specifies the type-length-value (TLV) elements to be sent in LLDP PDUs.
no	Negates any defined parameter
rap-backup	Use the rap-backup parameter to use the wired port on a Remote AP for local connectivity and troubleshooting when the AP cannot reach the controller. If the AP is not connected to the controller, no firewall policies will be applied when this option is enabled. (The AAA profile will be applied when the AP is connected to controller).
shutdown	Disable the wired AP port.
spanning-tree	Enables the spanning-tree protocol.
wired-ap-profile <profile>	Name of a wired AP profile to be used by devices connecting the AP's wired port. The wired AP profile defines the forwarding mode and switchport values used by the port.

Usage Guidelines

This command is only applicable to APs with Ethernet ports. Issue this command to enable or disable the wired port, define an AAA profile for wired port devices, and associate the port with an ethernet link profile that defines its speed and duplex values.

Example

The following command defines a AAA profile for wired port devices:

```
(host) (config) #ap wired-port-profile wiredport1
aaa-profile default-open
authentication-timeout 30
wired-ap-profile wiredapl
```

Command History

Release	Modification
ArubaOS 6.0	Command introduced
ArubaOS 6.3	The spanning-tree parameter was added.

apboot

```
apboot {all [global|local]|ap-group <group> [global|local]|ap-name <name>|ip-addr  
<ipaddr>|wired-mac <macaddr>}
```

Description

This command reboots the specified APs.

Syntax

Parameter	Description	Default
all	Reboot all APs.	all
global	Reboot APs on all controllers.	global
local	Reboot only APs registered on this controller. This is the default.	local
ap-group	Reboot APs in a specified group.	ap-group
global	Reboot APs on all controllers.	global
local	Reboot only APs registered on this controller. This is the default.	local
ap-name	Reboot the AP with the specified name.	ap-name
ip-addr	Reboot the AP at the specified IP address.	ip-addr
wired-mac	Reboot the AP at the specified MAC address.	wired-mac

Usage Guidelines

You should not normally need to use this command as APs automatically reboot when you reprovision them. Use this command only when directed to do so by your Dell representative.

Example

The following command reboots a specific AP:

```
(host)(config)# apboot ap-name Building3-Lobby
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable and Config mode on master controllers

apconnect

apconnect {ap-name <name>|bssid <bssid>|ip-addr <ipaddr>} parent-bssid <bssid>

Description

This command instructs a mesh point to disconnect from its current parent and connect to a new parent.

Syntax

Parameter	Description
ap-name <name>	Specify the name of the mesh point to be connected to a new parent.
bssid <bssid>	Specific the BSSID of the mesh point to be connected to a new parent.
ip-addr <ipaddr>	Specific the IP address of the mesh point to be connected to a new parent.
parent-bssid <bssid>	BSSID of the parent to which the mesh point should connect.

Usage Guidelines

To maintain a mesh topology created using the **apconnect** command, Dell suggests setting the mesh reselection-mode to **reselect-never**, otherwise the normal mesh reselection mechanisms could break up the selected topology.

Example

The following command connects the mesh point “meshpoint1” to a new parent with the specified BSSID.

```
(host) (config) #apconnect ap-name meshpoint1 parent-bssid 00:12:6d:03:1c:f1
```

Related Commands

Command	Description	Mode

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable and Config mode on master controllers

apdisconnect

apdisconnect {ap-name <name>|bssid <bssid>|ip-addr <ipaddr>}

Description

This command disconnects a mesh point from its parent.

Syntax

Parameter	Description
ap-name	Specifies the name of the parent AP.
bssid	Specifies the BSSID of the parent AP.
ip-addr	Specifies the IP address of the parent AP.

Usage Guidelines

Each mesh point learns about the mesh portal from its parent (a mesh node that is part of the path to the mesh portal). This command directs a mesh point to disassociate from its parent. The mesh point will attempt to associate with another neighboring mesh node, if available. The old parent is not eligible for re-association for 60 seconds after disconnection.

Example

The following command disconnects a specific mesh point from its parent:

```
(host) (config) #apdisconnect ap-name meshpoint1
```

Related Commands

Command	Description	Mode
apconnect	This command connects a mesh point to a new specified parent.	Enable or Config mode

  regulatory-domain-profile <profile>
  rf-optimization-profile <profile>
  virtual-ap <profile>
  voip-cac-profile <profile>
```

Description

This command configures an AP group.

Syntax

Parameter	Description	Range	Default
<group>	Name that identifies the AP group. The name must be 1-63 characters. NOTE: You cannot use quotes (") in the AP group name.	—	"default"
ap-system-profile	Configures AP administrative operations, such as logging levels. See ap system-profile on page 226 .	—	"default"
authorization-profile	Restrictive group for unauthorized AP.	—	—
clone	Name of an existing AP group from which profile names are copied.	—	—
dot11a-radio-profile	Configures 802.11a radio settings and load balancing for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 752 .	—	"default"

Parameter	Description	Range	Default
dot11a-traffic-mgmt-profile	Configures bandwidth allocation. See wlan traffic-management-profile on page 2334 .	—	—
dot11g-radio-profile	Configures 802.11g radio settings and load balancing for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 752 .	—	“default”
dot11g-traffic-mgmt-profile	Configures bandwidth allocation. See wlan traffic-management-profile on page 2334 .	—	—
enet0-port-profile	Configures the duplex and speed of the Ethernet interface 0 on the AP. For information on how these profiles are defined, see ap wired-port-profile on page 241 .	—	“default”
enet1-port-profile	Configures the duplex and speed of the Ethernet interface 1 on the AP. For information on how these profiles are defined, see ap wired-port-profile on page 241 .	—	“default”
enet2-port-profile	Configures the duplex and speed of an Ethernet interface 2 on the AP. These profiles are defined using the command ap wired-port-profile on page 241 .	—	“default”
enet3-port-profile	Configures the duplex and speed of an Ethernet interface 3 on the AP. These profiles are defined using the command ap wired-port-profile on page 241 .	—	“default”
enet4-port-profile	Configures the duplex and speed of an Ethernet 4 interface on the AP. For information on how these profiles are defined, see ap wired-port-profile on page 241 .	—	“default”
event-thresholds-profile	Configures Received Signal Strength Indication (RSSI) metrics. See rf event-thresholds-profile on page 776 .	—	“default”
ids-profile	Configures Dell's Intrusion Detection System (IDS). See ids profile on page 439 .	—	“default”

Parameter	Description	Range	Default
mesh-cluster-profile	Configures the mesh cluster profile for mesh nodes that are members of the AP group. There is a "default" mesh cluster profile; however, it is not applied until you provision the mesh node. See ap mesh-cluster-profile on page 191 .	—	"default"
priority	Configures the priority of the mesh cluster profile. If more than two mesh cluster profiles are configured, mesh points use this number to identify primary and backup profile(s). The lower the number, the higher the priority.	1-16	1
mesh-radio-profile	Configures the 802.11g and 802.11a radio settings for mesh nodes that are members of the AP group. See ap mesh-ht-ssid-profile on page 193 . Commands to configure mesh for outdoor APs require the Outdoor Mesh license.	—	"default"
no	Negates any configured parameter.	—	—
regulatory-domain-profile	Configures the country code and valid channels. See ap regulatory-domain-profile on page 217 .	—	"default"
rf-optimization-profile	Configure coverage hole and interference detection. See rf optimization-profile on page 782 .	—	"default"
virtual-ap	One or more profiles, each of which configures a specified WLAN. See wlan virtual-ap on page 2341 .	—	"default"
voip-cac-profile	Configures voice over IP (VoIP) call admission control (CAC) options. See wlan voip-cac-profile on page 2354 . This parameter requires the PEFNG license.	—	"default"

Usage Guidelines

AP groups are at the top of the configuration hierarchy. An AP group collects virtual AP definitions and configuration profiles, which are applied to APs in the group.

Example

The following command configures a virtual AP profile to the "default" AP group:

```
(host) (config) #ap-group default
                virtual-ap corpnet
```

Related Commands

View AP group settings using the command [show ap-group](#).

Command History:

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.2	Support for the mesh parameters was introduced
ArubaOS 3.4.1	The voip-cac-profile parameter required the PEF license.
ArubaOS 5.0	The voip-cac-profile parameter requires the PEFV license.
ArubaOS 6.0	The enet-port-profile parameters parameters were introduced.

ap-leds

ap-leds

```
{all | ap-group <ap-group> | ap-name <ap-name> | ip-addr <ip address> | wired-mac <mac address>} {global blink|normal}|{local blink|normal}
```

Description

This command allows you to set the behavior of an AP's LEDs.

Syntax

Parameter	Description
all	Controls the LED behavior for all APs
ap-group <ap-group>	Controls the LED behavior for APs in the specified group
ap-name <ap-name>	Controls the LED behavior for the AP with the specified name
ip-addr <ip-addr>	Controls the LED behavior for the AP with the specified IP address
wired-mac <mac-addr>	Controls the LED behavior for the AP with the specified MAC address
global	Selects all APs on all controllers
local	Selects all APs registered on this controller
blink	Causes the LEDs to blink for identification
normal	Restores the LEDs to their normal behavior

Usage Guidelines

Use the **ap-leds** command to make the LEDs on a defined set of APs either blink or display in the currently configured LED operating mode. Note that if the LED operating mode defined in the AP's system profile is set to "off", then the **normal** parameter in the **ap-leds** command will disable the LEDs. If the LED operating mode in the AP system profile is set to "normal" then the **normal** parameter in this command will allow the LEDs light as usual.

Example

The following command causes all local APs to blink their LEDs for identification purposes:

```
ap-leds all local blink
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced

Command Information

Platforms	Licensing	Command Mode
Available on all platforms	Base operating system	Config mode on master or local controllers

ap-move

```
ap-move
  all
  ap-group <ap-group>
  ap-name <ap-name>
```

Description

When HA is enabled, use this command to move an AP or group of APs to their standby controller.

Syntax

Parameter	Description
all	Move all APs.
ap-group <ap-group>	Move all APs belonging to the specified AP group.
ap-name <ap-name>	Move the specified AP.

Usage Guidelines

When HA is enabled on a pair of controllers, this command should be used when it is necessary to move a single AP, all APs in an ap-group, or all APs to switchover to their standby controller without an actual failure of the active controller. For example, this allows the network admin to manually move one or more APs to their standby controller and perform a planned upgrade or maintenance on the active controller.

Command History

Introduced in ArubaOS 6.3.

Command Information

Platforms	Licensing	Command Mode
Available on all platforms.	Base operating system	Enable mode on master or local controllers

  no ...
  regulatory-domain-profile <profile>
  rf-optimization-profile <profile>
  snmp-profile <profile>
  virtual-ap <profile>
  voip-cac-profile <profile>
```

Description

This command configures a specific AP.

Syntax

Parameter	Description	Default
<name>	Name that identifies the AP. By default, an AP's name can either be the AP's Ethernet MAC address, or if the AP has been previously provisioned with an earlier version of ArubaOS, a name in the format <building>.<floor>.<location>. The name must be 1-63 characters. NOTE: You cannot use quotes (") in the AP name.	—
ap-system-profile	Configures AP administrative operations, such as logging levels. See ap system-profile on page 226 .	"default"
authorization-profile	Restrictive group for unauthorized AP.	—
clone	Name of an existing AP name from which profile names are copied.	—
dot11a-radio-profile	Configures 802.11a radio settings for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 752 .	"default"

Parameter	Description	Default
dot11a-traffic-mgmt-profile	Configures bandwidth allocation. See wlan traffic-management-profile on page 2334 .	—
dot11g-radio-profile	Configures 802.11g radio settings for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 752 .	“default”
dot11g-traffic-mgmt-profile	Configures bandwidth allocation. See wlan traffic-management-profile on page 2334 .	—
enet0-profile	Configures the duplex and speed of the Ethernet 0 interface on the AP. See ap enet-link-profile on page 178 .	“default”
enet1-profile	Configures the duplex and speed of the Ethernet 1 interface on the AP. See ap enet-link-profile on page 178 .	“default”
event-thresholds-profile	Configures Received Signal Strength Indication (RSSI) metrics. See rf event-thresholds-profile on page 776 .	“default”
exclude-mesh-cluster-profile-ap	Excludes the specified mesh cluster profile from this AP. The Secure Enterprise Mesh license must be installed.	—
exclude-virtual-ap	Excludes the specified virtual AP profiles from this AP.	
ids-profile	Configures Dell's Intrusion Detection System (IDS). See ids profile on page 439 .	“default”
mesh-cluster-profile	Configures the mesh cluster profile for the AP (mesh node). There is a “default” mesh cluster profile; however, it is not applied until you provision the mesh node. See ap mesh-cluster-profile on page 191 . The Secure Enterprise Mesh license must be installed.	“default”
priority	Configures the priority of the mesh cluster profile. If more than two mesh cluster profiles are configured, mesh points use this number to identify primary and backup profile(s). The supported range of values is 1-16. The lower the number, the higher the priority.	1
mesh-radio-profile	Configures the 802.11g and 802.11a radio settings for the AP (mesh node). See ap mesh-ht-ssid-profile on page 193 .	“default”

Parameter	Description	Default
	The Secure Enterprise Mesh license must be installed.	
no	Negates any configured parameter.	—
regulatory-domain-profile	Configures the country code and valid channels. See ap regulatory-domain-profile on page 217 .	“default”
rf-optimization-profile	Configures load balancing and coverage hole and interference detection. See rf optimization-profile on page 782 .	“default”
snmp-profile	Configures SNMP-related parameters. See ap snmp-profile (deprecated) on page 221 .	“default”
virtual-ap	One or more profiles, each of which configures a specified WLAN. See wlan virtual-ap on page 2341 .	“default”
voip-cac-profile	Configures voice over IP (VoIP) call admission control (CAC) options. See wlan voip-cac-profile on page 2354 . This parameter requires the PEFNG license.	“default”

Usage Guidelines

Profiles that are applied to an AP group can be overridden on a per-AP name basis, and virtual APs can be added or excluded on a per-AP name basis. If a particular profile is overridden for an AP, all parameters from the overriding profile are used. There is no merging of individual parameters between the AP and the AP group to which the AP belongs.

Example

The following command excludes a virtual AP profile from a specific AP:

```
(host) (config) #ap-name 00:0b:86:c0:cf:d8
    exclude-virtual-ap corpnet
```

Related Commands

View AP settings using the command [show ap-name](#).

Command History:

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.2	Support for mesh parameters was introduced.
ArubaOS 3.4	License requirements changed in ArubaOS 3.4.1, so the voip-cac-profile parameter required the PEF license instead of the Voice Services Module license required in earlier versions.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

ap-regroup

```
ap-regroup {ap-name <name>|serial-num <num>|service-tag <service-tag>|wired-mac <macaddr>}<group>
```

Description

This command moves a specified AP into a group.

Syntax

Parameter	Description	Default
ap-name	Name of the AP.	—
serial-num	Serial number of the AP.	—
service-tag	Service tag of the AP.	—
wired-mac	MAC address of the AP.	—
<group>	Name that identifies the AP group. The name must be 1-63 characters.	“default”

Usage Guidelines

All APs discovered by the controller are assigned to the “default” AP group. An AP can belong to only one AP group at a time. You can move an AP to an AP group that you created with the **ap-group** command.

This command automatically reboots the AP.

Example

The following command moves an AP to the ‘corpnet’ group:

```
(host)(config) #ap-regroup wired-mac 00:0f:1e:11:00:00 corpnet
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.4.2.0	The service-tag parameter was introduced.

Command Information

Platforms	Licensing	Command Mode

ap-rename

```
ap-rename {ap-name <name>|serial-num <num>|service-tag <service-tag>|wired-mac <macaddr>}  
<new-name>
```

Description

This command changes the name of an AP to the specified new name.

Syntax

Parameter	Description
ap-name	Current name of the AP.
serial-num	Serial number of the AP.
service-tag	Service tag of the AP.
wired-mac	MAC address of the AP.
<new-name>	New name for the AP. The name must be 1-63 characters. NOTE: You cannot use quotes (") in the AP name.

Usage Guidelines

An AP name must be unique within your network.

This command automatically reboots the AP.

Example

The following command renames an AP:

```
(host) (config) #ap-rename wired-mac 00:0f:1e:11:00:00 building3-lobby
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.4.2.0	The service-tag parameter was introduced.

Command Information

app lync traffic-control

```
app lync traffic-control <profile-name>
  clone <source>
  no ...
  prioritize-desktop-sharing
  prioritize-file-transfer
  prioritize-video
  prioritize-voice
```

Description

This command creates a traffic control profile that allows the controller to recognize and prioritize a specific type of Lync traffic in order to apply QoS through the Lync Application Layer Gateway (ALG).

Syntax

Parameter	Description
clone	Copy configuration from another traffic control prioritization profile.
no ...	Include this parameter to disable Lync ALG for the specified traffic type.
prioritize-desktop-sharing	Issue this command to enable or disable prioritization of desktop-sharing traffic by Lync ALG.
prioritize-file-transfer	Issue this command to enable or disable prioritization of file-transfer traffic by Lync ALG.
prioritize-video	Issue this command to enable or disable prioritization of video traffic by Lync ALG.
prioritize-voice	Issue this command to enable or disable prioritization of voice traffic by Lync ALG.

Example

All Lync traffic types are recognized and prioritized by default. The following commands disables Lync ALG prioritization for desktop sharing traffic.

```
(host) (config) #app lync traffic-control default
(host) (Traffic Control Prioritization Profile "default") #no prioritize-desktop-sharing
```

Related Commands

Command History

Command	Description
<u>show ucc configuration traffic-control lync <profile-name></u>	Displays the Lync traffic control profile configuration in the controller.

Version	Description
ArubaOS 6.4	Command introduced. NOTE: This command replaces app lync traffic-control (deprecated) .

Command Information

Platforms	Licensing	Command Mode
All platforms	This command requires the PEFNG license	Config mode on master or local controllers

app lync traffic-control (deprecated)

```
app lync traffic-control
no ...
prioritize desktop-sharing
prioritize file-transfer
prioritize video
prioritize voice
```

Description

This command allows the controller to recognize and prioritize a specific type of Lync traffic in order to apply QoS through the Lync Application Layer Gateway (ALG).

Command History

Version	Description
ArubaOS 6.3	Command introduced.
ArubaOS 6.4	Command deprecated. NOTE: This command is replaced by app lync traffic-control <profile-name> .

arm move-sta

arm move-sta <client-mac> <newbssid>

Description

This command moves a client station to another BSSID.

Syntax

Parameter	Description
<mac>	MAC address of the client to be moved to another BSSID
<newbssid>	BSSID of the AP to which the client should associate.

Usage Guidelines

Issue this command to manually move a client to a different BSSID

Example

The following command moves a client with the MAC address **00:0B:86:01:7A:C0** to the BSSID **00:1C:B3:09:85:15**.

```
(host) (config) #arm move-sta 00:0B:86:01:7A:C0 00:1C:B3:09:85:15
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable or Config mode on master or local controllers

arp

arp <ipaddr> <macaddr>

Description

This command adds a static Address Resolution Protocol (ARP) entry.

Syntax

Parameter	Description
<ipaddr>	IP address of the device to be added.
<macaddr>	Hardware address of the device to be added, in the format xx:xx:xx:xx:xx:xx.

Usage Guidelines

If the IP address does not belong to a valid IP subnetwork, the ARP entry is not added. If the IP interface that defines the subnetwork for the static ARP entry is deleted, you will be unable to use the arp command to overwrite the entry's current values; use the no arp command to negate the entry and then enter a new arp command.

Example

The following command configures an ARP entry:

```
(host) (config) #arp 10.152.23.237 00:0B:86:01:7A:C0
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

audit-trail

audit-trail [all]

Description

This command enables an audit trail.

Syntax

Parameter	Description
all	Enables audit trail for all commands, including enable mode commands. The audit-trail command without this option enables audit trail for all commands in configuration mode.

Usage Guidelines

By default, audit trail is enabled for all commands in configuration mode. Use the **show audit-trail** command to display the content of the audit trail.

Example

The following command enables an audit trail:

```
(host) (config) #audit-trail
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

backup

backup {flash|pcmcia}

Description

This command backs up compressed critical files in flash.

Syntax

Parameter	Description
flash	Backs up flash directories to flashbackup.tar.gz file.
pcmcia	Backs up flash images to external PCMCIA flash card. This option can only be executed on controllers that have a PCMCIA slot.

Usage Guidelines

Use the **restore flash** command to untar and uncompress the flashbackup.tar.gz file.

Example

The following command backs up flash directories to the flashbackup.tar.gz file:

```
(host) (config) #backup flash
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable and Config modes on master controllers

banner motd

banner motd <delimiter> <textString>

Description

This command defines a text banner to be displayed at the login prompt when a user accesses the controller.

Syntax

Parameter	Description	Range
<delimiter>	Indicates the beginning and end of the banner text.	—
<textString>	The text you want displayed.	up to 1023 characters

Usage Guidelines

The banner you define is displayed at the login prompt to the controller. The banner is specific to the controller on which you configure it. The WebUI displays the configured banner at its login prompt, but you cannot use the WebUI to configure the banner.

The delimiter is a single character that indicates the beginning and the end of the text string in the banner. Select a delimiter that is not used in the text string you define, because the controller ends the banner when it sees the delimiter character repeated.

There are two ways of configuring the banner message:

- Enter a space between the delimiter and the beginning of the text string. The text can include any character except a quotation mark ("). Use quotation marks to enclose your text if you are including spaces (spaces are not recognized unless your text string is enclosed in quotation marks; without quotation marks, the text is truncated at the first space). You can also use the delimiter character within quotation marks.
- Press the **Enter** key after the delimiter to be placed into a mode where you can simply enter the banner text in lines of up to 255 characters, including spaces. Quotation marks are ignored.

Example

The following example configures a banner by enclosing the text within quotation marks:

```
(host)(config) #banner motd * "Welcome to my controller. This controller is in the production network, so please do not save configuration changes. Zach Jennings is awesome. Maintenance will be performed at 7:30 PM, so please log off before 7:00 PM."*
```

The following example configures a banner by pressing the **Enter** key after the delimiter:

```
(host)(config) #banner motd *
Enter TEXT message [maximum of 1023 characters].
Each line in the banner message should not exceed 255 characters.
End with the character '*'.
Welcome to my controller. This controller is in the production network, so please do not save configuration changes. Zach Jennings is awesome. Maintenance will be performed at 7:30 PM, so please log off before 7:00 PM.*
```

The banner display is as follows:

Welcome to my controller. This controller is in the production network, so please do not save configuration changes. Zach Jennings is awesome. Maintenance will be performed at 7:30 PM, so please log off before 7:00 PM.

Command History

This command was introduced in ArubaOS 1.0

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

boot

boot

```
cf-test [fast | read-only | read-write]
config-file <filename>
remote-node [all|ip-address <A.B.C.D>]
system partition [0 | 1]
verbose
```

Description

Configure the boot options for the controller.

Syntax

Parameter	Description
cf-test	Sets the type of compact flash test to run when booting the controller.
fast	Performs a fast test, which does not include media testing.
read-only	Performs a read-only media test.
read-write	Performs a read-write media test.
config-file	Sets the configuration file to use when booting the controller.
<filename>	Specifies the name of the configuration file from which to boot the controller.
remote-node	Reloads a branch controller.
all	Reloads all branch controllers on the network.
ip address <A.B.C.D>	Reloads the branch controller with the specified IP address.
system 0 1	Enter the keyword system followed by the partition number (0 or 1) that you want the controller to use during the next boot (login) of the controller. NOTE: A controller reload is required before the new boot partition takes effect.
verbose	Prints extra debugging information at boot.

Usage Guidelines

Use the following options to control the boot behavior of the controller:

- **cf-test**—Test the flash during boot.
- **config-file**—Set the configuration file to use during boot.
- **system**—Specify the system partition to use during the controller's next boot (login).
- **verbose**—Print extra debugging information during boot. The information is sent to the screen at boot time. Printing the extra debugging information is disabled using the `no boot verbose` command.

Example

The following command uses the configuration file `january-config.cfg` the next time the controller boots:

```
boot config-file january-config.cfg
```

The following command uses system partition 1 the next time the controller boots:

```
boot system partition 1
```

Command History

	Modification
ArubaOS 1.0	Introduced for the first time.
ArubaOS 6.0	The remote-node parameter was introduced.
ArubaOS 6.2	The remote-node parameter was deprecated.

Command Information

Platforms	Licensing	Command Mode

cellular profile

```
cellular profile <profile_name>
  dialer <group>
  driver acm|hso|option|sierra|ptumlusbnnet
  import <address>
  modeswitch {eject <params>}|rezero
  no
  priority <1-255>
  serial <sernum>
  tty <ttyport>
  user <login> password <password>
  vendor <vend_id> product <prod_id>
```

Description

Create new profiles to support new USB modems or to customize USB characteristics.

Syntax

Parameter	Description
cellular profile <profile_name>	Enter the keywords cellular profile followed by your profile name. This command changes the configuration mode and the command line prompt changes to: host (config-cellular <profile_name>)#
dialer <group>	Enter the keyword dialer followed by a group name to specify the dialing parameters for the carrier. The parameters tend to be common between service providers on the same type of network (CDMA vs. GSM) as displayed in the show dialer group command.
driver acm hso option sierra ptumlusbnnet	Enter the keyword driver followed by one of the driver options: • acm: Linux ACM driver. • hso: Option High Speed driver. • option: Option USB data card driver (default). • sierra: Sierra Wireless driver. • ptumlusbnnet: Pantech UML290 driver.
import <address>	Enter the keyword import followed by the USB device address as displayed in the show usb command. Import retrieves the vendor/product serial numbers from the USB device list and populates them into the profile.
modeswitch {eject <params>} rezero	Enter the keyword modeswitch followed by either: • eject followed by the CDROM device. • rezero: Send SCSI CDROM rezero command.

Parameter	Description
	Certain cellular devices must be modeswitched before the modem switches to data mode.
no	Enter the keyword no to negate the command and revert back to the defaults.
priority <1-255>	Enter the keyword priority to override the default cellular priority (100). Range: 1 to 255. Default: 100
serial <sernum>	Enter the keyword serial followed by the USB device serial number
tty <ttyport>	Enter the keyword tty followed by the Modem TTY port (i.e. ttyUSB0, ttyACM0)
user <login> password <password>	Enter the keyword user followed by your login, and then enter the keyword password followed by your password to establish user name authentication.
vendor <vend_id> product <prod_id> in hex	Enter the keyword vendor followed by the vendor ID in hexadecimal (see show usb on page 1955) and then enter the keyword product followed by the product ID listed in the show usb command.

Usage Guidelines

The cellular modems are plug-and-play and support most native USB modems. Cellular modems are activated only if it is the uplink with the highest priority (see [show uplink on page 1954](#)). However, new profiles can be created using this command to support new data cards or to customize card characteristics.

Command History

Introduced in ArubaOS 3.4.

Command Information

W-600 Series controllers	Base operating system	Config mode on master and local controllers

clear aaa auth-survivability-cache

clear aaa auth-survivability-cache

Description

This command allows you to clear the data that is currently in the local Survival Server cache.

Usage Guidelines

The **clear...cache** parameter has two sub-parameters:

- **all**: Clears all entries in the Authentication Survivability Cache.
- **station**: Clears the entry in the Authentication Survivability Cache for a particular station.
Specify the station with its MAC address in *A:B:C:D:E:F* format.

Example

To clear the Auth-Survivability cache:

```
(host)#clear aaa auth-survivability-cache <all> | <station MAC_address>
```

Command History

Version	Description
ArubaOS 6.4.3.0	Command introduced.

Command Information

Aruba 7000 Cloud Services Controllers	Base operating system	Config mode on master or local controllers

cfgm

```
cfgm {set config-chunk <kbytes>|set heartbeat <seconds>|set maximum-updates <number>|snapshot-  
timer <minutes>|sync-command-blocks <number>|sync-type complete|sync-type snapshot}
```

Description

This command configures the configuration module on the master controller.

Syntax

Parameter	Description	Range	Default
set config-chunk	Maximum packet size, in Kilobytes, that is sent every second to the local controller whenever the master controller sends a configuration to the local. If the connection between the master and local is slow or uneven, you can lower the size to reduce the amount of data that needs to be retransmitted. If the connection is very fast and stable, you can increase the size to make the transmission more efficient.	1-100	10 Kbytes
set heartbeat	Interval, in seconds, at which heartbeats are sent. You can increase the interval to reduce traffic load.	10-300	10 seconds
set maximum-updates	Maximum number of local controllers that can be updated at the same time with configuration changes. You can decrease this value if you have a busy network. You can increase this value to improve configuration synchronization.	2-25	5
snapshot-timer	Interval, in minutes, that the local controller waits for a configuration download from the master upon bootup or startup before loading the last snapshot configuration.	5-60	5 minutes
sync-command-blocks	To configure the number of command-list blocks. Each block contains a list of global configuration commands for each write-mem operation.	3-10	5
sync-type complete	The master sends full configuration file to the local.	—	—
sync-type snapshot	The master sends only the incremental configuration to the local. NOTE: By default, this configuration is enabled.	—	Enable

Usage Guidelines

By default, configuration updates on the controller are disabled to prevent any alterations to the controller configuration.

Example

The following command sets the maximum packet size as 20 KB per second whenever the master controller sends a configuration to the local :

```
(host) (config) #cfgm set config-chunk 20
```

Command History

This command was introduced in ArubaOS 3.1.

  voice
  vpdn
  web-cc cache <MD5-1> <MD5-2>
  web-cc stats
  wms
```

Description

This command clears various user-configured values from your running configuration.

Syntax

Parameter	Description
aaa	Clear all values associated with authentication profile.
authentication-server	Provide authentication server details to clear values specific to an authentication server or all authentication server. Parameters: • all — Clear all server statistics. • internal — Clear Internal server statistics. • ldap - Clear LDAP server statistics. • radius — Clear RADIUS server statistics. • tacacs — Clear TACACS server statistics.

Parameter	Description
device-id-cache	Clear all device ID cache. Parameters: • all — Clear all entries in the device ID cache. • mac — Clear entries in the device ID cache for MAC address.
load-balance	Clear load balance statistics. Parameters: • statistics — Clear load balance statistics.
multiple-server-accounting	Clear multiple server accounting statistics. Parameters: • statistics — Clear multiple server accounting statistics.
state	Clear internal status of authentication modules. Parameters: • configuration — Clear all configured objects. • debug-statistics — Clear debug statistics. • messages — Clear authentication messages that were sent and received.
acl	Clear ACL statistics.
hits	Clear ACL hit statistics
airgroup	Clear airgroup statistics and user entries from the user table.
cli-policy all	Clears AirGroup policies except CPPM policies.
global-credits statistics	Clears credits assigned to mDNS packets.
server	Clears AirGroup servers.
statistics	• blocked-queries — Clears the statistics of service IDs which were queried but not available in the AirGroup service table. • blocked-service-id — Clears the statistics for the list of blocked services. • cppm-entries — Clears the statistics that are displayed for show airgroup cppm entries command. • internal-state — Clears internal state statistics of mDNS module. • multi-controller — Clears the statistics maintained for multi-controller message exchanges. • query — Clears statistics maintained in the user and server table.

Parameter	Description
	• service — Clears statistics maintained in the AirGroup service table.
user	• Mac Address - Clears the AirGroup server Mac addresses. • dlna - Clears the AirGroup DLNA users. • mdns - Clears the AirGroup mDNS users. • all - Removes the current AirGroup user entries from the user table.
ap	Clear all AP related information.
arm bandwidth-management	Clears AP bandwidth management table counters. An AP can be specified by ap-name, BSSID, IPv4 address, or IPv6 address.
arm client-match	summary — Clears the client match summary information unsupported — Clears the MAC address of an unsteerable client or clients.
crash-info	Clears AP crash information. An AP can be specified by ap-name, IPv4 address, or IPv6 address.
debug	• bss-dmo-stats— Clears DMO debug statistics from a specific BSSID of an AP. • client-stats— Clears statistics from a client. • dot11r {efficiency-stat}— Clears 802.11r related stats. • lldp— Clears Link Layer Discovery Protocol. • radio-stats— Clears aggregate radio debug statistics of an AP.
mesh	Clear all mesh commands.
port	Toggle the link on the specified port.
remote flash-config	Clears the flash configuration from a specified AP. An AP can be specified by ap-name, BSSID, IPv4 address, or IPv6 address.
arm	Clear the following types of ARM client match information • client-match-summary • client-match-unsteerable
arp	Clear all ARP table information. You can either clear all information or enter the IP address of the ARP entry to clear a specific value.
counters	Clear all interface configuration values.
fastethernet	Clears configuration related to fastethernet ports.

Parameter	Description
<code>gigabitethernet</code>	Clears configuration related to fastethernet ports.
<code>port-channel <id></code>	Clears statistics related to a port-channel.
<code>tunnel</code>	Clears all tunnel configuration values on interface ports.
<code>vrrp [ipv6]</code>	Clears all VRRP configuration values on interface ports. Include the <code>ipv6</code> parameter to clear IPv6 counters.
<code>crypto</code>	Clears the specified crypto information.
<code>dp</code>	Clears crypto latest DP packets.
<code>ipsec sa</code>	Clears crypto ipsec state security associations.
<code>isakmp sa</code>	Clears crypto isakmp state security associations.
<code>stats</code>	Clears crypto statistics.
<code>datapath</code>	Clears all configuration values and statistics for the following datapath modules. • application {counters} • bridge {counters} • bwm {counters} • crypto {counters} • debug {performance} • dma {counters} • eap {counters} • frame {counters} • hardware {counters statistics} • ip-fragment-table {ipv4 ipv6} • ip-reassembly {counters} • maintenance {counters} • message-queue {counters} • mobility {stats} • network {ingress} • papi {counters} • route {counters} • route-cache {A.B.C.D counters} • session {counters} • ssl {counters}

Parameter	Description
	• station {counters} • tcp {counters} • tunnel {counters} • user {counters} • web-cc {counters} • wifi-reassembly {counters} • wmm {counters}
dot1x	Clears all 802.1X specific counters and supplicant statistics. Use the following parameters: • counters • supplicant-info
fault	Clears all SNMP fault configuration.
gap-db	Clears global AP database. This command is often used to clear all stale AP records. Use the following parameters: • ap-name • lms • wired-mac
ip	Clears all IP information from DHCP bindings, IGMP groups and IP mobility configuration. Use the following parameters: • dhcp • igmp {group proxy-mobility-group stats-counters} • mobile {multicast-vlan-table traffic trail}
ipc	Clears all inter process communication statistics. • statistics {app-ap app-id app-name}
ipv6	Clears all IPv6 session statistics, multicast listener discovery (MLD) group and member information, MLD statistics, counters, and DHCPv6 binding information. Use the following parameters: • datapath {session} • dhcp {binding} • mld {group proxy-mobility-group stats-counters} • neighbor
lldp	Clears lldp information on all the interfaces. Use the following parameters: • neighbors {interface gigabitethernet slot/port} • statistics {interface gigabitethernet slot/port}

Parameter	Description
loginsession	Clears loginsession information for a specific login session, as identified by the session id.
master-local-entry	Clears local controller information from the master controller LMS list. Specify the IP address of the local controller to be removed from master controller active LMS list.
master-local-session	Clear and reset master local TCP connection. Specify the IP address of either the master or local controller.
port	Clear all port statistics that includes link-event counters or all counters. Use the following parameters: • link-event • stats
provisioning-ap-list	Clear AP entries from the provisioning list.
provisioning-params	Clear provisioning parameters and reset them to the default configuration values.
rap-wml	Clear wired MAC lookup cache for a DB server.
update-counter	Clear all update counter statistics.
upgrade-images	Clear all upgrade images used by the centralized licensing feature.
voice	Clear all voice state information. Use the following parameters: • call-counters • call-status • statisticscac tspec-enforcement
vpdn	Clear all VPDN configuration for L2TP and PPTP tunnel. Use the following parameters: • tunnel l2tp id <l2tp-tunnel-id> • tunnel pptp id <pptp-tunnel-id>
web-cc cache <MD5-1> <MD5-2>	Clear web content category URLs from the datapath cache by specifying the two MD5 values of the URL to be removed from the cache. To view all entries in the datapath, and the MD5 values for each entry, issue the command show datapath web-cc .
web-cc stats	Clear all web content classification statistics. To view current statistics information, issue the command show web-cc stats .
wms	Clear all WLAN management commands. Use the following parameters: • ap—clear — All AP related commands. Specify the BSSID of the

Parameter	Description
	AP. • client— Clear all wired client related commands. Specify the MAC address of the client. • probe — Clear all probe information. Specify the BSSID of the probe.

Usage Guidelines

The clear command clears the specified parameters of their current values.

Example

The following command clears all aaa counters for all authentication servers:

```
(host) (config) #clear aaa authentication-server all
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.1	The following MLD parameters are added to the ipv6 option: • mld group • mld stats-counters
ArubaOS 6.3	• The device-id-cache, load-balance, multiple-server-accounting parameters were introduced under aaa parameter. • The airgroup parameter was introduced. • The dhcp binding parameter under ipv6 was introduced. • The proxy-mobility-group parameter under mld was introduced. • The ip-fragment-table parameter under datapath was introduced.
ArubaOS 6.4	• The lldp parameter was introduced. • The Server and User options were introduced under the clear aigroup command.
ArubaOS 6.4.2.0	• The web-cc cache and web-cc stats parameters were introduced. • The datapath web-cc parameter was introduced.
ArubaOS 6.4.3.0	• The clear counter tunnel interface limit was changed from 2147483647 to 16777215. • The global-credits statistics parameter was introduced. • The port-channel sub-parameter was introduced under the counters parameter.

Command Information

clear wms wired-mac

```
clear wms wired-mac [ all | gw-mac <mac> | monitored-ap-wm <mac> | prop-eth-mac <mac> | reg-  
ap-oui <mac> | system-gw-mac <mac> | system-wired-mac <mac> | wireless-device <mac>]
```

Description

Clear *learned* and *collected* Wired MAC information. Optionally, enter the MAC address, in nn:nn:nn:nn:nn:nn format, of the AP that has seen the Wired Mac.

Syntax

	Description
all	Clear all the learned and collected wired Mac information.
gw-mac <mac>	Clear the gateway wired Mac information collected from the APs.
monitored-ap-wm <mac>	Clear monitored AP wired Mac information collected from the APs.
prop-eth-mac <mac>	Clear the wired Mac information collected from the APs.
reg-ap-oui <mac>	Clear the registered AP OUI information collected from the APs.
system-gw-mac <mac>	Clear system gateway Mac information learned at the controller.
system-wired-mac <mac>	Clear system wired Mac information learned at the controller.
wireless-device <mac>]	Clear routers or potential wireless devices information.

clock append

clock append

Description

This command enables the timestamp feature, adding a date and time to the output of **show** commands.

Syntax

No parameters.

Usage Guidelines

When you enable the timestamp feature, the command-line interface includes a timestamp in the output of each show command indicating when the show command was issued. Note that the output of **show clock** and **show log** do not include timestamps, even when this feature is enabled. You can disable timestamps using the command **no clock append**.

Example

The following example enables the timestamp feature.

```
(host)(config) #clock append
```

Command History

This command was introduced in ArubaOS 6.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode

clock set

`clock set <year><month><day><time>`

Description

This command sets the date and time.

Syntax

Parameter	Description	Range
<code>year</code>	Sets the year. Requires all 4 digits.	Numeric
<code>month</code>	Sets the month. Requires the first three letters of the month.	Alphabetic
<code>day</code>	Sets the day.	1-31
<code>time</code>	Sets the time. Specify hours, minutes, and seconds separated by spaces.	Numeric

Usage Guidelines

You can configure the year, month, day, and time. You must configure all four parameters.

Specify the time using a 24-hour clock. You must specify the seconds.

Example

The following example configures the clock to January 1st of 2007, at 1:03:52 AM.

```
(host)(config) #clock set 2007 jan 1 1 3 52
```

Command History

This command was introduced in ArubaOS 1.0

Command Information

clock summer-time recurring

```
clock summer-time <WORD> [recurring]
    <1-4> <start day> <start month> <hh:mm>
    first <start day> <start month> <hh:mm>
    last <start day> <start month> <hh:mm>
    <1-4> <end day> <end month> <hh:mm>
    first <end day> <end month> <hh:mm>
    last <end day> <end month> <hh:mm>
    [<-23 - 23>]
```

Description

Set the software clock to begin and end daylight savings time on a recurring basis.

Syntax

Parameter	Description	Range
WORD	Enter the abbreviation for your time zone. For example, PDT for Pacific Daylight Time.	3-5 characters
1-4	Enter the week number to start/end daylight savings time. For example, enter 2 to start daylight savings time on the second week of the month.	1-4
first	Enter the keyword first to have the time change begin or end on the first week of the month.	—
last	Enter the keyword last to have the time change begin or end on the last week of the month.	—
start day	Enter the weekday when the time change begins or ends.	Sunday-Saturday
start month	Enter the month when the time change begins or ends.	January-December
hh:mm	Enter the time, in hours and minutes, that the time change begins or ends.	24 hours
-23 - 23	Hours offset from the Universal Time Clock (UTC).	-23 - 23

Usage Guidelines

This command subtracts exactly 1 hour from the configured time.

The WORD can be any alphanumeric string, but cannot start with a colon (:). A WORD longer than five characters is not accepted. If you enter a WORD containing punctuation, the command is accepted, but the timezone is set to UTC.

You can configure the time to change on a recurring basis. To do so, set the week, day, month, and time when the change takes effect (daylight savings time starts). You must also set the week, day, month, and time when the time changes back (daylight savings time ends).

The `start day` requires the first three letters of the day. The `start month` requires the first three letters of the month.

You also have the option to set the number of hours by which to offset the clock from UTC. This has the same effect as the [clock timezone](#) command.

Example

The following example sets daylight savings time to occur starting at 2:00 AM on Sunday in the second week of March, and ending at 2:00 AM on Sunday in the first week of November. The example also sets the name of the time zone to PST with an offset of UTC - 8 hours.

```
clock summer-time PST recurring 2 Sun Mar 2:00 first Sun Nov 3:00 -8
```

Command History

This command was introduced in ArubaOS 1.0

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

clock timezone

```
clock timezone <name> <-23 to 23>
```

Description

This command sets the time zone on the controller.

Syntax

Parameter	Description	Range
<name>	Name of the time zone.	3-5 characters
-23 to 23	Hours offset from UTC.	-23 to 23

Usage Guidelines

The **name** parameter can be any alphanumeric string, but cannot start with a colon (:). A time zone name longer than five characters is not accepted. If you enter a time zone name containing punctuation, the command is accepted, but the time zone is set to UTC.

Example

The following example configures the timezone to PST with an offset of UTC - 8 hours.

```
clock timezone PST -8
```

Command History

This command was introduced in ArubaOS 1.0

Command Information

cluster-member-custom-cert

```
cluster-member-custom-cert member-mac <mac> ca-cert <ca> server-cert <cert>  
    suite-b <gcm-128 | gcm-256>]
```

Description

This command sets the controller as a control plane security cluster root, and specifies a custom user-installed certificate for authenticating cluster members.

Syntax

Parameter	Description
member-mac <ca>	MAC address of the cluster member
ca-cert <ca>	Name of the CA certificate uploaded via the WebUI
ca-cert <ca>	Name of the CA certificate uploaded via the WebUI
server-cert <cert>	Name of the server certificate uploaded via the WebUI.
suite-b	To use Suite-B encryption in the secure communication between the cluster root and cluster member, specify one of the following Suite-B algorithms • gcm-128: Encryption using 128-bit AES-GCM • gcm-256: Encryption using 256-bit AES-GCM

Usage Guidelines

If your network includes multiple master controllers each with their own hierarchy of APs and local controllers, you can allow APs from one hierarchy to failover to any other hierarchy by defining a cluster of master controllers. Each cluster will have one master controller as its cluster root, and all other master controllers as cluster members.

To define a controller as a cluster root, issue one of the following commands on that controller:

- [cluster-member-custom-cert](#): Define the controller as a cluster root, and select a user-installed certificate to authenticate that cluster member.
- [cluster-member-factory-cert](#): Define the controller as a cluster root, and select a factory-installed certificate to authenticate that cluster member.
- [cluster-member-ip](#): Define the controller as a cluster root, and set the IPsec key to authenticate that cluster member.

For information on installing certificates on your controller, refer to the *Management Utilities* chapter of the *Dell Networking W-Series ArubaOS User Guide*.

Example

The following example selects a customer installed certificate for cluster member authentication.

```
(host) (config) # cluster-member-custom-cert member-mac 00:1E:37:CB:D4:52 ca-cert cacert1  
server-cert servercert1
```

cluster-member-factory-cert

cluster-member-factory-cert member-mac <mac>

Description

This command sets the controller as a control plane security cluster root, and specifies a custom user-installed certificate for authenticating cluster members.

Syntax

Parameter	Description
<mac>	MAC address of the user-installed certificate on the cluster member

Usage Guidelines

If your network includes multiple master controllers each with their own hierarchy of APs and local controllers, you can allow APs from one hierarchy to failover to any other hierarchy by defining a cluster of master controllers. Each cluster will have one master controller as its cluster root, and all other master controllers as cluster members.

To define a controller as a cluster root, issue one of the following commands on that controller:

- [cluster-member-custom-cert](#): Define the controller as a cluster root, and select a user-installed certificate to authenticate that cluster member.
- [cluster-member-factory-cert](#): Define the controller as a cluster root, and select a factory-installed certificate to authenticate that cluster member.
- [cluster-member-ip](#): Define the controller as a cluster root, and set the IPsec key to authenticate that cluster member.

For information on installing certificates on your controller, refer to the *Management Utilities* chapter of the *Dell Networking W-Series ArubaOS User Guide*.

Example

The following command sets the controller on which you issue command as a root controller, and adds the controller **172.21.18.18** as a cluster member with the IPsec key **ipseckey1**:

```
(host) (config) #cluster-member-factory-cert member-mac 00:1E:37:CB:D4:52
```

Related Commands

Parameter	Description	Mode

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on cluster root controllers

cluster-member-ip

```
cluster-member-ip <ip-address>  
    ipsec <key>
```

Description

This command sets the controller as a control plane security cluster root, and specifies the IPsec key for a cluster member.

Syntax

Parameter	Description
<ip-address>	Switch IP address of a control plane security cluster member. You can also use the IP address 0.0.0.0 to set a single IPsec key for all cluster members.
ipsec <key>	Configure the value of the IPsec key for secure communication between the cluster root and the specified cluster member. The key must be between 6-64 characters.

Usage Guidelines

If your network includes multiple master controllers each with their own hierarchy of APs and local controllers, you can allow APs from one hierarchy to failover to any other hierarchy by defining a cluster of master controllers. Each cluster will have one master controller as its cluster root, and all other master controllers as cluster members.

The master controller operating as the cluster root will use the control plane security feature to create a self-signed certificate, then certify its own local controllers and APs. Next, the cluster root will send the certificate to each cluster member, which in turn certifies their own local controllers and APs. Since all controllers and APs in the cluster get their certificates from the cluster root, they will all have the same trust anchor, and the APs can switch to any other controller in the cluster and still remain connected to the secure network.

Issue the [cluster-member-ip](#) command on the controller you want to define as the cluster root to set the IPsec key for secure communication between the cluster root and each cluster member. Use the IP address **0.0.0.0** in this command to set a single IPsec key for all member controllers, or repeat this command as desired to define a different IPsec key for each cluster member.

Once the cluster root has defined an IPsec key for all cluster members, you must access each of the member controllers and issue the command [cluster-root-ip](#) to define the IPsec key for communication to the cluster root.

Example

The following command sets the controller on which you issue command as a root controller, and adds the controller **172.21.18.18** as a cluster member with the IPsec key **ipseckey1**:

```
(host) (config) #cluster-member-ip 172.21.18.18 ipsec ipseckey1
```

cluster-root-ip

```
cluster-root-ip <ip-address>  
    ipsec <key>  
    ipsec-custom-cert root-mac1 <mac1> [root-mac2 <mac2>] ca-cert <ca> server-cert <cert>  
    [suite-b <gcm-128 | gcm-256>]  
    ipsec-factory-cert root-mac-1 <mac> [root-mac-1 <mac>]
```

Description

This command sets the controller as a control plane security cluster member, and defines the IPsec key or certificate for secure communication between the cluster member and the controller's cluster root.

Syntax

Parameter	Description
<ip-address>	The IP address of control plane security cluster root controller. To set a single IPsec key for all member controllers in the cluster use the IP address 0.0.0.0 .
ipsec <key>	Set the value of the IPsec pre-shared key for communication with the cluster root. This parameter must be have the same value as the IPsec key defined for the cluster member via the cluster-member-ip command.
ipsec-factory-cert	Use a factory-installed certificate for secure communication between the cluster root and the specified cluster member by specifying the MAC address of the certificate.
root-mac-1 <mac>	Specify MAC address of the cluster root.
root-mac-2 <mac>	Specify MAC address of the redundant cluster Root.
ipsec-custom-cert	Use a custom user-installed certificate for secure communication between the cluster root and the specified cluster member.
root-mac-1 <mac>	Specify the MAC address of the cluster-root's certificate.
root-mac-2 <mac>	(Optional) If your network has multiple master controllers, use this parameter to specify he MAC address of the redundant cluster-root's certificate.
ca-cert <ca>	Name of the CA certificate uploaded via the WebUI
server-cert <cert>	Name of the server certificate uploaded via the WebUI.
suite-b	To use Suite-B encryption in the secure communication between the cluster root and cluster member, specify one of the following Suite-B algorithms • gcm-128: Encryption using 128-bit AES-GCM • gcm-256: Encryption using 256-but AES-GCM

Usage Guidelines

If your network includes multiple master controllers each with their own hierarchy of APs and local controllers, you can allow APs from one hierarchy to failover to any other hierarchy by defining a cluster of master controllers. Each cluster will have one master controller as its cluster root, and all other master controllers as cluster members.

The master controller operating as the cluster root will use the control plane security feature to create a self-signed certificate, then certify its own local controllers and APs. Next, the cluster root will send the certificate to each cluster member, which in turn certifies their own local controllers and APs. Since all controllers and APs in the cluster get their certificates from the cluster root, they will all have the same trust anchor, and the APs can switch to any other controller in the cluster and still remain connected to the secure network. Issue the [cluster-member-ip](#) command on the controller you want to define as the cluster root to select the certificate or define the IPsec key for secure communication between the cluster root and each cluster member.

Once the cluster root has defined an IPsec key or certificate for all cluster members, you must access each of the member controllers and issue the command [cluster-root-ip](#) to define the IPsec key or certificate for communication to the cluster root.

For information on installing certificates on your controller, refer to the *Management Utilities* chapter of the *Dell Networking W-Series ArubaOS User Guide*.

Example

The following command defines the IPsec key for communication between the cluster member and the root controller **172.21.45.22**:

```
(host) (config) #cluster-root-ip 172.21.45.22 ipsec ipseckey1
```

Command History

Release	Modification
ArubaOS 5.0	Command introduced.
ArubaOS 6.1	The ipsec-factory-cert and ipsec-custom-cert parameters were introduced to allow certificate-based authentication of cluster members.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on cluster member controllers

configure terminal

configure terminal

Description

This command allows you to enter configuration commands.

Syntax

No parameters.

Usage Guidelines

Upon entering this command, the enable mode prompt changes to:

```
(host) (config) #
```

To return to enable mode, enter Ctrl-Z or exit.

Example

The following command allows you to enter configuration commands:

```
(host) # configure terminal
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

control-plane-security

```
control-plane-security
  auto-cert-allow-all
  auto-cert-allowed-addr <ipaddress-start> <ipaddress-end>
  auto-cert-prov
  cpsec-enable
  no ...
```

Description

Configure the control plane security profile by identifying APs to receive security certificates.

Syntax

Parameter	Description
auto-cert-allow-all	When you issue the control-plane-security auto-cert-allow-all command, the controller will send a certificate to all associated APs when auto certificate provisioning is enabled. When disabled, the controller sends certificates only to APs whose IP addresses are in the ranges specified by auto-cert-allowed-addr .
auto-cert-allowed-addr <ipaddress-start> <ipaddress-end>	Use this command to define a specific range of AP IP addresses. The controller will send certificates to the APs in this IP range when auto certificate provisioning is enabled. Identify a range by entering the starting IP address and the ending IP address in the range, separated by a single space. You can repeat this command as many times as necessary to define multiple IP ranges.
auto-cert-prov	Issue this command to enable automatic certificate provisioning. When this feature is enabled, the controller will attempt to send certificates to associated APs. To disable this feature, use the command no auto-cert-prov . Automatic certificate provisioning is disabled by default.

Parameter	Description
cpsec-enable	Issue this command to enable control plane security. To disable this feature, use the command no cpsec-enable . Control plane security is enabled by default.

Usage Guidelines

Controllers enabled with control plane security will only send certificates to APs that you have identified as valid APs on the network. If you are confident that all campus APs currently on your network are valid APs, you can configure automatic certificate provisioning to send certificates from the controller to each campus AP, or to all campus APs within a specific range of IP addresses. If you want closer control over each AP that gets certified, you can manually add individual campus APs to the secure network by adding each AP's information to a campus AP whitelist.

Example

The following command defines a range of IP addresses that should receive certificates from the controller, and enables the control plane security feature:

```
(host)(config) # control-plane-security
auto-cert-allowed-addr 10.21.18.10 10.21.10.90
cpsec-enable
```

controller-ip

```
controller-ip [loopback|vlan <VLAN ID>]  
no ...
```

Description

This command sets the controller IP to the loopback interface address or a specific VLAN interface address.

Syntax

Parameter	Description	Default
loopback	Sets the controller IP to the loopback interface.	disabled
vlan	Set the controller IP to a VLAN interface.	—
VLAN ID	Specifies the VLAN interface ID.	—

Usage Guidelines

This command allows you to set the controller IP to the loopback interface address or a specific VLAN interface address. If the controller IP command is not configured then the controller IP defaults to the loopback interface address. If the loopback interface address is not configured then the first configured VLAN interface address is selected. Generally, VLAN 1 is the factory default setting and thus becomes the controller IP address.

Example

The following command sets the controller IP address to VLAN interface 6.

```
(host) (config) #controller-ip vlan 6
```

Related Commands

```
(host) (config) #show controller-ip
```

Command History

Command Information

Platform	License	Command Mode
Available on all platforms	Base operating system	Config mode on master controllers

controller-ipv6

```
controller-ipv6 [loopback|{vlan <VLAN ID>}]  
no ...
```

Description

This command sets the default IPv6 address of the controller to the IPv6 loopback interface address or a specific VLAN interface address.

Syntax

Parameter	Description	Default
loopback	Sets the controller IP to the loopback interface.	disabled
vlan	Set the controller IP to a VLAN interface.	—
VLAN ID	Specifies the VLAN interface ID.	—

Usage Guidelines

This command allows you to set the default IPv6 address of the controller to the IPv6 loopback interface address or a specific IPv6 VLAN interface address. If the controller IPv6 command is not configured then the controller IP defaults to the loopback interface address. If the loopback interface address is not configured then the first configured VLAN interface address is selected. Generally, VLAN 1 is the factory default setting and thus becomes the controller IP address.

Example

The following command sets the controller IP address to VLAN interface 6.

```
(host) (config) #controller-ipv6 vlan 6
```

Related Commands

```
(host) (config) #show controller-ipv6
```

tftp: <tftphost> <filename> {flash: <destfilename> | system: partition [0|1]}
usb: partition <partition-number> <filename> flash: <destfilename>
```

Description

This command copies files to and from the controller.

Syntax

Parameter	Description
flash:	Copy the contents of the controller's flash file system, the system image, to a specified destination.
<srcfilename>	Full name of the flash file to be copied.
flash:	Copy the file to the flash file system.
<destfilename>	Specify the new name of the copied file.
tftp:	Copy the file to a TFTP server.
<tftphost>	Specify the IP address or hostname of the TFTP server.
usb:	Copy the file to an attached USB storage device.
partition	Specify the partition on the USB device.
ftp:	Copy a file from the FTP server. NOTE: Using this parameter, a password is required to access the FTP server. The password is masked, and must be entered in a separate line.
<ftphost>	Specify the IP address or hostname of the FTP server.
<user>	User account name required to access the FTP server.
<filename>	Full name of the file to be copied.
partition 0 1	Specify the system partition to save the file.

Parameter	Description
running-config	Copy the active, running configuration to a specified destination.
flash:	Copy the configuration to the flash file system.
<filename>	Specify the new name of the copied configuration file.
ftp:	Using FTP, copy the configuration to an FTP server. NOTE: Using this parameter, a password is required to access the FTP server. The password is masked, and must be entered in a separate line.
<ftphost>	Specify the IP address of the FTP server.
<user>	User account name required to access the FTP server.
<remote-dir>	Specify a remote directory, if needed.
startup-config	Copy the active, running configuration to the start-up configuration.
tftp:	Using TFTP, copy the configuration to a TFTP server
<tftphost>	Specify the IP address or hostname of the TFTP server.
scp:	Copy an ArubaOS image file or file from the flash file system using the Secure Copy protocol. The SCP server or remote host must support SSH version 2 protocol.
<scphost>	Specify the IP address of the SCP server or remote host.
<username>	User account name required to access the SCP server or remote host.
<filename>	Specify the absolute path of the filename to be copied.
flash:	Copy the file to the flash file system.
<destfilename>	Specify the new name of the copied file.
system:	Copy the file to the system partition.
startup-config	Copy the startup configuration to a specified flash file or to a TFTP server.
flash:	Copy the file to the flash file system.
<filename>	Specify the new name of the copied startup configuration file.
tftp:	Using TFTP, copy the startup configuration to a TFTP server

Parameter	Description
<tftphost>	Specify the IP address or hostname of the TFTP server.
system:	Copy the specified system partition
<srcpartition>	Disk partition from which to copy the system data, as either 0 or 1.
<destpartition>	Disk partition to copy the system data to, as either 0 or 1.
tftp:	Copy a file from the specified TFTP server to either the controller or another destination. This command is typically used when performing a system restoration, or to pull a specified file name into the wms database.
<tftphost>	Specify the IP address or hostname of the TFTP server.
<filename>	Full name of the file to be copied.
flash:	Copy the file to the flash file system
<destfilename>	Specify the new name of the copied file.
system	Copy the file to the system partition.
usb:	Copy a file from an attached USB device to the flash file system.
partition	Specify the partition on the USB device.
<filename>	Full name of the file to be copied.
flash:	Copy the file to the flash file system
<destfilename>	Specify the new name of the copied file.

Passwords Secured During FTP Copy

Password are masked when using FTP to copy a file to a remote system. In previous releases, the password was entered in clear text at the end of the copy command. Starting with ArubaOS 6.4.0.0, the password is masked, and must be entered in a separate line. If you use scripts to copy files from controllers, scripts used on controllers running previous releases of ArubaOS must be modified to support this new password behavior.

Old syntax:

```
(host) #copy running-config ftp: <ftphost> <user> <password> <filename>
```

New syntax:

```
(host) #copy running-config ftp: <ftphost> <user> <filename>
Password: <password>
```

In the following example, the password is entered on the second line, and is displayed in masked text.

```
(host) #copy running-config ftp: 192.168.1.2 adminuser runconfig
Password: *****
```

Usage Guidelines

Use this command to save back-up copies of the configuration file to an FTP or TFTP server, or to load a saved file from an FTP or TFTP server.

Three partitions reside on the file system flash. Totalling 256MB, the three partitions provide space to hold the system image files (in partitions 1 and 2 which are 45MB each) and user files (in partition 3, which is 165MB). System software runs on the system partitions; the database, DHCP, startup configuration, and logs are positioned on the user partition.

To restore a database, copy the database from the network server and import the database.

To restore a configuration file, copy the file from network server to the controller's flash system then copy the file from the flash system to the system configuration. This ensures that you do not accidentally overwrite your system startup configuration file.

Unlike the controller's flash, the USB device has more than two partitions; not just 0 and 1. When copying a file from a USB device, you must know which partition the target file is on. Use the **show storage** command to identify the location of the file to identify the correct USB partition.

Example

The following commands copy the configuration file named engineering from the TFTP server to the controller's flash file system and then uses that file as the startup configuration. This example assumes the startup configuration file is named default.cfg:

```
(host) (config) #copy tftp: 192.0.2.0 engineering flash: default.bak
copy flash: default.bak flash: default.cfg
```

Command History

This command was introduced in ArubaOS 1.0.

	Modification
ArubaOS 1.0	Introduced for the first time.
ArubaOS 6.2	The USB parameters introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable and Config modes on master controllers

cp-bandwidth-contract

cp-bandwidth-contract <name> {pps <1..64000>}

Description

This command configures a bandwidth contract traffic rate which can then be associated with a whitelist session ACL.

Syntax

Parameter	Description	Range	Default
<name>	Name of a bandwidth contract.	—	—
pps	Set a bandwidth rate in packets/seconds.	1-64000	—

Example

The following example configures a bandwidth contract named “cp-rate” with a rate of 100 pps.

```
(host) (config) #cp-bandwidth-contract cp-rate pps 100
```

Related Commands

Command	Description
show cp-bwcontracts	Display a list of Control Processor (CP) bandwidth contracts for whitelist ACLs.
firewall cp	This command creates a new whitelist ACL and can associate a bandwidth contract with that ACL.

Command History

Version	Modification
ArubaOS 3.4	Command introduced.
ArubaOS 6.4.3.0	The unit of bandwidth contract traffic rate changed from Mbps or Kbps to pps. The range for pps is 1-64000.

Command Information

Platforms	Licensing	Command Mode
All platforms	This command requires the PEFNG license.	Config mode on master controllers

crypto-local ipsec sa-cleanup

crypto-local ipsec sa-cleanup

Description

Issue this command to clean IPsec security associations (SAs).

Syntax

No parameters

Usage Guidelines

Use this command to remove old IPsec security associations if remote APs on your network still use an old SA after upgrading to a newer version of ArubaOS.

Command History

This command was introduced in ArubaOS 6.1.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

crypto dynamic-map

```
crypto dynamic-map <name> <priority>
  disable
  no ...
  set pfs {group1|group2|group14|group19|group20}
  set security-association lifetime kilobytes <kilobytes>
  set security-association lifetime seconds <seconds>
  set transform-set <name1> [<name2>] [<name3>] [<name4>]
  version v1|v2
```

Description

This command configures a new or existing dynamic map.

Syntax

Parameter	Description	Range	Default
<name>	Name of the map.	—	—
<priority>	Priority of the map.	1-10000	10000
no	Negates a configured parameter.	—	—
disable	Disables the dynamic map.	—	—
enable [bypass secret]	Enables the dynamic map using the bypass or secret. Bypass prompts for the enable mode login and password. Secret prompts for the enable password.	—	—
set pfs	Enables Perfect Forward Secrecy (PFS) mode. Use one of the following: • group1: 768-bit Diffie Hellman prime modulus group. • group2: 1024-bit Diffie Hellman • group14: 2048-bit Diffie Hellman. • group19: 256-bit random Diffie Hellman ECP modulus group. • group20: 384-bit random Diffie Hellman ECP modulus group.	—	group1
set security-association lifetime	Configures the lifetime for the security association (SA) in seconds or kilobytes.	—	—
seconds <seconds>	Lifetime for the SA in seconds.	300-86400	7200

Parameter	Description	Range	Default
<code>kilobytes <kilobytes></code>	Lifetime for the SA in kilobytes.	1000 - 1000000000	—
<code>set transform-set</code>	Name of the transform set for this dynamic map. You can specify up to four transform sets. You configure transform sets with the <code>crypto ipsec transform-set</code> command.	—	default-transform
<code>version</code>	Specify the version of IKE protocol the controller uses to set up a security association (SA) in the IPsec protocol suite • v1: IKEv1 • v2: IKEv2	—	v1

Usage Guidelines

Dynamic maps enable IPsec SA negotiations from dynamically addressed IPsec peers. Once you have defined a dynamic map, you can optionally associate that map with the default global map using the command [crypto map global-map](#).

Example

The following command configures a dynamic map:

```
(host) (config)# crypto dynamic-map dmap1 100
set pfs group2
set security-association lifetime seconds 300
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.1	The version parameter was introduced. The pfs parameter was modified to support the group19 and group20 PFS group values.
ArubaOS 6.3	The set security-association lifetime kilobytes and Diffie-Hellman set pfs group 14 parameters were added.
ArubaOS 6.4	The disable/enable parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	The group19 and group20 PFS options requires the Advanced Cryptography (ACR) license. All other parameters are available in the base operating system.	Config mode on master controllers

crypto ipsec

```
crypto ipsec
  mtu <max-mtu>
  transform-set <transform-set-mtu> esp-3des|esp-aes128|esp-aes128-gcm|esp-aes192|esp-
aes256|esp-aes256-gcm|esp-des esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
```

Description

This command configures IPsec parameters.

Syntax

Parameter	Description
mtu <max-mtu>	Configure the IPsec Maximum Transmission Unit (MTU) size. The supported range is 1024 to 1500 and the default is 1500.
transform-set <transform-set-mtu>	Create or modify a transform set.
esp-3des	Use ESP with 168-bit 3DES encryption.
esp-aes128	Use ESP with 128-bit AES encryption.
esp-aes128-gcm	Use ESP with 128-bit AES-GCM encryption.
esp-aes192	Use ESP with 192-bit AES encryption.
esp-aes256	Use ESP with 256-bit AES encryption.
esp-aes256-gcm	Use ESP with 256-bit AES-GCM encryption.
esp-des	Use ESP with 56-bit DES encryption.
esp-md5-hmac	Use ESP with the MD5 (HMAC variant) authentication algorithm
esp-null-hmac	Use ESP with no authentication. This option is not recommended.
esp-sha-hmac	Use ESP with the SHA (HMAC variant) authentication algorithm.

Usage Guidelines

Define the Maximum Transmission Unit (MTU) size allowed for network transmissions using IPsec security, and create or edit transform sets that define a specific encryption and authentication type.

Example

The following command configures 3DES encryption and MD5 authentication for a transform set named **set2**:

```
(host) (config)# crypto ipsec transform-set set2 esp-3des esp-md5-hmac
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The esp-aes128-gcm and esp-aes256-gcm transform-set parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	The esp-aes128-gcm and esp-aes56-gcm transform-set parameters require the Advanced Cryptography (ACR) license. All other parameters are available in the base OS.	Config mode on master controllers

crypto isakmp

```
crypto isakmp
  address <peer-address> netmask <mask>}
  disable
  eap-passthrough eap-mschapv2|eap-peap|eap-tls
  enable
  groupname <name>
  key <keystring> address <peer-address> netmask <mask>
  udpencap-behind-natdevice enable|disable
  packet-dump
```

Description

This command configures Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP).

Syntax

Parameter	Description
address	Configure the IP address for the group key.
<peer-address>	IP address for the group key, in dotted-decimal format.
netmask	Configure the IP netmask for the group key.
<mask>	Subnet mask for the group key.
disable	Disable IKE processing.
eap-passthrough	Select one of the following authentication types for IKEv2 user authentication using EAP. • eap-mschapv2 • eap-peap • eap-tls
enable	Enable IKE processing.
groupname	Configure the IKE Aggressive group name. Aggressive-mode IKE is a 3-packet IKE exchange that does not provide identity-protection, but is faster, because fewer messages are exchanged.
<name>	Name of the IKE aggressive group.
key	Configure the IKE preshared key.
<keystring>	Configure the value of the IKE PRE-SHARED key. The key must be between 6-64 characters long.

Parameter	Description
address	Configure the IP address for the group key.
<peer-address>	An IP for the group key, in dotted-decimal format.
netmask	Configure the netmask for the group key IP address.
<mask>	A subnet mask, in dotted-decimal format
udpencap-behind-natdevice	Configure NAT-T if controller is behind NAT device. (For Windows VPN Dialer only)
enable	Enable Nat-T. This is the recommended setting if the controller is behind a NAT device.
disable	Disable Nat-T.
packet-dump	Issue this command in enable mode to troubleshoot an IPsec tunnel establishment by looking at the packet exchanges between the controller and the remote AP or the other IPsec peer. The packet dump output is saved to a file named ike.pcap. NOTE: This is a testing feature only, and should not be enabled on a production network. To disable this feature, use the command no crypto isakmp packet-dump .

Usage Guidelines

Use this command to configure the IKE pre-shared key, set the EAP authentication method for IKEv2 clients using EAP user authentication, and enable source NAT if the IP addresses of clients need to be translated to access the network.

Example

The following command configures an ISAKMP peer IP address and subnet mask. After configuring an ISAKMP address and netmask, you will be prompted to enter the IKE preshared key.

```
(host) (config) #crypto isakmp address 10.3.14.21 netmask 255.255.255.0
Key:*****Re-Type Key:*****
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The eap-passthrough parameter was introduced.

Command Information

All platforms	Base operating system	Config mode on master controllers

crypto isakmp block-aruba-ca

```
crypto-local isakmp block-aruba-ca  
  enable  
  disable
```

Description

This command configures the controller to accept or reject Dell certified clients.

Syntax

Parameter	Description
enable	Accept Dell certified client certificates.
disable	Reject Dell certified client certificates and use custom certificates instead.

Example

This command configures a CA certificate:

```
crypto-local isakmp block-aruba-ca enable
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

crypto isakmp policy

```
crypto isakmp policy
  authentication pre-share|rsa-sig|ecdsa-256|ecdsa-384
  disable|enable [bypass|secret]
  encryption 3DES|AES128|AES192|AES256|DES
  group 1|2|14|19|20
  hash md5|sha|sha1-96|sha2-256-128|sha2-384-192
  prf PRF-HMAC-MD5|PRF-HMAC-SHA1|PRF-HMAC-SHA256|PRF-HMAC-SHA384
  lifetime <seconds>
  no disable
  version v1|v2
```

Description

This command configures Internet Key Exchange (IKE) policy parameters for the Internet Security Association and Key Management Protocol (ISAKMP).

Syntax

Parameter	Description
policy	Configure an IKE policy
<priority>	Specify a number from 1 to 10,000 to define a priority level for the policy. The higher the number, the higher the priority level.
authentication	Configure the IKE authentication method.
pre-share	Use Pre Shared Keys for IKE authentication. This is the default authentication type.
rsa-sig	Use RSA Signatures for IKE authentication.
ecdsa-256	Use ECDSA-256 signatures for IKE authentication.
ecdsa-384	Use ECDSA-384 signatures for IKE authentication.
disable	Disables the IKE policy.
enable [bypass secret]	Enables the IKE policy using the bypass or secret. Bypass prompts for the enable mode login and password. Secret prompts for the enable password.
encryption	Configure the IKE encryption algorithm.
3DES	Use 168-bit 3DES-CBC encryption algorithm. This is the default encryption value.
AES128	Use 128-bit AES-CBC encryption algorithm.

Parameter	Description
AES192	Use 192-bit AES-CBC encryption algorithm.
AES256	Use 256-bit AES-CBC encryption algorithm.
DES	Use 56-bit DES-CBC encryption algorithm.
group	Configure the IKE Diffie Hellman group.
1	Use the 768-bit Diffie Hellman prime modulus group. This is the default group setting.
2	Use the 1024-bit Diffie Hellman prime modulus group.
14	Use the 2048-bit Diffie Hellman DDH prime modulus group.
19	Use the 256-bit random Diffie Hellman ECP modulus group.
20	Use the 384-bit random Diffie Hellman ECP modulus group
hash	
md5	Use MD5 as the hash algorithm.
sha	Use SHA-1 as the hash algorithm. This is the default policy algorithm.
SHA1-96	Use SHA1-96 as the hash algorithm.
SHA2-256-128	Use SHA2-256-128 as the hash algorithm.
SHA2-384-192	Use SHA2-384-192 as the hash algorithm.
prf	Set one of the following pseudo-random function (PRF) values for an IKEv2 policy: • PRF-HMAC-MD5 (default) • PRF-HMAC-SHA1 • PRF-HMAC-SHA256 • PRF-HMAC-SHA384
lifetime <seconds>	Specify the lifetime of the IKE security association (SA), from 300 - 86400 seconds.
no	Disables the policy.
version	Specify the version of IKE protocol for the IKE policy

Parameter	Description
	• v1: IKEv1 • v2: IKEv2

Usage Guidelines

To define settings for a ISAKMP policy, issue the command **crypto isakmp policy <priority>** then press **Enter**. The CLI will enter config-isakmp mode, which allows you to configure the policy values.

Example

The following command configures an ISAKMP peer IP address and subnet mask.. After configuring an ISAKMP address and netmask, you will be prompted to enter the IKE preshared key.

```
(host)(config) #crypto isakmp policy1
(host)(config-isakmp) #auth rsa-sig
Key:*****Re-Type Key:*****
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The following parameters were introduced. • authentication ecdsa-256 • authentication ecdsa-384 • hash sha1-96 • hash sha2-256-128 • hash sha2-384-192 • prf
ArubaOS 6.3	The Diffie-Hellman group 14 parameter was introduced.
ArubaOS 6.4	The disable/enable and no parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	The following settings require the Advanced Cryptogram (ACR) license: • hash algorithm: SHA-256-128, SHA-384-192 • Diffie-Hellman (DH) Groups: 19 and 20 • Pseudo-Random Function (PRF): PRF-HMAC-SHA256, PRF-HMAC-SHA384 • Authentication: ecdsa-256 and ecdsa-384 All other parameters are supported in the base OS.	Config mode on master controllers

crypto-local ipsec-map

```
crypto-local ipsec-map <map> <priority>
  dst-net <ipaddr> <mask>
  force-natt
  no ...
  local-fqdn <local_id_fqdn>
  peer-cert-dn <peer-dn>
  peer-fqdn any-fqdn|{peer-fqdn <peer-id-fqdn>}
  peer-ip <ipaddr>
  pre-connect {disable|enable}
  set ca-certificate <cacert-name>
  set ike1-policy <policy-v1-number>
  set ikev2-policy <policy-v2-number>
  set pfs {group1|group2|group14|group19|group20}
  set security-association lifetime kilobytes <kilobytes>
  set security-association lifetime seconds <seconds>
  set server-certificate <cert-name>
  set transform-set <name1> [<name2>] [<name3>] [<name4>]
  src-net <ipaddr> <mask>
  trusted {disable|enable}
  version v1|v2
  vlan <vlan>
```

Description

This command configures IPsec mapping for site-to-site VPNs.

Syntax

Parameter	Description	Range	Default
<map>	Name of the IPsec map.	—	—
<priority>	Priority of the entry.	1-9998	—
dst-net	IP address and netmask for the destination network.	—	—
force-natt	Include this parameter to always enforce UDP 4500 for IKE and IPsec. This option is disabled by default.	—	—
no	Negates a configured parameter.	—	—
local-fqdn <local_id_fqdn>	If the local controller has a dynamic IP address, you must specify the fully qualified domain name (FQDN) of the controller to configure it as a initiator of IKE aggressive-mode.	—	—

Parameter	Description	Range	Default
peer-cert-dn <peer-dn>	If you are using IKEv2 to establish a site-to-site VPN to a statically addressed remote peer, identify the peer device by entering its certificate subject name in the Peer Certificate Subject Name field	—	—
peer-ip <ipaddr>	If you are using IKEv1 to establish a site-to-site VPN to a statically addressed remote peer, identify the peer device by entering IP address of the peer gateway. NOTE: If you are configuring an IPsec map for a static-ip controller with a dynamically addressed remote peer, you must leave the peer gateway set to its default value of 0.0.0.0.	—	—
peer-fqdn	For site-to-site VPNs with dynamically addressed peers, specify a fully qualified domain name (FQDN) for the controller.	any-fqdn fqdn-id	any-fqdn
any-fqdn	If the controller is defined as a dynamically addressed responder, you can select any-fqdn to make the controller a responder for all VPN peers,	—	—
fqdn-id <peer-id-fqdn>	Specify the FQDN of a peer to make the controller a responder for one specific initiator only.	—	—
pre-connect	Enables or disables pre-connection.	enable/ disable	disabled
set ikev1-policy <policy-v1-number>	Select an IKEv1 policy for the ipsec-map. Predefined policies are described in the table below.	—	—
set ikev2-policy <policy-v2-number>	Select IKEv2 policy for the ipsec-map. Predefined policies are described in the table below.	—	—
set ca-certificate <cacert-name>	User-defined name of a trusted CA certificate installed in the controller. Use the show crypto-local pki TrustedCA command to display the CA certificates that have been imported into the controller.	—	—
set pfs	If you enable Perfect Forward Secrecy (PFS) mode, new session keys are not derived from previously used session keys. Therefore, if a key is compromised, that compromised key will not affect any previous session keys. To enable this feature, specify one of the following Perfect Forward Secrecy modes:	group1 group2 group14 group19 group20	disabled

Parameter	Description	Range	Default
	group1 : 768-bit Diffie Hellman prime modulus group. group2: 1024-bit Diffie Hellman prime modulus group. group14: 2048-bit Diffie Hellman prime modulus group. group19: 256-bit random Diffie Hellman ECP modulus group. (For IKEv2 only) group20: 384-bit random Diffie Hellman ECP modulus group. (For IKEv2 only)		
set security-association lifetime	Configures the lifetime for the security association (SA).		
set seconds <seconds>	In seconds	300-86400	7200 seconds
kilobytes <kilobytes>	In kilobytes	1000 - 1000000000	—
set server-certificate <cert-name>	User-defined name of a server certificate installed in the controller. Use the show crypto-local pki ServerCert command to display the server certificates that have been imported into the controller.	—	—
set transform-set <name1>	Name of the transform set for this IPsec map. One transform set name is required, but you can specify up to four transform sets. Configure transform sets with the crypto ipsec transform-set command.	—	default-transform
src-net <ipaddr> <mask>	IP address and netmask for the source network.	—	—
trusted	Enables or disables a trusted tunnel.	enable/disable	disabled
version v1 v2	Select the IKE version for the IPsec map. v1: IKEv1 v2: IKEv2		v1
vlan <vlan>	VLAN ID. Enter 0 for the loopback.	1-4094	—

Usage Guidelines

You can use controllers instead of VPN concentrators to connect sites at different physical locations.

You can configure separate CA and server certificates for each site-to-site VPN. You can also configure the same CA and server certificates for site-to-site VPN and client VPN. Use the **show crypto-local ipsec-map** command to display the certificates associated with all configured site-to-site VPN maps; use the **tag <map>** option to display certificates associated with a specific site-to-site VPN map.

ArubaOS supports site-to-site VPNs with two statically addressed controllers, or with one static and one dynamically addressed controller. By default, site-to-site VPN uses IKE Main-mode with Pre-Shared-Keys to authenticate the IKE SA. This method uses the IP address of the peer, and therefore will not work for dynamically addressed peers.

To support site-site VPN with dynamically addressed devices, you must enable IKE Aggressive-Mode with Authentication based on a Pre-Shared-Key. A controller with a dynamic IP address must be configured to be the initiator of IKE Aggressive-mode for Site-Site VPN, while the controller with a static IP address must be configured as the responder of IKE Aggressive-mode.

Understanding Default IKE policies

ArubaOS includes the following default IKE policies. These policies are predefined and cannot be edited.

Table 6: *Default IKE Policy Settings*

Policy Name	Policy Number	IKE Version	Encryption Algorithm	Hash Algorithm	Authentication Method	PRF Method	Diffie-Hellman Group
Default protection suite	10001	IKEv1	3DES-168	SHA 160	Pre-Shared Key	N/A	2 (1024 bit)
Default RAP Certificate protection suite	10002	IKEv1	AES -256	SHA 160	RSA Signature	N/A	2 (1024 bit)
Default RAP PSK protection suite	10003		AES -256	SHA 160	Pre-Shared Key	N/A	2 (1024 bit)
Default RAP IKEv2 RSA protection suite	10004	IKEv2	AES -256	SSHA160	RSA Signature	hmac-sha1	2 (1024 bit)
Default Cluster PSK protection suite	10005	IKEv1	AES -256	SHA160	Pre-Shared Key	Pre-Shared Key	2 (1024 bit)

Policy Name	Policy Number	IKE Version	Encryption Algorithm	Hash Algorithm	Authentication Method	PRF Method	Diffie-Hellman Group
Default IKEv2 RSA protection suite	1006	IKEv2	AES - 128	SHA 96	RSA Signature	hmac-sha1	2 (1024 bit)
Default IKEv2 PSK protection suite	10007	IKEv2	AES - 128	SHA 96	Pre-shared key	hmac-sha1	2 (1024 bit)
Default Suite-B 128bit ECDSA protection suite	10008	IKEv2	AES - 128	SHA 256-128	ECDSA-256 Signature	hmac-sha2-256	Random ECP Group (256 bit)
Default Suite-B 256 bit ECDSA protection suite	10009	IKEv2	AES -256	SHA 384-192	ECDSA-384 Signature	hmac-sha2-384	Random ECP Group (384 bit)
Default Suite-B 128bit IKEv1 ECDSA protection suite	10010	IKEv1	AES-GCM-128	SHA 256-128	ECDSA-256 Signature	hmac-sha2-256	Random ECP Group (256 bit)
Default Suite-B 256-bit IKEv1 ECDSA protection suite	10011	IKEv1	AES-GCM-256	SHA 256-128	ECDSA-256 Signature	hmac-sha2-256	Random ECP Group (256 bit)

When using a default IKE (V1 or V2) policy for an IPsec map, the priority number should be the same as the policy number.

Examples

The following commands configures site-to-site VPN between two controllers:

```
(host) (config) #crypto-local ipsec-map sf-chi-vpn 100
src-net 101.1.1.0 255.255.255.0
dst-net 100.1.1.0 255.255.255.0
peer-ip 172.16.0.254
vlan 1
trusted
```

```
(host) (config) #crypto-local ipsec-map chi-sf-vpn 100
src-net 100.1.1.0 255.255.255.0
dst-net 101.1.1.0 255.255.255.0
peer-ip 172.16.100.254
vlan 1
trusted
```

For a dynamically addressed controller that initiates IKE Aggressive-mode for Site-Site VPN:

```
(host) (config) crypto-local ipsec-map <name> <priority>
src-net <ipaddr> <mask>
dst-net <ipaddr> <mask>
peer-ip <ipaddr>
local-fqdn <local_id_fqdn>
vlan <id>
pre-connect enable|disable
trusted enable
```

For the Pre-shared-key:

```
crypto-local isakmp key <key> address <ipaddr> netmask <mask>
```

For a static IP controller that responds to IKE Aggressive-mode for Site-Site VPN:

```
(host) (config) crypto-local ipsec-map <name2> <priority>
src-net <ipaddr> <mask>
dst-net <ipaddr> <mask>
peer-ip 0.0.0.0
peer-fqdn fqdn-id <peer_id_fqdn>
vlan <id>
trusted enable
```

For the Pre-shared-key:

```
crypto-local isakmp key <key> fqdn <fqdn-id>
```

For a static IP controller that responds to IKE Aggressive-mode for Site-Site VPN with One PSK for All FQDNs:

```
(host) (config) crypto-local ipsec-map <name2> <priority>
src-net <ipaddr> <mask>
peer-ip 0.0.0.0
peer-fqdn any-fqdn
vlan <id>
trusted enable
```

For the Pre-shared-key for All FQDNs:

```
crypto-local isakmp key <key> fqdn-any
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The peer-cert-dn and peer-fqdn parameters were introduced. The set pfs command introduced the group19 and group20 parameters.
ArubaOS 6.3	The set security-association lifetime kilobytes and Diffie-Hellman set pfs group 14 parameters were added.

Release	Modification

Command Information

Platforms	Licensing	Command Mode
All platforms	The group19 and group20 PFS options requires the Advanced Cryptography (ACR) license. All other parameters are available in the base operating system.	Config mode on master controllers

crypto-local isakmp ca-certificate

crypto-local isakmp ca-certificate <cacert-name>

Description

This command assigns the Certificate Authority (CA) certificate used to authenticate VPN clients.

Syntax

Parameter	Description
ca-certificate	User-defined name of a trusted CA certificate installed in the controller. Use the show crypto-local pki TrustedCA command to display the CA certificates that have been imported into the controller.

Usage Guidelines

You can assign multiple CA certificates. Use the **show crypto-local isakmp ca-certificate** command to view the CA certificates associated with VPN clients.

Example

This command configures a CA certificate:

```
crypto-local isakmp ca-certificate TrustedCA1
```

Command History

This command was introduced in ArubaOS 3.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

crypto-local isakmp certificate-group

```
crypto-local isakmp certificate-group server-certificate <server_certificate> ca-certificate <ca_cert-name>
```

Description

The command configures an IKE Certificate Group for VPN Clients.

Syntax

Parameter	Description	Range	Default
server-certificate <server_certificate>	The IKE server certificate name for VPN clients.	1-64 characters	—
ca-certificate <ca_cert-name>	The IKE CA Certificate for this server certificate.	1-64 characters	—

Usage Guidelines

This feature allows you to create a certificate group so you can access multiple types of certificates on the same controller.

Example

This command configures a certificate group that consists of server certificate named newtest with the CA certificate TrustedCA.

```
crypto-local isakmp certificate-group server-certificate newtest ca-certificate TrustedCA
```

Command History

This command was introduced in ArubaOS 6.1.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

crypto-local isakmp disable-aggressive-mode

crypto-local isakmp disable-aggressive-mode

Description

The command disables the IKEv1 aggressive mode.

Syntax

No parameters.

Usage Guidelines

The master-local communication by default uses IPsec aggressive mode when a PSK is used for authentication between controllers. You need to convert master-local communication to certificate-based IPsec authentication before disabling aggressive mode.

Disabling Aggressive Mode will impact other sessions which use aggressive mode such as Master-local IKE session with PSK.

Example

```
crypto-local isakmp disable-aggressive-mode
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

crypto_local isakmp disable-ipcomp

crypto-local isakmp disable-ipcomp

Description

This command disables IP compression on the master controller.

Syntax

No parameters.

Usage Guidelines

When this hardware-based compression feature is enabled, the quality of unencrypted traffic (such as Lync or Voice traffic) is not compromised by increased latency or decreased throughput.

Use this command to disable IP compression on a master controller in a master/local topology.

To disable IP compression on a branch controller, use the Smart Config WebUI. On the branch controller, navigate to **Configuration > BRANCH > Smart Config**.

Example

```
(boc_host) (config) #crypto-local isakmp disable-ipcomp
```

Command History

	Modification
ArubaOS 6.4.3.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

crypto-local isakmp dpd

```
crypto-local isakmp dpd idle-timeout <seconds> retry-timeout <seconds> retry-attempts <number>
```

Description

This command configures IKE Dead Peer Detection (DPD) on the local controller.

Syntax

Parameter	Description	Range	Default
idle-timeout	Idle timeout, in seconds.	10-3600	22 seconds
retry-timeout	Retry interval, in seconds.	2-60	2 seconds
retry-attempts	Number of retry attempts.	3-10	3

Usage Guidelines

DPD is enabled by default on the controller for site-to-site VPN.

Example

This command configures DPD parameters:

```
crypto-local isakmp dpd idle-timeout 60 retry-timeout 3 retry-attempts 5
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master and local controllers

crypto-local isakmp key

```
crypto-local isakmp key <key> {address <peer-ipaddr> netmask <mask>}|{fqdn <ike-id-fqdn>}|fqdn-any
```

Description

This command configures the IKE preshared key on the local controller for site-to-site VPN.

Syntax

Parameter	Description
key <key>	IKE preshared key value, between 6-64 characters. To configure a pre-shared key that contains non-alphanumeric characters, surround the key with quotation marks. For example: crypto-local isakmp key "key with spaces" fqdn-any .
address <peer-ipaddr>	IP address for the preshared key.
netmask <mask>	Netmask for the preshared key.
fqdn <ike-id-fqdn>	Configure the PSK for the specified FQDN.
fqdn-any	Configure the PSK for any FQDN.

Usage Guidelines

This command configures the IKE preshared key.

Example

The following command configures an IKE preshared key for site-to-site VPN:

```
crypto-local isakmp key R8nD0mK3y address 172.16.100.1 netmask 255.255.255.255
```

Command History

Version	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 3.4	The fqdn and fqdn-any parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master and local controllers

crypto-local isakmp permit-invalid-cert

crypto-local isakmp permit-invalid-cert

Description

This command allows invalid or expired certificates to be used for site-to-site VPN.

Syntax

No parameters.

Usage Guidelines

This command allows invalid or expired certificates to be used for site-to-site VPN.

Command History

This command was introduced in ArubaOS 3.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master and local controllers

crypto-local isakmp sa-cleanup

crypto-local isakmp sa-cleanup

Description

This command enables the cleanup of IKE SAs.

Syntax

No parameters.

Usage Guidelines

This command removes expired ISAKMP SAs from the controller.

Command History

This command was introduced in ArubaOS 6.1.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master and local controllers

crypto-local isakmp server-certificate

crypto-local isakmp server-certificate <cert-name>

Description

This command assigns the server certificate used to authenticate the controller for VPN clients using IKEv1 or IKEv2

Syntax

Parameter	Description
server-certificate	User-defined name of a server certificate installed in the controller. Use the show crypto-local pki ServerCert command to display the server certificates that have been imported into the controller.

Usage Guidelines

This certificate is only for VPN clients and not for site-to-site VPN clients. You can assign separate server certificate for use with VPN clients using IKEv1 and clients using IKEv2. Use the **show crypto-local isakmp server-certificate** command to view the server certificate associated with VPN clients. You must import and configure server certificates separately on master and local controllers.

There is a default server certificate installed in the controller, however this certificate does not guarantee security for production networks. Best practices is to replace the default certificate with a custom certificate issued for your site or domain by a trusted CA. You can use the WebUI to generate a Certificate Signing Request (CSR) to submit to a CA and then import the signed certificate received from the CA into the controller. For more information, see "Managing Certificates" in the *Dell Networking W-Series ArubaOS User Guide*.

Example

This command configures a server certificate:

```
crypto-local isakmp server-certificate MyServerCert
```

Command History

This command was introduced in ArubaOS 3.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master and local controllers

crypto-local isakmp xauth

`crypto-local isakmp xauth`

Description

This command enables IKE XAuth for VPN clients.

Syntax

No parameters.

Usage Guidelines

The **no crypto-local isakmp xauth** command disables IKE XAuth for VPN clients. This command only applies to VPN clients that use certificates for IKE authentication. If you disable XAuth, then a VPN client that uses certificates will not be authenticated using username/password. You must disable XAuth for Cisco VPN clients using CAC Smart Cards.

Example

This command disables IKE XAuth for Cisco VPN clients using CAC Smart Cards:

```
no crypto-local isakmp xauth
```

Command History

This command was introduced in ArubaOS 3.2.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master and local controllers

crypto-local pki

```
crypto-local pki
  CRL <name> <filename>
  IntermediateCA <name> <filename>
  OCSPResponderCert <certname> <filename>
  OCSPSignerCert <certname> <filename>
  PublicCert <name> <filename>
  ServerCert <name> <filename>
  TrustedCA <name> <filename>
  global-ocsp-signer-cert
  rcp <name>
```

Issue this command to configure a local certificate, OCSP signer or responder certificate and Certificate Revocation List (CRL). You can also list revocation checkpoints and enable the responder service.

Syntax

Parameter	Description
CRL	Specifies a Certificate Revocation list. Validation of the CRL is done when it imported through the WebUI (requires the CA to have been already present). CRLs can only be imported through the WebUI.
<name>	Name of the CRL.
<filename>	Original imported filename of the CRL.
IntermediateCA	Configures an intermediate CA certificate
<name>	Name of the intermediate CA certificate.
<filename>	Original imported filename of the CRL.
OCSPResponderCert	Configures a OCSP responder certificate.
<certname>	Name of responder certificate.
<filename>	Original imported filename of the responder certificate.
OCSPSignerCert	Configures a OCSP signer certificate.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.
PublicCert	Public key of a certificate. This allows an application to identify an exact certificate.
<certname>	Name of the signer certificate.

Parameter	Description
<filename>	Original imported filename of the signer certificate.
ServerCert	Server certificate. This certificate must contain both a public and a private key (the public and private keys must match). You can import a server certificate in either PKCS12 or x509 PEM format; the certificate is stored in x509 PEM DES encrypted format on the controller.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.
TrustedCA	Trusted CA certificate. This can be either a root CA or intermediate CA. Dell encourages (but does not require) an intermediate CA's signing CA to be the controller itself.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.
global-ocsp-signer-cert	Specifies the global OCSP signer certificate to use when signing OCSP responses if there is no check point specific OCSP signer certificate present. If the ocsp-signer-cert is not specified, OCSP responses are signed using the global OCSP signer certificate. If this is not present, than an error message is sent out to clients. NOTE: The OCSP signer certificate (if configured) takes precedence over the global OCSP signer certificate as this is check point specific.
rcp <name>	Specifies the revocation check point. A revocation checkpoint is automatically created when a TrustedCA or IntermediateCA certificate is imported on the controller.
service-ocsp-responder	This is a global knob that turns the OCSP responder on or off. The default is off (disabled). To enable this option a CRL must be configured for this revocation checkpoint as this is the source of revocation information in the OCSP responses.

Usage Guidelines

This command lets you configure the controller to perform real-time certificate revocation checks using the Online Certificate Status Protocol (OCSP) or traditional certificate validation using the Certificate Revocation List (CRL) client. Refer to the *Certificate Revocation* chapter in the *Dell Networking W-Series ArubaOS 6.4.x User Guide* for more information on how to configure this feature using both the WebUI and CLI.

Example

This example configures the controller as an OCSP responder.

The revocation check point is specified as CARoot. (The revocation check point CARoot was automatically created when the CARoot certificate was previously uploaded to this controller.) The OCSP signer certificate is RootCA-Ocsp_signer. The CRL file is Security1-WIN-05PRNGEKA0-CA-unrevoked.crl The OCSP responder is enabled.

```
crypto-local pki service-ocsp-responder
crypto-local pki rcp CARoot
```

```
ocsp-signer-cert RootCA-Ocsp_signer
crl-location file Security1-WIN-05PRGNGEKAO-CA-unrevoked.crl
enable-ocsp-responder
```

Related Commands

Command	Description	Mode
crypto-local pki rcp	Specifies the certificates that are used to sign OSCP responses for this revocation check point	Config mode
show crypto-local pki	This command shows local certificate, OSCP signer or responder certificate and CRL data and statistics.	Config mode

Command History

Version	Modification
ArubaOS 3.2	Command introduced.
ArubaOS 6.1	The following parameters were introduced: • CRL • Intermediate CA • OCSPResponderCert • OCSPSignerCert • global-ocsp-signer-cert • rcp • service-ocsp-responder

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

crypto-local pki rcp

crypto-local pki rcp

```
<name> [crl-location <file>][enable-ocsp-responder][ocsp-responder-cert <ocsp-responder-  
cert>][ocsp-signer-cert <ocsp-signer-cert>]  
[ocsp-url <ocsp-url>][revocation-check [None|<method1>|<method2>]]
```

Description

Use this command to specify the certificates used to sign OCSF for the revocation check point.

Syntax

Parameter	Description
rcp	Specifies the revocation check point. A revocation checkpoint is automatically created when a TrustedCA or IntermediateCA certificate is imported on the controller.
crl-location <file>	Location of the CRL that is used for the rcp. The specified CRL filename must be previously imported onto the controller before using this option.
enable-ocsp-responder	Enables the OCSF Responder for this revocation checkpoint. The default is disabled.
ocsp-responder-cert <ocsp-responder-cert>	Specifies the certificate that is used to verify OCSF responses. The certificate name has to be one of the certificates shown as output when the CLI command <code>show crypto-local pki ocsfrespondercert</code> is used.
ocsp-signer-cert <ocsp-signer-cert>	Specifies the certificate that is used to sign OCSF responses for this revocation check point. The OCSF signer certificate must be previously imported on to the controller (using the WebUI). The OCSF signer cert can be the same trusted CA as the check point, a designated OCSF signer certificate issued by the same CA as the check point or some other local trusted authority. If the ocsp-signer-cert is not specified, OCSF responses are signed using the global OCSF signer certificate. If that is not present, than an error message is sent out to clients. NOTE: The OCSF signer certificate (if configured) takes precedence over the global OCSF signer certificate as this is check point specific.
ocsp-url <ocsp-url>	Configures the OCSF Server URL. The URL has to be in the form of <code>http://my.responder.com/path</code> . This parameter can contain only one responder URL at time.

Parameter	Description
<code>revocation-check None <method1> <method2></code>	Configures the revocation check methods used for this rcp. Options include: • None (default)- No revocation checks are performed for certificates being verified against this trusted CA. • CRL- CRL is used for the revocation check method. • OCSP- OCSP is used for the revocation check method. You can configure one fallback method.

Usage Guidelines

This command lets you configure the check methods that are used for this revocation check point.. You can configure the controller to perform real-time certificate revocation checks using the Online Certificate Status Protocol (OCSP) or traditional certificate validation using the Certificate Revocation List (CRL) client. Refer to the *Certificate Revocation* chapter in the *Dell Networking W-Series ArubaOS 6.4.x User Guide* for more information on how to configure this feature using both the WebUI and CLI.

Example

This example configures an OCSP client with the revocation check method as OCSP with CRL configured as the back up method.

The OCSP responder certificate is configured as RootCA-Ocsp_responder. The corresponding OCSP responder service is available at <http://10.4.46.202/ocsp>. The revocation check method is OCSP with CRL configured as the back up method.

```
crypto-local pki rcp CARoot
ocsp-responder-cert RootCA-Ocsp_responder
ocsp-url http://10.4.46.202/ocsp
crl-location file Security1-WIN-05PRNGEKA0-CA-unrevoked.crl
revocation-check ocsp crl
```

crypto map global-map

```
crypto map global-map <map-number> ipsec-isakmp {dynamic <dynamic-map-name>}|{ipsec <ipsec-map-name>}
```

Description

This command configures the default global map.

Syntax

Parameter	Description
<map-number>	
dynamic	Use a dynamic map.
<dynamic-map-name>}	Name of the dynamic map.
ipsec	Use a IPsec map.
<ipsec-map-name>	Name of an IPsec map.

Usage Guidelines

This command identifies the dynamic or ipsec map used as the default global map. If you have not yet defined a dynamic or ipsec map, issue the command [crypto map global-map](#) or [crypto-local ipsec-map](#) to define map parameters.

Example

The following command configures the global map with the dynamic map named *dynamic_map_2*.

```
(host)(config) #crypto map global-map 2 ipsec-isakmp dynamic dynamic_map_2
```

Command History

This command was introduced in ArubaOS 3.0

Command Information

Platforms	Licensing	Command Mode

crypto

crypto pki

```
csr {rsa key_len <key_val> |{ec curve-name <key_val>} common_name <common_val> country  
<country_val> state_or_province <state> city <city_val> organization <organization_val>  
unit <unit_val> email <email_val>
```

```
expirycheck
```

Description

Generate a certificate signing request (CSR) for the captive portal feature.

Syntax

Parameter	Description
rsa key_len <key_val>	Generate a certificate signing request with a Rivest, Shamir and Adleman (RSA) key with one of the following supported RSA key lengths: • 1024 • 2048 • 4096
ec curve-name <key_val>	Generate a certificate signing request with an elliptic-curve (EC) key, with one of the following EC types: • secp256r1 • secp384r1
common_name <common_val>	Specify a common name, e.g., www.yourcompany.com.
country <country_val>	Specify a country name, e.g., US or CA.
state_or_province <state>	Specify the name of a state or province.
city <city_val>	Specify the name of a city.
organization <organization_val>	Specify the name of an organization unit, e.g., sales.
unit <unit_val>	Specify a unit value, e.g. EMEA.
email <email_val>	Specify an email address, in the format name@mycompany.com.
expirycheck	Run an expiry check on all certificates on the controller.

Usage Guidelines

Use this command in enable mode to generate a CSR for the Captive Portal feature or to see all controller certificates are expiring.

Display the CSR output by entering the command **show crypto pki csr**.

Example

The following command configures a CSR for a user with the email address *jdoe@example.com*.

```
(host)(config) #crypto pki csr key 1024 common_name www.example.lcom country US state_or_province ca city Sunnyvale organization engineering unit pubs email jdoe@example.com
```

Command History

Release	Modification
ArubaOS 3.1	Command introduced.
ArubaOS 6.1	The ec curve-name parameter was introduced to support certificate signing requests using an elliptic-curve (EC) key

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

crypto pki-import

```
crypto pki-import {der|pem|pfx|pkcs12|pkcs7}  
{CRL|IntermediateCA|OCSPResponderCert|OCSPSignerCert|PublicCert|ServerCert|TrustedCA} <name>
```

Description

Import certificates for the captive portal feature.

Syntax

Parameter	Description
der	Import the following certificates in DER format.
CRL <name>	Import a CRL.
IntermediateCA <name>	Import an intermediate CA certificate.
OCSPResponderCert <name>	Import an OCSP Responder certificate.
OCSPSignerCert <name>	Import an OCSP Signer certificate.
PublicCert <name>	Import a public certificate.
ServerCert <name>	Import a server certificate.
TrustedCA <name>	Import a trusted CA certificate.
pem	Import a certificate in x509 PEM format. See certificate types under the der parameter.
pfx	Import a certificate in PFX format. See certificate types under the der parameter.
pkcs12	Import a certificate in PKCS12 format. See certificate types under the der parameter.
pkcs7	Import a certificate in PKCS7 format. See certificate types under the der parameter.

Usage Guidelines

Use this command in enable mode to install a CSR for the Captive Portal feature.

Example

The following command installs a server certificate in DER format.

```
(host)(config) #crypto pki-import der ServerCert cert_20
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The CRL , IntermediateCA , OCSPResponderCert , OCSPSignerCert parameters were added.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

database synchronize

database synchronize period <minutes>|captive-portal-custom

Description

This command manually synchronizes the database between a pair of redundant master controllers

Syntax

Parameter	Description
captive-portal custom	Includes custom captive portal files..
period	Configures the interval for automatic database synchronization.
<minutes>	Interval in minutes. Range is 1 — 25200 minutes.

Usage Guidelines

This command takes effect immediately. If a peer is not configured, the controller displays an error message.

Use the **database synchronize period** command in config mode to configure the interval for automatic database synchronization. Use the **database synchronize rf-plan-data** command to include RF plan data when synchronizing in standby mode.

Example

The following commands cause the database on the active master controller to synchronize with the standby in 25 minute intervals. The synchronization includes RF plan data.

```
(host) (config) #database synchronize period 25
```

Command History

Version	Description
ArubaOS 3.0	Command introduced.
ArubaOS 6.3	The captive-portal-custom parameter was introduced. The parameter rf-plan-data is deprecated.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable and Config modes on master controllers

delete

```
delete {filename <filename>|ssh-host-addr <ipaddr>|ssh-known-hosts}
```

Description

This command deletes a file or RSA signature entry from flash.

Syntax

Parameter	Description
filename	Name of the file to be deleted.
ssh-host-addr	Deletes the entry stored in flash for the RSA host signature created when you run the copy scp command.
ssh-known -hosts	Deletes all entries stored in flash for the RSA host signatures created when you run the copy scp command.

Usage Guidelines

To prevent running out of flash file space, you should delete files that you no longer need.

The **copy scp** command creates RSA signatures whenever it connects to a new host. These host signatures are stored in the flash file system.

Example

The following command deletes a file:

```
(host) #delete filename december-config-backup.cfg
```

The following command deletes an RSA signature entry from flash:

```
(host) #delete ssh-host-addr 10.100.102.101
```

The following command deletes all RSA signature entries from flash:

```
(host) #delete ssh-known-hosts
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master controllers

destination

destination <STRING> <A.B.C.D> [invert]

Description

This command configures the destination name and address.

Syntax

Parameter	Description	Range
STRING	Destination name.	Alphanumeric
A.B.C.D	Destination IP address or subnet.	—
invert	Specifies all destinations except this one.	—

Usage Guidelines

You can configure the name and IP address of the destination. You can optionally configure the subnet, or invert the selection.

Example

The following example configures a destination called “Home” with an IP address of 10.10.10.10.

```
(host) (config) #destination Home 10.10.10.10
```

Command History

Can be used only on the master controller.	Requires the PEF NG license	Config mode on master controllers

dialer group

```
dialer group <name>
dial-string <string>
init-string <string>
no ...
```

Description

Configure a dialer group with dialing parameters for a USB modem.

Syntax

Parameter	Description
dial-string	The dial string column specifies the number to dial.
init-string	The init string can contain carrier-specific dialing options for the USB modem. You can often find these settings in online forums or from your ISP.

Usage Guidelines

Use this command to configure dial settings for a USB modem connected to a W-600 Series controller.

Example

```
(host) (config) dialer group gsm_us
    init-string AT+CGDCONT=1,"IP","ISP.CINGULAR"
```

Command History

Introduced in ArubaOS 3.4.

Command Information

Platforms	Licensing	Command Mode
W-600 Series controllers	Base operating system	Config mode on master and local controllers

dir

dir

Description

This command displays a list of files stored in the flash file system.

Syntax

No parameters.

Usage Guidelines

Use this command to view the system files associated with the controller.

Output from this command includes the following:

- The first column contains ten place holders that display the file permissions.
 - First place holder: Displays `-` for a file or `d` for directory.
 - Next three place holders: Display file owner permissions: `r` for read access, `w` for write access permissions, `x` for executable.
 - Following three place holders: Display member permissions: `r` for read access or `x` for executable.
 - Last three place holders: Display non-member permissions: `r` for read access or `x` for executable.
- The second column displays the number of links the file has to other files or directories.
- The third column displays the file owner.
- The fourth column displays group/member information.
- The remaining columns display the file size, date and time the file was either created or last modified, and the file name.

Example

The following command displays the files currently residing on the system flash:

```
(host) #dir
```

The following is sample output from this command:

```
-rw-r--r-- 1 root root 9338 Nov 20 10:33 class_ap.csv
-rw-r--r-- 1 root root 1457 Nov 20 10:33 class_sta.csv
-rw-r--r-- 1 root root 16182 Nov 14 09:39 config-backup.cfg
-rw-r--r-- 1 root root 14174 Nov 9 2005 default-backup-11-8-05.cfg
-rw-r--r-- 1 root root 16283 Nov 9 12:25 default.cfg
-rw-r--r-- 1 root root 22927 Oct 25 12:21 default.cfg.2006-10-25_20-21-38
-rw-r--r-- 2 root root 19869 Nov 9 12:20 default.cfg.2006-11-09_12-20-22
```

Command History

Introduced in ArubaOS 1.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable and Config modes on local or master controllers

disable-whitelist-sync

disable-whitelist-sync

Description

This command disables whitelist synchronization with local or Cloud Services Controller on the master controller. Whitelist database synchronization is enabled by default.

Syntax

No parameters.

Usage Guidelines

By default, the whitelist database synchronization is enabled between the master and local or cloud services controller. Once the whitelist database entries are synchronized across all controllers, issue the **disable-whitelist-sync** command on the master controller to disable the synchronization. Configuring this parameter reduces the number of database queries on the master controller.

Enable this parameter to synchronize the whitelist database with all local or Cloud Services controllers. Once synchronized, issue the **disable-whitelist-sync** command to disable the synchronization. Enabling this parameter may increase the number of database queries on the master controller. Use this command when the number of APs and local or Cloud Services controllers is high in the network.

Enabling the whitelist database synchronization may increase the **mysqldb** process CPU utilization on the master controller if there is a large number of whitelist entries and local or cloud services controllers terminating on the master.

Example

The following command disables whitelist synchronization.

```
(host) (config) #disable-whitelist-sync
Whitelist sync has been disabled
```

The following command re-enables whitelist synchronization if it was manually disabled.

```
(host) (config) #no disable-whitelist-sync
Whitelist sync has been enabled
```

Command History

Version	Description
ArubaOS 6.4.3.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controller.

dot1x

```
high-watermark <1-32000>  
stm-throttling percent <throttling%>  
no ...
```

Use this command only under the supervision of Dell support.

Description

Use this command under the guidance of Dell support to configure the maximum and minimum thresholds of the table that contains 802.1X sessions being processed.

Syntax

Parameter	Description
high-watermark	The maximum entries in the Active table. When the number of entries in the Active Table reaches the High WaterMark value, new requests are queued on the Pending Table
stm-throttling	Use this command to enable STM throttling when the total entries in Pending Table are greater than (stm-throttling perceng) * (high watermark).

Command History

Introduced in ArubaOS 6.3.1.0

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master or local controllers

dpi

dpi

```
custom-app <name> <http/s uri host> <http/s uri path>
global-bandwidth-contract {app <name>[downstream |upstream] [kbits|mbits <value>}} |
{appcategory <name>[downstream |upstream] [kbits|mbits <value>}}
```

Description

This command configures Deep-Packet Inspection and the global bandwidth contract for an application or application category for the AppRF feature.

Syntax

Parameter	Description
custom-app	The application or application category.
<name>	Name of the application or application category.
<http/s uri host>	HTTP or HTTPS URI host of the application or application category.
<http/s uri path>	HTTP or HTTPS URI path of the application or application category.
global-bandwidth-contract	Configures the global bandwidth contract for an application or application category.
app <name>	Name of the application. For a complete list of supported applications, issue the command show dpi application all .
appcategory <name>	Name of the application category. For a complete list of supported application categories, issue the command show dpi application category all .
downstream	Bandwidth contract to downstream traffic.
upstream	Bandwidth contract to upstream traffic.
kbits <value>	Specify bandwidth in kbits per second. Range: 256-2000000.
mbits <value>	Specify bandwidth in mbits per second. Range: 1-2000.

Usage Guidelines

You can configure bandwidth contracts to limit application and application categories on an application or global level.

Example

To configure global bandwidth contracts:

```
(host) (config) #dpi global-bandwidth-contract [app|appcategory]
<name> [downstream|upstream] [kbits|mbits] <256..2000000>
```

To show global bandwidth contract configuration output:

```
(host) #show dpi global-bandwidth-contract all
(host) #show dpi global-bandwidth-contract app name
(host) #show dpi global-bandwidth-contract appcategory name
```

Command History

Introduced in ArubaOS 6.4

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on local or master controllers

dynamic-ip

dynamic-ip restart

Description

This command restarts the PPPoE or DHCP process.

Syntax

No parameters.

Usage Guidelines

This command can be used to renegotiate DHCP or PPPoE parameters. This can cause new addresses to be assigned on a VLAN where the DHCP or PPPoE client is configured.

Command History

This command was introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers

eject usb

eject usb:

Description

Use this command to eject a USB device from your controller.

Usage Guidelines

Use this command to safely remove an external USB device,

Example

```
(host) #eject usb:
```

Command History

Command introduced in ArubaOS 6.2

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	User mode on master or local controllers in enable mode.

enable

enable

Description

This user mode command switches the controller into enable mode. The enable mode allows you to access privileged commands.

Usage Guidelines

To enter enable mode, you are prompted for the password configured during the controller's initial setup. Passwords display as asterisks (*) when you enter them.

To change the password, use the config mode [enable secret](#) command. If you lose or forget the enable mode password, resetting the default admin user password also resets the enable mode password to "enable". See the *Dell Networking W-Series ArubaOS User Guide* for more information about resetting the admin and enable mode passwords.

When you are in enable mode, the CLI prompt ends with the hash (#) character.

Example

The following example allows you to enter enable mode on the controller.

```
(host) >enable
Password: *****
(host) #
```

Command History

Command introduced in ArubaOS 1.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	User mode on master or local controllers

enable bypass

```
enable bypass
no enable bypass
```

Description

This config mode command allows you to bypass the enable password prompt and go directly to the privileged command mode.

Usage Guidelines

Use this command when you want to access the privileged mode directly after logging in to the controller and not be prompted to enter an enable mode password.

To restore the enable mode password prompt, use the config mode command. `no enable bypass`.

Example

The following example allows bypass the enable mode password prompt.

```
(host) #configure terminal
Enter Configuration commands, one per line. End with CNTL/Z
```

```
(host) (config) #enable bypass
(host) (config) #
```

Command History

Version	Modification
ArubaOS 6.0	Command introduced

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master or local controllers

enable secret

enable secret

Description

This config mode command allows you to change the password for enable mode.

Usage Guidelines

Use this command to change the password for enable mode. To reset the password to the factory default of "enable", use the `no enable` command.

The password must not contain a space and special characters.

Example

The following example allows you to change the password for enable mode.

```
(host) #configure terminal
Enter Configuration commands, one per line. End with CNTL/Z

(host) (config) #enable secret
Password:*****
Re-Type password: *****
(host) (config) #
```

Command History

Version	Modification
ArubaOS 1.0	Command introduced
ArubaOS 3.3.2	Updated with restriction of the secret phase

Command Informatio

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master or local controllers

encrypt

encrypt {disable|enable}

Description

This command allows passwords and keys to be displayed in plain text or encrypted.

Syntax

Parameter	Description	Default
disable	Passwords and keys are displayed in plain text	—
enable	Passwords and keys are displayed encrypted	enabled

Usage Guidelines

Certain commands, such as **show crypto isakmp key**, display configured key information. Use the **encrypt** command to display the key information in plain text or encrypted.

Example

The following command allows passwords and keys to be displayed in plain text:

```
(host) #encrypt disable
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master or local controllers

esi group

esi group <name> [no] [[ping <attributes>]] [server <server>]

Description

This command configures an ESI group.

Syntax

Parameter	Description
no	Negates any configured parameter.
ping	Specify the name of a set of ping checking attributes defined via the command esi ping . Only one set is allowed.
server	Specify the name of a server to be added or removed from the ESI group. You define ESI servers via the command esi server .

Usage Guidelines

Use the `show esi group` command to show ESI group information.

Example

The following command sets up the ESI group named “fortinet.”

```
(host) (config) #esi group fortinet
    ping default
    server forti_1
```

Command History

Introduced in ArubaOS 2.5

Command Information

Platform	License	Command Mode

esi parser domain

```
esi parser domain <name>
    [no] |
    [peer <peer-ip>] |
    [server <ipaddr>]
```

Description

This command configures an ESI syslog parser domain.

Syntax

Parameter	Description
no	Negates any configured parameter
peer	(Optional.) Specify the IP address of an another controller in this domain. These controllers are notified when the user cannot be found locally. This command is needed only when multiple controllers share a single ESI server
server	Specify the IP address of the ESI server to which the controller listens.

Usage Guidelines

The ESI parser is a generic syslog parser on the controller that accepts syslog messages from external third-party appliances such as anti-virus gateways, content filters, and intrusion detection systems. It processes syslog messages according to user-defined rules and takes configurable actions on the corresponding system users.

ESI servers (see [esi server on page 383](#)) are configured into domains to which ESI syslog parser rules (see [esi parser rule on page 377](#)) are applied.

Use the **show esi parser domains** command to show ESI parser domain information.

Example

The following commands configure a virus syslog parser domain named “fortinet” which contains the ESI server “forti_1” with the trusted IP address configured using the command [esi server](#).

```
(host) (config) #esi parser domain fortinet
server 10.168.172.3
```

Command History

Introduced in ArubaOS 3.1.

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master or local controllers

esi parser rule

```
esi parser rule <rule_name>
    [condition <expression>] |
    [domain <name>] |
    [enable]
    [match {ipaddr <expression> | mac <expression> | user <expression> }] |
    [no] |
    [position <position>] |
    [set {blacklist | role <role>} |
    [test {msg <msg> | file <filename>}]
```

Description

This command creates or changes an ESI syslog parser rule.

Syntax

Parameter	Description	Range	Default
condition	Specifies the REGEX (regular expression) pattern that uniquely identifies the syslog.	—	—
domain	(Optional.) Specify the ESI syslog parser domain to which this rule applies. If not specified, the rule matches with all configured ESI servers.	—	—
enables	Enables this rule. Note: The condition, user match, and set action parameters must be configured before the rule can be enabled.	—	Not enabled
match	Specifies the user identifier to match, where <code>ipaddr</code> , <code>mac</code> , and <code>user</code> take a REGEX pattern that uniquely identifies the user.	—	—
no	Negates any configured parameter.	—	—
position	Specifies the rule's priority position.	1–32; 1 highest	—
set	Specifies the action to take: blacklist the user or change the user role. Note: The role entity should be configured before it is accepted by the ESI rule.	—	—
test	Test the regular expression output configured in the <code>esi parser rules</code> command. You can test the expressions against a specified syslog message, or test the expression against a sequence of syslog messages contained in a file.	—	—

Usage Guidelines

The user creates an ESI rule by using characters and special operators to specify a pattern that uniquely identifies a syslog message. This “condition” defines the type of message and the ESI domain to which this message pertains. The rule contains three major fields:

- Condition: The pattern that uniquely identifies the syslog message type.
- User: The username identifier. It can be in the form of a name, MAC address, or IP address.
- Action: The action to take when a rule match occurs.

Once a condition match occurs, no further rule-matching will be made. For the matching rule, only one action can be defined.

For more details on the character-matching operators, repetition operators, and expression anchors used to define the search or match target, refer to the *External Services Interface* chapter in the *Dell Networking W-Series ArubaOS 6.4.x User Guide*.

Use the **show esi parser rules** command to show ESI parser rule information. Use the **show esi parser stats** command to show ESI parser rule statistical information

Examples

The following command sets up the Fortigate virus rule named “forti_rule.” This rule parses the virus detection syslog scanning for a condition match on the log_id value (log_id=) and a match on the IP address (src=).

```
(host) (config) #esi parser rule forti_rule
          condition "log_id=[0-9]{10}[ ]"
          match ipaddr "src=(.*)[ ]"
          set blacklist
          domain fortinet
          enable
```

In this example, the corresponding ESI expression is:

```
< Sep 26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4 >
```

The following example of the test command tests a rule against a specified single syslog message.

```
test msg "26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4"
```

```
< 26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4 >
=====
```

```
Condition:      Matched with rule "forti_rule"
User:           ipaddr = 1.2.3.4
=====
```

The following example of the test command tests a rule against a file named test.log, which contains several syslog messages.

```
test file test.log
```

```
< Sep 26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4 >
=====
```

```
Condition:      Matched with rule "forti_rule"
User:           ipaddr = 1.2.3.4
=====
```

```
< Oct 18 10:43:40 cli[627]: PAPI_Send: To: 7f000001:8372 Type:0x4 Timed out. >
=====
```

```
Condition:      No matching rule condition found
=====
```

```
< Oct 18 10:05:32 mobileip[499]: <500300> <DEBUG> |mobileip| Station 00:40:96:a6:a1:a4,
10.0.100.103: DHCP FSM received event: RECEIVE_BOOTP_REPLY current: PROXY_DHCP_NO_PROXY,
next: PROXY_DHCP_NO_PROXY >
=====
Condition:      No matching rule condition found
=====
```

Command History

Introduced in ArubaOS 3.1

Command Information

Platform	License	Command Mode
Available on all platforms.	Requires the PEFNG license	Config mode on master and local controllers

esi parser rule-test

```
esi parser rule-test
    [file <filename>] |
    [msg <msg>]
```

Description

This command allows you to test all of the enabled parser rules.

Syntax

Parameter	Description
file	Tests against a specified file containing more than one syslog message.
msg	Tests against a syslog message, where <msg> is the message text.

Usage Guidelines

You can test the enabled parser rules against a syslog message input, or run the expression through a file system composed of syslog messages. The command shows the match result as well as the user name parsed for each message.

Example

The following command tests against a specified single syslog message.

```
(host) (config) #esi parser rule-test msg "26 18:30:02 log_
id=0100030101 type=virus subtype=infected src=1.2.3.4"
```

```
< 26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4 >
=====
Condition:      Matched with rule "forti_rule"
User:          ipaddr = 1.2.3.4
=====
```

The following command tests against a file named test.log, which contains several syslog messages.

```
esi parser rule-test file test.log
```

```
< Sep 26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4 >
=====
Condition:      Matched with rule "forti_rule"
User:          ipaddr = 1.2.3.4
=====

< Oct 18 10:43:40 cli[627]: PAPI_Send: To: 7f000001:8372 Type:0x4 Timed out. >
=====
Condition:      No matching rule condition found
=====

< Oct 18 10:05:32 mobileip[499]: <500300> <DEBUG> |mobileip| Station 00:40:96:a6:a1:a4,
10.0.100.103: DHCP FSM received event: RECEIVE_BOOTP_REPLY current: PROXY_DHCP_NO_PROXY,
next: PROXY_DHCP_NO_PROXY >
=====
Condition:      No matching rule condition found
```

=====

Command History

Introduced in ArubaOS 3.1

Command Information

Platform	License	Command Mode

esi ping

```
esi ping <ping-name>
    [frequency <seconds>] |
    [no] |
    [retry-count <count>] |
    [timeout <seconds>] |
```

Description

This command specifies the ESI ping health check configuration.

Syntax

Parameter	Description	Range	Default
frequency	Specifies the ping frequency in seconds.	1-65536	
no	Negates any configured parameter	—	—
retry-count	Specifies the ping retry count	1-65536	2
timeout	Specifies the ping timeout in seconds.	1-65536	2

Usage Guidelines

Use the [show esi ping](#) command to show ESI ping information.

Example

The following command specifies the ping health check attributes.

```
(host) (config) #esi ping default
    frequency 5
    retry-count 2
    timeout 2
```

Command History

Introduced in ArubaOS 2.5

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master and local controllers

esi server

```
esi server <name>
    [dport <tcp-udp-port>] |
    [mode {bridge | nat | route}] |
    [no] |
    [trusted-ip-addr <ip-addr> [health-check]] |
    [trusted-port <slot/port>] |
    [untrusted-ip-port <ip-addr> [health-check]] |
    [untrusted-port <slot/port>]
```

Description

This command configures an ESI server.

Syntax

Parameter	Description
dport	Specifies the NAT destination TCP/UDP port.
mode	Specifies the ESI server mode of operation: bridge, nat, or route
no	Negates any configured parameter.
trusted-ip-addr	Specifies the server IP address on the trusted network. As an option, you can also enable a health check on the specified address
trusted-port	Specifies the port connected to the trusted side of the ESI server; slot/port format.
untrusted-ip-addr	Specifies the server IP address on the untrusted network. As an option, you can also enable a health check on the specified address
untrusted-port	Specifies the port connected to the untrusted side of the ESI server.

Usage Guidelines

Use the **show esi server** command to show ESI server information.

Example

The following command specifies the ESI server attributes.

```
(host) (config) #esi server forti_1
mode route
trusted-ip-addr 10.168.172.3
untrusted-ip-addr 10.168.171.3
```

Command History

Introduced in ArubaOS 2.5.

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master and local controllers

exit

exit

Description

This command exits the current CLI mode.

Syntax

No parameters.

Usage Guidelines

Upon entering this command in a configuration sub-mode, you are returned to the configuration mode. Upon entering this command in configuration mode, you are returned to the enable mode. Upon entering this command in enable mode, you are returned to the user mode. Upon entering this command in user mode, you are returned to the user login.

Example

The following sequence of **exit** commands return the user from the interface configuration sub-mode to the user login:

```
(host) (config-if) #exit
(host) (config) #exit
(host) #exit
(host) >exit
User:
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Available in the following command modes: • User • Enable • Config • Config sub-modes

export

```
export gap-db <filename>
```

Description

This command exports the global AP database to the specified file.

Syntax

Parameter	Description
<filename>	Name of the file to which the global AP database is exported.

Usage Guidelines

This command is intended for system troubleshooting. You should run this command only when directed to do so by a Dell support representative.

The global AP database resides on a master controller and contains information about known APs on all controllers in the system. You can view the contents of the global AP database with the **show ap database** command.

Example

The following command exports the global AP database to a file:

```
(host) #export gap-db global-ap-db
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

file syncing profile

```
file syncing profile
  file-syncing-enable
  no
  sync-time
```

Description

This command allows the user to configure the file syncing profile.

Syntax

Parameter	Description	Range	Default
file-syncing-enable	Enables file syncing on the controller.	—	enabled
no	Negates any configured parameter.	—	—
sync-time	Configures the time, in minutes, between file syncs.	30 - 180	30 minutes

Usage Guidelines

This command enables or disables the file syncing. Additionally, the time between syncs can be configured as part of the file syncing profile.

Example

The following example shows how to enable the file syncing.

```
(host) (config) #file syncing profile
(host) (File syncing profile) #file-syncing-enable
```

Command History

This command was introduced in ArubaOS 6.4.1.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers.

fips

fips [disable|enable]

This command applies only to the FIPS version of ArubaOS.

Description

This command enables and disables the FIPS mode of operation.

Syntax

Parameter	Description
enable	Enables the FIPS mode of operation.
disable	Disables the FIPS mode of operation.

Usage Guidelines

This command enables or disables the FIPS mode of operation. You can view the FIPS mode of operation status using the [show fips](#) command.

Example

The following example shows how to enable the FIPS mode of operation.

```
(host) #fips enable
```

Command History

This command was introduced in ArubaOS-FIPS 2.4.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

  session-voip-timeout
  shape-mcast
  stall-crash
  voip-wmm-content-enforcement
  web-cc
  web-cc-cache-miss-drop
```

Description

This command configures firewall options on the controller.

Syntax

Parameter	Description	Range	Default
allow-stun	Allows ICE-STUN based firewall traversal.	—	enabled
allow-tri-session	Allows three-way session when performing destination NAT. This option should be enabled when the controller is not the default gateway for wireless clients and the default gateway is behind the controller. This option is typically used for captive portal configuration.	—	disabled
amsdu	Aggregated Medium Access Control Service Data Units (AMSDU) packets are dropped if this option is enabled.	—	disabled
attack-rate arp <1-16384> {blacklist drop} cp <1-16384> grat-arp <1-16384> {blacklist drop} ping <1-16384> session <1-16384> tcp-syn <1-16384>	Sets rates which, if exceeded, can indicate a denial of service attack. • arp: Monitor/police ARP attack (non Gratuitous ARP). • cp: Monitor/police Control Processor (CP) attack. • grat-arp: Monitor/police Gratuitous ARP attack. • ping: Monitor ping attack. • session: Monitor IP session attack. • tcp-syn: Monitor TCP SYN attack. NOTE: <1-16384> denotes the number of arp, cp, grat-arp, ping, session, or tcp-syn requests per 30 seconds.	1-16384	—
bwcontracts-subnet-broadcast	Applies bw contracts to local subnet broadcast traffic.	—	—
cp	See firewall cp on page 398		
cp-bandwidth-contract	See firewall cp-bandwidth-contract on page 401		

Parameter	Description	Range	Default
deny-inter-user-bridging	Prevents the forwarding of Layer2 traffic between wired or wireless users. You can configure user role policies that prevent Layer3 traffic between users or networks but this does not block Layer2 traffic. This option can be used to prevent traffic, such as Appletalk or IPX from being forwarded. If enabled, traffic (all non-IP traffic) to untrusted port or tunnel is also blocked.	—	disabled
deny-inter-user-traffic	Denies downstream traffic between users in a wireless network (untrusted users) by disallowing layer2 and layer3 traffic. This parameter does not depend on the deny-inter-user-bridging parameter being enabled or disabled.	—	disabled
deny-source-routing	Disallows forwarding of IP frames with source routing with the source routing options set.	—	disabled
disable-ftp-server	Disables the FTP server on the controller. Enabling this option prevents FTP transfers. Enabling this option could cause APs to not boot up. You should not enable this option unless instructed to do so by a Dell representative.	—	disabled
disable-stateful-h323-processing	Disables stateful H.323 processing.	—	disabled
disable-stateful-sccp-processing	Disables SCCP processing.	—	disabled
disable-stateful-sip-processing	Disables monitoring of exchanges between a voice over IP or voice over WLAN device and a SIP server. This option should be enabled only when there is no VoIP or VoWLAN traffic on the network.	—	disabled

Parameter	Description	Range	Default
disable-stateful-sips-processing	Configure the controller to read SIP signaling messages sent by Lync clients on port 5061.	—	enabled
disable-stateful-ua-processing	Disables stateful UA processing.	—	disabled
disable-stateful-vocera-processing	Disables stateful VOCERA processing.	—	disabled
dpi	Enables Deep-Packet Inspection (DPI)	—	disabled
drop-ip-fragments	When enabled, all IP fragments are dropped. You should not enable this option unless instructed to do so by a Dell representative.	—	disabled
enable-bridging	Enables bridging when the controller is in factory default.	—	disabled
enable-per-packet-logging	Enables logging of every packet if logging is enabled for the corresponding session rule. Normally, one event is logged per session. If you enable this option, each packet in the session is logged. You should not enable this option unless instructed to do so by a Dell representative, as doing so may create unnecessary overhead on the controller.	—	disabled
enforce-tcp-handshake	Prevents data from passing between two clients until the three-way TCP handshake has been performed. This option should be disabled when you have mobile clients on the network as enabling this option will cause mobility to fail. You can enable this option if there are no mobile clients on the network.	—	disabled
enforce-tcp-sequence	Enforces the TCP sequence numbers for all packets.	—	disabled

Parameter	Description	Range	Default
gre-call-id-processing	Creates a unique state for each PPTP tunnel. Do not enable this option unless instructed to do so by a technical support representative.	—	disabled
imm-fb	Immediately free buffers on W-7200 controllers. Do not enable this option unless instructed to do so by a technical support representative.	—	—
jumbo	Enables jumbo frames processing.	—	disabled
local-valid-users	Adds only IP addresses, which belong to a local subnet, to the user-table.	—	disabled
log-icmp-error	Logs received ICMP errors. You should not enable this option unless instructed to do so by a Dell representative.	—	disabled
optimize-dad-frames	Reduce flooding of IPv4 Gratuitous ARPs/IPv6 Duplicate Address Detection (DAD) frames onto wireless clients.	—	enabled
prevent-dhcp-exhaustion	Enable check for DHCP client hardware address against the packet source MAC address. This command checks the frame's source-MAC against the DHCPv4 client hardware address and drops the packet if it does not match. Enabling this feature prevents a client from submitting multiple DHCP requests with different hardware addresses, thereby preventing DHCP pool depletion.	—	disabled
prohibit-arp-spoofing	Detects and prohibits arp spoofing. When this option is enabled, possible arp spoofing attacks are logged and an SNMP trap is sent.	—	disabled

Parameter	Description	Range	Default
prohibit-ip-spoofing	Detects IP spoofing (where an intruder sends messages using the IP address of a trusted client). When this option is enabled, source and destination IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.	—	enabled in IPv4 disabled in IPv6
prohibit-rst-replay	Closes a TCP connection in both directions if a TCP RST is received from either direction. You should not enable this option unless instructed to do so by a Dell representative.	—	disabled
session-idle-timeout	Time, in seconds, that a non-TCP session can be idle before it is removed from the session table. You should not modify this option unless instructed to do so by a Dell representative.	16-259	15 seconds
session-mirror-destination	This parameter is deprecated. Use the packet-capture command.	—	—
session-mirror-ipsec	This parameter is deprecated. Use the packet-capture command.	—	—
session-tunnel-fib	Enable session tunnel-based forwarding. NOTE: Best practices is to enable this parameter only during maintenance window or off-peak production hours.	—	disabled
session-voip-timeout	Idle session timeout, in seconds, for sessions that are marked as voice sessions. If no voice packet exchange occurs over a voice session for the specified time, the voice session is removed.	16-300	300 seconds
shape-mcast	Enables multicast optimization and provides excellent streaming quality regardless of the amount of VLANs or IP IGMP groups that are used.	—	disabled
stall-crash	Triggers datapath crash on stall detection. Applies to the to W-	—	enabled

Parameter	Description	Range	Default
	7200 Series controllers only.		
voip-wmm-voip-content-enforcement	If traffic to or from the user is inconsistent with the associated QoS policy for voice, the traffic is reclassified to best effort and data path counters incremented. This parameter requires the PEFNG license.	—	disabled
web-cc	Enables web content classification for all HTTP traffic. Once enabled, ArubaOS enforces ACLs and bandwidth policies associated with web content categories or reputation levels. NOTE: On enabling web-cc, the web-cc feature usage information will be sent to Dell at every 7 days interval.	—	disabled
web-cc-cache-miss-drop	Issue this command to allow the controller to drop any packets that do not match any web content category or reputation levels in the controller's internal web content cache.	—	disabled

Usage Guidelines

This command configures global firewall options on the controller.

Example

The following command disallows forwarding of non-IP frames between users:

```
firewall deny-inter-user-bridging
```

Related Commands

firewall cp

```
firewall cp
  ipv4|ipv6 deny|permit <ip-addr><ip-mask>|any|{host <ip-addr>} proto{<ip-protocol-number>
  ports <start port number><end port number>}|ftp|http|https|icmp|snmp|ssh|telnet|tftp
  [bandwidth-contract <name>]

no...
```

Description

This command creates whitelist session ACLs. Whitelist ACLs consist of rules that explicitly permit or deny session traffic from being forwarded or not to the controller. This prohibits traffic from being automatically forwarded to the controller if it was not specifically denied in a blacklist. The maximum number of entries allowed in the whitelist is 64.

Syntax

Parameter	Description	Range	Default
ipv4 ipv6	Specifies ipv4 or ipv6.	—	—
deny permit <ip-addr><ip-mask>	Specifies the entry to reject (deny) on the session ACL whitelist. Specifies an entry that is allowed (permit) on the session ACL whitelist.	—	—
any	Specifies any IPv4 or IPv6 source address.	—	—
host <ip-addr>	Indicates a specific IPv4 or IPv6 source address.	—	—
proto	Protocol that the session traffic is using.	—	—
IP protocol number	Specifies the IP protocol number that is permitted or denied.	1-255	—
start port	Specifies the starting port, in the port range, on which session traffic is running.	1-65535	—
end port	Specifies the last port, in the port range, on which session traffic is running.	1-65535	—
ftp	Specifies the File Transfer Protocol.	—	—
http	Specifies the Hypertext Transfer Protocol.	—	—
https	Specifies the Secure HTTP Protocol.	—	—
icmp	Specifies the Internet Control Message Protocol.	—	—

Parameter	Description	Range	Default
snmp	Specifies the Simple Network Management Protocol.	—	—
ssh	Specifies the Secure Shell.	—	—
telnet	Specifies the Telnet protocol.	—	—
tftp	Specifies the Trivial File Transfer Protocol.	—	—
bandwidth-contract <name>	Specify the name of a bandwidth contract defined via the cp-bandwidth-contract command.	—	—

Usage Guidelines

This command turns the session ACL from a blacklist to a whitelist. A rule must exist that explicitly permits the session before it is forwarded to the controller and the last rule in the list denies everything else.

Example

The following command creates a whitelist ACL that allows on with the source address as 10.10.10.10 and the source mask as 2.2.2.2. The protocol is FTP and the bandwidth contract name is mycontract.

```
(host) (config-fw-cp) #ipv4 permit 10.10.10.10 2.2.2.2 proto ftp bandwidth-contract name mycontract
```

The following command creates a a whitelist ACL entry that denies traffic using protocol 2 on port 5000 from being forwarded to the controller:

```
(host) (config-fw-cp) #deny proto 6 ports 5000 6000
```

Related Commands

Command	Description	Mode

firewall cp-bandwidth-contract

```
firewall cp-bandwidth-contract {auth|route|sessmirr|trusted-mcast|trusted-ucast  
|untrusted-mcast|untrusted-ucast} <Rate>
```

Description

This command configures bandwidth contract traffic rate limits, in packets per second, to prevent denial of service attacks.

Syntax

Parameter	Description	Range	Default
auth	Specifies the traffic rate limit that is forwarded to the authentication process.	1-65535 pps	976 pps
route	Specifies the traffic rate limit that needs ARP requests.	1-65535 pps	976 pps
sessmirr	Specifies the session mirrored traffic forwarded to the controller.	1-65535 pps	976 pps
trusted-mcast	Specifies the trusted multicast traffic rate limit.	1-65535 pps	1953 pps
trusted-ucast	Specifies the trusted unicast traffic rate limit.	1-65535 pps	65535 pps
untrusted-mcast	Specifies the untrusted multicast traffic rate limit.	1-65535 pps	1953 pps
untrusted-ucast	Specifies the untrusted unicast traffic rate limit.	1-65535 pps	9765 pps

Usage Guidelines

This command configures firewall bandwidth contract options on the controller.

Example

The following command disallows forwarding of non-IP frames between users:

```
(host) (config) #firewall deny-inter-user-bridging
```

All platforms	Base operating system	Config mode on master or local controllers.

guest-access-email

```
guest-access-email
  smtp-port
  smtp-server
  no...
```

Description

This command configures the SMTP server which is used to send guest email. Guest email is generated when a guest user account is created or when the Guest Provisioning user sends guest user account email a later time.

Syntax

Parameter	Description	Range	Default
smtp-port	Identifies the SMTP port through which the guest-access email is sent.	—	—
<Port number>	The SMTP port number.	1-65535	25
smtp-server	The SMTP server to which the controller sends the guest-access email.	—	—
<IP-Address>	The SMTP server's IP address.	—	—
no	Deletes the command configuration	—	—

Usage Guidelines

As part of the guest provisioning feature, the **guest-access-email** command allows you to set up the SMTP port and server that process guest provisioning email. This email process sends email to either the guest or the sponsor whenever a guest user account is created or when the Guest Provisioning user manually sends email from the Guest Provisioning page.

Example

The following command creates a guest-access email profile and sends guest user email through SMTP server IP address 1.1.1.1 on port 25.

```
(host) (config) #guest-access-email
(host) (Guest-access Email Profile) #
(host) (Guest-access Email Profile) #smtp-port 25
(host) (Guest-access Email Profile) #smtp-server 1.1.1.1
```

  controller-v6 <ipv6> role active|dual|standby
  heartbeat
  heartbeat-interval <heartbeat-interval>
  heartbeat-threshold <heartbeat-threshold>
  no
  over-subscription
  pre-shared-key <key>
  preemption
  state-sync
```

Description

This command configures the High Availability:Fast Failover feature by assigning controllers to a high-availability group, and defining the deployment role for each controller.

Parameter	Description
group-membership	Displays the high availability group in which the controller is a member.
group-profile <profile>	Create a new high availability group, or define settings for an existing group
clone	Name of an existing high availability profile from which parameter values are copied.
controller <controller>	IPv4 address of a controller that should be added to the specified high availability group.
role	Assign one of the following roles to each controller in the high availability group. • Active: Controller is active and is serving APs. • Dual: Controller serves some APs and acts as a standby controller for other APs. • Standby: Controller does not serve APs, as only acts as a standby in case of failover.
controller-v6 <controller-v6>	IPv6 address of a controller that should be added to the specified high availability group.
role	Assign one of the following roles to each controller in the high availability group. • Active: Controller is active and is serving APs. • Dual: Controller serves some APs and acts as a standby controller for other APs. • Standby: Controller does not serve APs, as only acts as a

Parameter	Description
	standby in case of failover.
heartbeat	The high availability inter-controller heartbeat feature allows for faster AP failover from an active controller to a standby controller, especially in situations where the active controller reboots or loses connectivity to the network.
heartbeat-interval <heartbeat-interval>	Enter a heartbeat interval in the Heartbeat Interval field to define how often inter-controller heartbeats are sent. Range: 100-1000 ms; Default:100ms
heartbeat-threshold <heartbeat-threshold>	Enter a heartbeat threshold in the Heartbeat Threshold field to define the number of heartbeats that must be missed before the APs are forced to fail over to the standby controller. Range: 3-10 heartbeats; Default: 5 heartbeats
no	Negates or removes any configured parameter.
over-subscription	The standby controller oversubscription feature allows a standby controller to support connections to standby APs beyond the controller's original rated AP capacity. Starting with ArubaOS 6.4.0.0, a W-7200 Series controller acting as a standby controller can oversubscribe to standby APs by up to four times that controller's rated AP capacity, and a standby W-6000M3 controller module or W-3600 controller can oversubscribe by up to two times its rated AP capacity, as long as the tunnels consumed the standby APs do not exceed the maximum tunnel capacity for that standby controller.
pre-shared-key <key>	Define a pre-shared key to be used with the state synchronization feature.
preemption	If you include this optional parameter to enable preemption, an AP that has failed over to a standby controller attempts to connect back to its original active controller once that controller is reachable again. When you enable this setting, the AP will wait for the time specified by the lms-hold-down-period parameter in the ap system-profile profile before the standby AP attempts to switch back to original controller.
state-sync	State synchronization improves failover performance by synchronizing PMK and Key cache values from the active controller to the standby controller, allowing clients to authenticate on the standby controller without repeating the complete 802.1X authentication process. NOTE: To use the state synchronization feature, configure a pre-shared key with the pre-shared-key parameter.

Usage Guidelines

The High Availability:Fast Failover feature supports redundancy models with an active controller pair, or an active/standby deployment model with one backup controller supporting one or more active controllers. Each of these clusters of active and backup controllers comprises a high-availability group. Note that all active and backup controllers within a single high-availability group must be deployed in a single master-local topology.

The High Availability: Fast Failover features works across Layer-3 networks, so there is no need for a direct Layer-2 connection between controllers in a high-availability group.

By default, an AP's active controller is the controller to which the AP first connects when it comes up. Other dual mode or standby mode controllers in the same High Availability group become potential standby controllers for that AP. This feature does not require that the active controller act the configuration master for the local standby controller . A master controller in a master-local deployment can act as an active or a standby controller .

When the AP first connects to its active controller, that controller sends the AP the IP address of a standby controller, and the AP attempts to connect to the standby controller. If an AP that is part of a cluster with multiple backup controllers fails to connect to the first standby controller, the active controller will select a new standby controller for that AP, and the AP will attempt to connect to that standby controller. APs using control plane security establish an IPsec tunnel to their standby controllers. APs that are not configured to use control plane security send clear, unencrypted information to the standby controller.

An AP will failover to its backup controller if it fails to contact its active controller through regular heartbeats and keepalive messages, or if the user manually triggers a failover using the WebUI or CLI.

A controller using this feature can have one of three high availability roles – **active**, **standby** or **dual**. An active controller serves APs, but cannot act as a failover standby controller for any AP except the ones that it serves as active. A standby controller acts as a failover backup controller, but cannot be configured as the primary controller for any AP. A dual controller can support both roles, and acts as the active controller for one set of APs, and also acts as a standby controller for another set of APs.

Examples

The following commands configures a high availability group, and assigns controllers and roles to each controller in the group.

```
(host) (config) #ha group-profile new
(host) (HA group information "new") #controller 192.0.2.2 role active
(host) (HA group information "new") #controller 192.0.2.3 role active
(host) (HA group information "new") #controller 192.0.2.4 role standby
(host) (HA group information "new") #preemption
```

halt

halt

Description

This command halts all processes on the controller.

Syntax

No parameters.

Usage Guidelines

This command gracefully stops all processes on the controller. You should issue this command before rebooting or shutting down to avoid interrupting processes.

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system.	Enable mode on master and local controllers.

help

help

Description

This command displays help for the CLI.

Syntax

No parameters.

Usage Guidelines

This command displays keyboard editing commands that allow you to make corrections or changes to the command without retyping.

You can also enter the question mark (?) to get various types of command help:

- When typed at the beginning of a line, the question mark lists all commands available in the current mode.
- When typed at the end of a command or abbreviation, the question mark lists possible commands that match.
- When typed in place of a parameter, the question mark lists available options.

Example

The following command displays help:

```
(host) #help
```

iap trusted-branch-db

```
iap trusted-branch-db
  add {mac-address <mac-address>}
  allow-all
  del {mac-address <mac-address>}
  del-all
```

Description

This command is used to configure an IAP-VPN branch as trusted.

Syntax

Parameter	Description
add	Configure an IAP trusted branch entry.
mac-address <mac-address>	MAC-address of an AP.
allow-all	Configure all branches as trusted.
del	Delete an IAP trusted branch entry.
mac-address <mac-address>	MAC-address of AP.
del-all	Delete all trusted branch entries.

Example

The following command configures a specific IAP-VPN branch as trusted:

```
(host) (config) #iap trusted-branch-db add mac-address 01:01:0e:3e:4c:33
```

The following is the output of the above command:

```
Trusted branch added
```

This following command configures all IAP-VPN branches as trusted:

```
(host) (config) #iap trusted-branch-db allow-all
```

The following is the output of the above command:

```
All IAP+VPN branches are trusted
```

ids ap-classification-rule change

```
id-classification-rule <rule-name>
  check-min-discovered-aps
  classify-to-type [neighbor | suspected-rogue]
  clone
  conf-level-incr
  discovered-ap-cnt <discovered-ap-cnt>
  match-ssids
  no
  snr-max <value>
  snr-min <value>
  ssid <ssid>
```

Description

Configure the AP classification rule profile.

Syntax

Parameter	Description	Range	Default
<rule-name>	Enter the AP classification rule profile name.	—	—
check-min-discovered-aps	Have the rule check for the minimum number of APs	true false	true
classify-to-type [neighbor suspected-rogue]	Specify if the type the AP will be classified, neighbor or suspected-rogue, if the rule is matched.	—	suspected-rogue
clone	Copy data from another AP classification rule profile	—	—
conf-level-incr	Increase the confidence level (in percentage) when the rule matches	0-100	5
discovered-ap-cnt <discovered-ap-cnt>	Enter the keyword discovered-ap-cnt followed by the number of APs to be discovered.	0-100	0
match-ssids	Match SSIDs; match or do not match	true false	false
no	Negates any configured parameter	—	—
snr-max <value>	Use the maximum SNR value	0-100	0
snr-min <value>	Use the minimum SNR value	0-100	0

Parameter	Description	Range	Default
ssid <ssid>	Enter the keyword ssid followed by the SSID string to be matched or excluded	—	—

Usage Guidelines

AP classification rule configuration is performed only on a master controller. If AMP is enabled via the mobility-manager command, then processing of the AP classification rules is disabled on the master controller. A rule is identified by its ASCII character string name (32 characters maximum). The AP classification rules have one of the following specifications:

- SSID of the AP
- SNR of the AP
- Discovered-AP-Count or the number of APs that can see the AP

Once you have created an AP classification rule, but must enable it by adding it to the IDS AP Matching Rules profile:

```
ids ap-rule-matching
    rule-name <name>
```

SSID specification

Each rule can have up to 6 SSID parameters. If one or more SSIDs are specified in a rule, an option of whether to match any of the SSIDs, or to not match all of the SSIDs can be specified. The default is to check for a match operation.

SNR specification

Each rule can have only one specification of the SNR. A minimum and/or maximum can be specified in each rule and the specification is in SNR (db).

Discovered-AP-Count specification

Each rule can have only one specification of the Discovered-AP-Count. Each rule can specify a minimum or maximum of the Discovered-AP-count. The minimum or maximum operation must be specified if the Discovered-AP-count is specified. The default setting is to check for the minimum discovered-AP-count.

Example

The following example configures the AP Configuration Rule Profile named "rule1", then enables the rule by adding it to the IDS AP Matching Rules profile.

```
(host) (config) #ids ap-classification-rule rule1
(host) (IDS AP Classification Rule Profile "rule1") #check-min-discovered-aps
(host) (IDS AP Classification Rule Profile "rule1") #classify-to-type neighbor
(host) (IDS AP Classification Rule Profile "rule1") !
(host) (config) #ap-rule-matching rule-name rule1
```

Description

This command configures traffic anomalies for denial of service (DoS) attacks.

Syntax

Parameter	Description	Range	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	“default”
ap-flood-inc-time	Time, in seconds, during which a configured number of fake AP beacons must be received to trigger an alarm.	0-36000	3600 seconds
ap-flood-quiet-time	After an alarm has been triggered by a fake AP flood, the time, in seconds, that must elapse before an identical alarm may be triggered.	60-360000	900 seconds
ap-flood-threshold	Number of fake AP beacons that must be received within the flood increase time to trigger an alarm.	0-100,000	50
assoc-rate-thresholds	Rate threshold for associate request frames.	—	—
auth-rate-thresholds	Rate threshold for authenticate frames.	—	—
block-ack-dos-quiet-time	Time to wait, in seconds, after detecting an attempt to reset the receive window using a forged block ACK add.	60-360000 seconds	900 seconds
chopchop-quiet-time	Time to wait, in seconds, after detecting a ChopChop attack after which the check can be resumed.	60-360000 seconds	900 seconds

Parameter	Description	Range	Default
client-ht-40mhz-intol-quiet-time <seconds>	Controls the quiet time (when to stop reporting intolerant STAs if they have not been detected), in seconds, for detection of 802.11n 40 MHz intolerance setting.	60-360000 seconds	900 seconds
client-flood-inc-time	Number of consecutive seconds over which the client count is more than the threshold.	0-36000 seconds	3 seconds
client-flood-quiet-time	Time to wait, in seconds, after detecting a client flood before continuing the check.	60-360000 seconds	900 seconds
client-flood-threshold	Threshold for the number of spurious clients in the system.	0-100000	150
clone	Copy data from another IDS Denial Of Service Profile.	—	—
cts-rate-quiet-time	Time to wait, in seconds, after detecting a CTS rate anomaly after which the check can be resumed.	60-360000 seconds	900 seconds
cts-rate-threshold	Number of CTS control packets over the time interval that constitutes an anomaly.	0-100000	5000
cts-rate-time-interval	Time interval, in seconds, over which the packet count should be checked.	1-120 seconds	5 seconds
deauth-rate-thresholds	Rate threshold for deauthenticate frames.	—	—
detect-ap-flood	Enables detection of flooding with fake AP beacons to confuse legitimate users and to increase the amount of processing needed on client operating systems.	true false	false
detect-block-ack-dos	Enable/disable detection of attempts to reset traffic receive windows using forged Block ACK Add messages.	true false	true

Parameter	Description	Range	Default
detect-chopchop-attack	Enable/disable detection of ChopChop attack.	true false	false
detect-client-flood	Enable/disable detection of client flood attack.	true false	disable
detect-cts-rate-anomaly	Enable/disable detection of CTS rate anomaly.	true false	disable
detect-disconnect-station	In a station disconnection attack, an attacker spoofs the MAC address of either an active client or an active AP. The attacker then sends deauthenticate frames to the target device, causing it to lose its active association. Use this command to enable the detection of disconnect station attack.	true false	enable
detect-eap-rate-anomaly	Enables Extensible Authentication Protocol (EAP) handshake analysis to detect an abnormal number of authentication procedures on a channel and generate an alarm when this condition is detected.	true false	false
detect-fata-jack-attack	Enable/disable detection of FATA-Jack attack	true false	enable
detect-ht-40mhz-intolerance	Enables or disables detection of 802.11n 40 MHz intolerance setting, which controls whether stations and APs advertising 40 MHz intolerance will be reported.	true false	false
detect-invalid-address	Enable/disable detection of invalid address combinations	true false	false
detect-malformed-association-request	Enable/disable detection of malformed association requests.	true false	disable
detect-malformed-auth-frame	Enable/disable detection of malformed authentication frames	true false	disable

Parameter	Description	Range	Default
detect-malformed-htie	Enable/disable detection of malformed HT IE	true false	false
detect-malformed-large-duration	Enable/disable detection of unusually large durations in frames	true false	true
detect-omerta-attack	Enable/disable detection of Omerta attack	true false	enable
detect-overflow-eapol-key	Enable/disable detection of overflow EAPOL key requests	true false	disable
detect-overflow-ie	Enable/disable detection of overflow Information Elements (IE)	true false	disable
detect-power-save-dos-attack	Enable/disable detection of Power Save DoS attack	true false	enable
detect-rate-anomalies	Enable/disable detection of rate anomalies	true false	disable
detect-rts-rate-anomaly	Enable/disable detection of RTS rate anomaly	true false	disable
detect-tkip-replay-attack	Enable/disable detection of TKIP replay attack	true false	disable
disassoc-rate-thresholds	Rate threshold for disassociate frames.	—	—
disconnect-deauth-disassoc-threshold	Rate thresholds for Disassociate frames	1-50	8
disconnect-sta-assoc-resp-threshold	The number of successful Association Response or Reassociation response frames seen in an interval of 10 seconds that should trigger this event.	1-30	5
disconnect-sta-quiet-time	After a station disconnection attack is detected, the time, in seconds, that must elapse before another identical alarm can be generated.	60-360000seconds	900 seconds

Parameter	Description	Range	Default
eap-rate-quiet-time	After an EAP rate anomaly alarm has been triggered, the time, in seconds, that must elapse before another identical alarm may be triggered.	60-360000	900 seconds
eap-rate-threshold	Number of EAP handshakes that must be received within the EAP rate time interval to trigger an alarm.	0-100000	60
eap-rate-time-interval	Time, in seconds, during which the configured number of EAP handshakes must be received to trigger an alarm.	1-120 seconds	3 seconds
fata-jack-quiet-time	Time to wait, in seconds, after detecting a FATA-jack attack after which the check can be resumed.	60-360000 seconds	900 seconds
invalid-address-combination-quiet-time	Time to wait, in seconds, after detecting an invalid address combination after which the check can be resumed.	60-360000 seconds	900 seconds
malformed-association-request-quiet-time	Time to wait, in seconds, after detecting a malformed association request after which the check can be resumed.	60-360000 seconds	900 seconds
malformed-auth-frame-quiet-time	Time to wait, in seconds, after detecting a malformed authentication frame after which the check can be resumed.	60-360000 seconds	900 seconds
malformed-htie-quiet-time	Time to wait, in seconds, after detecting a malformed HT IE after which the check can be resumed.	60-360000 seconds	900 seconds
malformed-large-duration-quiet-time	Time to wait, in seconds, after detecting a large duration for a frame after which the check can be resumed.	60-360000 seconds	900 seconds
no	Negates any configured parameter.	—	—

Parameter	Description	Range	Default
omerta-quiet-time	Time to wait, in seconds, after detecting an Omerta attack after which the check can be resumed.	60-360000 seconds	900 seconds
omerta-threshold	The Disassociation packets received by a station as a percentage of the number of data packets sent, in an interval of 10 seconds.	1-100	10%
overflow-eapol-key-quiet-time	Time to wait, in seconds, after detecting a overflow EAPOL key request after which the check can be resumed.	60-360000 seconds	900 seconds
overflow-ie-quiet-time	Time to wait, in seconds, after detecting a overflow IE after which the check can be resumed.	60-360000 seconds	900 seconds
power-save-dos-min-frames	The minimum number of Power Management OFF packets that are required to be seen from a station, in intervals of 10 second, in order for the Power Save DoS check to be done.	1-1000	120
power-save-dos-quiet-time	Time to wait, in seconds, after detecting a Power Save DoS attack after which the check can be resumed.	60-360000 seconds	900 seconds
power-save-dos-threshold	The Power Management ON packets sent by a station as a percentage of the Power Management OFF packets sent, in intervals of 10 second, which will trigger this event.	1- 100 %	80%
probe-request-rate-thresholds	Rate threshold for probe request frames.	—	—
probe-response-rate-thresholds	Rate threshold for probe response frames.	—	—
rts-rate-quiet-time	Time to wait, in seconds, after detecting an RTS rate anomaly after which the check can be resumed.	60-360000 seconds	900 seconds

Parameter	Description	Range	Default
<code>rts-rate-threshold</code>	Number of RTS control packets over the time interval that constitutes an anomaly.	0-100000	5000
<code>rts-rate-time-interval</code>	Time interval, in seconds, over which the packet count should be checked.	1-120 seconds	5 seconds
<code>spoofed-deauth-blacklist</code>	Enables detection of a deauth attack initiated against a client associated to an AP. When such an attack is detected, the client is quarantined from the network to prevent a man-in-the-middle attack from being successful.	true false	false
<code>tkip-replay-quiet-time</code>	Time to wait, in seconds, after detecting a TKIP replay attack after which the check can be resumed.	60-360000 seconds	900 seconds

Usage Guidelines

DoS attacks are designed to prevent or inhibit legitimate clients from accessing the network. This includes blocking network access completely, degrading network service, and increasing processing load on clients and network equipment.

Example

The following command enables a detection in the DoS profile named "floor2":

```
(host) (config) #ids dos-profile floor2
(host) (IDS Denial Of Service Profile "floor2") detect-ap-flood
```

Command History

Release	Modification
ArubaOS 3.0	Command Introduced.
ArubaOS 3.3	Updated with support for high-throughput IEEE 802.11n standard.
ArubaOS 3.4	<code>detect-disconnect-sta</code> and <code>disconnect-sta-quiet-time</code> parameters deprecated.

Release	Modification
ArubaOS 6.0	Deprecated predefined profiles and added numerous DoS profile options
ArubaOS 6.1	Added the following parameter in support of Detection of the Meiners Power Save DoS attack, including event notification to the user. <pre> detect-power-save-dos-attack power-save-dos-min-frames power-save-dos-quiet-time power-save-dos-threshold </pre>

Deprecated Predefined Profiles

Deprecated DOS profile:

- ids-dos-disabled
- ids-dos-low-setting
- ids-dos-medium-setting
- ids-dos-high-setting

```

Description

Configure an IDS general profile.

Syntax

Parameter	Description	Range	Default
<profile-name>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	"default"
adhoc-ap-inactivity-timeout	Ad hoc (IBSS) AP inactivity timeout in number of scans.	5-36000 seconds	5 seconds
adhoc-ap-max-unseen-timeout	Ageout time in seconds since ad hoc (IBSS) AP was last seen.	5-36000 seconds	5 seconds
ap-inactivity-timeout	Time, in seconds, after which an AP is aged out.	5-36000 seconds	5 seconds

Parameter	Description	Range	Default
ap-max-unseen-timeout	Ageout time, in seconds, since AP was last seen.	5-36000 seconds	600 seconds
clone	Name of an existing IDS general profile from which parameter values are copied.	—	—
frame-types-for-rssi all ba ctrl dhigh dlow dnull mgmt pr	Select frame types to be used in AM RSSI calculation. Frame types: all—All types of frames. This frame type overrides any other frame types. ba—Block ACK frame types. ctrl—All control frames except ACK. dhigh—Data frames more than 36 Mbps except null data frames. dlow—Data frames less than 36 Mbps except null data frames. dnull—Null data frames. mgmt—All management frames except probe request. pr—Probe request frames. NOTE: Configure this parameter under the supervision of Dell Technical Support.	—	ba, ctrl, dlow, dnull, mgmt, pr
ids-events logs-and-traps logs-only none traps-only]	Enable or disable IDS event generation from the AP. Event generation from the AP can be enabled for syslogs, traps, or both. This does not affect generation of IDS correlated events on the switch.	—	logs-and-traps
max-monitored-stations	Maximum number of monitored stations. NOTE: This parameter is currently available on the W-AP220 Series access points only. NOTE: Configure this parameter under the supervision of Dell Technical Support.	1024-4096	1024
max-unassociated-stations	Maximum number of unassociated stations. NOTE: This parameter is currently available on W-AP220 Series access points only. NOTE: Configure this parameter under the supervision of Dell Technical Support.	256-4096	256

Parameter	Description	Range	Default
min-pot-ap-beacon-rate	Minimum beacon rate acceptable from a potential AP, in percentage of the advertised beacon interval.	0-100	25%
min-pot-ap-monitor-time	Minimum time, in seconds, a potential AP has to be up before it is classified as a real AP.	2-36000	2 seconds
mobility-manager-rtls	Enable/disable RTLS communication with the configured mobility-manager	enable disable	disabled
mon-stats-update-interval	Time interval, in seconds, for AP to update the switch with stats for monitored devices. Minimum is 60.	60-360000 seconds	60 seconds
no	Negates any configured parameter.	—	—
packet-snr-threshold	Set the packet Signal to Noise Ratio (SNR) threshold. All packets with SNR below this threshold is dropped from IDS and ARM processing. No packets are dropped if the threshold is set to 0. NOTE: Configure this parameter under the supervision of Dell Technical Support.	0-90 dB	0
send-adhoc-info-to-controller	Enable or disable sending adhoc information to the controller from the AP.	enable disable	disable
signature-quiet-time	After a signature match is detected, the time to wait, in seconds, to resume checking.	60-360000 seconds	900 seconds
sta-inactivity-timeout	Time, in seconds, after which a station is aged out.	30-360000 seconds	60 seconds
sta-max-unseen-timeout	Ageout time, in seconds, since station was last seen. Minimum is 5.	5-36000 seconds	5 seconds
wired-containment	Enable containment from the wired side.	true false	false

Parameter	Description	Range	Default
wired-containment-ap-adj-mac	Enable/disable wired containment of MACs offset by one from APs BSSID.	true false	false
wired-containment-susp-l3-rogue	The basic wired containment feature enabled using the wired-containment command contains layer-3 APs whose wired interface MAC addresses are either the same as (or one character off from) their BSSIDs. This feature can also identify and contain an AP with a preset wired MAC address that is completely different from the AP's BSSID if the MAC address that the AP provides to wireless clients as the 'gateway MAC' is offset by one character from its wired MAC address. NOTE: This feature requires that the following wired-containment parameter in the ids general-profile is also enabled, and that the confidence level of the suspected rogue exceeds the level configured by the suspect-rogue-containment and suspect-rogue-conf-level parameters in the ids unauthorized-device-profile.	true	false
wireless-containment deauth-only none tarpit-all-sta tarpit-non-valid-sta	Enable wireless containment including Tarpit Shielding. Tarpit shielding works by steering a client to a tarpit so that the client associates with it instead of the AP that is being contained. deauth-only—Containment using deauthentication only. none—Disable wireless containment. tarpit-all-sta—Wireless containment by tarpit of all stations. tarpit-non-valid-sta—Wireless containment by tarpit of non-valid clients.	—	deauth-only
wireless-containment-debug	Enable/disable debug of containment from the wireless side. Note: Enabling this debug option will cause containment to <i>not</i> function properly.	true false	false

Usage Guidelines

This command configures general IDS profile attributes.

Example

The following command enables containment in the general IDS profile:

```
(host) (config) #ids general-profile floor7
(host) (IDS General Profile "floor7") #wired-containment
(host) (IDS General Profile "floor7") #wireless-containment tarpit-all-sta
```

```
(host) (IDS General Profile "floor7") #wireless-containment-debug
```

Command History

Version	Description
ArubaOS 3.0	Command Introduced
ArubaOS 5.0	Introduced the mobility-manager-rtls parameter.
ArubaOS 6.0	Deprecated predefined profiles and added numerous General profile options
ArubaOS 6.3	Introduced the wired-containment-susp-l3-rogue parameter.
ArubaOS 6.4.2.3	The following parameters were introduced: • packet-snr-threshold • frame-types-for-rssi • max-monitored-stations • max-unassociated-stations

Deprecated Predefined Profiles

Deprecated General profiles:

- ids-general-disabled
- ids-general-high-setting

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the RFprotect license.	Config mode on master controllers

Warning Message for Containment Features

The feature for enabling wireless containment under the **IDS Unauthorized Device** profile and **IDS Impersonation** profile may be in violation of certain Federal Communications Commission (FCC) regulatory statutes. To address this, a warning message will be issued each time the command is enabled through the CLI. The warning message will appear after the command is executed.

ids impersonation-profile

```
ids impersonation-profile <name>
  ap-spoofing-quiet-time
  beacon-diff-threshold <percent>
  beacon-inc-wait-time <seconds>
  beacon-wrong-channel-quiet-time
  clone <profile>
  detect-ap-impersonation
  detect-ap-spoofing
  detect-beacon-wrong-channel
  detect-hotspotter
  hotspotter-quiet-time
  no ...
  protect-ap-impersonation
```

Description

This command configures anomalies for impersonation attacks.

Syntax

Parameter	Description	Range	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	"default"
ap-spoofing-quiet-time	Time to wait in seconds after detecting AP Spoofing after which the check can be resumed. Minimum wait time is 60.		60 seconds
beacon-diff-threshold	Percentage increase in beacon rates that triggers an AP impersonation event.	0-100	50%
beacon-inc-wait-time	Time, in seconds, after the beacon difference threshold is crossed before an AP impersonation event is generated.	—	3 seconds
beacon-wrong-channel-quiet-time	Time to wait, in seconds, after detecting a beacon with the wrong channel after which the check can be resumed.	60-360000 seconds	900 seconds
clone	Name of an existing IDS impersonation profile from which parameter values are copied.	—	—

Parameter	Description	Range	Default
detect-ap-impersonation	Enables detection of AP impersonation. In AP impersonation attacks, the attacker sets up an AP that assumes the BSSID and ESSID of a valid AP. AP impersonation attacks can be done for man-in-the-middle attacks, a rogue AP attempting to bypass detection, or a honeypot attack.	—	true
detect-ap-spoofing	Enable/disable AP Spoofing detection	—	enable
detect-beacon-wrong-channel	Enable/disable detection of beacons advertising the incorrect channel	—	disable
detect-hotspotter	Enable/disable detection of the Hotspotter attack to lure away valid clients.	—	disable
hotspotter-quiet-time	Time to wait in seconds after detecting an attempt to Use the Hotspotter tool against clients.	60-360000 seconds	900 seconds
no	Negates any configured parameter.	—	—
protect-ap-impersonation	When AP impersonation is detected, both the legitimate and impersonating AP are disabled using a denial of service attack.	—	false

Usage Guidelines

A successful man-in-the-middle attack will insert an attacker into the data path between the client and the AP. In such a position, the attacker can delete, add, or modify data, provided he has access to the encryption keys. Such an attack also enables other attacks that can learn a client's authentication credentials. Man-in-the-middle attacks often rely on a number of different vulnerabilities.

Example

The following command enables detections in the impersonation profile:

```
(host) (config) #ids impersonation-profile floor1
(host) (IDS Impersonation Profile "floor1") #detect-beacon-wrong-channel
(host) (IDS Impersonation Profile "floor1") #detect-ap-impersonation
```

Command History

Version	Modification
ArubaOS 3.0	Command Introduced
ArubaOS 3.4	detect-sequence-anomaly, sequence-diff, sequence-quiet-time, sequence-time-tolerance parameters deprecated.
ArubaOS 6.0	Deprecated predefined profiles and added numerous Impersonation profile options

Deprecated Predefined Profiles

IDS Impersonation profile:

- ids-impersonation-disabled
- ids-impersonation-high-setting

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the RFprotect license	Config mode on master controllers

ids management-profile

```
event-correlation
    [logs-and-traps | logs-only | none | traps-only]
event-correlation-quiet-time <value>
```

Description

Manage the event correlation.

Syntax

Parameter	Description	Range	Default
event-correlation logs-and-traps logs-only none traps-only	Correlation mode for IDS event traps and syslogs (logs). Event correlation can be enabled with generation of correlated logs, traps, or both. To disable correlation, enter the keyword none .		logs-and-traps
event-correlation-quiet-time <value>	Time to wait, in seconds, after generating a correlated event after which the event could be raised again. This only applies to events that are repeatedly raised by an AP.	30-360000 seconds	900 seconds

Usage Guidelines

Manage the events correlation for IDS event traps and syslogs (logs).

Example

```
(host) (config) #ids management-profile
(host) (IDS Management Profile) #event-correlation-quiet-time 30
(host) (IDS Management Profile) #event-correlation logs-and-traps
```

Command History

Release	Modification
ArubaOS 6.0	Command introduced

Command Information

Platforms	Licensing	Command Mode
Available on all platforms	Requires the RFprotect license	Config mode on master controllers

ids profile

```
ids profile <name>  
    clone <profile>  
    dos-profile <profile>  
    general-profile <profile>  
    impersonation-profile <profile>  
    no ...  
    signature-matching-profile <profile>  
    unauthorized-device-profile <profile>
```

Description

This command defines a set of IDS profiles.

Syntax

Parameter	Description	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	"default"
clone	Name of an existing IDS profile from which parameter values are copied.	—
dos-profile	Name of a IDS denial of service profile to be applied to the AP group/name. See ids dos-profile on page 421 .	"default"
general-profile	Name of an IDS general profile to be applied to the AP group/name. See ids general-profile on page 430 .	"default"
impersonation-profile	Name of an IDS impersonation profile to be applied to the AP group/name. See ids impersonation-profile on page 435 .	"default"
no	Negates any configured parameter.	—
signature-matching-profile	Name of an IDS signature matching profile to be applied to the AP group/name. See ids signature-matching-profile on page 443 .	"default"
unauthorized-device-profile	Name of an IDS unauthorized device profile to be applied to the AP group/name. See ids unauthorized-device-profile on page 448 .	"default"

Usage Guidelines

This command defines a set of IDS profiles that you can then apply to an AP group (with the **ap-group** command) or to a specific AP (with the **ap-name** command).

Example

The following command defines a set of IDS profiles:

```
(host) (config) #ids profile floor2
(host) (IDS Profile "floor2") #dos-profile dos1
      general-profile general1
      impersonation-profile mitml
      signature-matching-profile sig1
      unauthorized-device-profile unauth1
```

Command History

ids rate-thresholds-profile

```
ids rate-thresholds-profile <name>
  channel-inc-time <seconds>
  channel-quiet-time <seconds>
  channel-threshold
  clone <profile>
  no ...
  node-quiet-time <seconds>
  node-threshold <number>
  node-time-interval <seconds>
```

Description

This command configures thresholds that are assigned to the different frame types for rate anomaly checking.

Syntax

Parameter	Description	Range	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	“default”
channel-inc-time	Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm.	0 - 360000 seconds	15 seconds
channel-quiet-time	After a channel rate anomaly alarm has been triggered, the time that must elapse before another identical alarm may be triggered. This option prevents excessive messages in the log file.	60-360000	900 seconds
channel-threshold	Number of a specific type of frame that must be exceeded within a specific interval in an entire channel to trigger an alarm.	any	300
clone	Name of an existing IDS rate thresholds profile from which parameter values are copied.	—	—
no	Negates any configured parameter.	—	—
node-quiet-time	After a node rate anomaly alarm has been triggered, the time, in seconds, that must elapse before another identical alarm may be triggered. This option prevents excessive messages in the log file.	60-360000	900 seconds
node-threshold	Number of a specific type of frame that must be exceeded within a specific interval for a particular client MAC address to trigger an alarm.	0 - 100000 frames	200
node-time-interval	Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm.	1-120	15 seconds

Usage Guidelines

A profile of this type is attached to each of the following 802.11 frame types in the IDS denial of service profile:

- Association frames
- Disassociation frames
- Deauthentication frames
- Probe Request frames
- Probe Response frames
- Authentication frames

Example

The following command configures frame thresholds:

```
(host) (config) #ids rate-thresholds-profile Lobby
(host) (IDS Rate Thresholds Profile "Lobby") #channel-threshold 250
```

Command History

Version	Modification
ArubaOS 3.0	Command Introduced
ArubaOS 6.0	Deprecated predefined profiles

Deprecated Predefined Profiles

Deprecated the predefined profile with probe-request-response-threshold.

ids signature-matching-profile

```
ids signature-matching-profile <name>  
    clone <profile>  
    no ...  
    signature <profile>
```

Description

This command contains defined signature profiles.

Syntax

Parameter	Description	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	"default"
clone	Name of an existing IDS signature matching profile from which parameter values are copied.	—
no	Negates any configured parameter.	—
signature	Name of a signature profile. See ids signature-profile on page 445 .	—

Usage Guidelines

You can include one or more predefined signature profiles or a user-defined signature profile in a signature matching profile.

Example

The following command configures a signature matching profile:

```
(host) (config) IDS signature matching LobbyEast  
(host) (IDS Signature Matching Profile "LobbyEast") #signature Null-Probe-Response
```

Command History

Version	Modification
ArubaOS 3.0	Command Introduced
ArubaOS 6.0	Deprecated predefined profiles

Deprecated Predefined Profiles

Deprecated Signature Matching profile:

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the RFprotect license	Config mode on master controllers

ids signature-profile

```
ids signature-profile <name>
  bssid <macaddr>
  clone <profile>
  dst-mac <macaddr>
  frame-type {assoc|auth|beacon|control|data|deauth|disassoc|mgmt|probe-request|probe-
  response
  no ...
  payload <pattern> [offset <number>]
  seq-num <number>
  src-mac <macaddr>
```

Description

This command configures signatures for wireless intrusion detection.

Syntax

Parameter	Description	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	"default"
bssid	BSSID field in the 802.11 frame header.	—
clone	Name of an existing IDS signature profile from which parameter values are copied.	—
dst-mac	Destination MAC address in the 802.11 frame header.	—
frame-type	Type of 802.11 frame. For each type of frame, further parameters can be specified to filter and detect only the required frames.	—
assoc	Association frame type	
auth	Authentication frame type	
beacon	Beacon frame type	
control	All control frames	
data	All data frames	
deauth	Deauthentication frame type	
disassoc	Disassociation frame type	
mgmt	Management frame type	

Parameter	Description	Default
probe-request	Frame type is probe request	
probe-response	Frame type is probe response	
ssid	For beacon, probe-request, and probe-response frame types, specify the SSID as either a string or hex pattern.	—
ssid-length	For beacon, probe-request, and probe-response frame types, specify the length, in bytes, of the SSID. Maximum length is 32 bytes.	—
no	Negates any configured parameter.	—
payload <pattern>	Pattern at a fixed offset in the payload of an 802.11 frame. Specify the pattern to be matched as a string or hex pattern. Maximum length is 32 bytes.	—
offset	When a payload pattern is configured, specify the offset in the payload where the pattern is expected to be found in the frame.	—
seq-num	Sequence number of the frame.	—
src-mac	Source MAC address in the 802.11 frame header.	—
valid-ap	Matches a valid AP SSID	—

Example

The following command configures a signature profile:

```
(host) (config) #ids signature-profile floor4
(host) (IDS Signature Profile "floor4") #frame-type assoc
(host) (IDS Signature Profile "floor4") #src-mac 00:00:00:00:00:00
```

Usage Guidelines

The following describes the configuration for the predefined signature profiles:

Signature Profile	Parameter	Value
AirJack	frame-type	beacon ssid = AirJack
ASLEAP	frame-type	beacon ssid = asleep
Deauth-Broadcast	frame-type	deauth
	dst-mac	ff:ff:ff:ff:ff:ff

Signature Profile	Parameter	Value
Netstumbler Generic	payload	offset=3 pattern=0x00601d
	payload	offset=6 pattern=0x0001
Netstumbler Version 3.3.0x	payload	offset=3 pattern=0x00601d
	payload	offset=12 pattern=0x000102
Null-Probe-Response	frame-type	probe-response ssid length = 0

  wireless-hosted-network-quiet-time
```

Description

This command configures detection of unauthorized devices, as well as rogue AP detection and containment.

Syntax

Parameter	Description	Range	Default
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.	—	"default"
adhoc-using-valid-ssid-quiet-time	Time to wait, in seconds, after detecting an adhoc network using a valid SSID, after which the check can be resumed.	60-360000	900 seconds
allow-well-known-mac	Allows devices with known MAC addresses to classify rogues APs. Depending on your network, configure one or more of the following options for classifying rogue APs: • hsrp—Routers configured for HSRP, a Cisco-proprietary redundancy protocol, with the HSRP MAC OUI 00:00:0c. • iana—Routers using the IANA MAC OUI 00:00:5e. • local-mac—Devices with locally administered MAC addresses starting with 02. • vmware—Devices with any of the following VMWare OUIs: 00:0c:29, 00:05:69, or 00:50:56 • vmware1—Devices with VMWare OUI 00:0c:29. • vmware2—Devices with VMWare OUI 00:05:69. • vmware3—Devices with VMWare OUI 00:50:56. If you modify an existing configuration, the new configuration overrides the original configuration. For example, if you configure <code>allow-well-known-mac hsrp</code> and then configure <code>allow-well-known-mac iana</code>, the original configuration is lost. To add more options to the original configuration, include all of the required options, for example: <code>allow-well-known-mac hsrp iana</code>.	—	—

Parameter	Description	Range	Default
	Use caution when configuring this command. If the neighboring network uses similar routers, those APs might be classified as rogues. If containment is enabled, clients attempting to associate to an AP classified as a rogue are disconnected through a denial of service attack. To clear the well known MACs in the system, use the following commands: • <code>clear wms wired-mac</code>: This clears all of the learned wired MAC information on the controller. • <code>reload</code>: This reboots the controller.		
<code>cfg-valid-11a-channel</code>	List of valid 802.11a channels that third-party APs are allowed to use.	34-165	N/A
<code>cfg-valid-11g-channel</code>	List of valid 802.11b/g channels that third-party APs are allowed to use.	1-14	N/A
<code>classification</code>	Enable/disable rogue AP classification. A rogue AP is one that is unauthorized and plugged into the wired side of the network. Any other AP seen in the RF environment that is not part of the valid enterprise network is considered to be interfering — it has the potential to cause RF interference but it is not connected to the wired network and thus does not represent a direct threat.	—	true
<code>clone</code>	Name of an existing IDS rate thresholds profile from which parameter values are copied.	—	—
<code>detect-adhoc-network</code>	Enable detection of adhoc networks.	—	false
<code>detect-adhoc-using-valid-ssid</code>	Enable/disable detection of adhoc networks using valid/protected SSIDs	—	enable
<code>detect-bad-wep</code>	Enables detection of WEP initialization vectors that are known to be weak and/or repeating. A primary means of cracking WEP keys is to capture 802.11 frames over an extended period of time and search for implementations that are still used by many legacy devices.	—	false

Parameter	Description	Range	Default
detect-ht-greenfield	Enables or disables detection of high-throughput devices advertising greenfield preamble capability.	—	false
detect-invalid-mac-oui	Enables checking of the first three bytes of a MAC address, known as the organizationally unique identifier (OUI), assigned by the IEEE to known manufacturers. Often clients using a spoofed MAC address do not use a valid OUI and instead use a randomly generated MAC address. Enabling MAC OUI checking causes an alarm to be triggered if an unrecognized MAC address is in use.	—	false
detect-misconfigured-ap	Enables detection of misconfigured APs. An AP is classified as misconfigured if it is classified as valid and does not meet any of the following configurable parameters: - valid channels - encryption type - list of valid AP MAC OUIs - valid SSID list	—	false
detect-sta-assoc-to-rogue	Enable/disable detection of station association to rogue AP.		enable
detect-unencrypted-valid-client	Enable/disable detection of unencrypted valid clients.	—	enable
detect-valid-client-misassociation	Enable/disable detection of misassociation between a valid client and an unsafe AP. This setting can detect the following misassociation types: • MisassociationToRogueAP • MisassociationToExternalAP • MisassociationToHoneypotAP • MisassociationToAdhocAP • MisassociationToHostedAP	—	enable
detect-valid-ssid-misuse	Enable/disable detection of Interfering or Neighbor APs using valid/protected SSIDs.	—	disable
detect-windows-bridge	Enables detection of Windows station bridging.	—	true
detect-wireless-bridge	Enables detection of wireless bridging.	—	false

Parameter	Description	Range	Default
detect-wireless-hosted-network	If enabled, this feature can detect the presence of a wireless hosted network. When a wireless hosted network is detected this feature sends a “Wireless Hosted Network” warning level security log message and the <i>wlsxWirelessHostedNetworkDetected</i> SNMP trap. If there are clients associated to the hosted network, this feature will send a “Client Associated To Hosted Network” warning level security log message and the <i>wlsxClientAssociatedToHostedNetworkDetected</i> SNMP trap.	—	enable
mac-oui-quiet-time	Time, in seconds, that must elapse after an invalid MAC OUI alarm has been triggered before another identical alarm may be triggered.	60-360000 seconds	900 seconds
no	Negates any configured parameter.	—	—
oui-classification	Enable/disable OUI based rogue AP classification	—	enable
overlay-classification	Enable/disable overlay rogue AP classification	—	enable
privacy	Enables encryption as a valid AP configuration.	—	false
prop-wm-classification	Enable/disable rogue AP classification through propagated wired MACs	—	true
protect-adhoc-enhanced	Enables advanced protection from open/WEP adhoc networks. When enhanced adhoc containment is carried out, a new repeatable event, syslog and SNMP trap will be generated for each containment event.	—	false
protect-adhoc-network	Enables protection from adhoc networks using WPA/WPA2 security. When adhoc networks are detected, they are disabled using a denial of service attack.	—	false
protect-high-throughput	Enables or disables protection of high-throughput (802.11n) devices.	—	false

Parameter	Description	Range	Default
protect-ht-40mhz	Enables or disables protection of high-throughput (802.11n) devices operating in 40 MHz mode.	—	false
protect-misconfigured-ap	Enables protection of misconfigured APs.	—	false
protect-ssid	Enables use of SSID by valid APs only.	—	false
protect-valid-sta	When enabled (true), does not allow valid stations to connect to a non-valid AP.	—	false
protect-windows-bridge	Enable/disable protection of a windows station bridging	—	disabled
protect-wireless-hosted-network	When you enable the wireless hosted network protection feature, the controller enforces containment on a wireless hosted network by launching a denial of service attack to disrupt associations between a Windows 7 software-enabled Access Point (softAP) and a client, and disrupt associations between the client that is hosting the softAP and any access point to which the host connects. When a wireless hosted network triggers this feature, wireless hosted network protection sends the Wireless Hosted Network Containment and Host of Wireless Network Containment warning level security log messages, and the <i>wlsxWirelessHostedNetworkContainment</i> and <i>wlsxHostOfWirelessNetworkContainment</i> SNMP traps. NOTE: The existing generic containment SNMP traps and log messages will also be sent when Wireless Hosted Network Containment or Host of Wireless Network Containment is enforced.	—	disabled
require-wpa	When enabled (true), any valid AP that is not using WPA encryption is flagged as misconfigured.	—	false
rogue-containment	Rogue APs can be detected (see classification) but are not automatically disabled. This option automatically shuts down rogue APs. When this option is enabled (true), clients attempting to associate to an AP classified as a rogue are disconnected through a denial of service attack.	—	false

Parameter	Description	Range	Default
suspect-rogue-conf-level	Confidence level of suspected Rogue AP to trigger containment. When an AP is classified as a suspected rogue AP, it is assigned a 50% confidence level. If multiple APs trigger the same events that classify the AP as a suspected rogue, the confidence level increases by 5% up to 95%. In combination with suspected rogue containment, this option configures the threshold by which containment should occur. Suspected rogue containment occurs only when the configured confidence level is met.	50-100%	60%
suspect-rogue-containment	Suspected rogue APs are treated as interfering APs, thereby the controller attempts to reclassify them as rogue APs. Suspected rogue APs are not automatically contained. In combination with the configured confidence level (see suspect-rogue-conf-level), this option contains the suspected rogue APs.	—	false
unencrypted-valid-client-quiet-time	Time to wait, in seconds, after detecting an unencrypted valid client after which the check can be resumed.	60-360000 seconds	900 seconds
valid-and-protected-ssid	List of valid and protected SSIDs.	—	—
valid-oui	List of valid MAC OUIs.	—	—
valid-wired-mac	List of MAC addresses of wired devices in the network, typically gateways or servers.	—	—
wireless-bridge-quiet-time	Time, in seconds, that must elapse after a wireless bridge alarm has been triggered before another identical alarm may be triggered.	60-360000 seconds	900 seconds
wireless-hosted-network-quiet-time	The wireless hosted network detection feature sends a log message and trap when a wireless hosted network is detected. The quiet time defined by this parameter sets the amount of time, in seconds, that must elapse after a wireless hosted network log message or trap has been triggered before an identical log message or trap can be sent again.	60-360000 seconds	900 seconds

Usage Guidelines

Unauthorized device detection includes the ability to detect and disable rogue APs and other devices that can potentially disrupt network operations.

Example

The following command copies the settings from the `ids-unauthorized-device-disabled` profile and then enables detection and protection from adhoc networks:

```
(host) (config) #ids unauthorized-device-profile floor7
(host) (IDS Unauthorized Device Profile "floor7") #unauth1
(host) (IDS Unauthorized Device Profile "floor7") #clone ids-unauthorized-device-disable
(host) (IDS Unauthorized Device Profile "floor7") #detect-adhoc-network
(host) (IDS Unauthorized Device Profile "floor7") #protect-adhoc-network
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3	Update with support for the high-throughput IEEE 802.11n standard. Also, introduced <code>allow-well-known-mac</code> , <code>suspect-rogue-conf-level</code> , and <code>suspect-rogue-containment</code> parameters.
ArubaOS 6.0	Deprecated predefined profiles
ArubaOS 6.1	Added the detect-valid-ssid-misuse parameter to internally generate a list of valid SSIDs to use in addition to the user configured list of Valid and Protected SSIDs.
ArubaOS 6.3	Added the following parameters • <code>protect-adhoc-enhanced</code> • <code>detect-wireless-hosted-network</code> • <code>wireless-hosted-network-quiet-time</code> • <code>protect-wireless-hosted-network</code>

Deprecated Predefined Profiles

IDS Unauthorized Device profile:

- `ids-unauthorized-device-disabled`
- `ids-unauthorized-device-medium-setting`
- `ids-unauthorized-device-high-setting`

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the RFprotect license	Config mode on master controllers

ids wms-general-profile

```
wms general
  adhoc-ap-ageout-interval <adhoc-ap-ageout-interval>
  ap-ageout-interval <ap-ageout-interval>
  collect-stats
  learn-ap
  learn-system-wired-macs
  no
  persistent-neighbor
  persistent-valid-sta
  poll-interval <poll-interval>
  poll-retries <poll-retries>
  propagate-wired-macs
  sta-ageout-interval <sta-ageout-interval>
  stat-update
```

Description

This command configures the WLAN management system (WMS).

Syntax

Parameter	Description	Range	Default
adhoc-ap-ageout-interval <adhoc-ap-ageout-interval>	Time, in minutes, that an adhoc (IBSS) AP remains unseen before it is deleted (ageout) from the database.	?	30 minutes
ap-ageout-interval <ap-ageout-interval>	Time, in minutes, that an AP remains unseen by any probes before it is deleted from the database.	?	30 minutes
collect-stats	Enables collection of statistics (up to 25,000 entries) on the master controller for monitored APs and clients. This only applies when MMS is not configured.	—	disabled
learn-ap	Enables “learning” of non-Dell APs.	—	disabled
learn-system-wired-macs	Enable or disable “learning” of wired MACs at the controller.	—	disabled
no	Negates any configured parameter.	—	—
persistent-neighbor	Do not age out known AP neighbors.	—	disabled
persistent-valid-sta	Do not age out valid stations.	—	?

Parameter	Description	Range	Default
<code>poll-interval</code> <poll-interval>	Interval, in milliseconds, for communication between the controller and Dell AMs. The controller contacts the AM at this interval to download AP to station associations, update policy configuration changes, and download AP and station statistics.	(any)	60000 milliseconds (1 minute)
<code>poll-retries</code> <poll-retries>	Maximum number of failed polling attempts before the polled AM is considered to be down.	(any)	2
<code>propagate-wired-macs</code>	Enables the propagation of the gateway wired MAC information.	—	enabled
<code>sta-ageout-interval</code> <sta-ageout-interval>	Time, in minutes, that a client remains unseen by any probes before it is deleted from the database.	?	30 minutes
<code>stat-update</code>	Enables statistics updating in the database.	—	enabled

Usage Guidelines

By default, non-Dell APs that are connected on the same wired networks as Dell APs are classified as “rogue” APs. Enabling AP learning classifies non-Dell APs as “valid” APs. Typically, you would want to enable AP learning in environments with large numbers of existing non-Dell APs and leave AP learning enabled until all APs in the network have been detected and classified as valid. Then, disable AP learning and reclassify any unknown APs as interfering.

VLAN Trunking

In deployments where Dell APs are not placed on every VLAN and where it is *not* possible to trunk all VLANs to a Dell AP, enable the parameter **learned-system-wired-mac**. When this is enabled, ArubaOS is able to classify rogues on all the VLANs that belong to the Dell controller, as long as Dell APs can see the rogues in the air. If there are VLANs in the network residing on a third party controller and if those VLANs are trunked to a port on the Dell controller, enabling this feature will allow detection of rogues on those VLANs as well.

Master/Local

When **learned-system-wired-mac** is enabled in a master/local deployment, the learning of Wired and Gateway MACs will happen at each local controller. For topologies with local controllers in geographical locations, the local controller collects the Wired and Gateway MAC info and passes it to the APs that are connected to it. Even though the locals do the collection of Wired and Gateway MACs, the master is still be responsible for classification.

Example

The following command enables AP learning:

```
(host) (IDS WMS General Profile) #learn-ap
```

To disable AP learning:

```
(host) (IDS WMS General Profile) #no learn-ap
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.1	Added parameter learned-system-wired-mac

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

ids wms-local system-profile

```
ids wms-locals-profile <profile>
  max-rbtree-entries <number>
  max-system-wm <number>
  max-threshold <number>
  system-wm-update-interval <number>]
```

Description

This command sets the local configuration parameters to control the size of the Wired MAC table and APs and Stations.

Syntax

Parameter	Description
max-rbtree-entries	Set the max threshold for the total number of AP and Station RBTREE entries.
max-system-wm	Set the max number of system wired MAC table entries learned at the controller. Range: 1-2000 Default: 1000
max-threshold	Set the max threshold for the total number of APs and Stations.
system-wm-update-interval	Set the interval, in minutes, for repopulating the system wired MAC table at the controller. Range: 1 to 30 minutes Default: 8 minutes

Usage Guidelines

The **wms-local system** command is used for configuring commands that are local, not global. This means in a master-local system, the configuration parameter is modifiable at each individual controller, and the setting on one controller does not affect the setting on other controllers.

Increasing the max threshold limit will cause an increase in usage in the memory by WMS. In general, each entry will consume about 500 bytes of memory. If the setting is bumped up by 2000, then it will cause an increase in WMS memory usage by 1MB.

Example

The following commands first set the interval time for repopulating the MAC table to 10 minutes and then sets the maximum number of APs and stations to 500.

```
(host) (config) #ids wms-locals-profile system system-wm-update-interval 10
(host) (config)# ids wms-locals-profile system max-threshold 500
```

Command History

Release	Modification
ArubaOS 3.	Introduced
ArubaOS 6.1	Local configuration parameters to control the size of the Wired MAC table <code>max-system-wm</code> and <code>system-wm-update-interval</code>
ArubaOS 6.1.3	The wms-local command was renamed to ids wms-local-system-profile .

ifmap

```
ifmap cppm
  enable
  no
  server host <host>
  port <port>
  username<username>
  passwd <password>
```

Description

This command is used in conjunction with ClearPass Policy Manager. It sends HTTP User Agent Strings and mDNS broadcast information to ClearPass so that it can make more accurate decisions about what types of devices are connecting to the network.

Syntax

Parameter	Description	Default
enable	Enables the IFMAP protocol.	—
server	Configures the CPPM IF-MAP server.	—
host <host>	IP address/hostname of the CPPM IF-MAP server.	—
port <port>	Port number for the CPPM IF-MAP server. The range is 1-65535.	443
username<username>	Username for the user who performs actions on the CPPM IF-MAP server. The name must be between 1-255 bytes in length.	—
passwd <password>	Password of the user who performs actions on the CPPM IF-MAP server. The password must be between 6-100 bytes in length.	—

Example

This example configures IFMAP and enables it.

```
(host) (config) #ifmap
(host) (config) #ifmap cppm
(host) (CPPM IF-MAP Profile) #server host <host>
(host) (CPPM IF-MAP Profile) #port <port>
(host) (CPPM IF-MAP Profile) #passwd <passwd>
(host) (CPPM IF-MAP Profile) #enable
```

Usage Guidelines

Use this command in conjunction with ClearPass Policy Manager.

  xsec {point-to-point <macaddr> <key> allowed vlan <vlans> [<mtu>]|vlan <vlan>}
```

Description

This command configures a FastEthernet or GigabitEthernet interface on the controller.

Syntax

Parameter	Description	Range	Default
<slot>	<slot> is always 1.	—	—
<module>	<slot>/<module>/<port> (7000 Series only)		
<port>	Number assigned to the network interface embedded in the controller. Port numbers start at 0 from the left-most position.	—	—
bandwidth-contract	Apply a bandwidth contract to all upstream of downstream traffic, or to traffic for a specified application or application category NOTE: This feature is only supported on W-7000 Series and W-7200 Series controllers	—	—

Parameter	Description	Range	Default
<name>	Name of a bandwidth contract configured with the aaa bandwidth-contract command. If you specify a bandwidth contract name <i>before</i> you specify an application or application category, the bandwidth contract is applied to all downstream or upstream traffic.		
app <name>	Name of the application to which the bandwidth contract is applied. For a complete list of supported applications, issue the command show dpi application all .	—	—
appcategory <name>	Name of the application category to which the bandwidth contract is applied. For a complete list of supported applications, issue the command show dpi application category all .	—	—
downstream	Apply the bandwidth contract to downstream traffic.	—	—
upstream	Apply the bandwidth contract to upstream traffic.	—	—
exclude <app> <appcategory>	Use this parameter to exclude application or application category traffic from a bandwidth contract.		
description	String that describes this interface.	—	—
duplex	Transmission mode on the interface: full or half-duplex or auto to automatically adjust transmission.	auto/full/half	auto
ip access-group	Applies the specified access control list (ACL) to the interface. Use the ip access-list command to configure an ACL. NOTE: This parameter requires the PEFNG license.	—	—
in	Applies ACL to interface's inbound traffic.	—	—
out	Applies ACL to interface's outbound traffic.	—	—

Parameter	Description	Range	Default
session	Applies session ACL to interface and optionally to a selected VLAN associated with this port.	—	—
tunneled-node-port	Enable tunneled node capability on the interface.	—	disabled
no	Negates any configured parameter.	—	—
jumbo	Enables or disables jumbo frame MTU configured via firewall on a port.	—	disabled
lacp			
group <id> mode [active passive]			
port-priority			
timeout			
lldp	Configures an LLDP functionality on an interface.	—	—
fast-transmit-counter <1-8>	Set the number of the LLDP data units sent each time fast LLDP data unit transmission is triggered	1-8	4
fast-transmit-interval <1-3600>	Set the LLDP fast transmission interval in seconds.	1-3600	1
med	Enables the LLDP MED protocol.	—	disabled
receive	Enables processing of LLDP PDU received.	—	disabled
transmit	Enables LLDP PDU transmit.	—	disabled
transmit-hold <1-100>	Set the transmit hold multiplier.	1-100	4
transmit-interval <1-3600>	Sets the transmit interval in seconds.	1-3600	30
port monitor	Monitors another interface on the controller.	—	—

Parameter	Description	Range	Default
priority-map	Applies a priority map to the interface. Use the priority-map command to configure a priority map which allows you to map ToS and CoS values into high priority traffic queues.	—	—
shutdown	Causes a hard shutdown of the interface.	—	—
spanning-tree	Enables Rapid spanning tree or Per-VLAN spanning tree.	—	enabled
bpduguard	Enables bpduguard on the edge ports.	—	disabled
cost	Administrative cost associated with the spanning tree.	1-65535	19 (Fast Ethernet) 4 (Gigabit Ethernet)
point-to-point	Set interface as point to point.	—	disabled
port-priority	Spanning tree priority of the interface. A lower setting brings the port closer to root port position (favorable for forwarding traffic) than does a higher setting. This is useful if ports may contend for root position if they are connected to an identical bridge.	0-255	128
portfast	Enables forwarding of traffic from the interface.	—	disabled
vlan	Configure the vlan instance.	1-4094	disabled
speed	Sets the interface speed: 10 Mbps, 100 Mbps, or auto configuration.	10 100 auto	auto
switchport	Sets switching mode parameters for the interface.	—	—
access vlan	Sets the interface as an access port for the specified VLAN. The interface carries traffic only for the specified VLAN.	—	1
mode	Sets the mode of the interface to access or trunk mode only.	access trunk	access

Parameter	Description	Range	Default
trunk	Sets the interface as a trunk port for the specified VLANs. A trunk port carries traffic for multiple VLANs using 802.1q tagging to mark frames for specific VLANs. You can include all VLANs configured on the controller, or add or remove specified VLANs. Specify native to identify the native VLAN for the trunk mode interface. Frames on the native VLAN are not 802.1q tagged.	—	—
trusted	Set this interface and range of VLANs to be trusted. VLANs not included in the trusted range of VLANs will be, by default, untrusted. Trusted ports and VLANs are typically connected to internal controlled networks, while untrusted ports connect to third-party APs, public areas, or other networks to which access controls should be applied. When Dell APs are attached directly to the controller, set the port to be trusted.	—	enabled
vlan <word>	Sets the supplied range of VLANs as trusted. All remaining become untrusted automatically. For example, If you set a VLAN range as: vlan 1-10, 100-300, 301, 305-400, 501-4094 Then all VLANs in this range are trusted and all others become untrusted by default. You can also use the no trusted vlan command to explicitly make an individual VLAN untrusted. The no trusted vlan command is additive and adds given vlans to the existing untrusted vlan set. However, if you execute the trusted vlan <word> command, it overrides any earlier untrusted VLANs or a range of untrusted VLANs and creates a new set of trusted VLANs. NOTE: A port supports a user VLAN range from 1-4094. If you want to set all VLANs (1-4094) on a port as untrusted then mark the port itself as untrusted. By default the port and all its associated VLANs are trusted.	1-4094	—
tunneled-node-port		—	—
xsec	Enables and configures the Extreme Security (xSec) protocol.	—	—

Parameter	Description	Range	Default
	NOTE: You must purchase and install the xSec software module license in the controller.		
point-to-point	MAC address of the controller that is the xSec tunnel termination point, and the 16-byte shared key used to authenticate the controllers to each other. The key must be the same on both controllers.	—	—
allowed vlan	VLANs that are allowed on the xSec tunnel.	—	—
mtu	(Optional) MTU size for the xSec tunnel.	—	—
vlan	xSec VLAN ID. For controller-to-controller communications, both controllers must belong to the same VLAN.	1-4094	—

Usage Guidelines

Use this command to configure settings for the controller interface, including duplex, LLDP and switchport settings. You can issue the **show port status** command to obtain information about the interfaces currently available on the controller.

Interface Bandwidth Contracts

W-7000 Series controllers have the ability to classify and identify applications on the network. If a W-7000 Series controller is configured as a branch controller, you can create bandwidth contracts to limit traffic for individual applications (or categories of applications) either sent from or received by a selected interface. There are two basic models for using this feature.

- **Limiting lower-priority traffic:** If there is a lower-priority application or application type that you want to limit, apply a bandwidth contract just to that application, and allow all other application traffic to pass without any limits.
- **Protecting higher-priority traffic:** If you want to guarantee bandwidth for a company-critical application or application group, you can add that application to an exception list, then apply a bandwidth contract to all remaining traffic.

You can apply bandwidth contracts using one or both of these models. Each interface supports up to 64 bandwidth contracts.

Interface contract Precedence

An interface bandwidth contract is applied to downstream traffic before a user-role bandwidth contract is applied, and for upstream traffic, the user-role bandwidth contract is applied before the interface bandwidth contract. For all traffic using compression and encryption, bandwidth contracts are applied after that traffic is compressed and encrypted. If you apply more than one bandwidth contract to any specific category type, then the bandwidth contracts are applied in the following order.

1. A contract that explicitly excludes an application
2. A contract that explicitly excludes an application category
3. A contract that applies to a specific application

4. A contract that applies to a specific application category
5. A generic bandwidth contract, not specific to any application or application category

Example

The following commands configure an interface as a trunk port for a set of VLANs:

```
(host) (config) # interface fastethernet 1/2
(host) (config-range)# switchport mode trunk
(host) (config-range)# switchport trunk native vlan 10
(host) (config-range)# switchport trunk allowed vlan 1,10,100
```

The following commands configure trunk port 1/2 with test-acl session for VLAN 2.

```
(host) (config) # interface range fastethernet 1/2
(host) (config-range)# switchport mode trunk
(host) (config-range)# ip access-group
(host) (config-range) # ip access-group test session vlan 2
```

The following commands configure a interface bandwidth contract for a high-priority application.

```
(host) (config) # interface gigabitethernet 1/1
(host) (config) # bw-contract protectlync exclude app alg-lync-voice downstream
```

Related Commands

```
(host) #show interface {fastethernet|gigabitethernet} <slot>/<port>
(host) #show datapath port vlan-table <slot>/<port>
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.4	The trusted VLAN and ip access-group session vlan parameters were introduced.
ArubaOS 3.4.1	The trusted vlan <word> parameter was added.
ArubaOS 6.1	The parameter muxport was changed to tunneled-node-port
ArubaOS 6.3	The jumbo parameter was added to enable or disable jumbo frame MTU configured via firewall on port.
ArubaOS 6.4	The lldp parameter was added.
ArubaOS 6.4.3.0	The bw-contract parameter was introduced. The bpduguard , point-to-point , and vlan parameters were introduced as part of spanning-tree .

Command Information

Platforms	Licensing	Command Mode
All platforms, except for the interface bandwidth contract feature, which is limited to W-7000 Series controllers only.	This command is available in the base operating system. The ip access-group parameter requires the PEFNG license. The xsec parameter requires the xSec license.	Config mode on master and local controllers

interface loopback

```
interface loopback
  ip address <ipaddr>
  ipv6 address <ipv6-prefix>
  no ...
```

Description

This command configures the loopback address on the controller.

Syntax

Parameter	Description
ip address	Host IP address in dotted-decimal format. This address should be routable from all external networks.
ipv6 address	Host IPv6 address that is routable from all external networks.
no	Negates any configured parameter.

Usage Guidelines

If configured, the loopback address is used as the controller's IP address. If you do not configure a loopback address for the controller, the IP address assigned to VLAN 1 is used as the controller's IP address. After you configure or modify a loopback address, you need to reboot the controller.

Example

The following command configures a loopback address:

```
(host) (config) #interface loopback
  ip address 10.2.22.220
```

Command History

interface port-channel

```
interface port-channel <id>
  add {fastethernet|gigabitethernet} <slot>/<port>
  del {fastethernet|gigabitethernet} <slot>/<port>
  description <LINE>
  ip access-group <acl> {in|out|session {vlan <vlanId>}}
  jumbo
  no ...
  shutdown
  spanning-tree [portfast]
  switchport {access vlan <vlan>|mode {access|trunk}|
    trunk {allowed vlan {<vlans>|add <vlans>|all|except <vlans>|remove <vlans>}|
    native vlan <vlan>}
  trusted {vlan <word>}
  xsec {point-to-point <macaddr> <key> allowed vlan <vlans> [<mtu>]|vlan <vlan>}
```

Description

This command configures an Ethernet port channel.

Syntax

Parameter	Description	Range	Default
port-channel	ID number for this port channel.	0-7	—
add	Adds the specified FastEthernet or GigabitEthernet interface to the port channel. You cannot specify both FastEthernet and GigabitEthernet interfaces for the same port channel.	—	—
del	Deletes the specified FastEthernet or GigabitEthernet interface to the port channel.	—	—
description <LINE>	A character string describing this port-channel.	up to 60 characters	—
ip access-group	Applies the specified access control list (ACL) to the interface. Use the ip access-list command to configure an ACL. NOTE: This command requires the PEFNG license.	—	—
in	Applies ACL to interface's inbound traffic.	—	—
out	Applies ACL to interface's outbound traffic.	—	—
session	Applies session ACL to interface and optionally to a selected VLAN associated with this port.	—	—
jumbo	Enable or disables jumbo frame MTU configured via firewall on a port channel.		Disabled

Parameter	Description	Range	Default
no	Negates any configured parameter.	—	—
shutdown	Causes a hard shutdown of the interface.	—	—
spanning-tree	Enables spanning tree.	—	—
portfast	Enables forwarding of traffic from the interface.	—	—
switchport	Sets switching mode parameters for the interface.	—	—
access vlan	Sets the interface as an access port for the specified VLAN. The interface carries traffic only for the specified VLAN.	—	—
mode	Sets the mode of the interface to access or trunk mode only.	—	—
trunk	Sets the interface as a trunk port for the specified VLANs. A trunk port carries traffic for multiple VLANs using 802.1q tagging to mark frames for specific VLANs. You can include all VLANs configured on the controller, or add or remove specified VLANs.	—	—
native	Specifies the native VLAN for the trunk mode interface. Frames on the native VLAN are not 802.1q tagged.	—	—
trusted	Set this interface and range of VLANs to be trusted. VLANs not included in the trusted range of VLANs will be, by default, untrusted. Trusted ports and VLANs are typically connected to internal controlled networks, while untrusted ports connect to third-party APs, public areas, or other networks to which access controls should be applied. When Dell APs are attached directly to the controller, set the port to be trusted.	—	disabled
vlan <word>	Sets the supplied range of VLANs as trusted. All remaining become untrusted automatically. For example, if you set a VLAN range as: vlan 1-10, 100-300, 301, 305-400, 501-4094 Then all VLANs in this range are trusted and all others become untrusted by default. You can also use the no trusted vlan command to explicitly make an individual VLAN untrusted. The no trusted vlan command is additive and adds given vlans to the existing untrusted vlan set.	1-4094	—

Parameter	Description	Range	Default
	However, if you execute the trusted vlan <word> command, it overrides any earlier untrusted VLANs or a range of untrusted VLANs and creates a new set of trusted VLANs. NOTE: A port supports a user VLAN range from 1-4094. If you want to set all VLANs (1-4094) on a port as untrusted then mark the port itself as untrusted. By default the port and all its associated VLANs are trusted.		
xsec	Enables and configures the Extreme Security (xSec) protocol. NOTE: You must purchase and install the xSec software module license in the controller.	—	—
point-to-point	MAC address of the controller that is the xSec tunnel termination point, and the 16-byte shared key used to authenticate the controllers to each other. The key must be the same on both controllers.	—	—
allowed vlan	VLANs that are allowed on the xSec tunnel.	—	—
mtu	(Optional) MTU size for the xSec tunnel.	—	—
vlan	xSec VLAN ID. For controller-to-controller communications, both controllers must belong to the same VLAN.	1-4094	—

Usage Guidelines

A port channel allows you to aggregate ports on a controller. You can configure a maximum of 8 port channels per supported controller with a maximum of 8 interfaces per port channel.

Note the following when setting up a port channel between a controller and a Cisco switch (such as a Catalyst 6500 Series Switch):

- There must be no negotiation of the link parameters.
- The port-channel mode on the Cisco switch must be “on”.

Example

The following command configures a port channel:

```
(host) (config) #interface port channel 7
    add fastethernet 1/1
    add fastethernet 1/2
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.4	The trusted VLAN and ip access-group session vlan parameters were introduced.
ArubaOS 3.4.1	The trusted vlan <word> parameter was added.
ArubaOS 6.3	The jumbo parameter was added.
ArubaOS 6.4.3.0	The description parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
	This command is available in the base operating system. The ipaccess-group parameter requires the PEFNG license. The xsec parameter requires the xSec license.	Config mode on master and local controllers

interface-profile voip-profile

```
interface-profile voip-profile <profile-name>
  clone <source>
  no{...}
  voip-dot1p <priority>
  voip-dscp <value>
  voip-mode [auto-discover | static]
  voip-vlan <VLAN-ID>
```

Description

This command creates a VoIP profile that can be applied to any interface or an interface group.

Syntax

Parameter	Description	Range	Default
<profile-name>	Name of the VoIP profile.	1-32 characters; cannot begin with a numeric character	—
voip-dot1p <priority>	Specifies the dot1p priority.	—	—
voip-dscp <value>	Specifies the DSCP value for the voice VLAN	—	—
voip-mode [auto-discover static]	Specifies the mode of VoIP operation. • auto-discover - Operates VoIP on auto discovery mode. • static - Operates VoIP on static mode.	—	static
voip-vlan <vlan id>	Specifies the Voice VLAN ID.	—	—

Usage Guidelines

Use this command to create VoIP VLANs for VoIP phones. Creating a VoIP profile does not apply the configuration to any interface or interface group. To apply the VoIP profile, use the `interface gigabitethernet` and `interface-group` commands.

Example

The following command configures a VoIP profile:

```
interface-profile voip-profile VoIP_PHONES
voip-dot1p 100
voip-dscp 125
voip-mode auto-discover
voip-vlan 126
```

interface range

```
interface range {fastethernet|gigabitethernet} <slot>/<port>-<port>
    duplex {auto|full|half}
    ip access-group <acl> {in|out|session {vlan <vlanId>}}
    no ...
    poe [cisco]
    shutdown
    spanning-tree [cost <value>] [port-priority <value>] [portfast]
    speed {10|100|auto}
    switchport {access vlan <vlan>|mode {access|trunk}|
        trunk {allowed vlan {<vlans>|add <vlans>|all|except <vlans>|remove <vlans>}}|
        native vlan <vlan>}}
    trusted {vlan <word>}
```

Description

This command configures a range of FastEthernet or GigabitEthernet interfaces on the controller.

Syntax

Parameter	Description	Range	Default
range	Range of Ethernet ports in the format <slot>/<port>-<port>.	—	—
duplex	Transmission mode on the interface: full- or half-duplex or auto to automatically adjust transmission.	auto/full/half	auto
ip access-group	Applies the specified access control list (ACL) to the interface. Use the ip access-list command to configure an ACL.	—	—
in	Applies ACL to interface's inbound traffic.	—	—
out	Applies ACL to interface's outbound traffic.	—	—
session	Applies session ACL to interface and optionally to a selected VLAN associated with this port.	—	—
no	Negates any configured parameter.	—	—
poe	Enables Power-over-Ethernet (PoE) on the interface.	—	—
cisco	Enables Cisco-style PoE on the interface.	—	—
shutdown	Causes a hard shutdown of the interface.	—	—
spanning-tree	Enables spanning tree.	—	—

Parameter	Description	Range	Default
cost	Administrative cost associated with the spanning tree.	1-65535	—
port-priority	Spanning tree priority of the interface. A lower setting brings the port closer to root port position (favorable for forwarding traffic) than does a higher setting. This is useful if ports may contend for root position if they are connected to an identical bridge.	0-255	
portfast	Enables forwarding of traffic from the interface.	—	—
speed	Sets the interface speed: 10 Mbps, 100 Mbps, or auto configuration.	10 100 auto	auto
switchport	Sets switching mode parameters for the interface.	—	—
access vlan	Sets the interface as an access port for the specified VLAN. The interface carries traffic only for the specified VLAN.	—	—
mode	Sets the mode of the interface to access or trunk mode only.	—	—
trunk	Sets the interface as a trunk port for the specified VLANs. A trunk port carries traffic for multiple VLANs using 802.1q tagging to mark frames for specific VLANs. You can include all VLANs configured on the controller, or add or remove specified VLANs. Specify native to identify the native VLAN for the trunk mode interface. Frames on the native VLAN are not 802.1q tagged.	—	—
trusted	Set this interface and range of VLANs to be trusted. VLANs not included in the trusted range of VLANs will be, by default, untrusted. Trusted ports and VLANs are typically connected to internal controlled networks, while untrusted ports connect to third-party APs, public areas, or other networks to which access controls should be applied. When Dell APs are attached directly to the controller, set the port to be trusted.	—	enabled
vlan <word>	Sets the supplied range of VLANs as trusted. All remaining become untrusted automatically. For example, If you set a VLAN range as: vlan 1-10, 100-300, 301, 305-400, 501-4094	1-4094	—

Parameter	Description	Range	Default
	Then all VLANs in this range are trusted and all others become untrusted by default. You can also use the no trusted vlan command to explicitly make an individual VLAN untrusted. The no trusted vlan command is additive and adds given vlans to the existing untrusted vlan set. However, if you execute the trusted vlan <word> command, it overrides any earlier untrusted VLANs or a range of untrusted VLANs and creates a new set of trusted VLANs. NOTE: A port supports a user VLAN range from 1-4094. If you want to set all VLANs (1-4094) on a port as untrusted then mark the port itself as untrusted. By default the port and all its associated VLANs are trusted.		

Usage Guidelines

Use the show port status command to obtain information about the interfaces available on the controller.

Example

The following command configures a range of interface as a trunk port for a set of VLANs:

```
interface range fastethernet 1/12-15
  switchport mode trunk
  switchport trunk native vlan 10
  switchport trunk allowed vlan 1,10,100
```

Command History

<value>}|{hello-interval <value>}|{message-digest-key <id>}|{priority <value>}|{retransmit-
interval <value>}|{transmit-delay <value>}}
  ipv6 address X:X:X:X::X
  mtu <mtu>
  no ...
  shutdown
  trusted
  tunnel
    destination <ip-addr>| remote-node-master-ip|{ipv6 <ipv6-addr>}
    keepalive {<interval> <retries>}|<cisco>
    mode gre {<num>|ip|ipv6
    source <ip-addr>|controller-ip|loopback|{vlan <vlan-id>}}|{ ipv6 <ipv6-addr>|loopback|
controller-ip|{vlan <vlan id>}}
    vlan <vlan id>
```

Description

This command configures a Layer-2 or Layer-3 GRE tunnel between a controller and another GRE-capable device.

Syntax

Parameter	Description	Range	Default
tunnel <number>	Tunnel Identification number. The tunnel ID used here does not have to match the tunnel ID used in the other controller.	1-16777215	—
description	String that describes this tunnel.	—	—
inter-tunnel-flooding	Enables inter-tunnel flooding.	—	Enabled
ip	IP address of the Layer 3 tunnel. This represents the entrance to the tunnel. NOTE: This address should be a unique, non-routable IP address. Enter the following values: • address: The interface IP address of the Layer-3 tunnel. • <ipaddr>: An IPv4 address. NOTE: The IP address should not be part of any subnet in your network, nor does it have to be routable in your network. It is used as a gateway for routing your private subnets (i.e., non-routable VLANs) within the GRE tunnel.	—	—

Parameter	Description	Range	Default
	- internal: IP address allocated from the Remote-Node pool. <ipmask>: IP address allocated from the Remote-Node pool. - ospf: OSPF interface command.		
ipv6	IPv6 address of the Layer-3 GRE tunnel. NOTE: This IP address can be configured only for a Layer-3 GRE tunnel (refer to the "<i>mode gre</i>" parameter below for details).	-	-
mode gre	This parameter a) specifies the tunnel encapsulation method as GRE and b) allows you to specify whether it is a Layer-2 or Layer-3 GRE tunnel. <16-bit protocol number> The 16-bit protocol number uniquely identifies a GRE tunnel. The number format is numeric. The controllers at both endpoints of the tunnel must be configured with the same protocol number. The protocol number does not necessarily have to match the protocol number of the encapsulated frame. The controller encapsulates the entire frame, including the Layer-2 header. - ip Specifies an IPv4 Layer-3 GRE tunnel. The protocol number is set to 0x0800 and is not configurable. Traffic is redirected into the tunnel using a static route or a session ACL policy. The controller encapsulates the Layer-3 packet only. - ipv6 Specifies an IPv6 Layer-3 GRE tunnel. The protocol number is set to 0x86DD and is not configurable. Traffic is redirected into the tunnel using a static route or a session ACL policy. The controller encapsulates the Layer-3 packet only.		
mtu	MTU size for the interface.	1024 - 9216	Enabled IPv4: 1100 IPv6: 1500
no	Negates any configured parameter.	—	—
shutdown	Causes a hard shutdown of the interface.	—	—
trusted	When Trusted is enabled: Any device can send any traffic through the GRE tunnel without having to be	—	Disabled

Parameter	Description	Range	Default
	authenticated. • When Trusted is disabled: Any device that is a source of traffic and is sent through the tunnel must be authenticated to be able to send the traffic. If the device is not authenticated, traffic from that device will be subject to the restrictions of the Initial Role specified in the Wired Access AAA Profile. This is the default. For related information, see aaa authentication wired.		
tunnel	Configures tunneling. The default is an IPv4 Layer-3 GRE tunnel.	—	mode gre ip
destination	The destination IP address for the GRE tunnel endpoint. • <ip-addr> IPv4 address for the GRE tunnel's endpoint. • ipv6 <ipv6-addr> IPv6 address for the GRE tunnel's endpoint. • <remote-node-destination-ip> This option provides branch controller support for the case in which the branch controller receives all its configuration data from the master controller. In the remote-node profile on the master, you can specify the tunnel's destination as remote-node-master-ip. When this configuration is applied on the branch controller, the tunnel destination is replaced with the branch controller's specified master IP address.	—	—
keepalive	Enables sending of periodic keepalive frames on the tunnel to determine the tunnel status (up or down). You can optionally set the interval at which keepalive frames are sent, and the number of times the frames are resent before a tunnel is considered to be down.	—	Disabled
<interval>	Number of seconds at which keepalive frames are sent.	1-86400	10 seconds
<retries>	Number of consecutive times that the keepalives fail before the tunnel is considered to be down.	0-1024	3

Parameter	Description	Range	Default
<code><cisco></code>	The <cisco> option enables keepalive interoperability for Layer-3 tunnels between controllers and Cisco network devices. Dell sets the keepalive packet's GRE protocol field to 0x801; however, Cisco sets the GRE protocol field to 0. When this option is enabled, the Dell controller automatically sets the GRE protocol value to 0.		Disabled
<code>source</code>	The local endpoint of the tunnel on the controller. This can be one of the following: • <code><A.B.C.D></code>: Specify an IPv4 address. • <code>controller-ip</code>: IPv4 address of the controller. • <code>loopback</code>: Loopback interface configured on the controller. • <code>vlan <vlanid></code>: Specify the VLAN interface ID. • <code>ipv6</code>: Specify one of the following IPv6 options: ■ <code><X:X:X:X::X></code>: Specify the IPv6 address. ■ <code>controller-ip</code>: IPv4 address of the controller. ■ <code>loopback</code>: IPv6 loopback interface configured on the controller. ■ <code>vlan <vlan id></code>: Specify the VLAN interface ID.	—	—
<code>vlan</code>	Specifies the VLANs to be included in this tunnel. • <code><vlan id></code> Specify the VLAN interface ID. NOTE: You can configure a VLAN only if the tunnel mode is set to Layer-2 (<code>mode gre <16-bit protocol number></code>). If the tunnel mode is not set to Layer-2 mode, the system displays an error message: <i>Tunnel is an IP [v6] GRE Tunnel. Change the mode before adding this.</i>	—	—

Usage Guidelines

You can configure a Layer-2 or Layer-3 GRE tunnel between a Dell controller and another GRE-capable device. The default is an IPv4 Layer-3 GRE tunnel (**tunnel mode gre ip**).

In Layer-3 GRE tunnels, IPv6 encapsulated in IPv4 and IPv4 encapsulated in IPv6 are not supported. The only Layer-3 GRE modes supported are IPv4 encapsulated in IPv4 and IPv6 encapsulated in IPv6.

You can direct traffic into the tunnel using a static route (by specifying the tunnel as the next hop for a static route) or a session-based access control list (ACL).

Configuration Examples

Layer-2 GRE Tunnel

The following CLI command configures a Layer-2 GRE tunnel:

The following are the required configurations to create the Layer-2 GRE tunnel between controllers named Controller-1 and Controller-2:

Controller-1 Configuration

```
(Controller-1) (config) # interface tunnel 101
description "IPv4 Layer-2 GRE 101"
tunnel mode gre 1
tunnel source vlan 10
tunnel destination 20.20.20.249
tunnel keepalive
trusted
tunnel vlan 101
```

Controller-2 Configuration

```
(Controller-2) (config) # interface tunnel 101
description "IPv4 Layer-2 GRE 101"
tunnel mode gre 1
tunnel source vlan 20
tunnel destination 10.10.10.249
tunnel keepalive
trusted
tunnel vlan 101
```

IPv4 Layer-3 GRE Tunnel

The following CLI command examples configure a Layer-3 GRE tunnel for IPv4 between two controllers.

The following are the required configurations to create the IPv4 Layer-3 GRE tunnel between controllers named Controller-1 and Controller-2:

Controller-1 Configuration

```
(Controller-1) (config) # interface tunnel 202
description "IPv4 L3 GRE 101"
tunnel mode gre ip
ip address 1.1.1.1 255.255.255.255
tunnel source vlan 10
tunnel destination 20.20.20.249
trusted
```

Controller-2 Configuration

```
(Controller-2) (config) # interface tunnel 202
description "IPv4 L3 GRE 202"
tunnel mode gre ip
ip address 1.1.1.2 255.255.255.255
tunnel source vlan 20
tunnel destination 10.10.10.249
trusted
```

IPv6 Layer-3 GRE Tunnel

The following CLI command examples configure a Layer-3 GRE tunnel for IPv6 between two controllers.

The following are the required configurations to create the IPv6 Layer-3 GRE tunnel between controllers named Controller-1 and Controller-2:

Controller-1 Configuration

```
(Controller-1) (config) # interface tunnel 106
description "IPv6 Layer-3 GRE 106"
tunnel mode gre ipv6
ip address 2001:1:2:1::1
tunnel source vlan 10
tunnel destination 2001:1:2:2020::1
trusted
```

Controller-2 Configuration

```
(Controller-2) (config) # interface tunnel 206
description "IPv6 Layer-3 GRE 206"
tunnel mode gre ipv6
ip address 2001:1:2:1::2
tunnel source vlan 20
tunnel destination 2001:1:2:1010::1
trusted
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 3.2	The keepalive parameter was introduced.
ArubaOS 6.4	The checksum parameter was deprecated. Tunnel destination ipv6 , tunnel mode gre ipv6 , tunnel source ipv6 , parameters were introduced.
ArubaOS 6.4.3.0	• The tunnel interface limit was changed from 2147483647 to 16777215. • Introduced the <remote-node-master-ip> option to the tunnel destination parameter. • Introduced the <cisco> option to the tunnel keepalive parameter.

  no ...
  operstate {up}
  option-82 {ap-name essid}|{mac [essid]}
  shutdown
  suppress-arp
```

Description

This command configures a VLAN interface.

Syntax

Parameter	Description	Range	Default
vlan	VLAN ID number.	1-4094	—
bandwidth-contract <name>	Name of the bandwidth contract to be applied to this VLAN interface. When applied to a VLAN, the contract limits both broadcast and multicast traffic. Use the aaa bandwidth-contract command to configure a bandwidth contract.	—	—
bcmc-optimization	Enables broadcast and multicast traffic optimization to prevent flooding of broadcast and multicast traffic on VLANs. If this feature is enabled on uplink ports, any controller-generated Layer-2 packets will be dropped.	—	disabled
description	String that describes this interface.	—	802.1q VLAN
ip	Configures IPv4 for this interface.		
access-group <name> in	Assigns an access list to inbound traffic on the interface, where <name> is the name of an access list.		

Parameter	Description	Range	Default
address	Configures the IP address for this interface, which can be one of the following: <ipaddr> <netmask> • dhcp-client: use DHCP to obtain the IP address • internal: IP address allocated from the branch group config. • pppoe: use PPPoE to obtain the IP address	—	—
helper-address	IP address of the DHCP server for relaying DHCP requests for this interface. If the DHCP server is on the same subnetwork as this VLAN interface, you do not need to configure this parameter.	—	—
igmp	Enables IGMP and/or IGMP snooping on this interface.	—	—
local-proxy-arp	Enables local proxy ARP.	—	—
nat inside	Enables source network address translation (NAT) for all traffic routed from this VLAN. CAUTION: All ports on the controller are assigned to VLAN 1 by default. Do not enable the nat inside option for VLAN 1, as this will prevent IPsec connectivity between the controller and its IPsec peers.	—	—
ospf	Define an OSPF area. See ip ospf on page 542 for complete details on this command.	—	—
pppoe-max-segment-size	Configures the TCP maximum segment size in bytes.	128	—
pppoe-password	Configures the PAP password on the PPPoE Access Concentrator for the switch.	1–80	—
pppoe-service-name	Configures the PPPoE service name.	1–80	—
pppoe-username	Configures the PAP username on the PPPoE Access Concentrator for the switch.	1–80	—
routing	Enables layer-3 forwarding on the VLAN interface. To disable layer-3 forwarding, you must configure the IP address for the interface and specify no ip routing .	—	(enabled)
ipv6	Configures IPv6 for this interface.	—	—

Parameter	Description	Range	Default
address	Configures the link local address or the global unicast address for this interface.	—	—
dhcp	Configures dynamic host configuration protocol for IPv6. server - Configures the DHCPv6 pool for the vlan.	—	—
mld	Enables Multicast Listener Discovery (MLD) on this interface. snooping — Configures the MLD snooping on this interface. proxy —Configures MLD proxy on the following interfaces. • fastethernet • gigabitethernet • port-channel	—	—
nd {ra reachable-time retransmit-time}	Configures the IPv6 neighbor discovery options. • ra—configures the following router advertizement options: • dns—Configures IPv6 recursive DNS server • enable—Enables IPv6 RA • hop-limit—Configures RA hop-limit • interval—Configures RA interval • life-time—Configures RA lifetime • managed-config-flag—Enables hosts to use DHCP server for stateful address autoconfiguration • mtu—Configures maximum transmission unit for RA • other-config-flag—Enables hosts to use DHCP server for other non-address stateful autoconfiguration • preference—Configures a router preference • prefix—Configures IPv6 RA prefix • reachable-time—configures neighbor discovery reachable time • retransmit-time—configures neighbor discovery retransmit time	—	—
no	Negates any configured parameter.	—	—

Parameter	Description	Range	Default
mtu	MTU setting for the VLAN.	1024-1500	—
multimode-auth	MultiMode Authentication Support on VLAN	—	—
operstate up	Set the state of the interface to be up.	—	—
option-82 {ap-name [essid] mac [essid]}	Allows a DHCP relay agent to insert circuit specific information into a request that is being forwarded to a DHCP server. The controller, when acting as a DHCP relay agent, needs to be able to insert information about the AP and SSID through which a client is connecting into the DHCP request. Many service providers use this mechanism to make access control decisions. You can include: • AP name or AP name and ESSID. • MAC address or MAC address and ESSID.	—	—
shutdown	Causes a hard shutdown of the interface.	—	—
suppress-arp	Prevents flooding of ARP broadcasts on all the untrusted interfaces.	—	—

Usage Guidelines

All ports on the controller are assigned to VLAN 1 by default. Use the **interface fastethernet | gigabitethernet** command to assign a port to a configured VLAN. Use the **show interface vlan** and **show user** commands to view DHCP option-82 related output.

Example

The following command configures a VLAN interface:

```
(host) (config) #interface vlan 16
ip address 10.26.1.1 255.255.255.0
ip helper-address 10.4.1.22
```

All platforms	Base operating system	Config mode on master and local controllers

interface vlan ipv6

```
interface vlan <vlan ID>
  ipv6 {address <ipv6-address> link-local | [<ipv6-prefix>/<prefix-length> | eui-64]
  ipv6 dhcp server <pool-name>
  ipv6 mld [snooping]
  ipv6 nd {ra [dns | enable | hop-limit | interval | life-time | managed-config-flag | mtu |
  other-config-flag | preference | prefix] | reachable-time <value> | retransmit-time
  <value>}}
```

Description

This command configures the IPv6 link local address or the global unicast address, and the IPv6 router advertisement parameters for this interface.

Syntax

Parameter	Description	Range	Default
<ipv6 address> link-local	Configures the specified IPv6 address as the link local address for this interface.	—	—
<ipv6-prefix>/<prefix-length>	Specify the IPv6 prefix/prefix-length to configure the global unicast address for this interface.	—	—
eui-64	Specify this optional parameter to configure the global unicast address in Extended Universal Identifier 64 bit format (EUI-64) for this interface.	—	—
ipv6 dhcp server <pool-name>	Specify the DHCPv6 server pool name for this VLAN. The configured DHCPv6 pool subnet must match the interface prefix for DHCPv6 Server to be active.	—	—
ipv6 nd	Configures the IPv6 neighbor discovery options for router advertisement functionality.	—	—
ra	Configures the following router advertisement options: • dns—Configures IPv6 recursive DNS server. • enable—Enables IPv6 RA. • hop-limit—Configures RA hop-limit. • interval—Configures RA interval. • life-time—Configures RA lifetime. • managed-config-flag—Enables hosts to use DHCP server for stateful address autoconfiguration	—	—

Parameter	Description	Range	Default
	• mtu—Configures maximum transmission unit for RA. • other-config-flag—Enables hosts to use DHCP server for other non-address stateful autoconfiguration. • preference—Configures a router preference. • prefix—Configures IPv6 RA prefix.		
<code>reachable-time <value></code>	Configures the neighbor discovery reachable time in msec.	0 - 3,600,000	0
<code>retransmit-time <value></code>	Configures the neighbor discovery retransmit time in msec.	0 - 3,600,000	

Usage Guidelines

You can use this command to configure the IPv6 link local address and the global unicast address for this interface.

Example

The following example configures the link local address for the VLAN 1.

```
(host) (conf)# interface vlan 1
(config-subif)#ipv6 address fe80::b:8600:50d:7700 link-local
```

The following example configures the global unicast address in EUI-64 format for the VLAN 1.

```
(host) (conf)# interface vlan 1
(config-subif)#ipv6 address 2001:DB8:0:3::/64 eui-64
```

Command History

Release	Modification
ArubaOS 6.1	This command was introduced.

interface vlan ip igmp proxy

```
interface vlan <vlan>  
    ip igmp snooping|{proxy fastethernet|gigabitethernet <slot>/<port>}
```

Description

This command enables IGMP and/or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Syntax

Parameter	Description
snooping	Enable IGMP snooping. The IGMP protocol enables an router to discover the presence of multicast listeners on directly-attached links. Enable IGMP snooping to limit the sending of multicast frames to only those nodes that need to receive them.
proxy	Enable IGMP on this interface.
fastethernet	Enable IGMP proxy on the FastEthernet (IEEE 802.3) interface.
gigabitethernet	Enable IGMP proxy on the GigabitEthernet (IEEE 802.3) interface.
<slot>/<port>	Any command that references a Fast Ethernet or Gigabit Ethernet interface requires that you specify the corresponding port on the controller in the format <slot>/<port>. <slot> is always 1, except when referring to interfaces on the W-6000 controller (slots 0-3). The <port> parameter refers to the network interfaces that are embedded in the front panel of the W-3000 Series controller, or a W-6000M3 controller module installed in a W-6000 controller chassis. Port numbers start at 0 from the left-most position.

Usage Guidelines

The newer IGMP proxy feature and the older IGMP snooping feature cannot be enabled at the same time, as both features add membership information to multicast group table. For most multicast deployments, you should enable the IGMP Proxy feature on all VLAN interfaces to manage all the multicast membership requirements on the controller. If IGMP snooping is configured on some of the interfaces, there is a greater chance that multicast information transfers may be interrupted.

Example

The following example configures IGMP proxy for vlan 2. IGMP reports from the controller would be sent to the upstream router on fastethernet port 1/3.

```
(host) (conf)# interface vlan 2  
    (conf-subif)# ip igmp proxy fastethernet 1/3
```

Related Commands

This release of ArubaOS supports version 1 of the Multicast Listener Discovery (MLD) protocol (MLDv1). MLDv1, defined in RFC 2710, is derived from version 2 of the IPv4 Internet Group Management Protocol (IGMPv2)

Issue the command **interface vlan <vlan> ipv6 mld** to enable the MLD protocol and allow an IPv6 router to discover the presence of multicast listeners on directly-attached links. Use the CLI command **interface vlan <vlan> ipv6 mld snooping**, and the IPv6 router will send multicast frames to only those nodes that need to receive them.

Command History

This command was introduced in ArubaOS 3.4

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

ip access-list eth

```
ip access-list eth {<number>|<name>}  
  deny {<ethertype> [<bits>]|any} [mirror] [position]  
  no ...  
  permit {<ethertype> [<bits>]|any} [mirror] [position]
```

Description

This command configures an Ethertype access control list (ACL).

Syntax

Parameter	Description	Range
eth	Enter a name, or a number in the specified range.	200-299
deny	Reject the specified packets, which can be one of the following: - Ethertype in decimal or hexadecimal (0-65535) and optional wildcard (0-65535) - any: match any Ethertype Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination, or set the position of the ACL. The default position is last, a position of 1 puts the ACL at the top of the list.	—
no	Negates any configured parameter.	—
permit	Allow the specified packets, which can be one of the following: - Ethertype in decimal or hexadecimal (0-65535) and optional wildcard (0-65535) - any: match any Ethertype Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination, or set the position of the ACL. The default position is last, a position of 1 puts the ACL at the top of the list.	—

Usage Guidelines

The Ethertype field in an Ethernet frame indicates the protocol being transported in the frame. This type of ACL filters on the Ethertype field in the Ethernet frame header, and is useful when filtering non-IP traffic on a physical port. This ACL can be used to permit IP frames while blocking other non-IP protocols such as IPX or Appletalk.

If you configure the mirror option, define the destination to which mirrored packets are sent in the firewall policy. For more information, see [firewall on page 389](#).

Example

The following command configures an Ethertype ACL:

```
(host) (config) #ip access-list eth 200  
  deny 809b
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3	The mirror parameter was introduced.

ip access-list extended

```
ip access-list extended {<number>|<name>}  
  deny <protocol> <source> <dest>  
  ipv6  
  no ...  
  permit <protocol> <source> <dest>
```

Description

This command configures an extended access control list (ACL). To configure IPv6 specific rules, use the `ipv6` keyword for each rule.

Syntax

Parameter	Description	Range
extended	Enter a name, or a number in the specified range.	100-199, 2000-2699
ipv6	Use the <code>ipv6</code> keyword to add IPv6 specific rules.	—
deny	Reject the specified packets.	—
<protocol>	Protocol, which can be one of the following: • Protocol number between 0-255 • any: any protocol • icmp: Internet Control Message Protocol • igmp: Internet Gateway Message Protocol • tcp: Transmission Control Protocol • udp: User Datagram Protocol	—
<source>	Source, which can be one of the following: • Source address (IPv4 or IPv6) and wildcard • any: any source • host: specify a single host IP address	—
<dest>	Destination, which can be one of the following: • Destination address (IPv4 or IPv6) and wildcard • any: any destination • host: specify a single host IP address	—
no	Negates any configured parameter.	—
permit	Allow the specified packets.	

Parameter	Description	Range
<protocol>	Protocol, which can be one of the following: - Protocol number between 0-255 - any: any protocol - icmp: Internet Control Message Protocol - igmp: Internet Gateway Message Protocol - tcp: Transmission Control Protocol - udp: User Datagram Protocol	—
<source>	Source, which can be one of the following: Source address (IPv4 or IPv6) and wildcard any: any source host: specify a single host IP address	—
<dest>	Destination, which can be one of the following: Destination address (IPv4 or IPv6) and wildcard any: any destination host: specify a single host IP address	—

Usage Guidelines

Extended ACLs are supported for compatibility with router software from other vendors. This ACL permits or denies traffic based on the source or destination IP address or IP protocol.

Example

The following command configures an extended ACL:

```
(host) (config) #ip access-list extended 100
deny any host 1.1.21.245 any
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master and local controllers

ip access-list mac

```
ip access-list mac {<number>|<name>}  
    deny {<macaddr>[<wildcard>]|any|host <macaddr>} [mirror]  
    no ...  
    permit {<macaddr>[<wildcard>]|any|host <macaddr>} [mirror]
```

Description

This command configures a MAC access control list (ACL).

Syntax

Parameter	Description	Range
mac	Configures a MAC access list. Enter a name, or a number in the specified range.	700-799, 1200-1299
deny	Reject the specified packets, which can be the following: MAC address and optional wildcard any: any packets host: specify a MAC address Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination.	—
no	Negates any configured parameter.	—
permit	Allow the specified packets, which can be the following: MAC address and optional wildcard any: any packets host: specify a MAC address Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination.	—

Usage Guidelines

MAC ACLs allow filtering of non-IP traffic. This ACL filters on a specific source MAC address or range of MAC addresses.

If you configure the mirror option, define the destination to which mirrored packets are sent in the firewall policy. For more information, see [firewall on page 389](#).

Example

The following command configures a MAC ACL:

```
(host) (config) #ip access-list mac 700  
    deny 11:11:11:00:00:00
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.3	The mirror parameter was introduced.

ip access-list route

```
ip access-list route <name>
  <source> <dest> <service> <action> forward|route {ipsec-map <ipsec-map-name>}|{next-hop-
  list <next-hop-list-name>}|{tunnel <tunnel-id>}|{tunnel-group <tunnelgroupname>} [position
  <position>]
```

Description

This command configures an access control list (ACL) for policy-based routing (PBR).

Syntax

Parameter	Description
<source>	The traffic source, which can be one of the following: • alias <name>: specify the network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases) • any: match any traffic • host <ip-addr>: specify a single host IP address • localip: specify the local IP address to match traffic • network <ip-addr> <netmask>: specify the IP address and netmask • user: represents the IP address of the user
<dest>	The traffic destination, which can be one of the following: • alias <name>: specify the network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases) • any: match any traffic • host <ip-addr>: specify a single host IP address • localip: specify the local IP address to match traffic • network <ip-addr> <netmask>: specify the IP address and netmask • user: represents the IP address of the user
<service>	Network service to which the ACL is applied. The service can be one of the following: • <0-255>: IP protocol number (0-255) • <string>: name of a network service (use the show netservice command to see configured services) • any: match any traffic • app <string>: application name. (For a complete list of supported applications, issue the command show dpi application all.) • appcategory <string>: application category name. (For a complete list of supported applications, issue the command show dpi application all.) • tcp <0-65535>: specify the TCP destination port number (0-65535) • tcp source <0-65535>: TCP source port number

Parameter	Description
	udp <0-65535>: UDP destination port number (0-65535) udp source <0-65535>: UDP source port number
<action>	Action if rule is applied, which can be one of the following: forward: Explicitly define an ACL with a forward action to skip policy-based routing for traffic which would otherwise match another policy-based routing rule. route ipsec-map <ipsec-map-name>: Redirected over a VPN tunnel by specifying the ipsec-map name. For more information on IPsec maps, see crypto-local ipsec-map. route next-hop-list <next-hop-list-name>: Packets can be routed to a nexthop router on a nexthop list by specifying the nexthop list name. For more information on nexthop lists, see ip nexthop-list. route tunnel <tunnel-id>: Packets can be redirected over an L3 GRE tunnel. route tunnel-group <tunnelgroupname>: Packets can be redirected over an L3 GRE tunnel group. For more information on tunnel groups, see tunnel-group. [position <position>]: (Optional) Specify the position of the forwarding or routing rule. (1 is first, default is last)

Usage Guidelines

Policy-based routing is an optional feature that allows packets to be routed based on access control lists (ACLs) configured by the administrator. By default, when a controller receives a packet for routing, it looks up the destination IP in the routing table and forwards the packet to the nexthop router. If policy-based routing is configured, the nexthop device can be chosen based on a defined access control list.

In a typical deployment scenario with multiple uplinks, the default route only uses one of the uplink next-hops for forwarding packets. If a nexthop becomes unreachable, the packets will not reach their destination. If your deployment uses policy-based routing based on a nexthop list, any of the uplink nexthops could be used for forwarding traffic. This requires a valid ARP entry (Route-cache) in the system for all the policy-based routing nexthops.

Example

The following command configures a routing access list using an IPsec map.

```
(host)(config)# ip access-list route pbr1
    any any udp 100 route ipsec-map VPN1
```

ip access-list session

```
ip access-list session <accname>
  <source> <dest> <service> <action> [<extended action>]
  ipv6 <source> <dest> <service> <action> [<extended action>]
  no ...
```

Description

This command configures an access control list (ACL) session. To create IPv6 specific rules, use the `ipv6` keyword.

Syntax

Parameter	Description
<accname>	Name of an access control list session.
ipv6	Use the <code>ipv6</code> keyword to create IPv6 specific rules.
<source>	The traffic source, which can be one of the following: alias: specify the network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases) any: match any traffic host: specify a single host IP address localip: specify the local IP address to match traffic network: specify the IP address and netmask user: represents the IP address of the user
<dest>	The traffic destination, which can be one of the following: alias: specify the network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases) any: match any traffic host: specify a single host IP address localip: specify the local IP address to match traffic network: specify the IP address and netmask user: represents the IP address of the user
<service>	Network service, which can be one of the following: IP protocol number (0-255) name of a network service (use the <code>show netservice</code> command to see configured services) any: match any traffic app: application name. (For a complete list of supported applications, issue the command show dpi application all .)

Parameter	Description
	appcategory: application category name. (For a complete list of supported applications, issue the command show dpi application all.) tcp destination port number: specify the TCP port number (0-65535) tcp source: TCP/UDP source port number udp: specify the UDP port number (0-65535) web-cc-category: name of an a web content category. For the full list of available web content categories, issue the command show web-cc categories. web-cc-reputation: any of the predefined web content reputation levels. • high-risk • low-risk • moderate-risk • suspicious • trustworthy
<action>	Action if rule is applied, which can be one of the following: deny: Reject packets. Applicable to both IPv4 and IPv6. dst-nat: Performs destination NAT on packets. Forward packets from source network to destination; re-mark them with destination IP of the target network. This action functions in tunnel/decrypt-tunnel forwarding mode. User should configure the NAT pool in the controller. dual-nat: Performs both source and destination NAT on packets. Source IP and destination IP is changed as per the NAT pool configured. This action functions in tunnel/decrypt-tunnel forwarding mode. User should configure the NAT pool in the controller. permit: Forward packets. Applicable to both IPv4 and IPv6. redirect: Specify the location to which packets are redirected. The following are applicable only to IPv4: • Datapath destination ID (0-65535). • esi-group: Specify the ESI server group configured with the esi group command. • tunnel: Specify the ID of the tunnel configured with the interface tunnel command. webcc-reputation: Assign one of the predefined web content reputation levels to the packets. The following are applicable only to IPv6: • tunnel: Specify the ID of the tunnel configured with the interface tunnel command. • tunnel-group: Specify the tunnel-group configured with the interface tunnel command. route: Specify the next hop to which packets are routed, which can be one of the following: • dst-nat: Destination IP changes to the IP configured from the NAT pool. This action functions in bridge/split-tunnel forwarding mode. User should configure the NAT pool in the controller. • src-nat:Source IP changes to RAP's external IP. This action functions in bridge/split-tunnel forwarding mode and uses implied NAT pool.

Parameter	Description
	src-nat: Performs source NAT on packets. Source IP changes to the outgoing interface IP address (implied NAT pool) or from the pool configured (manual NAT pool). This action functions in tunnel/decrypt-tunnel forwarding mode.
<extended action>	Optional action if rule is applied, which can be one of the following: blacklist: blacklist user if ACL gets applied. classify-media: Monitors user UDP packets to classify them as media and tag accordingly. NOTE: Use this parameter only for voice and video signaling and control sessions as it causes deep packet inspection of all UDP packets from/to users. disable-scanning: pause ARM scanning while traffic is present. Note that you must enable "VoIP Aware Scanning" in the ARM profile for this feature to work. dot1p-priority: specify 802.1p priority (0-7) log: generate a log message mirror: mirror all session packets to datapath or remote destination If you configure the mirror option, define the destination to which mirrored packets are sent in the firewall policy. For more information, see firewall on page 389. next-hop-list: Route packet to the next hop in the list. position: specify the position of the rule (1 is first, default is last) queue: assign flow to priority queue (high/low) send-deny-response: if <action> is deny, send an ICMP notification to the source time-range: specify time range for this rule (configured with time-range command) tos: specify ToS value (0-63)
no	Negates any configured parameter.

Usage Guidelines

Session ACLs define traffic and firewall policies on the controller. You can configure multiple rules for each policy, with rules evaluated from top (1 is first) to bottom. The first match terminates further evaluation. Generally, you should order more specific rules at the top of the list and place less specific rules at the bottom of the list. The ACL ends with an implicit deny all. To configure IPv6 rules, use the `ipv6` keyword followed by the regular ACL keywords.

Example

The following CLI configuration shows how pre-classification and post-classification occurs during enforcement.

Each application has an implicit set of ports that are used for communication. In phase 1, if an application ACE entry is hit, the traffic matching this application's implicit port is allowed (as governed by the application ACE). The DPI engine can monitor the exchange on these ports and determine the application. Once the application is determined, phase 2 occurs when an evaluation is done to determine the final outcome for the session.

The following CLI configuration example is a user role with both the global and role session ACLs:

```
ip access-list session global-sacl
ip access-list session apprf-employee-sacl
ip access-list session control
    any any app gmail-chat permit
```

```
any any app youtube permit
any any any deny
```

This example shows a DPI rule along with a L3/L4 rule with forwarding action in the same ACL.

```
ip access-list session AppRules
  any any app Facebook permit tos 45
  any any app YouTube deny
  any any appcategory peer-to-peer deny
  any any tcp 23 permit
  network 40.1.0.0/16 any tcp 80 permit tos 60
  network 20.1.0.0/16 any tcp 80 src-nat
!
ip access-list session NetRules
  network 80.0.0.0/24 any tcp 80 deny
  network 60.0.0.0/24 any tcp 80 dual-nat pool <pool1>
  network 10.0.0.0/24 any tcp 80 dst-nat
!
user-role Role1
  session-acl AppRules
  session-acl NetRules
!
```

The following command configures a session ACL with IPv4 and IPv6 address:

```
(host) (config)#ip access-list session common
(host) (config-sess-common)#host 10.12.13.14 any any permit
(host) (config-sess-common)#ipv6 host 11:12:11:11::2 any any permit
```

The following example displays information for an ACL called mylist.

```
(host) (config) #show ip access-list mylist
ip access-list session mylist
mylist
-----
Priority Source Destination Service Application Action TimeRange Log Expired Queue
TOS 8021P Blacklist Mirror DisScan ClassifyMedia IPv4/6 Contract
-----
-- -----
1 any any app gmail deny 4 Low
```

Command History

Release	Modification
ArubaOS 3.0	This command was introduced.
ArubaOS 6.3	The any tcp source parameter was introduced.
ArubaOS 6.4	The redirect parameter was introduced under action. The app , and appcategory parameters were introduced under service.
ArubaOS 6.4.2.0	The web-cc-category and web-cc-reputation parameters were introduced, allowing users to define an ACL for a web content category or web content reputation type.

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master controllers

ip access-list standard

```
ip access-list standard {<number>|<name>}  
  deny {<ipaddr> <wildcard>|any|host <ipaddr>}  
  no ...  
  permit {<ipaddr> <wildcard>|any|host <ipaddr>}
```

Description

This command configures a standard access control list (ACL).

Syntax

Parameter	Description	Range
standard	Enter a name, or a number in the specified range.	1-99, 1300-1399
ipv6	Use the ipv6 keyword to create IPv6 specific standard rules.	
deny	Reject the specified packets, which can be the following: IP address and optional wildcard any: any packets host: specify a host IP address	—
no	Negates any configured parameter.	—
permit	Allow the specified packets, which can be the following: IP address and optional wildcard any: any packets host: specify a host IP address	—

Usage Guidelines

Standard ACLs are supported for compatibility with router software from other vendors. This ACL permits or denies traffic based on the source address of the packet.

Example

The following command configures a standard ACL:

```
(host) (config) #ip access-list standard 1  
  permit host 10.1.1.244
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master controllers

ip cp-redirect-address

ip cp-redirect-address <ipaddr> | disable

Description

This command configures a redirect address for captive portal.

Syntax

Parameter	Description
<ipaddr>	Host address with a 32-bit netmask. This address should be routable from all external networks.
disable	Disables automatic DNS resolution for captive portal.

Usage Guidelines

This command redirects wireless clients that are on different VLANs (from the controller's IP address) to the captive portal on the controller.

If you have the Next Generation Policy Enforcement Firewall (PEFNG) license installed in the controller, modify the captive portal session ACL to permit HTTP/S traffic to the destination **cp-redirect-address <ipaddr>** instead of **mswitch**. If you do not have the PEFNG license installed in the controller, the implicit captive-portal-profile ACL is automatically modified when you issue this command.

Example

The following command configures a captive portal redirect address:

```
(host) (config) #ip cp-redirect-address
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip default-gateway

```
ip default-gateway <ipaddr>[{import cell|dhcp|pppoe}|{ipsec <name>}] <cost>
```

Description

This command configures the default gateway for the controller.

Syntax

Parameter	Description
<ipaddr>	IP address of the default gateway.
import	Use a gateway IP address obtained through the cell interface, DHCP or PPPoE. The default gateway is imported into the routing table and removed when the uplink is no longer active.
cell	Use a gateway IP address obtained through the cell interface.
dhcp	Use a gateway IP address obtained DHCP.
pppoe	Use a gateway IP address obtained through PPPoE.
ipsec <name>	Define a static route using an ipsec map.
<cost>	Distance metric for this route.

Usage Guidelines

You can use this command to set the default gateway to the IP address of the interface on the upstream router or switch to which you connect the controller. If you define more than one dynamic gateway type, you must also define a cost for the route to each gateway. The controller will first attempt to obtain a gateway IP address using the option with the lowest cost. If the controller is unable to obtain a gateway IP address, it will then attempt to obtain a gateway IP address using the option with the next-lowest path cost.

Example

The following command configures the default gateway for the controller:

```
(host) (config) #ip default-gateway 10.1.1.1
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip dhcp excluded-address

```
ip dhcp excluded-address <low-ipaddr> [<high-ipaddr>]
```

Description

This command configures an excluded address range for the DHCP server on the controller.

Syntax

Parameter	Description
<low-ipaddr>	Low end of range of IP addresses. For example, you can enter the IP address of the controller so that this address is not assigned.
<high-ipaddr>	High end of the range of IP addresses.

Usage Guidelines

Use this command to specifically exclude certain addresses from being assigned by the DHCP server. Ensure that the statically assigned IP addresses are excluded.

Example

The following command configures an excluded address range:

```
ip dhcp excluded-address 192.168.1.1 192.168.1.255
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in base operating system	Config mode on master controllers

ip dhcp pool

```
ip dhcp pool <name>
  default-router <ipaddr> ...
  dns-server {<ipaddr> ... |import}
  domain-name <name>
  lease <days> <hours> <minutes>
  netbios-name-server {<ipaddr> ... |import}
  network <ipaddr> {<netmask>|<prefix>}
  no ...
  option <code> ip <ipaddr>
  pooltype ipupsell|private|public
  vendor-class-identifier
```

Description

This command configures a DHCP pool on the controller.

Syntax

Parameter	Description
default-router	IP address of the default router for the DHCP client. The client should be on the same subnetwork as the default router. You can specify up to eight IP addresses.
dns-server	IP address of the DNS server, which can be one of the following:
<address>	IP address of the DNS server. You can specify up to eight IP addresses.
import	Use the DNS server address obtained through PPPoE or DHCP.
domain-name	Domain name to which the client belongs.
lease	The amount of time that the assigned IP address is valid for the client. Specify the lease in <days> <hours> <minutes>.
netbios-name-server	IP address of the NetBIOS Windows Internet Naming Service (WINS) server, which can be one of the following:
<address>	IP address of the WINS server. You can specify up to eight IP addresses.
import	Use the NetBIOS name server address obtained through PPPoE or DHCP.
network	Range of addresses that the DHCP server may assign to clients, in the form of <ipaddr> and <netmask> or <ipaddr> and <prefix> (/n).
no	Negates any configured parameter.
option	Client-specific option code and IP address. See RFC 2132, "DHCP Options and BOOTP Vendor Extensions".

Parameter	Description
pooltype	Configure one of the following DHCP Pool types • ipupsell: Configure the DHCP pool as an IP upsell pool • private: Configure the DHCP pool as private • public: Configure the DHCP pool as public
vendor-class-identifier	Send the ArubaAP vendor ID to clients.

Usage Guidelines

A DHCP pool should be created for each IP subnetwork for which DHCP services should be provided. DHCP pools are not specifically tied to VLANs, as the DHCP server exists on every VLAN. When the controller receives a DHCP request from a client, it examines the origin of the request to determine if it should respond. If the IP address of the VLAN matches a configured DHCP pool, the controller answers the request.

Example

The following command configures a DHCP pool:

```
(host) (config) #ip dhcp pool floor1
    default-router 10.26.1.1
    dns-server 192.168.1.10
    domain-name floor1.test.com
    lease 0 8 0
    network 10.26.1.0 255.255.255.0
```

Command History

Introduced in ArubaOS 3.0

ip domain lookup

ip domain lookup

Description

This command enables Domain Name System (DNS) hostname to address translation.

Syntax

There are no parameters for this command.

Usage Guidelines

This command is enabled by default. Use the **no** form of this command to disable.

Example

The following command enables DNS hostname translation:

```
(host)(config) #ip domain lookup
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip domain-name

ip domain-name <name>

Description

This command configures the default domain name.

Syntax

Parameter	Description
domain-name	Name used to complete unqualified host names. Do not specify the leading dot (.).

Usage Guidelines

The controller uses the default domain name to complete hostnames that do not contain domain names. You must have at least one domain name server configured on the controller (see [ip name-server on page 538](#)).

Example

The following command configures the default domain name:

```
(host) (config) #ip domain-name yourdomain.com
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip igmp

```
ip igmp
  last-member-query-count <number>
  last-member-query-interval <seconds>
  max-members-per-group <val>
  query-interval <seconds>
  query-response-interval <.1 seconds>
  quick-client-convergence
  robustness-variable <2-10>
  ssm-range
  startup-query-count <number>
  startup-query-interval <seconds>
  version-l-router-present-timeout <seconds>
```

Description

This command configures Internet Group Management Protocol (IGMP) timers and counters.

Syntax

Parameter	Description	Range	Default
last-member-query-count	Number of group-specific queries that the controller sends before assuming that there are no local group members.	1-65535	2
last-member-query-interval	Maximum time, in seconds, that can elapse between group-specific query messages.	1-65535 seconds	10 seconds
max-members-per-group	Configure maximum members per group.	1-65535	300
query-interval	Interval, in seconds, at which the controller sends host-query messages to the multicast group address 224.0.0.1 to solicit group membership information.	1-65535 seconds	125 seconds
query-response-interval	Maximum time, in 1/10th seconds, that can elapse between when the controller sends a host-query message and when it receives a response. This must be less than the query-interval.	1-65535 seconds	100 (10 seconds)
quick-client-convergence	Trigger IGMP reports from client during roaming.	—	—
robustness-variable	Increase this value to allow for expected packet loss on a subnetwork.	2-10	2
ssm-range	Configure the start IP address and mask IP address for ssm-range.	—	—

Parameter	Description	Range	Default
startup-query-count	Number of queries that the controller sends out on startup, separated by startup-query-interval. The default is the robustness-variable value.	1-65535	2
startup-query-interval	Interval, in seconds, at which the controller sends general queries on startup.	1-65535 seconds	1/4 of the query interval
version-1-router-present-timeout	Timeout, in seconds, if a version 1 IGM router is detected.	1-65535 seconds	400 seconds

Usage Guidelines

IGMP is used to establish and manage IP multicast group membership. See RFC 3376, "Internet Group Management Protocol, version 3" for more information.

Example

The following command configures IGMP:

```
(host) (config) #ip igmp
    query-interval 130
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.1	Added parameters: max-members-per-group and quick-client-convergence
ArubaOS 6.4	The ssm-range parameter is introduced.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip local

```
ip local pool <name> <start-ipaddr> [<end-ipaddr>]
```

Description

This command configures a local IP pool for Layer-2 Tunnel Protocol (L2TP).

Syntax

Parameter	Description
pool	Name for the address pool.
<start-ipaddr>	Starting IP address for the pool.
<end-ipaddr>	(Optional) Ending IP address for the pool.

Usage Guidelines

VPN clients can be assigned IP addresses from the L2TP pool.

Example

The following command configures an L2TP pool:

```
(host) (config) #ip local pool 10.1.1.1 10.1.1.99
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip mobile active-domain

```
ip mobile active-domain <name>
```

Description

This command configures the mobility domain that is active on the controller.

Syntax

Parameter	Description
active-domain	Name of the mobility domain.

Usage Guidelines

All controllers are initially part of the “default” mobility domain. If you use the “default” mobility domain, you do not need to specify this domain as the active domain on the controller. However, once you assign a controller to a user-defined domain, the “default” mobility domain is no longer an active domain on the controller.

Example

The following command assigns the controller to a user-defined mobility domain:

```
(host) (config) #ip mobile active-domain campus1
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip mobile domain

```
ip mobile domain <name>
  description <descr>
  hat <home-agent> description <dscr>
  no
```

Description

This command configures the mobility domain on the controller.

Syntax

Parameter	Description
<name>	Name of the mobility domain.
description <descr>	Description of the mobility domain. The description can be a maximum of 30 characters (including spaces).
hat	Configures a home agent table (HAT) entry.
<home-agent>	The IP address of the home agent controller that requires mobility service.
description <dscr>	Description of the Home Agent Table (HAT) entry. The description can be a maximum of 30 characters (including spaces).
no	Negates any configured parameter.

Usage Guidelines

You configure the HAT on a master controller; the mobility domain information is pushed to all local controllers that are managed by the same master.

HAT entries map subnetworks or VLANs and the home agents. The home agent is typically the controller's IP address. The home agent's IP address must be routable; that is, all controllers that belong to the same mobility domain must be able to reach the home agent's IP address.

The maximum number of mobility datapath tunnels supported is 32. A maximum of 32 hat entries can be configured if the hat entries are not VRRP IP addresses. If VRRP IP addresses are configured in the hat table the maximum number of hat entries supported is less than 32 as for each VRRP entry in HAT more than two datapath tunnels are considered.

The controller looks up information in the HAT to obtain the IP address of the home agent for a mobile client. Because there can be multiple home agents on a subnetwork, the HAT can contain more than one entry for the same subnetwork.

Example

The following command configures HAT entries:

```
(host) (mobility-domain) #ip mobile domain east_building
(host) (mobility-domain) #hat 192.0.2.1 description "East building entries"
(host) (mobility-domain) #show ip mobile domain east_building
```

```

Mobility Domains:, 1 domain(s)
-----
Domain name east_building
Home Agent Table
Home Agent      Description
-----
192.0.2.1       East building entries

```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.0	A new parameter, description is added for providing more information about a HAT entry.
ArubaOS 6.3	Under the hat <home-agent> command, following parameters are deprecated: • <netmask> • <VLAN-ID> • <home-agent> • description <dscr> The above command is replaced by the hat <home-agent> description <dscr> command.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip mobile foreign-agent

```
ip mobile foreign-agent {lifetime <seconds> | max-visitors <number> |  
registrations {interval <msecs> | retransmits <number>}}
```

Description

This command configures the foreign agent for IP mobility.

Syntax

Parameter	Description	Range	Default
lifetime	Requested lifetime, in seconds, as per RFC 3344, "IP Mobility Support for IPv4".	10-65534	180 seconds
max-visitors	Maximum number of active visitors.	0-5000	5000
registrations	Frequency at which re-registration messages are sent to the home agent:		
interval	Retransmission interval, in milliseconds	100-10000	1000 milliseconds
retransmits	Maximum number of times the foreign agent attempts mobile IP registration message exchanges before giving up.	0-5	3

Usage Guidelines

A foreign agent is the controller which handles all mobile IP communication with a home agent on behalf of a roaming client.

Example

The following command configures the foreign agent:

```
(host) (config) #ip mobile foreign-agent registration interval 10000
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip mobile home-agent

```
ip mobile home-agent {max-bindings <number>|replay <seconds>}
```

Description

This command configures the home agent for IP mobility.

Syntax

Parameter	Description	Range	Default
max-bindings	Maximum number of mobile IP bindings. This option is an additional limitation to control the maximum number of roaming users. When the limit is reached, registration requests from the foreign agent fail which causes a mobile client to set a new session on the visited controller, which will become its home controller.	0-5000	5000
replay	Time difference, in seconds, for timestamp-based replay protection, as described by RFC 3344, "IP Mobility Support for IPv4". 0 disables replay.	0-300	7 seconds

Usage Guidelines

A home agent for a mobile client is the controller where the client first appears when it joins the mobility domain. The home agent is the single point of contact for the client when it roams.

Example

The following command configures the home agent:

```
(host) (config) #ip mobile home-agent replay 100
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip mobile packet-trace

ip mobile packet-trace <mac-address>

Description

This command enables packet tracing for the given mac address.

Use this command with caution. It replaces the existing users with user entries from the imported file.

Syntax

Platform	License
<mac-address>	The MAC address of the host

Usage Guidelines

Executing this command enables packet tracing for the given mac address. This is used for troubleshooting purposes only.

Example

The following command enables packet tracing for the host:

```
(host) (config) #ip mobile packet-trace 00:40:96:a6:a1:a4
```

Command History

This command was available in ArubaOS 3.4.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ip mobile proxy

```
ip mobile proxy auth-sta-roam-only |event-threshold <number>|log-trail | no-service-timeout
<seconds> | on-association | refresh-stale-ip
stale-timeout <seconds> | trail-length <number> |trail-timeout <seconds>
```

Description

This command configures the proxy mobile IP module in a mobility-enabled controller.

Syntax

Parameter	Description	Range	Default
auth-sta-roam-only	Allows a client to roam only if has been authenticated. If a client has not been authenticated, no mobility service is offered if it roams to a different VLAN or controller.	—	enabled
event-threshold	Maximum number of mobility events (events that can trigger mobility) handled per second. Mobility events above this threshold are ignored. This helps to control frequent mobility state changes when the client bounces back and forth on APs before settling down.	1-65535	25
log-trail	Enables logging at the notification level for mobile client moves.	—	enabled
no-service-timeout	Time, in seconds, after which mobility service expires. If nothing has changed from the previous state, the client is given another bridge entry but it will have limited connectivity.	30-60000	180 seconds
on-association	Enabling this option triggers mobility on station association. Mobility move detection is performed when the client associates with the controller and not when the client sends packets. Mobility on association can speed up roaming and improve connectivity for devices that can trigger mobility if they do not send many uplink packets. Downside is security; an association is all it takes to trigger mobility. This option is applicable only if layer-2 security is enforced. It is recommended to retain the default settings as this option causes more load in the system due to exchange of extra messages between controllers in the mobility domain.	—	disabled
refresh-stale-ip	Mobility forces station to renew its stale IP (assuming its DHCP) by deauthorizing the station.		

Parameter	Description	Range	Default
stale-timeout	Number of seconds the mobility state is retained after the loss of connectivity. This allows authentication state and mobility information to be preserved on the home agent controller. The default is 60 seconds but can be safely increased. Note that in many case a station state is deleted without waiting for the stale timeout; user delete from management, foreign agent to foreign agent handoff, etc. (This is different from the no-service-timeout; no-service-timeout occurs up front while the stale-timeout begins when mobility service is provided but the connection is disrupted for some reason.)	30-3600	60 seconds
stand-alone-AP	Enables support for third party or standalone APs. When this is enabled, broadcast packets are not used to trigger mobility and packets from untrusted interfaces are accepted. If mobility is enabled, you must also enable standalone AP for the client to connect to the controller's untrusted port. If the controller learns wired users via the following methods, enable standalone AP: • Third party AP connected to the controller through the untrusted port. • Clients connected to ENET1 on APs with two ethernet ports. • Wired user connected directly to the controller's untrusted port.	—	disabled
trail-length	Specifies the maximum number of entries (client moves) stored in the user mobility trail.	1-100	30
trail-timeout	Specifies the maximum interval, in seconds, an inactive mobility trail is held.	120-86400	3600 seconds

Usage Guidelines

The *proxy mobile IP module* in a mobility-enabled controller detects when a mobile client has moved to a foreign network and determines the home agent for a roaming client. The proxy mobile IP module performs the following functions:

- Derives the address of the home agent for a mobile client from the HAT using the mobile client's IP address. If there is more than one possible home agent for a mobile client in the HAT, the proxy mobile IP module uses a discovery mechanism to find the current home agent for the client.
- Detects when a mobile client has moved. Client moves are detected based on ingress port and VLAN changes and mobility is triggered accordingly. For faster roaming convergence between AP(s) on the same controller, it is recommended that you keep the "on-association" option enabled. This helps trigger mobility as soon as 802.11 association packets are received from the mobile client.

Example

The following command enables the packet trace for the given MAC address:

```
ip mobile packet-trace 00:40:96:a6:a1:a4
```

Command History

Version	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.2	The <code>re-home</code> parameter was deprecated as the re-homing functionality is no longer available.
ArubaOS 6.3	The <code>block-dhcp-release</code> , <code>dhcp aggressive-transaction</code> , <code>dhcp ignore-options</code> , <code>dhcp max-requests <0-50></code> , <code>dhcp transaction-hold <1-100></code> , <code>dhcp transaction- timeout <10-600></code> , <code>stand-alone-AP</code> parameters are deprecated.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system.	Config mode on master controllers

ip mobile revocation

ip mobile revocation {interval <msec>|retransmits <number>}

Description

This command configures the frequency at which registration revocation messages are sent.

Syntax

Parameter	Description	Range	Default
interval	Retransmission interval, in milliseconds.	100-10000 ms	1000 ms
retransmits	Maximum number of times the home agent or foreign agent attempts mobile IP registration/revocation message exchanges before giving up.	0-5	3

Usage Guidelines

A home agent or foreign agent can send a registration revocation message, which revokes registration service for the mobile client. For example, when a mobile client roams from one foreign agent to another, the home agent can send a registration revocation message to the first foreign agent so that the foreign agent can free any resources held for the client.

Example

The following command configures registration revocation messages:

```
(host) (config) #ip mobile revocation interval 2000
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system.	Config mode on master controllers

ip mobile trail (deprecated)

```
ip mobile trail {host IP address | host MAC address}
```

Description

This command configures the capture of association trail for all devices.

Command History

Version	Description
ArubaOS 3.0	Command introduced
ArubaOS 6.1	Command deprecated

ip name-server

```
ip name-server <ipaddr>
```

Description

This command configures servers for name and address resolution.

Syntax

Parameter	Description
<ip-addr>	IP address of the server.

Usage Guidelines

You can configure up to six servers using separate commands. Specify one or more servers when you configure a default domain name (see [ip domain-name on page 522](#)).

Example

The following command configures a name server:

```
ip name-server 10.1.1.245
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system.	Config mode on master controllers

ip nat

```
ip nat pool <name> <start-ipaddr> <end-ipaddr> [<dest-ipaddr>]
```

Description

This command configures a pool of IP addresses for network address translation (NAT).

Syntax

Parameter	Description
pool	Name of the NAT pool.
<start-ipaddr>	IP address that defines the beginning of the range of source NAT addresses in the pool.
<end-ipaddr>	IP address that defines the end of the range of source NAT addresses in the pool.
<dest-ipaddr>	Destination NAT IP address.

Usage Guidelines

This command configures a NAT pool which you can reference in a session ACL rule (see [ip access-list session on page 509](#)).

Example

The following command configures a NAT pool:

```
(host) (config) #ip nat pool 2net 2.1.1.1 2.1.1.125
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	This command requires the PEFNG license.	Config mode on master and local controllers

ip nexthop-list

```
ip nexthop-list <string>
  ip {<ip-addr>} [{dhcp vlan <id>} priority <0-255>]
  ipsec-map <name>
  preemptive-failover
```

Description

Define a nexthop list for policy-based routing.

Syntax

Parameter	Description
<name>	Name of the nexthop list
ip <ip-addr>	IP address of the nexthop device
ip dhcp vlan <id>	VLAN ID of the VLAN used by the nexthop device. If the VLAN gets an IP address using DHCP, and the default gateway is determined by the VLAN interface, the gateway IP is used as the nexthop IP address.
ipsec-map <map_name>	Packets can be redirected over a VPN tunnel by specifying the ipsec-map name.
preemptive-failover	This column indicates whether preemptive failover is enabled or disabled. If preemption is enabled and a higher priority nexthop becomes reachable again, packets are again forwarded to the higher priority nexthop.

Usage Guidelines

A nexthop IP is the IP address of a adjacent router or device with layer-2 connectivity to the controller. If the controller uses policy-based routing to forwards packets to a nexthop device and that device becomes unreachable, the packets matching the policy will not reach their destination. The Nexthop list provides redundancy for the nexthop devices by forwarding the traffic to a backup nexthop device in case of failures. If active nexthop device on the list becomes unreachable, traffic matching a policy-based routing ACL is forwarded using the highest-priority active nexthop on the list.

A maximum of 4 nexthops can be added to a nexthoplist. Each nexthop can be assigned a priority, which decides the order of selection of the nexthop. If a higher priority nexthop goes down, the next higher priority nexthop which is active is chosen for forwarding. If all the nexthops are configured with same priority, the order is determined based on the order in which they are configured. If all the nexthops are down, traffic is passed regular destination based forwarding.

In a typical deployment scenario with multiple uplinks, the default route only uses one of the uplink next-hops for forwarding packets. If a nexthop becomes unreachable, the packets will not reach their destination. If your deployment uses policy-based routing based on a nexthop list, any of the uplink nexthops could be used for forwarding traffic. This requires a valid ARP entry (route-cache) in the system for all the policy-based routing nexthops.

In a branch controller deployment, the site uplinks can obtain their IP addresses and default gateway using DHCP. In such deployments, the nexthop-list configuration can use the VLAN IDs of uplink VLANs. If the VLAN gets an IP address using DHCP, and the default gateway is determined by the VLAN interface, the gateway IP is

used as the nexthop IP address. Branch deployments may also require policy-based redirection of traffic to different VPN tunnels. The nexthop list allows you to select an IPsec map to redirect traffic through IPsec tunnels.

Example

The following command configures a list of next hops.

```
(host) (config) # ip nexthop-list list1
(host) (config-nexthop-list) # ip 10.1.1.41 priority 1
(host) (config-nexthop-list) # ip 172.21.18.170 priority 2
(host) (config-nexthop-list) # ip 192.18.140.20 priority 3
```

ip ospf

```
ip ospf area {authentication message-digest | cost <cost> | dead-interval <seconds> | hello-interval <seconds> | message-digest-key <keyid> <passwd> | priority <number> | retransmit-interval <seconds> | transmit-delay <seconds>}
```

Description

Configure OSPF on the VLAN interface.

Syntax

Parameter	Description	Range	Default
area	Enable OSPF on a specific interface by entering the IP address of the router that will use OSPF.		
authentication message-digest	Set the OSPF authentication mode to message digest.		disabled
cost <cost>	Set the cost associated with the OSPF traffic on an interface.	1 to 65535	1
dead-interval <seconds>	Set the elapse interval (seconds) since the last hello-packet was received from the router. After the interval elapses, the neighboring routers declare the router dead.	1 to 65535 seconds	40
hello-interval <seconds>	Set the elapse interval (seconds) between hello packets sent on the interface.	1 to 65535 seconds	10
message-digest-key <keyid> <passwd>	Enable OSPF MD5 authentication and set the key identification and a character string password.	<keyid> = 1 to 256	No default
priority <number>	Set the priority number of the interface to determine the DR.	0 to 255	1
retransmit-interval <seconds>	Set the retransmission time between link state advertisements for adjacencies belonging to the interface. NOTE: Set the time interval long enough to prevent unnecessary retransmissions.	1 to 65535 seconds	5

Parameter	Description	Range	Default
transmit-delay <seconds>	Set the elapse time before retransmitting link state update packets on the interface.	1 to 65535 seconds	1

Usage Guidelines

When configuring OSPF over multiple vendors, use this command to ensure that all routers use the same cost. Otherwise, OSPF may route improperly.

ip probe

```
ip probe default
  burst-size <size>
  frequency <frequency>
  mode ping
  no
  retries <count>
```

Description

This command configures WAN health-check ping-probes for measuring WAN availability and latency on branch controller uplinks.

Syntax

Parameter	Description
burst-size <size>	Number of probes to be sent during the probe frequency interval defined by the frequency parameter of this profile. Range: 1-16, Default 5
frequency <frequency>	Probe interval, in seconds. The WAN health-check feature sends the number of probes defined by the burst-size parameter during each frequency interval defined by this frequency parameter. Range: 10-65535, Default 10
mode ping	Enable this feature by issuing the mode ping command. Ping is the only mode currently supported by this feature.
no	Remove or negate any configured parameter
retries <count>	Number of times the controller attempts to resend a probe. Range: 1-255, Default 5

Usage Guidelines

The health-check feature uses ping-probes to check reachability and latency from the branch controller to datacenter through each of the branch controller's WAN uplinks. Latency is calculated based on the round-trip time (RTT) of ping responses. Ping settings are configured globally using the **ip probe default** command.

Examples

The following commands enable this feature, and reduce the default probe frequency interval and probe burst size.

```
ip probe default
  burst-size 3
  frequency 5
  mode ping
```

ip radius

```
ip radius {nas-ip <ipaddr>|rfc-3576-server udp-port <port>|source-interface {loopback|vlan <vlan>}}
```

Description

This command configures global parameters for configured RADIUS servers.

Syntax

Parameter	Description	Range	Default
nas-ip	NAS IP address to send in RADIUS packets. A server-specific NAS IP configured with the aaa authentication-server radius command supersedes this configuration.	—	—
rfc-3576-server	Configures the UDP port to receive requests from a RADIUS server that can send user disconnect and change-of-authorization messages, as described in RFC 3576, “Dynamic Authorization Extensions to Remote Dial In User Service (RADIUS)”. See the aaa rfc-3576-server command to configure the server. NOTE: This parameter can only be used on the master controller.	—	—
udp-port	UDP port to receive server requests.	0-65535	3799
source-interface	Interface for all outgoing RADIUS packets. The IP address of the specified interface is included in the IP header of RADIUS packets. The interface can be one of the following:	—	—
loopback	The loopback interface.	—	—
vlan	The specified VLAN.	—	—

Usage Guidelines

This command configures global RADIUS server parameters. If the **aaa authentication-server radius** command configures a server-specific NAS IP, the server-specific IP address is used instead.

Example

The following command configures a global NAS IP address sent in RADIUS packets:

```
(host) (config) #ip radius nas-ip 192.168.1.245
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	The ip radius rfc-3576-server udp-port command requires the PEFNG license. Other commands are available in the base operating system.	Config mode on master and local controllers

ids rap-wml-server-profile

```
ids rap-wml-server-profile <server-name>
ageout <period>
cache{disable|enable
clone
db-name <name>
ip-addr<ipaddr>
password <password>
type mssql|mysql
user <name>
```

Description

Use this command to specify the name and attributes of a MySQL or an MSSQL server.

Syntax

Parameter	Description	Default
ageout	(Optional) Specifies the cache ageout period, in seconds.	0
cache	(Optional) Enables the cache, or disables the cache.	Disabled
clone	Copies configuration settings from an existing profile.	
db-name	(Optional) Specifies the name of the MySQL or MSSQL database.	—
ip-addr	(Optional) Specifies the IP address of the named MSSQL server.	0.0.0.0
no	Negates any configured parameter.	—
password	(Optional) Specifies the password required for database login.	—
type	(Optional) Specifies the server type.	—
user	(Optional) Specifies the user name required for database login.	—

Usage Guidelines

Use the **show rap-wml cache** command to show the cache of all lookups for a database server. Use the **show rap-wml servers** command to show the database server state. Use the **show rap-wml wired-mac** command to show wired MAC discovered on traffic through the AP.

Example

```
(host) (config) #ids rap-wml-server-profile mysqlserver type mysql ip-addr 10.4.11.10 db-name
automatedtestdatabase user sa password sa
ids rap-wml-table-profile mysqlserver table-name mactest_undelimited timestamp-
column time lookup-time 600
```

```
ids rap-wml-table-profile table-name mysqlserver mactest_delimited mac-delimiter : timestamp-  
column time lookup-time 600
```

This example configures an MSSQL server and sets up associated rap-wml table attributes for that server.

```
(host) (config) # ids rap-wml-server-profile mssqlserver type mssql ip-addr  
10.4.11.11 db-name automatedtestdatabase user sa password sa  
ids rap-wml-table-profile mssqlserver table-name mactest_undelimited timestamp-  
column time lookup-time 600  
ids rap-wml-table-profile mssqlserver table-name mactest_delimited mac-delimiter : timestamp-  
column time lookup-time 600
```

Command History

Release	Modification
ArubaOS 2.0	Command introduced
ArubaOS 6.1	This command was renamed from rap-wml to ids rap-wml-server-profile .

Command Information

Platforms	Licensing	Command Mode
All platforms	Requires the RF Protect license.	Config mode on master controllers

ids rap-wml-table-profile

```
ids rap-wml-table-profile <profile>
clone <profile>
column-name <column-name>
lookup-time <lookup-time>
mac-delimiter <char>
no ...
<table-name>
timestamp-column <timestamp-column-name>
```

Description

Use this command to specify the name and attributes of the database table to be used for lookup.

Syntax

Parameter	Description	Default
<profile>	Name of an ids rap-wml-table profile	—
clone	Makes a copy of an existing profile	—
column-name	Specifies the database column name with the MAC address.	—
lookup-time	Specifies how far back—in seconds—to look for the MAC address. Use 0 seconds to lookup everything.	0
mac-delimiter	Specifies the optional delimiter character for the MAC address in the database.	No delimiter
no	Negates the rap-wml table for the named server.	—
table-name	Specifies the database table name.	—
timestamp-column <timestamp-column-name>	Specify the database column name with the timestamp last seen.	—

Usage Guidelines

Use the **ids rap-wml-server-profile <servername>** command to configure a MySQL or an MSSQL server, then use the **ids rap-wml-table-profile** command to configure the associated database table for the server.

Example

This example configures a MySQL server and sets up associated rap-wml table attributes for that server.

```
(host) (config) #ids rap-wml-server-profile mysqlserver type mysql ip-addr 10.4.11.10 db-name
automatedtestdatabase user sa password sa
ids rap-wml-table-profile mysqlserver table-name mactest_undelimited timestamp-
column time lookup-time 600
```

```
ids rap-wml-table-profile table-name mysqlserver mactest_delimited mac-delimiter : timestamp-  
column time lookup-time 600
```

This example configures an MSSQL server and sets up associated rap-wml table attributes for that server.

```
(host) (config) # ids rap-wml-server-profile mssqlserver type mssql ip-addr  
10.4.11.11 db-name automatedtestdatabase user sa password sa  
ids rap-wml-table-profile mssqlserver table-name mactest_undelimited timestamp-  
column time lookup-time 600  
ids rap-wml-table-profile mssqlserver table-name mactest_delimited mac-delimiter : timestamp-  
column time lookup-time 600
```

All platforms	Requires the RF Protect license.	Config mode on master controllers

ip route

```
ip route <destip> <destmask> {<nexthop> [<cost>]|ipsec <name>|null 0}
```

Description

This command configures a static route on the controller.

Syntax

Parameter	Description
<destip>	Enter the destination IP address in dotted decimal format (A.B.C.D).
<destmask>	Enter the destination netmask in dotted decimal format (A.B.C.D).
<nexthop> [<cost>]	Enter the forwarding router address in dotted decimal format (A.B.C.D). Optionally, enter the distance metric (cost) for this route. The cost prioritizes routing to the destination. The lower the cost, the higher the priority.
ipsec <name>	Enter the keyword ipsec followed by the ipsec map name to use a static ipsec route map.
null 0	Enter the key word null 0 to designate a null interface.

Usage Guidelines

This command configures a static route on the controller other than the default gateway. Use the **ip default-gateway** command to set the default gateway to the IP address of the interface on the upstream router or switch to which you connect the controller.

Example

The following command configures a static route:

```
(host) (config) #ip route 172.16.0.0 255.255.0.0 10.1.1.1
```

Related Commands

ArubaOS 3.0	Command introduced.
ArubaOS 6.4.3.0	The <nexthop> [<cost>] parameters was introduced, which supports routing using a next-hop list.

Command Information

Platform	License	Command Mode
All platforms	Base Operating System	Config mode on master and local controllers

ipv6 cp-redirect-address

ipv6 cp-redirect-address <ip6addr> | disable

Description

This command configures a redirect address for captive portal.

Syntax

Parameter	Description
<ip6addr>	This address should be routable from all external networks.
disable	Disables automatic DNS resolution for captive portal.

Usage Guidelines

This command redirects wireless clients that are on different VLANs (from the controller's IP address) to the captive portal on the controller.

If you have the Next Generation Policy Enforcement Firewall (PEFNG) license installed in the controller, modify the captive portal session ACL to permit HTTP/S traffic to the destination **cp-redirect-address <ip6addr>** instead of **mswitch**. If you do not have the PEFNG license installed in the controller, the implicit captive-portal-profile ACL is automatically modified when you issue this command.

Example

The following command configures a captive portal redirect address:

```
(host) (config) #ipv6 cp-redirect-address
```

Command History

Introduced in ArubaOS 6.1

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ipv6 default-gateway

ipv6 default-gateway <ipv6-address> <cost>

Description

This command configures an IPv6 default gateway.

Syntax

Parameter	Description
<ipv6-address>	Specify the IPv6 address of the default gateway.
cost	Specify the distance metric to select the routing protocol that determines the way to learn the route.

Usage Guidelines

This command configures an IPv6 default gateway.

Example

The following command configures an IPv6 default gateway:

```
(host) (config) #ipv6 default-gateway 2cce:205:160:100::fe 1
```

Command History

Introduced in ArubaOS 6.1

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ipv6 dhcp excluded-address

ipv6 dhcp excluded-address <low-address> [<high-address>]

Description

This command configures an excluded IPv6 address range for the DHCPv6 server on the controller.

Syntax

Parameter	Description
<low-ipaddr>	Low end of range of IPv6 addresses. For example, you can enter an IPv6 address that should not be assigned.
<high-ipaddr>	High end of the range of IPv6 addresses.

Usage Guidelines

Use this command to specifically exclude certain IPv6 addresses from being assigned by the DHCPv6 server. Ensure that the statically assigned IPv6 addresses are excluded.

Example

The following command configures an excluded IPv6 address range:

```
(host) (config-dhcpv6)#ipv6 dhcp excluded-address 2002:570:20::2 2002:570:20::25
```

Command History

Introduced in ArubaOS 6.2

Command Information

Platform	License	Command Mode
Available on all platforms	Available in base operating system	Config mode on master controllers

ipv6 dhcp pool

```
ipv6 dhcp pool <pool-name>
  dns-server <ipv6-address>
  domain-name <domain>
  lease <days> <hours> <minutes> <seconds>
  network <network prefix>
  no ...
  option <code> {ip <ipv6-addr> | text <string>}
  preference <1-255>
```

Description

This command configures a DHCPv6 pool on the controller.

Syntax

Parameter	Description
dns-server	IPv6 address of the DNS server.
domain-name	Domain name to which the client belongs.
lease	The amount of time that the assigned IPv6 address is valid for the client. Specify the lease in <days> <hours> <minutes> <seconds>. The default value is 12 hours.
network	The DHCPv6 network prefix.
no	Negates any configured parameter.
option	Client-specific option code and IPv6 address or text. See RFC 3315, "Dynamic Host Configuration Protocol for IPv6 (DHCPv6)".
preference	The DHCPv6 server preference.

Usage Guidelines

A DHCPv6 pool should be created for each IPv6 subnetwork for which DHCPv6 services should be provided. DHCPv6 pools are not specifically tied to VLANs, as the DHCPv6 server exists on every VLAN. When the controller receives a DHCPv6 request from a client, it examines the origin of the request to determine if it should respond. If the IPv6 address of the VLAN matches a configured DHCPv6 pool, the controller answers the request.

Example

The following command configures a DHCPv6 pool:

```
(host) (config) #ipv6 dhcp pool DHCPv6
  dns-server 2001:470:20::2
  domain-name test.org
  lease 0 12 0 0
  network 2001:470:20::/64
  option 24 text "Domain Search List"
  preference 25
```

Command History

Introduced in ArubaOS 6.3.

ipv6 enable

ipv6 enable

Description

This command enables IPv6 packet processing globally. This option is disabled by default.

Syntax

No parameters.

Usage Guidelines

This command enables IPv6 packet processing globally.

Command History

This command was introduced in ArubaOS 6.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ipv6 firewall

```
ipv6 firewall
  attack-rate {ping <number>|session <number>|tcp-syn <number>}
  deny-inter-user-bridging |
  drop-ip-fragments |
  enable-per-packet-logging |
  enforce-tcp-handshake |
  prohibit-ip-spoofing |
  prohibit-rst-replay |
  session-idle-timeout <seconds> |
  session-mirror-destination {ip-address <ipaddr>}|{port <slot/<port>}
```

Description

This command configures firewall options on the controller for IPv6 traffic.

Syntax

Parameter	Description	Range	Default
attack-rate	Sets rates which, if exceeded, can indicate a denial of service attack.		
ping	Number of ICMP pings per 30 seconds, which if exceeded, can indicate a denial of service attack. Recommended value is 120.	1-16384	—
session	Number of TCP or UDP connection requests per 30 seconds, which if exceeded, can indicate a denial of service attack. Recommended value is 960.	1-16384	—
tcp-syn	Number of TCP SYN messages per 30 seconds, which if exceeded, can indicate a denial of service attack. Recommended value is 960.	1-16384	—
deny-inter-user-bridging	Prevents the forwarding of Layer-2 traffic between wired or wireless users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic. This option can be used to prevent Appletalk or IPX traffic from being forwarded.	—	disabled
drop-ip-fragments	When enabled, all IP fragments are dropped. You should not enable this option unless instructed to do so by a Dell representative.	—	disabled

Parameter	Description	Range	Default
enable-per-packet-logging	Enables logging of every packet if logging is enabled for the corresponding session rule. Normally, one event is logged per session. If you enable this option, each packet in the session is logged. You should not enable this option unless instructed to do so by a Dell representative, as doing so may create unnecessary overhead on the controller.	—	disabled
enforce-tcp-handshake	Prevents data from passing between two clients until the three-way TCP handshake has been performed. This option should be disabled when you have mobile clients on the network as enabling this option will cause mobility to fail. You can enable this option if there are no mobile clients on the network.	—	disabled
prohibit-ip-spoofing	Detects IP spoofing (where an intruder sends messages using the IP address of a trusted client). When this option is enabled, IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.	—	disabled
prohibit-rst-replay	Closes a TCP connection in both directions if a TCP RST is received from either direction. You should not enable this option unless instructed to do so by a Dell representative.	—	disabled
session-idle-timeout	Time, in seconds, that a non-TCP session can be idle before it is removed from the session table. You should not modify this option unless instructed to do so by a Dell representative.	16-259	15 seconds
ip-address <ipaddr>	Send mirrored session packets to the specified IP address		
port <slot>/<port>	Send mirrored session packets to the specified controller port.		

Usage Guidelines

This command configures global firewall options on the controller for IPv6 traffic.

Example

The following command disallows forwarding of non-IP frames between IPv6 clients:

```
(host) (config) #ipv6 firewall deny-inter-user-bridging
```

Command History

Version	Description
ArubaOS 3.3	Command introduced
ArubaOS 6.1	The ipv6 firewall enable command was deprecated. Use the command ipv6 enable to enable/disable ipv6 packet/firewall processing on the controller.
ArubaOS 6.3	The session-mirror-destination parameter has been deprecated.
ArubaOS 6.4.1	The valid range for the following parameters was changed to <1-16384>: • ping • session • tcp-syn

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system, except for noted parameters	Config mode on master controllers

ipv6 neighbor

ipv6 neighbor <ipv6addr> vlan <vlan#> <mac>

Description

This command configures an IPv6 static neighbor on a VLAN interface.

Syntax

Parameter	Description
<ipv6addr>	Specify the IPv6 address of the neighbor entry.
vlan <vlan#>	Specify the VLAN ID.
<mac>	Specify the 48-bit hardware address of the neighbor entry.

Usage Guidelines

You can configure an IPv6 static neighbor on a VLAN interface.

Example

The following command configures an IPv6 static neighbor on VLAN 1:

```
(host) (config) #ipv6 neighbor 2cce:205:160:100::fe vlan 1 00:0b:86:61:13:28
```

ipv6 mld

```
ipv6 mld
  query-interval
  query-response-interval
  robustness-variable
  ssm-range
```

Description

This command configures the IPv6 MLD (Multi-listener discovery) parameters.

Syntax

Parameter	Description
query-interval	Specify the time interval in seconds (1-65535) between general queries sent by the querier. The default value is 125 seconds. By varying this value, you can tune the number of MLD messages on the link; larger values cause MLD queries to be sent less often.
query-response-interval	Specify the maximum response delay in deciseconds (1/10 seconds) that can be inserted into the periodic general queries. The default value is 100 deciseconds. By varying this value, you can tune the burstiness of MLD messages on the link; larger values make the traffic less bursty, as node responses are spread out over a larger interval. NOTE: The number of seconds represented by this value must be less than the query interval.
robustness-variable	Specify a value between 2 to 10. The default value is 2. The robustness variable allows you to tune for the expected packet loss on a link. If a link is expected to be lossy, you can increase this value. NOTE: You must not configure the robustness variable as 0 or 1.
ssm-range	Specify the source specific multicast IPv6 range. This variable allows you to configure a valid multicast IPv6 address range for which SSM semantics needs to be applied. The default IPv6 SSM address range is FF3X::4000:1 - FF3X::FFFF:FFFF.

Usage Guidelines

You can modify the default values of the MLD parameters for IPv6 MLD snooping. You must enable IPv6 MLD snooping for these values to take effect. For more information on enabling IPv6 MLD snooping, see [interface vlan on page 490](#).

Example

The following command configures the query interval of 200 seconds for IPv6 MLD snooping:

```
(host) (config) #ipv6 mld
(host) (config-mld) # query-interval 200
```

Command History

Release	Modification
ArubaOS 6.1	Command introduced
ArubaOS 6.4	The ssm-range parameter was introduced.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

ipv6 proxy-ra

```
ipv6 proxy-ra  
interval
```

Description

This command configures an interval for proxy Router Advertisement.

Syntax

Parameter	Description
<code>interval</code>	Configures proxy Router Advertisement Interval (180-1800 sec). This overrides interface Router Advertisement interval value if its value is lesser.

Usage Guidelines

This command configures interval for proxy Router Advertisement.

Example

The following command configures a global NAS IPv6 address sent in RADIUS packets:

```
(host) (config) #ipv6 proxy-ra interval 200
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system.	Config mode on master and local controllers

ipv6 radius

```
ipv6 radius {nas-ip6 <ipv6-addr>|source-interface {loopback|vlan <vlan> <ip6addr>}}
```

Description

This command configures global parameters for configured IPv6 RADIUS servers.

Syntax

Parameter	Description
nas-ip6	NAS IPv6 address to send in RADIUS packets. A server-specific NAS IPv6 configured with the aaa authentication-server radius command supersedes this configuration.
source-interface	Interface for all outgoing RADIUS packets. The IPv6 address of the specified interface is included in the IP header of RADIUS packets. The interface can be one of the following:
loopback	The loopback interface.
vlan	The specified VLAN.

Usage Guidelines

This command configures global IPv6 RADIUS server parameters. If the `aaa authentication-server radius` command configures a server-specific NAS IPv6 address, the server-specific IPv6 address is used instead.

Example

The following command configures a global NAS IPv6 address sent in RADIUS packets:

```
(host) (config) #ipv6 radius nas-ip6 2001:470:20::2
```

Command History

This command was introduced in ArubaOS 6.3.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system.	Config mode on master and local controllers

ipv6 route

```
ipv6 route {ipv6-prefix/prefix-length} | ipv6-next-hop | null | vlan [vlanid] | link-local-next-hop}
| cost
```

Description

This command configures static IPv6 routes on the controller.

Syntax

Parameter	Description
<ipv6-prefix/prefix-length>	Specify the IPv6 address and the prefix length of the destination.
<ipv6-next-hop>	Specify the next-hop IPv6 address or null 0 to terminate or discard the packets. Listed below are the following options: • X:X:X::X-IPv6 address of next-hop. The address should only be a Global IPv6 address. • null-Null interface • vlan-Vlan for link local for next-hop • <vlanid>-Vlan-id for link local next-hop • X:X:X::X-IPv6 link local address of next-hop
<cost>	Specify the distance metric to select the routing protocol that determines the way to learn the route.

Usage Guidelines

You can configure static IPv6 routes on the controller.

Example

The following command configures a static IPv6 route on the controller:

```
(host) (config) #ipv6 route 2cce:205:160:100::/64 2001:205:160:100::ff 1
(host) (config) #ipv6 route 2000:eab::/64 vlan 1 fe80::1a:1e00:a00:9f0
```

Command History

Release	Modification
ArubaOS 6.1	This command was introduced.
ArubaOS 6.4	The vlan parameter was introduced.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

kernel coredump

[no] kernel coredump

Use this command under the supervision of Dell Global Technical Support.

Description

This command enables the controller to capture the snapshot of the working memory of the control plane when the control plane has terminated abnormally.

An additional flash memory available check is imposed on core dump. If less than 100 MB of space is left on the flash, the extra core dump chunks get discarded.

Syntax

Parameter	Description	Range	Default
coredump	Enable kernel core dump on the controller.	—	Disabled

Usage Guidelines

After issuing this command, you may run the **write memory** command to save the configuration. This will enable the kernel core dumps across reboots.

Example

The following example enables kernel core dump on the controller:

```
(host) (config) #kernel coredump
```

Use the following command to save the configuration change using the CLI:

```
(host) (config) #write memory
```

Use the following command to view the kernel core dump status using the CLI:

```
(host) (config) #show running-config | include kernel
Building Configuration...
kernel coredump
```

Command History

Version	Description
ArubaOS 6.4.2.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

lacp group

```
lacp group <group_number> mode {active | passive}
```

Description

Enable Link Aggregation Control Protocol (LACP) and configure LACP on the interface.

Parameter	Description
<group_number>	Enter the link aggregation group (LAG) number. Range: 0-7
mode {active passive}	Enter the keyword mode followed by either the keyword active or passive . - Active mode—the interface is in active negotiating state. LACP runs on any link that is configured to be in the active state. The port in an active mode also automatically initiates negotiations with other ports by initiating LACP packets. - Passive mode—the interface is <i>not</i> in an active negotiating state. LACP runs on any link that is configured in a passive state. The port in a passive mode responds to negotiations requests from other ports that are in an active state. Ports in passive state respond to LACP packets.

Usage Guidelines

LACP is disabled by default; this command enables LACP. If the group number assigned contains static port members, the command is rejected.

Related Command

Command	Description
<u>show lacp</u>	View the LACP configuration status
<u>show lacp sys-id</u>	View the LACP system ID information

lACP timeout

lACP timeout {long | short}

Description

Configure the timeout period for the LACP session.

Syntax

Parameter	Description
long	Enter the keyword long to set the LACP session to 90 seconds. This is the default.
short	Enter the keyword short to set the LACP session to 3 seconds.

Usage Guidelines

The timeout value is the amount of time that a port-channel interface waits for a LACPDU (Link Aggregation Control Protocol data unit) from the remote system before terminating the LACP session. The default time out value is 90 seconds (long).

Related Commands

Command	Description

lcd-menu

lcd-menu

```
[no] disable menu [maintenance [factory-default| media-eject| qui-quick-setup | media-eject  
| system-halt | system-reboot | upgrade-image [partition0 | partition1]] upload-config]]
```

Description

This command allows you to enable or disable the LCD menu either completely or for specific operations.

Syntax

Parameter	Description	Default
lcd-menu	Enters the LCD menu configuration mode.	
no	Delete the specified LCD menu option.	
disable	Disables (or enables) the complete LCD menu.	
maintenance	Disables (or enables) the maintenance LCD menu.	Enabled
factory-default	Disables (or enables) the return to factory default option in the LCD menu.	Enabled
media-eject	Disables (or enables) the media eject option in the LCD menu.	Enabled
system-halt	Disables (or enables) the system halt option in the LCD menu.	Enabled
system-reboot	Disables (or enables) the system reboot in the LCD menu.	Enabled
upgrade-image	Disables (or enables) the upgrade image option in the LCD menu.	Enabled
partition 0 partition 1	Disables (or enables) image upgrade on the specified partition (0 or 1).	Enabled
upload-config	Disables (or enables) the upload config option in the LCD menu.	Enabled

Usage Guidelines

You can use this command to disable executing the maintenance operations using the LCD menu. You can use the no form of these commands to enable the specific LCD menu. For example, the following commands enable system halt and system reboot options:

```
(host) (config) #lcd-menu  
(host) (lcd-menu) #no disable menu maintenance system-halt  
(host) (lcd-menu) #no disable menu maintenance system-reboot
```

You can use the following show command to display the current LCD settings:

```
(host) #show lcd-menu  
lcd-menu  
-----  
Menu                                     Value  
----                                     -  
menu maintenance upgrade-image partition0 enabled  
menu maintenance upgrade-image partition1 enabled  
menu maintenance system-reboot reboot-stack enabled  
menu maintenance system-reboot reboot-local enabled
```

```

menu maintenance system-halt halt-stack          enabled
menu maintenance system-halt halt-local          enabled
menu maintenance upgrade-image                   enabled
menu maintenance upload-config                   enabled
menu maintenance factory-default                 enabled
menu maintenance media-eject                     enabled
menu maintenance system-reboot                   enabled
menu maintenance system-halt                     enabled
menu maintenance gui-quick-setup                 enabled
menu maintenance                                enabled
menu                                              enabled

```

Example

The following example disables the LCD menu completely:

```

(host) #configure terminal
(host) (config) #lcd-menu
(host) (lcd-menu) #disable menu

```

The following example disables executing the specified maintenance operation using the LCD menu:

```

(host) #configure terminal
(host) (config) #lcd-menu
(host) (lcd-menu) #disable menu maintenance ?
factory-default          Disable factory default menu
gui-quick-setup          Disable quick setup menu on LCD
media-eject              Disable media eject menu on LCD
system-halt              Disable system halt menu on LCD
system-reboot            Disable system reboot menu on LCD
upgrade-image            Disable image upgrade menu on LCD
upload-config            Disable config upload menu on LCD
(host) (lcd-menu) #disable menu maintenance upgrade-image ?
partition0               Disable image upgrade on partition 0
partition1               Disable image upgrade on partition 1

```

Command History

Introduced in ArubaOS 6.2

Command Information

Platform	License	Command Mode
W-7200 controller series only.	Available in the base operating system	Config mode on master controllers

license

```
license
  add <key>
  del <key>
  export <filename>
  import <filename>
  profile centralized-licensing-enable
  report <filename>
  server-ip <ip-addr>
  server-redundancy {license-vrrp <id>}|[peer-ip-address <ip-addr>]}
```

Description

This command allows you to install, delete, and manage software licenses on the controller.

Syntax

Parameter	Description
add	Installs the software license key in the controller. The key is normally sent to you via email. This parameter is available in enable mode.
del	Removes the software license key from the controller. The key is normally sent to you via email. This parameter is available in enable mode.
export	Exports the license database on the controller to the specified file in flash. This parameter is available in enable mode.
import	Replaces the license database on the controller with the specified file in flash. The system serial numbers referenced in the imported file must match the numbers on the controller. This parameter is available in enable mode.
profile centralized-licensing-enable	This command enables the centralized licensing feature, and is available in config mode. Centralized licensing simplifies licensing management by distributing licenses installed on one controller to other controllers on the network. One controller acts as a centralized license database for all other controllers connected to it, allowing all controllers to share a pool of unused licenses. The primary and backup licensing server can share single set of licenses, eliminating the need for a redundant license set on the backup server. Local licensing client controllers maintain information sent from the licensing server even if licensing client controller and licensing server controller can no longer communicate
report	Saves a license report to the specified file in flash. This parameter is available in enable mode.

Parameter	Description
<code>server-ip <ip-addr></code>	Enter the IP address of the licensing server. This command is available in config mode.
<code>server-redundancy</code>	Use this command to specify configure server redundancy for the centralized licensing feature. This command is available in config mode.
<code>license-vrrp <id></code>	Use this command to specify a VRRP instance to be used for the centralized licensing feature. This command is available in config mode. By default, the master controller in a master-local topology is the primary licensing server. If this master controller already has a redundant standby master, that redundant master will automatically act the backup licensing server with no additional configuration. If your primary licensing server does not yet have a redundant standby controller and you want to use a backup server with the centralized licensing feature, you must identify a second controller you want to designate as the backup licensing server, and define a virtual router on the primary licensing server. For details, see vrrp.
<code>peer-ip-address <ip-addr></code>	Enter the IP address of the backup licensing server. This command is available in config mode.

Usage Guidelines

Obtain a Dell software license certificate from your Dell sales representative or authorized reseller. Use the certificate ID and the system serial number to obtain a software license key which you install in the controller. Starting with ArubaOS 6.3, you no longer need to reboot a controller after adding or deleting a license.

Users that are not very familiar with this procedure may wish to use the License Management page in the WebUI to install and manage licenses on the controller.

Centralized licensing simplifies licensing management by distributing licenses installed on one controller to other controllers on the network. One controller acts as a centralized license database for all other controllers connected to it, allowing all controllers to share a pool of unused licenses. The primary and backup licensing server can share single set of licenses, eliminating the need for a redundant license set on the backup server. Local licensing client controllers maintain information sent from the licensing server even if licensing client controller and licensing server controller can no longer communicate.

You can use the centralized licensing feature in a master-local topology with a redundant backup master, or in a multi-master network where all the masters are connected to a single W-AirWave server. In the master-local topology, the master controller acts as the primary licensing server, and the redundant backup master acts as the backup licensing server. In a multi-master network, one controller must be designated as a primary server and a second controller configured as a backup licensing server.

Centralized licensing can distribute the following license types:

- AP
- PEFNG
- RF PProtect
- xSec
- ACR

Centralized licensing allows the primary and backup licensing server controllers share a single set of licenses. If you do not enable this feature, the master and backup master controller each require separate, identical license sets. The two controllers acting as primary and backup license servers must use the same version of ArubaOS, and must be connected on the same broadcast domain using the Virtual Router Redundancy Protocol (VRRP). Other client controllers on the network connect to the licensing server using the VRRP virtual IP address configured for that set of redundant servers. By default, the primary licensing server uses the configured virtual IP address. However, if the controller acting as the primary licensing server becomes unavailable, the secondary licensing server will take ownership of the virtual IP address, allowing licensing clients to retain seamless connectivity to a licensing server.

When you enable centralized licensing, information about the licenses already installed on the individual client controllers are sent to the licensing server, where they are added into the server's licensing table. The information in this table is then shared with all client controllers as a pool of available licenses. When a client controller uses a license in the available pool, it communicates this change to the licensing server master controller, which updates the table before synchronizing it with the other clients.

Client controllers do not share information about factory-installed or built-in licenses to the licensing server. A controller using the centralized licensing feature will use its built-in licenses before it consumes available licenses from the license pool. As a result, when a client controller sends the licensing server information about the licenses that client is using, it only reports licenses taken from the licensing pool, and disregards any built-in licenses used. For example, if a controller has a built-in 16-AP license and twenty connected APs, it will disregard the built-in licenses being used, and will report to the licensing server that it is using only four AP licenses from the license pool.

When centralized licensing is first enabled on the licensing server, its licensing table only contains information about the licenses installed on that server. When the clients contact the server, the licensing server adds the client licenses to the licensing table, then it sends the clients back information about the total available licenses for each license type. In the following example, the licenses installed on two client controllers are imported into the license table on the license server. The licensing server then shares the total number of available licenses with other controllers on the network.

For complete information on the centralized licensing feature, refer to the *Dell Networking W-Series ArubaOS User Guide*.

Examples

The following command adds a license key on the controller:

```
license add 890BobXs-cVPCb3aJ-7FbCijhZ-BuQPtuI4-RjLJW6Pl-n5K
```

Access the command-line interface of the licensing server, and issue the following commands in config mode:

```
(host) (config) #license profile
(host) (License provisioning profile) #centralized-licensing-enable
```

If the licensing server already has a dedicated redundant standby controller, that standby controller will automatically become the backup license server. If the primary licensing server in your deployment does not have a redundant master controller but you want to define a backup server for the licensing feature, issue the following commands on the licensing server.

```
(host) (License provisioning profile) #License server-redundancy
(host) (License provisioning profile) #License-vrrp <vrId>
(host) (License provisioning profile) #Peer-ip-address <ip>
```

If you are deploying centralized licensing on a cluster of master controllers, access the command-line interface of a licensing client controller, and issue the following commands in config mode:

```
(host) (config) #license profile
(host) (License provisioning profile) #centralized-licensing-enable
(host) (License provisioning profile) # license server-ip <ip>
```

Command History

Version	Description
ArubaOS 3.0	Command introduced
ArubaOS 6.3	The following commands were introduced to support the centralized licensing feature: • profile centralized-licensing-enable • server-ip <ip-addr> • server-redundancy {license-vrrp <id>} [peer-ip-address <ip-addr>}

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable or config mode on master and local controllers

local-custom-cert

```
local-custom-cert local-mac <lmac> ca-cert <ca> server-cert <cert>  
  
suite-b <gcm-128 | gcm-256>
```

Description

This command configures the user-installed certificate for secure communication between a local controller and a master controller.

Syntax

Parameter	Description
<lmac>	MAC address of the local controller's user-installed certificate.
ca-cert <ca>	User-defined name of a trusted CA certificate installed on the local controller. Use the show crypto-local pki TrustedCA command to display the CA certificates that have been imported into the controller.
server-cert <cert>	User-defined name of a server certificate installed on the local controller. Use the show crypto-local pki ServerCert command to display the server certificates that have been imported into the controller.
suite-b	If you configure your master controllers to use IKEv2 and custom-installed certificates, you can optionally use Suite-B cryptographic algorithms for IPsec encryption. Specify one of the following options: • gcm-128 Use 128-bit AES-GCM Suite-B encryption • gcm-256 Use 256-bit AES-GCM Suite-B encryption

Usage Guidelines

Use this command on a master controller to configure the custom certificate for communication with a local controller. On the local controller, use the **masterip** command to configure the IP address and certificates for the master controller. If your master and local controllers use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Example

The following command configures the local controller with a user-installed certificate:

```
(host) (config) #local-custom-cert local-mac 00:16:CF:AF:3E:E1 ca-cert cacert1 server-cert  
servercert1
```

Related Commands

Command	Description	Mode
show local-cert-mac	Display the IP, MAC address and certificate configuration of local controllers in a master-local configuration	Config mode on master controllers.

Command History

Introduced in ArubaOS 6.1

Command Information

Platform	License	Command Mode
Available on all platforms	The suite-b gcm-128 and suite-b gcm-256 encryption options for IPsec custom certificates requires the Advanced Cryptography (ACR) license. All other parameters are available in the base operating system	Config mode on master controllers

local-factory-cert

local-factory-cert local-mac <lmac>

Description

This command configures the factory-installed certificate for secure communication between a local controller and a master controller.

Syntax

Parameter	Description
<lmac>	MAC address of the local controller's factory-installed certificate.

Usage Guidelines

Use this command on a master controller to configure the factory certificate for communication with a local controller. On the local controller, use the **masterip** command to configure the IP address and certificates for the master controller. If your master and local controllers use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Example

The following command configures the local controller with a factory-installed certificate:

```
(host) (config) #local-factory-cert local-mac 00:16:CF:AF:3E:E1
```

Related Commands

Command	Description	Mode
show local-cert-mac	Display the IP, MAC address and certificate configuration of local controllers in a master-local configuration	Config mode on master controllers.

Command History

Introduced in ArubaOS 6.1

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

localip

```
localip <ipaddr>  
    ipsec <key>
```

Description

This command configures the IP address and preshared key for the local controller on a master controller.

Syntax

Parameter	Description
<ipaddr>	IP address of the local controller. Use the 0.0.0.0 address to configure a global preshared key for all inter-controller communications.
ipsec <key>	To establish the master-local IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.

Usage Guidelines

Use this command on a master controller to configure the IP address and preshared key or certificates for communication with a local controller. On the local controller, use the **masterip** command to configure the IP address and preshared key for the master controller.

If your master and local controllers use a pre-shared key for authentication, they will create the IPsec tunnel using IKEv1.

Example

The following command configures the local controller with a pre-shared key:

```
(host) (config) #localip 0.0.0.0 ipsec gw1234xyz
```

Command History

Command introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

local-userdb add

```
local-userdb add {generate-username|username <name>} {generate-password|password <passwd>}  
[comment <g_comments>][email <email>] [expiry {duration <minutes>|time <hh/mm/yyyy> <hh:mm>}]  
[guest-company <g_company>][guest-fullname <g_fullname>][guest-phone <g-phone>][mode disable]  
[opt-field-1 <opt1>][opt-field-2 <opt2>][opt-field-3 <opt3>][opt-field-4 <opt4>][remote-ip  
<ip-addr>][role <role>][sponsor-dept <sp_dept>][sponsor-mail <sp_email>][sponsor-fullname <sp_  
fullname>][sponsor-name <sp_name>]  
[start-time <mm/dd/yyyy> <hh:mm>]
```

Description

This command creates a user account entry in the controller's internal database.

Syntax

Parameter	Description	Range	Default
generate-username	Automatically generate and add a username.	—	—
username	Add the specified username.	1 - 64 characters	—
generate-password	Automatically generate a password for the username.	—	—
password	Add the specified password for the username.	6 - 128 characters	—
comments	Comments added to the user account.	—	—
email	Email address for the user account.	—	—
expiry	Expiration for the user account. If this is not set, the account does not expire.	—	no expirati on
duration	Duration, in minutes, for the user account.	1- 21474836 47	—
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.	—	—
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Dell wireless network.		
guest-fullname	The guest's full name.		
guest-phone	The guest's phone number.		

Parameter	Description	Range	Default
mode	Enables or disables the user account,	—	Disable
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.	—	—
opt-field-2	Same as opt-field-1.	—	—
opt-field-3	Same as opt-field-1.	—	—
opt-field-4	Same as opt-field-1.	—	—
remote-ip	IP address assigned to the remote peer.		
role	Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method.	—	guest
sponsor-dept	The guest sponsor's department name NOTE: A sponsor is the guest's primary contact for the visit.	—	—
sponsor-email	The sponsor's email address.	—	—
sponsor-fullname	The sponsor's full name.	—	—
sponsor-name	The sponsor's name.	—	—
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.	—	—

Usage Guidelines

When you specify the internal database as an authentication server, client information is checked against the user accounts in the internal database. You can modify an existing user account in the internal database with the `local-userdb modify` command, or delete an account with the `local-userdb del` command.

By default, the internal database in the master controller is used for authentication. Issue the `aaa authentication-server internal use-local-switch` command to use the internal database in a local controller; you then need to add user accounts to the internal database in the local controller.

Example

The following command adds a user account in the internal database with an automatically-generated username and password:

```
(host) #local-userdb add generate-username generate-password expiry duration 480
```

The following information is displayed when you enter the command:

```
GuestConnect
Username: guest4157
Password: cDFD1675
Expiration: 480 minutes
```

Related Commands

Command	Description	Mode
show local-userdb	Use this command to show the parameters displayed in the output of this command.	Enable and Config modes
show local-userdb-guest	Use this command to show the parameters displayed in the output of the local-userdb-guest add command.	Enable and Config modes
mgmt-user	Use the webui-cacert <certificate name> command if you want an external authentication server to derive the management user role. This is helpful if there are a large number of users who need to be authenticated. Use the mgmt-user webui-cacert <certificate_name>serial <number> <username> <role> command if you want the authentication process to use previously configured certificate name and serial number to derive the user role.	Config mode

Command History

	Modification
ArubaOS 3.0	Introduced for the first time.
ArubaOS 3.4	The guest, sponsor and optional field parameters were added.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system. The role parameter requires the PEFNG license.	Enable mode on master controllers.

local-userdb-ap add (deprecated)

```
local-userdb-ap add mac-address <macaddr> ap-group <group>  
    ap-name <ap-name>  
    description <desc>  
    full-name <full-name>  
    remote-ip <ip-addr>
```

Description

This command adds a Remote AP entry to the Remote AP whitelist table.

Command History

	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.2	Command replaced by whitelist-db rap add .

local-userdb-ap del

```
local-userdb-ap del mac-address <mac-addr> [all]
```

Description

This command deletes a Remote AP entry from the obsolete Remote AP database.

Syntax

Parameter	Description
mac-address <mac-addr>	MAC address of the remote AP to be removed from the Remote AP database.
all	Remove all entries from the whitelist.

Usage Guidelines

When you upgrade from ArubaOS 5.0-6.1 to ArubaOS 6.2 or later, the remote AP whitelist table will automatically move from the legacy remote AP whitelist to the newer remote AP whitelist. Issue the **local-userdb-ap del** command to delete any AP entries that did not properly move to the new table during the upgrade procedure. Entries in the newer remote AP whitelist can be removed using the command [whitelist-db rap del](#).

Example

The example below deletes a Remote AP from the obsolete Remote AP whitelist.

```
(host)(config) #local-userdb-ap del mac-addr 00:0b:86:c3:58:38
```

Related Commands

Command	Description

show interface port-channel	View information on a specified port channel interface

Command	Description
show local-userdb-ap	Display the obsolete Remote AP whitelist.
whitelist-db rap del	Delete a remote AP from the current remote AP whitelist table.

Command History

Version	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.3	The all parameter was added to delete all entries from the obsolete remote AP database

local-userdb-ap modify (deprecated)

```
local-userdb-ap modify mac-address <macaddr>  
    ap-name <ap-name>  
    description <desc>  
    full-name <full-name>  
    remote-ip <ip-addr>
```

Description

This command modifies a Remote AP entry in the Remote AP whitelist table.

Command History

	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.2	Command replaced by whitelist-db rap modify .

local-userdb-ap revoke (deprecated)

```
local-userdb-ap revoke mac-address <macaddr>  
    revoke-comment <comment>
```

Description

Revoke a lost or stolen remote AP to prevent unauthorized users from accessing the company's corporate network

Command History

	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.2	Command deprecated. For ArubaOS 6.3 or later, use or whitelist-db cpsec revoke

local-userdb-branch

```
local-userdb-branch add|del|modify mac-address <mac-address> remote-node-profile  
<remote-node-profile> <hostname>
```

Description

This command adds a branch controller to the branch controller whitelist. You can also delete the whitelist entry using this command.

Syntax

Parameter	Description	Range
mac-address <mac-address>	MAC address of the branch controller in colon-separated six-octet format.	—
branch-config-group <branch-config-group>	The branch config group to be assigned to that branch controller	1 – 64 characters
<hostname>	host name of the master controller	—

Usage Guidelines

A master controller can only assign a configuration profile to a branch controller in its branch controller whitelist. To assign a different configuration to an unprovisioned branch controller, you must delete the whitelist entry and create a new branch controller whitelist entry with the correct branch group configuration. A branch group configuration has to be validated before it is configured and pushed to a branch controller.

If your network includes multiple master controllers under a single master controller the output of this command shows all branch and master controllers on the network. By default, this command displays all entries in the whitelist. To display only part of the branch controller whitelist, include the **start <offset>** parameters to start displaying the branch controller whitelist at the specified entry value. You can also include the optional **mac-address <mac-addr>** parameters to display values for a single branch controller entry.

Example

Adding an RN to the Whitelist

To add an RN to the RN whitelist, access the command-line interface of the RNC, enter enable mode, then issue the command

```
local-userdb-branch add mac-address <mac-address> branch-config-group <branch-config-group>
```

where **<mac-address>** is the MAC address of the branch controller in colon-separated six-octet format, and **<branch-config-group>** is the name of the branch config group you want to assign to that branch controller.

Example:

```
(branch-master) #local-userdb-branch add mac-address 00:16:CF:AF:3E:E1 branch-config-group  
Location_1
```

Note that you cannot change the profile assigned to the branch controller in the whitelist entry. To assign a different branch config group to an unprovisioned branch controller, you must delete the whitelist entry and create a new whitelist entry with the correct branch config group.

Removing an RN from the Whitelist

When you remove an entry for an active RN from the RN whitelist on the RNC, that RN no longer receives configuration or license updates from the RNC, but continues to operate as previously configured. As the license server is the RNC, any operation related to the licensing does not work after it is detached. If you remove an individual RN entry from the RN whitelist before that RN is connected to the network, that RN is not automatically provisioned as a RN, and remains inactive on the network until manually provisioned.

To remove an RN from the RN whitelist, access the command-line interface of the RNC, access enable mode, then enter the command

```
local-userdb-branch del mac-address <mac-address>
```

where **<mac-address>** is the MAC address of the RN, in colon-separated six-octet format.

Example:

```
(branch-master) (config) #local-userdb-branch del mac-address 00:16:CF:AF:3E:E1
```

Related Commands

local-userdb del

```
local-userdb {del username <name>|del-all}
```

Description

This command deletes entries in the controller's internal database.

Syntax

Parameter	Description
del username	Deletes the user account for the specified username.
del-all	Deletes all entries in the internal database.

Usage Guidelines

User account entries created with expirations are automatically deleted from the internal database at the specified expiration. Use this command to delete an entry before its expiration or to delete an entry that was created without an expiration.

Example

The following command deletes a specific user account entry:

```
(host)#local-userdb del username guest4157
```

Command History

Introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

local-userdb export

local-userdb export <filename>

Description

This command exports the internal database to a file.

Use this command with caution. It replaces the existing users with user entries from the imported file.

Syntax

Parameter	Description
export	Saves the internal database to the specified file in flash.

Usage Guidelines

After using this command, you can use the **copy** command to transfer the file from flash to another location.

Example

The following command saves the internal database to a file:

```
(host)#local-userdb export jan-userdb
```

Command History

Introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

local-userdb fix-database

local-userdb fix-database

Description

This command deletes and reinitializes the internal database.

Syntax

No parameters.

Usage Guidelines

Before using this command, you can save the internal database with the **local-userdb export** command.

Command History

Introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

local-userdb-guest add

```
local-userdb-guest add {generate-username|username <name>} {generate-password|password  
<passwd>} [comment <g_comments>] [email <email>] [expiry {duration <minutes>|time <hh/mm/yyyy>  
<hh:mm>}] [guest-company <g_company>] [guest-fullname <g_fullname>] [guest-phone <g-phone>] [mode  
disable] [opt-field-1 <opt1>] [opt-field-2 <opt2>] [opt-field-3 <opt3>] [opt-field-4 <opt4>]  
[sponsor-dept <sp_dept>] [sponsor-mail <sp_email>] [sponsor-fullname <sp_fullname>] [sponsor-name  
<sp_name>]  
[start-time <mm/dd/yyyy> <hh.mm>]
```

Description

This command creates a guest user in a local user database.

Syntax

Parameter	Description	Range	Default
generate-username	Automatically generate and add a guest username.	—	—
username	Add the specified guest username.	1 - 64 characters	—
generate-password	Automatically generate a password for the username.	—	—
password	Add the specified password for the username.	6 - 128 characters	—
comments	Comments added to the guest user account.	—	—
email	Email address for the guest user account.	—	—
expiry	Expiration for the user account. If this is not set, the account does not expire.	—	no expiration
duration	Duration, in minutes, for the user account.	1-2147483647	—
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.	—	—
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Dell wireless network.		
guest-fullname	The guest's full name.		

Parameter	Description	Range	Default
guest-phone	The guest's phone number.		
mode	Enables or disables the user account,	—	Disable
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.	—	—
opt-field-2	Same as opt-field-1.	—	—
opt-field-3	Same as opt-field-1.	—	—
opt-field-4	Same as opt-field-1.	—	—
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.	—	—
sponsor-email	The sponsor's email address.	—	—
sponsor-fullname	The sponsor's full name.	—	—
sponsor-name	The sponsor's name.	—	—
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.	—	—

Usage Guidelines

When you specify the internal database as an authentication server, client information is checked against the user accounts in the internal database. You can modify an existing user account in the internal database with the **local-userdb-guest modify** command, or delete an account with the **local-userdb-guest del** command.

By default, the internal database in the master controller is used for authentication. Issue the **aaa authentication-server internal use-local-switch** command to use the internal database in a local controller; you then need to add user accounts to the internal database in the local controller.

Example

The following command adds a guest user in the internal database with an automatically-generated username and password:

```
(host) #local-userdb-guest add generate-username generate-password expiry none
```

The following information is displayed when you enter the command:

```
GuestConnect
Username: guest-5433352
Password: mBgJ6764
Expiration: none
```

local-userdb-guest del

local-userdb-guest {del username <name>|del-all}

Description

This command deletes entries in the controller's internal database.

Syntax

Parameter	Description
del username	Deletes the user account for the specified username.
del-all	Deletes all entries in the internal database.

Usage Guidelines

User account entries created with expirations are automatically deleted from the internal database at the specified expiration. Use this command to delete an entry before its expiration or to delete an entry that was created without an expiration.

Example

The following command deletes a specific user account entry:

```
(host) #local-userdb-guest del username guest4157
```

```
local-userdb-guest modify username <name> [comments <g_comments>] [email <email>] [expiry  
{duration <minutes>|time <hh/mm/yyyy> <hh:mm>}] [guest-company <g_company>] [guest-fullname <g_  
fullname>] [guest-phone <g-phone>] [mode disable] [opt-field-1 <opt1>] [opt-field-2 <opt2>] [opt-  
field-3 <opt3>] [opt-field-4 <opt4>] [password <passwd>] [sponsor-dept <sp_dept>] [sponsor-mail  
<sp_email>] [sponsor-fullname <sp_fullname>] [sponsor-name <sp_name>] [start-time <mm/dd/yyyy>  
<hh:mm>]
```

Description

This command modifies an existing guest user entry in the controller's internal database.

Syntax

Parameter	Description	Range	Default
username	Name of the existing user account entry.	1 – 64 characters	—
comments	Comments added to the user account.	—	—
email	Email address for the use account.	—	—
expiry	Expiration for the user account. If this is not set, the account does not expire.	—	no expiration
duration	Duration, in minutes, for the user account.	1-2147483647	—
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.	—	—
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Dell wireless network.		
guest-fullname	The guest's full name.		
guest-phone	The guest's phone number.		
mode	Enables or disables the user account,	—	Disable
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.	—	—

Parameter	Description	Range	Default
opt-field-2	Same as opt-field-1.	—	—
opt-field-3	Same as opt-field-1.	—	—
opt-field-4	Same as opt-field-1.	—	—
password	User's password	1– 6 characters	—
sponsor-dept	The guest sponsor's department name NOTE: A sponsor is the guest's primary contact for the visit.	—	—
sponsor-email	The sponsor's email address.	—	—
sponsor-fullname	The sponsor's full name.	—	—
sponsor-name	The sponsor's name.	—	—
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.	—	—

Usage Guidelines

Use the **show local-userdb-guest** command to view the current user account entries in the internal database.

Example

The following command disables a guest user account in the internal database:

```
(host)local-userdb-guest modify username guest4157 mode disable
```

Command History

Introduced in ArubaOS 3.4.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable and config modes on master controllers.

local-userdb-guest send-email

local-userdb-guest send-email <username> [to-guest] [to-sponsor]

Description

This command causes the controller to send email to the guest and/or sponsor any time a guest user is created.

Syntax

Parameter	Description	Range	Default
<username>	Name of the guest	1 – 64 characters	—
to-guest	Allows you to send email to the guest user's address.	—	—
to-sponsor	Allows you to send email to the sponsor's email address.	—	—

Usage Guidelines

This command allows the guest provisioning user or network administrator to causes the controller to send email to the guest and/or sponsor any time a guest user is created.

Example

The following command causes the controller to send an email to the sponsor alerting them that the guest user "Laura" was just created.

```
(host)# local-userdb-guest send-email Laura to-sponsor
```

Command History

Introduced in ArubaOS 3.4.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers

local-userdb import

local-userdb import <filename>

Description

This command replaces the internal database with the specified file from flash.

Syntax

Parameter	Description
import	Replaces the internal database with the specified file.

Usage Guidelines

This command replaces the contents of the internal database with the contents in the specified file. The file must be a valid internal database file saved with the **local-userdb export** command.

Example

The following command imports the specified file into the internal database:

```
(host)#local-userdb import jan-userdb
```

Command History

Introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

local-userdb maximum-expiration

local-userdb maximum-expiration <minutes>

Description

This command configures the maximum time, in minutes, that a guest account in the internal database can remain valid.

Syntax

Parameter	Description	Range
maximum-expiration	Maximum time, in minutes, that a guest account in the internal database can remain valid.	1-2147483647

Usage Guidelines

The user in the guest-provisioning role cannot create guest accounts that expire beyond the configured maximum time. This command is not available to the user in the guest-provisioning role.

Example

The following command sets the maximum time for guest accounts in the internal database to 8 hours (480 minutes):

```
(host) (config) #local-userdb maximum-expiration 480
```

Command History

Introduced in ArubaOS 3.0.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Configuration mode on master controllers.

local-userdb modify

```
local-userdb modify username <name> [comments <g_comments>] [email <email>] [expiry {duration  
<minutes>|time <hh/mm/yyyy> <hh:mm>}] [guest-company <g_company>] [guest-fullname <g_fullname>]  
[guest-phone <g-phone>] [mode disable] [opt-field-1 <opt1>] [opt-field-2 <opt2>] [opt-field-3  
<opt3>] [opt-field-4 <opt4>] [remote-ip <ip-addr>] [role <role>] [sponsor-dept <sp_dept>] [sponsor-  
mail <sp_email>] [sponsor-fullname <sp_fullname>] [sponsor-name <sp_name>] [start-time  
<mm/dd/yyyy> <hh:mm>]
```

Description

This command modifies an existing user account entry in the controller's internal database.

Syntax

Parameter	Description	Range	Default
username	Name of the existing user account entry.	1 – 64 characters	—
comments	Comments added to the user account.	—	—
email	Email address for the use account.	—	—
expiry	Expiration for the user account. If this is not set, the account does not expire.	—	no expiration
duration	Duration, in minutes, for the user account.	1-2147483647	—
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.	—	—
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Dell wireless network.		
guest-fullname	The guest's full name.		
guest-phone	The guest's phone number.		
mode	Enables or disables the user account,	—	Disable
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.	—	—

Parameter	Description	Range	Default
opt-field-2	Same as opt-field-1.	—	—
opt-field-3	Same as opt-field-1.	—	—
opt-field-4	Same as opt-field-1.	—	—
remote-ip	IP address assigned to the remote peer.		
role	Role for the user. This parameter requires the PEFNG license.	—	guest
sponsor-dept	The guest sponsor's department name NOTE: A sponsor is the guest's primary contact for the visit.	—	—
sponsor-email	The sponsor's email address.	—	—
sponsor-fullname	The sponsor's full name.	—	—
sponsor-name	The sponsor's name.	—	—
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.	—	—

Usage Guidelines

Use the **show local-userdb** command to view the current user account entries in the internal database.

Example

The following command disables an existing user account in the internal database:

```
(host)# local-userdb modify username guest4157 mode disable
```

Command History

	Modification
ArubaOS 3.0	Introduced for the first time.
ArubaOS 3.4	The guest, sponsor and optional parameters were added.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Enable mode on master controllers.

local-userdb-branch

```
local-userdb-branch add|del|modify mac-address <mac-address> remote-node-profile  
<remote-node-profile> <hostname>
```

Description

This command adds a branch controller to the branch controller whitelist. You can also delete the whitelist entry using this command.

Syntax

Parameter	Description	Range
mac-address <mac-address>	MAC address of the branch controller in colon-separated six-octet format.	—
branch-config-group <branch-config-group>	The branch config group to be assigned to that branch controller	1 – 64 characters
<hostname>	host name of the master controller	—

Usage Guidelines

A master controller can only assign a configuration profile to a branch controller in its branch controller whitelist. To assign a different configuration to an unprovisioned branch controller, you must delete the whitelist entry and create a new branch controller whitelist entry with the correct branch group configuration. A branch group configuration has to be validated before it is configured and pushed to a branch controller.

If your network includes multiple master controllers under a single master controller the output of this command shows all branch and master controllers on the network. By default, this command displays all entries in the whitelist. To display only part of the branch controller whitelist, include the **start <offset>** parameters to start displaying the branch controller whitelist at the specified entry value. You can also include the optional **mac-address <mac-addr>** parameters to display values for a single branch controller entry.

Example

Adding an RN to the Whitelist

To add an RN to the RN whitelist, access the command-line interface of the RNC, enter enable mode, then issue the command

```
local-userdb-branch add mac-address <mac-address> branch-config-group <branch-config-group>
```

where **<mac-address>** is the MAC address of the branch controller in colon-separated six-octet format, and **<branch-config-group>** is the name of the branch config group you want to assign to that branch controller.

Example:

```
(branch-master) #local-userdb-branch add mac-address 00:16:CF:AF:3E:E1 branch-config-group  
Location_1
```

Note that you cannot change the profile assigned to the branch controller in the whitelist entry. To assign a different branch config group to an unprovisioned branch controller, you must delete the whitelist entry and create a new whitelist entry with the correct branch config group.

Removing an RN from the Whitelist

When you remove an entry for an active RN from the RN whitelist on the RNC, that RN no longer receives configuration or license updates from the RNC, but continues to operate as previously configured. As the license server is the RNC, any operation related to the licensing does not work after it is detached. If you remove an individual RN entry from the RN whitelist before that RN is connected to the network, that RN is not automatically provisioned as a RN, and remains inactive on the network until manually provisioned.

To remove an RN from the RN whitelist, access the command-line interface of the RNC, access enable mode, then enter the command

```
local-userdb-branch del mac-address <mac-address>
```

where **<mac-address>** is the MAC address of the RN, in colon-separated six-octet format.

Example:

```
(branch-master) (config) #local-userdb-branch del mac-address 00:16:CF:AF:3E:E1
```

local-userdb send-to-guest

local-userdb send-to-guest

Description

This command automatically sends email to the guest when the guest user is created.

Syntax

No parameters.

Usage Guidelines

A guest is the person who needs guest access to the company's Dell wireless network. Email is sent directly to the guest after the guest user is created. When configuring the guest provisioning feature, the guest user is generally created by Guest Provisioning user. This is the person who is responsible for signing in guests at your company.

Example

```
(host) (config) #local-userdb send-to-guest
```

Command History

Introduced in ArubaOS 3.4.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Configuration mode on master controllers.

local-userdb send-to-sponsor

local-userdb send-to-sponsor

Description

This command automatically sends email to the guest's sponsor when the guest user is created.

Syntax

No parameters.

Usage Guidelines

The sponsor is the guest's primary contact. Email is sent directly to the guest's sponsor after the guest user is created. When configuring the guest provisioning feature, the sponsor is generally created by the Guest Provisioning user. This is the person who responsible for signing in guests at your company.

Example

```
(host) (config) #local-userdb send-to-sponsor
```

Command History

Introduced in ArubaOS 3.4.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Configuration mode on master controllers.

location

location <string>

Description

This command configures the location of the controller.

Syntax

Parameter	Description
location	A text string that specifies the system location.

Usage Guidelines

Use this command to indicate the location of the controller. You can use a combination of numbers, letters, characters, and spaces to create the name. To include a space in the name, use quotation marks to enclose the text string.

To change the existing name, enter the command with a different string. To unconfigure the location, enter "" at the prompt.

Example

The following command configures the location:

```
(host) (config) #location "Building 10, second floor, room 21E"
```

Command History

Introduced in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

location-server-feed

enable
disable

Description

This command allows sends RSSI information from APs to a location management server.

Syntax

Parameter	Description
enable	Enable the feed that sends RSSI information to a location management server. This feature is disabled by default.
disable	Disable the feed that sends RSSI information to a location management server. This feature is disabled by default.

Usage Guidelines

This command allows APs to send RSSI information to a location management server, which can use that information to compute the location of stations seen in the network.

Example

The following command configures the location:

```
(host) (config) #location-server-feed enable
```

Command History

Introduced in ArubaOS 6.3

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

logging

logging [ipaddr|ipv6addr|facility|level]

Description

Use this command to specify the IP address of the remote logging server, facility, severity, and the type.

Syntax

Parameter	Description	Range	Default
ipaddr	To set the remote logging server IPv4 address.		A.B.C.D
ipv6addr	To set the remote logging server IPv6 address.		X:X:X:X::X
facility	To set the remote logging server facility.	local 0 to local7	—
level	To set the logging level upto which the messages are logged.		

Usage Guidelines

The local use facilities (local0, local1, local2, local3, local4, local5, local6, and local7) are not reserved for specific message-generating sources, and can be used for sending syslog messages. Use the [show logging](#) command to verify that the device sends logging messages.

Example

The following command adds the remote logging server with the IP address 10.1.2.3 with a user log type using local4.

```
(host) (config) #logging 1.1.1.1 user facility local4
```

Command History

Introduced in ArubaOS 6.0

severity|type

Command History

This command was introduced in ArubaOS 3.0

Release	Modification
ArubaOS 6.0	Command introduced.
ArubaOS 6.3	The severity and type parameters were deprecated. The ipv6addr parameter was introduced.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

logging facility

logging facility <facility>

Description

Use this command to set the facility to use when logging to the remote syslog server.

Syntax

Parameter	Description	Range
<facility>	The facility to use when logging to a remote syslog server.	local0 to local7

Usage Guidelines

The local use facilities (local0, local1, local2, local3, local4, local5, local6, and local7) are not reserved for specific message-generating sources, and can be used for sending syslog messages.

Example

The following command sets the facility to local4.

```
(host) (config) #logging facility local4
```

Command History

Introduced in ArubaOS 2.5

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master controllers

logging level

logging level <level> <category> [process <process>] [subcat <subcategory>]

Description

Use this command to set the categories or subcategories and the severity levels of messages that are logged.

Syntax

Parameter	Description
<level>	The message severity level, which can be one of the following (in order of severity level):
emergencies	(0) Panic conditions that occur when the system becomes unstable.
alerts	(1) Any condition requiring immediate attention and correction.
critical	(2) Any critical conditions, such as hard drive errors.
errors	(3) Error conditions.
warnings	(4) Warning messages.
notifications	(5) Significant events of a non-critical and normal nature.
informational	(6) Messages of general interest to system users.
debugging	(7) Messages containing information for debugging purposes.
<category>	Message category, which can be one of the following:
ap-debug	AP troubleshooting messages. You must specify a debug value.
network	Network messages.
arm-user-debug	ARM user troubleshooting messages. You must specify a MAC address.
security	Security messages.
system	System messages.
user	User messages.
user-debug	User troubleshooting messages. You must specify a MAC address.

Parameter	Description
wireless	Wireless messages.
process	Controller process, which can be one of the following:
aaa	AAA logging
activate	Integration and communication with an Activate server
approc	AP processes
armd	ARM processes
authmgr	User authentication
certmgr	Certificate manager
cfgm	Configuration Manager
cpsec	Control plane security
crypto	VPN (IKE/IPsec)
cts	Transport service
dbsync	Database synchronization
dds	logging for DDS processes
dhcpcd	DHCP packets
esi	External Services Interface
extifmgr	External Interface Manager
fpapps	Layer 2 and 3 control
fw_visibility	Firewall visibility processes
gsmmgr	GSM manager
ha_mgr	High availability manager
httpd	Apache
hwmon	Hardware monitoring
iapmgr	Instant AP manager process
ipstm	Instant station manager process

Parameter	Description
l2tp	L2TP
licensemgr	License manager
localdb	Local database
mdns	Multicast DNS proxy
mobileip	Mobile IP
OSPF	OSPF logging
packetfilter	Packet filtering of messaging and control frames
pim	Protocol Independent Multicast
pppoed	PPPoE
pptp	PPTP
processes	Run-time processes
profmgr	Profile Manager
publisher	Publish subscribe service
ravd	Router Advertisement daemon
rfm	RF Troubleshooting Manager
snmp	SNMP
spectrum	Spectrum analysis processes
stm	Station management
syslogdwrap	Syslogd wrap
traffic	Traffic
ucm	UCM processes
wms	Wireless management (master controller only)
subcat	Message subcategory, which depends upon the message category specified. The following lists the subcategories available for each message category: ap-debug: all

Parameter	Description
	- network: all, dhcp, mobility, packet-dump - security: aaa, all, dot1x, firewall, ike, mobility, packet-trace, vpn, webserver - system: all, configuration, messages, snmp, webserver, amon - user: all, captive-portal, dot1x, radius, voice, vpn - user-debug: all, configuration - wireless: all

Usage Guidelines

There are eight logging severity levels, each with its associated types of messages. Each level also includes the levels below it. For example, if you set the logging level to informational (6), all messages from level 0 through level 5 (from emergencies through notifications) are also logged. The warnings severity level is set by default for all message categories.

Only the **logging level warnings security subcat ids** and **logging level warnings security subcat ids-ap** subcategories are enabled by default. Other subcategories are not generated by default even their severity is **warning** or higher. Issue the **logging level** command to enable all other message subcategories.

Example

The following command logs critical system messages.

```
logging level critical system
```

Command History

Version	Description
ArubaOS 2.5	Command introduced
ArubaOS 6.3	- A new subcategory amon is added in the logging level command to account for AMON related logging messages. - A new process mdns is added to view mDNS debug messages.
ArubaOS 6.4	A new process category ha_mgr is added to manage high availability processes.

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master and local controllers

loginsession

loginsession timeout <minutes>

Description

This command configures the time management session (via Telnet or SSH) remains active without user activity.

Syntax

Parameter	Description	Range	Default
timeout	Number of seconds or minutes that a management session remains active without any user activity.	5-60 minutes or 1-3600 seconds, 0 to disable	15 minutes

Usage Guidelines

The management user must re-login to the controller after a Telnet or SSH session times out. If you set the timeout value to 0, sessions do not time out. The TCP session timeout for wireless and wired user sessions through the controller is 15 minutes; this timeout for user sessions is not configurable.

Example:

The following command configures management sessions on the controller to not time out:

```
(host) (config) #loginsession timeout 0
```

Command History

This command was available in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Requires the PEFNG license	Config mode on master controllers

logout

logout

Description

This command exits the current CLI session.

Syntax

No parameters.

Usage Guidelines

Use this command to leave the current CLI session and return to the user login.

Example

The following command exits the CLI session:

```
(host) >logout
User:
```

Command History

This command was available in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	User mode on local or master controllers

mac-address-table

```
mac-address-table static <macaddr> {fastethernet|gigabitethernet} <slot>/<port> vlan <vlan>
```

Description

This command adds a static entry to the MAC address table.

Syntax

Parameter	Description	Range
<macaddr>	Media Access Control (MAC) address, in the format xx:xx:xx:xx:xx:xx.	—
<slot>	<slot> is always 1.	—
<port>	Number assigned to the network interface embedded in the controller. Port numbers start at 0 from the left-most position.	
vlan	ID number of the VLAN.	1-4094

Usage Guidelines

The MAC address table is used to forward traffic between ports on the controller. The table includes addresses learned by the controller. This command allows you to manually enter static addresses that are bound to specific ports and VLANs.

Example

The following command configures a MAC address table entry:

```
(host) (config) #mac-address-table static 00:0b:86:f0:05:60 fastethernet 1/12 vlan 22
```

Command History

Available in ArubaOS 3.0

Command Information

Platform	License	Command Mode
Available on all platforms	Available in the base operating system	Config mode on master and local controllers

master-redundancy master-vrrp

master-redundancy master-vrrp <id>

Description

This command associates a VRRP instance with master controller redundancy.

Syntax

Parameter	Description	Range
<id>	The virtual router ID for the VRRP instance configured with the vrrp command.	1-255

Usage Guidelines

To maintain a highly redundant network, you can use a controller as a standby for the master controller. The underlying protocol used is VRRP which you configure using the **vrrp** command.

Example

The following command configures VRRP for the initially preferred master controller:

```
(host) (config) #vrrp 22
    vlan 22
    ip address 10.200.22.254
    priority 110
    preempt
    description Preferred-Master
    tracking master-up-time 30 add 20
    no shutdown
master-redundancy
    master-vrrp 22
    peer-ip-address 192.168.2.1 ipsec qwerTY012
```

The following shows the corresponding VRRP configuration for the peer controller.

```
(host) (config) #vrrp 22
    vlan 22
    ip address 10.200.22.254
    priority 100
    preempt
    description Backup-Master
    tracking master-up-time 30 add 20
    no shutdown
master-redundancy
    master-vrrp 22
    peer-ip-address 192.168.22.1 ipsec qwerTY012
```

Command History

This command was introduced in ArubaOS 3.0.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

masterip

```
masterip <ipaddr>
    ipsec <key> [interface uplink|{vlan <id>}] [fqdn <fqdn>]
    ipsec-custom-cert master-mac1 <mac1> [master-mac2 <mac2>] ca-cert <ca> server-cert <cert>
    [interface uplink|{vlan <id>}] [fqdn <fqdn>] [suite-b gcm-128|gcm-256]
    ipsec-factory-cert master-mac1 <mac1> [master-mac2 <mac2>] [interface uplink|{vlan <id>}]
    [fqdn <fqdn>]
```

Description

This command configures the IP address and preshared key or certificate for the master controller on a local controller.

Syntax

Parameter	Description
<ipaddr>	IP address of the master controller.
ipsec <key>	To establish the master-local IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.
ipsec-custom-cert	Use a custom-installed certificate on the master controller to establish a master-local IPsec tunnel using IKEv2.
master-mac1 <mac1>	The MAC address of the certificate on the Master.
master-mac2 <mac2>	(Optional) the MAC address of the certificate on the backup master controller.
ca-cert <ca>	User-defined name of a trusted CA certificate installed on the master controller. Use the show crypto-local pki TrustedCA command to display the CA certificates that have been imported into the controller.
server-cert <cert>	User-defined name of a server certificate installed on the master controller. Use the show crypto-local pki ServerCert command to display the server certificates that have been imported into the controller.
interface	Specify the uplink or VLAN interface on the master controller to initiate IKE.
uplink	Use the master controller's current active uplink to initiate IKE.
vlan <id>	Specify a VLAN interface on the master controller to initiate IKE. If you do not specify a VLAN, the controller IP will be used.

Parameter	Description
<code>fqdn <fqdn></code>	Identify a dynamically addressed local controller by entering the Fully Qualified Domain Name (FQDN) of the controller.
<code>suite-b</code>	If you configure your master and local controllers to use IKEv2 and custom-installed certificates, you can optionally use Suite-B cryptographic algorithms for IPsec encryption. Specify one of the following options: • gcm-128 Use 128-bit AES-GCM Suite-B encryption • gcm-256 Use 256-bit AES-GCM Suite-B encryption
<code>ipsec-factory-cert</code>	Use the factory-installed certificate on the master controller to establish a master-local IPsec tunnel using IKEv2.
<code>master-mac1 <mac1></code>	The MAC address of the certificate on the Master.
<code>master-mac2 <mac2></code>	(Optional) the MAC address of the certificate on the backup master controller.
<code>interface</code>	Specify the uplink or VLAN interface on the master controller to initiate IKE.
<code>uplink</code>	Use the master controller's current active uplink to initiate IKE.
<code>vlan <id></code>	Specify a VLAN interface on the master controller to initiate IKE. If you do not specify a VLAN, the controller IP will be used.
<code>fqdn <fqdn></code>	Identify a dynamically addressed local controller by entering the Fully Qualified Domain Name (FQDN) of the controller.

Usage Guidelines

Use this command on a local controller to configure the IP address and preshared key or certificate for secure communication with the master controller. On the master controller, use the **localip** command to configure the IP address and preshared key or certificate for a local controller.

Changing the IP address of the master on a local controller requires a reboot of the local controller

If your master and local controllers use a pre-shared key for authentication, they will create the IPsec tunnel using IKEv1. If your master and local controllers use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Example

The following command configures the master controller with a pre-shared key:

```
(host) (config) #masterip 10.1.1.250 ipsec gw1234567
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The ipsec-factory-cert and ipsec-custom-cert parameters were introduced to allow certificate-based authentication of master and local controllers.

Command Information

Platform	License	Command Mode
Available on all platforms	The suite-b gcm-128 and suite-b gcm-256 encryption options for IPsec custom certificates requires the Advanced Cryptography (ACR) license. All other parameters are available in the base operating system	Available in Config mode on local controllers

master-redundancy peer-ip

```
master-redundancy peer-ip <ipaddr>
    ipsec <key>
    ipsec-custom-cert master-mac <mac> ca-cert <ca> server-cert <cert> [suite-b gcm-128|gcm-256]
    ipsec-factory-cert master-mac <mac>
```

Description

This command configures the IP address and preshared key or certificate for a redundant master controller on another master controller.

Syntax

Parameter	Description
<ipaddr>	IP address of the redundant controller. Use the 0.0.0.0 address to configure a global preshared key for all inter-controller communications.
ipsec <key>	To establish the master-master IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.
ipsec-custom-cert	Use a custom-installed certificate on the controller to establish the master-master IPsec tunnel using IKEv2
master-mac <mac>	The MAC address of the certificate on the redundant master controller.
ca-cert <ca>	User-defined name of a trusted CA certificate installed on the redundant master controller. Use the show crypto-local pki TrustedCA command to display the CA certificates that have been imported into the controller.
server-cert <cert>	User-defined name of a server certificate installed on on the redundant master controller. Use the show crypto-local pki ServerCert command to display the server certificates that have been imported into the controller.
suite-b	If you configure your master controllers to use IKEv2 and custom-installed certificates, you can optionally use Suite-B cryptographic algorithms for IPsec encryption. Specify one of the following options: • gcm-128 Use 128-bit AES-GCM Suite-B encryption • gcm-256 Use 256-bit AES-GCM Suite-B encryption
ipsec-factory-cert	Use the factory-installed certificate on the master controller to establish a master-local IPsec tunnel using IKEv2.
master-mac <mac>	The MAC address of the certificate on the redundant master controller.

Usage Guidelines

Use this command on a master controller to configure the IP address and preshared key or certificates for communication with a redundant master controller.

If your master controllers use a pre-shared key for authentication, they will create the IPsec tunnel using IKEv1. If your master and local controllers use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Example

The following command configures the local controller on a master controller:

```
(host) (config) #peer-ip 10.4.62.5 ipsec-custom-cert master-mac 00:02:2D:11:55:4D ca-cert  
cacert1 server-cert server1
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.1	The ipsec-factory-cert and ipsec-custom-cert parameters were introduced to allow certificate-based authentication of master and local controllers.

Command Information

Platform	License	Command Mode
Available on all platforms	The suite-b gcm-128 and suite-b gcm-256 encryption options for IPsec custom certificates requires the Advanced Cryptography (ACR) license. All other parameters are available in the base operating system	Config mode on master controllers

mgmt-server profile

```
mgmt-server profile <profile-name>
  clone
  airgroupinfo-enable
  location-enable
  misc-enable
  monitored-info-enable
  monitored-stats-enable
  no
  sessions-enable
  stats-enable
  tag-enable
  uccmonitoring-enable
  voiceinfo-enable
```

Description

Configure a management server profile on the controller for an W-AirWave management server or for an Analytics Location Engine (ALE) that should receive Advanced Monitoring (AMON) protocol messages filtered based on the profile settings. The default profiles provided for the AMP server (default-amp) and ALE (default-ale) are editable using this command.

Syntax

Parameter	Description
<profile-name>	Associate the controller to an W-AirWave management server by entering the IP address of the W-AirWaveserver.
clone	Use this command to copy from another configuration profile.
airgroup-enable	If enabled, the messages related to the AirGroup feature will be sent to the management server.
location-enable	If enabled, Station RSSI/AP Neighbor messages will be sent to the management server.
misc-enable	If enabled, the AP system statistics, specifications, and station steer information will be sent to the management server.
monitored-info-enable	If enabled, the monitored AP or station information will be sent to the management server.
monitored-stats-enable	If enabled, the monitored AP or station statistics will be sent to the management server.
no	Disables the specified message filter.
sessions-enable	If enabled, the firewall DNA, application, and aggregate session messages will be sent to the management server.
stats-enable	If enabled, the statistics for Radio, virtual APs, and clients will be sent to the management server.

Parameter	Description
tag-enable	If enabled, tag messages will be sent to the management server.
uccmonitoring-enable	If enabled, the messages about the unified communications manager will be sent to the management server.
voiceinfo-enable	If enabled, the voice call records will be sent to the management server.

Usage Guidelines

Use this command to create a new management server profile on the controller or to edit the default profiles.

If you delete a management server profile that is applied to a destination server, you must re-apply a different profile to the server or re-create the same profile for the message filtering process to continue.

Example

The following command configures a management server profile:

```
(host) (config) #mgmt-server profile AMP-profile
(host) (Mgmt Config profile "AMP-profile") #location-enable
(host) (Mgmt Config profile "AMP-profile") #voiceinfo-enable
```

Command History

	Modification
ArubaOS 6.3.1	Command introduced.
ArubaOS 6.4	The uccmonitoring-enable and airgroup-enable parameters were introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms		Config mode on master controllers

mgmt-server type

```
mgmt-server type
  ale primary-server <ip-addr> profile <profile-name>
  amp primary-server <ip-addr> profile <profile-name>
```

Description

Register a management server with the controller by specifying the IP address of an W-AirWave management server or Analytics and Location Engine that should receive messages from the controller using the Advanced Monitoring (AMON) protocol. You must also specify the management configuration profile in which the AMON message filtering settings can be done.

Syntax

Parameter	Description
<code>ale primary-server <ip-addr> profile <profile></code>	Associate the controller to analytics and location engine by entering the IP address of the location server and the management configuration profile.
<code>amp primary-server <ip-addr> profile <profile></code>	Associate the controller to an W-AirWave management server by entering the IP address of the W-AirWaveserver and the management configuration profile.

Example

The following command defines a primary W-AirWaveManagement server.

```
(host) (config) #mgmt-server type amp primary-server 192.168.6.2 profile default-amp
```

Command History

	Modification
ArubaOS 3.4	Command introduced.
ArubaOS 6.1	The secondary-server parameter was deprecated.
ArubaOS 6.3	The xc parameter was introduced.
ArubaOS 6.3.1	The xc parameter was changed to ale and a new profile parameter was introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms		Config mode on master controllers

mgmt-user

```
mgmt-user <username> <role> <password>
mgmt-user localauth-disable
mgmt-user ssh-pubkey client-cert <certificate> <username>
<role> <rcp>
mgmt-user webui-cacert <certificate_name> serial <number> <username> <role>
```

Description

This command configures an administrative user.

Syntax

Parameter	Description	Default
<username>	Name of the user. You can create a maximum of 10 management users. NOTE: If you configure a root management user, you can use special characters except for double-byte characters.	—
<role>	Role assigned to the user. Predefined roles include: • guest-provisioning: Allows the user to create guest accounts on a special WebUI page. • location-api-mgmt: Permits access to location API information. You can log into the CLI; however, you cannot use any CLI commands. • network-operations: Permits access to Monitoring, Reports, and Events pages in the WebUI. You can log into the CLI; however, you can only use a subset of CLI commands to monitor the controller. • read-only: Permits access to CLI show commands or WebUI monitoring pages only. • root: Permits access to all management functions on the controller.	—
<password>	NOTE: You are prompted for the <password> for this user after you type in <role> and press Enter. The password must have a minimum of six characters. You can use special characters in the management user password. The restrictions are as follows: • You cannot use double-byte characters • You cannot use the question mark (?) • You cannot use white space <space>	—
localauth-disable	Disables authentication of management users based on the results returned by the authentication server. To cancel this setting, use the no form of the command: no mgmt-user localauth-disable	Enabled

Parameter	Description	Default
	To verify if authentication of local management user accounts is enabled or disabled, use the following command: show mgmt-user local-authentication-mode	
ssh-pubkey	Configures certificate authentication of administrative users using the CLI through SSH.	—
client-cert	Name of the X.509 client certificate for authenticating administrative users using SSH.	—
<username>	Name of the user.	—
<role>	Role assigned to the authenticated user.	—
<rcp>	Revocation Checkpoint for the ssh user's client certificate. The rcp checks the revocation status of the SSH user's client certificate before permitting access.	—
webui-cacert	The client certificate for authenticating administrative users using the WebUI.	—
<certificate_name>	The CA certificate. If configured, certificate authentication and authorization are automatically completed using an authentication server.	—
serial	Serial number of the client certificate.	—
<username>	Name of the user.	—
<role>	Role assigned to the authenticated user.	—

Usage Guidelines

You can configure client certificate authentication of WebUI or SSH management users (by default, only username/password is used). To configure certificate authentication for the WebUI or SSH, use the web-server mgmt-auth certificate or ssh mgmt-auth public-key commands, respectively.

Use **webui-cacert <certificate name>** command if you want an external authentication server to derive the management user role. This is helpful if there are a large number of users who need to be authenticated.

Or, use the **mgmt-user webui-cacert <certificate_name> serial <number> <username> <role>** if you want the authentication process to use previously configured certificate name and serial number to derive the user role.

Use the **mgmt-user webui-cacert <certificate_name> serial <number> <username> <role> <rcp>** command if you want to configure an optional RCP for an ssh-pubkey user.

Example

See the web-server and ssh command descriptions for examples of certificate and public key authentication. The following command configures a management user and role:

```
(host) (config) #mgmt-user zach_jennings root
```

Password: *****
Re-Type password: *****

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 3.1	The ssh-pubkey and webui-cacert parameters were introduced.
ArubaOS 3.2	The network-operations role was introduced.
ArubaOS 3.3	The location-api-mgmt role and localauth-disable parameters were introduced.
ArubaOS 3.4	The webui-cacert <certificate name> parameter had additional functionality introduced.
ArubaOS 6.3	The < rcp > parameter was introduced.

Command Information

mobility-manager

```
mobility-manager <ipaddr> user <username> <password> [interval <secs>]  
[retrycount <number>] [udp-port <port>] [rtls <rtls-udp-port>] trap-version {1|2c|3}
```

Description

This command allows the controller to communicate with an MMS server.

Usage Guidelines

This command needs to be configured before the controller can communicate with the MMS server. This command performs three tasks:

- Configures the IP address of the MMS server. In previous ArubaOS releases, this was done with the mobility-server command.
- Creates an SNMP version 3 user profile with the configured <username> and <password>. This allows SNMP SETs from the MMS server to be received by the controller. The authentication protocol is Secure Hash Algorithm (SHA) and Data Encryption Standard (DES) is used for encryption. If <username> and <password> match an existing SNMP v3 user profile, the existing one is used. Otherwise, a new profile is created.

This username and password must be used when adding this controller to the MMS server in the MMS Dashboard.

- Allows SNMP traps and notifications to be sent to the MMS server IP address, by adding this MMS server as a trap receiver.
- Optionally enables the MMS server to function as a Real Time Location System (RTLS) server to receive location information via APs from RTLS tags or other devices.

Use the show mobility-manager command to check the current status of the configured MMS servers.

Example

The following command configures the IP address and SNMP user profile for the MMS server:

```
(host) (config)# mobility-manager 10.2.1.245 user mms-user my-password.
```

Command History

This command was introduced in ArubaOS 3.1.

netdestination

```
netdestination <name>
  description <description6>
  host <ipaddr> [position <number>]
  invert
  name
  network <ipaddr> <netmask> [position <number>]
  no ...
  range <start-ipaddr> <end-ipaddr> [position <number>]
```

Description

This command configures an alias for an IPv4 network host, subnetwork, or range of addresses.

Syntax

Parameter	Description
<name>	Name for this host or domain. Maximum length is 63 characters.
description	Description about the this destination up to 128 characters long.
host	Configures a single IPv4 host and its position in the list.
invert	Specifies that the inverse of the network addresses configured are used. For example, if a network of 172.16.0.0 255.255.0.0 is configured, this parameter specifies that the alias matches everything except this subnetwork.
network	An IPv4 subnetwork consisting of an IP address and netmask.
no	Negates any configured parameter.
range	A range of IPv4 addresses consisting of sequential addresses between a lower and an upper value. The maximum number of addresses in the range is 16. If larger ranges are needed, convert the range into a subnetwork and use the network parameter.

Usage

Aliases can simplify configuration of session ACLs, as you can use an alias when specifying the traffic source and/or destination it in multiple session ACLs. Once you configure an alias, you can use it to manage network and host destinations from a central configuration point, because all policies that reference the alias will be updated automatically when you change the alias.

When using the **invert** option, use caution when defining multiple aliases, as entries are processed one at a time. As an example, consider a netdestination configured with the following two network hosts:

```
netdestination dest1 invert
network 1.0.0.0 255.0.0.0
network 2.0.0.0 255.0.0.0
```

A frame from http://1.0.0.1 would match the first alias entry, (which allows everything except for 1.0.0.0/8) so the frame would be rejected. However, it would then be compared against the second alias, which allows everything except for 2.0.0.0/8, and the frame would be permitted.

Example

The following command configures an alias for an internal network:

```
(host) (config) #netdestination Internal
network 10.1.0.0 255.255.0.0
```

Command History

Release	Modification
ArubaOS 3.0	Command introduced
ArubaOS 6.1	Host functionality now only supports IPv4 subnets.
ArubaOS 6.2	Name parameter has maximum character length.

Command Information

Platforms	Licensing	Command Mode

netdestination6

```
netdestination6 <name>
  description <description6>
  host <ipaddr> [position <number>]
  invert
  name
  network <ipaddr> <netmask> [position <number>]
  no ...
  range <start-ipaddr> <end-ipaddr> [position <number>]
```

Description

This command configures an alias for an IPv6 network host, subnetwork, or range of addresses.

Syntax

Parameter	Description	Default
<name>	Name of the IPv6 destination host or subnetwork up to 63 characters long.	
description	Description about the IPv6 netdestination up to 128 characters long.	-
host	Configures a single IPv6 host and position in the list.	—
invert	Specifies that the inverse of the network addresses configured are used. For example, if a network of fe80:0:0:0:0:ac10:0/128 is configured, this parameter specifies that the alias matches everything except this subnetwork.	—
network	An IPv6 subnetwork consisting of an IP address and netmask.	—
no	Negates any configured parameter.	—
range	A range of IPv6 addresses consisting of sequential addresses between a lower and an upper value. The maximum number of addresses in the range is 16. If larger ranges are needed, convert the range into a subnetwork and use the network parameter.	—

Usage Guidelines

Aliases can simplify configuration of session ACLs, as you can use an alias when specifying the traffic source and/or destination. Once you configure an alias, you can use it in multiple session ACLs.

When using the **invert** option, use caution when defining multiple aliases, as entries are processed one at a time. As an example, consider a netdestination configured with the following two network hosts:

```
netdestination6 dest1 invert
network 2002:0:0:0:0:0:100:0/128
network 2002:0:0:0:0:0:200:0/128
```

A frame from http://1.0.0.1 would match the first alias entry, (which allows everything except for 2002:0:0:0:0:0:100:0/128) so the frame would be rejected. However, it would then be compared against the second alias, which allows everything except for 2002:0:0:0:0:0:200:0/128, and the frame would be permitted.

Example

The following command configures an alias for an internal network:

```
(host) (config) #netdestination6 Internal  
network fe80:0:0:0:0:0:a01:0/128
```

Command History

Release	Modification
ArubaOS 6.1	Command introduced
ArubaOS 6.3	A new field, description has been introduced to provide a description about the netdestination up to 128 characters long.
ArubaOS 6.3	Maximum length allowed for netdestination6 <name> is now 63 characters.

All platforms	Requires the Policy Enforcement Firewall license.	Config mode on master controllers

netexthdr

```
netexthdr <alias-name>  
    eh <eh-type> deny | permit
```

Description

This command allows you to edit the packet filter options in the extension header (EH).

Syntax

Parameter	Description	Default
<alias-name>	Specify the EH alias name.	default
eh <eh-type>	Specify one of the following EH types: • <0-255>: Matches the IPv6 next header type • authentication: Matches the IPv6 authentication header • dest-option: Matches the IPv6 destination-option header • esp: Matches the IPv6 encapsulation security payload header • fragment: Matches the IPv6 fragment header • hop-by-hop: Matches the IPv6 hop-by-hop header • mobility: Matches the IPv6 mobility header • routing: Matches the IPv6 routing header	—
deny	Denies the IPv6 packets matching the specified extended header type.	—
permit	Permits the IPv6 packets matching the specified extended header type. NOTE: By default, all the EH types are supported in the default EH.	—

Usage Guidelines

ArubaOS firewall is enhanced to process the IPv6 extension header (EH) to enable IPv6 packet filtering. You can filter the incoming IPv6 packets based on the EH type. You can edit the packet filter options in the default EH, using this command. By default, the default EH alias permits all EH types.

Example

The following command denies the IPv6 packets matching the specified extended header type in the default EH:

```
(host) (config) #netexthdr default  
(host) (config-exthdr) #eh authentication deny
```

Related Commands

```
(host) #show netexthdr <alias-name>
```

netSERVICE

```
netSERVICE <name> <protocol>|tcp|udp {list <port>,<port>}|{<port> [<port>]}  
[ALG <service>]
```

Description

This command configures an alias for network protocols.

Syntax

Parameter	Description	Range
netSERVICE	Name for this alias.	—
<protocol>	IP protocol number.	0-255
tcp	Configure an alias for a TCP protocol	
udp	Configure an alias for a UDP protocol	
list <port>,<port>	Specify a list of non-contiguous port numbers, by entering up to six port numbers, separated by commas.	0-65535
<port> [<port>]	TCP or UDP port number. You can specify a single port number, or define a port range by specifying both the lower and upper port numbers.	0-65535
ALG	Application-level gateway (ALG) for this alias.	—
<service>	Specify one of the following service types: • dhcp: Service is DHCP • dns: Service is DNS • ftp: Service is FTP • h323: Service is H323 • noe: Service is Alcatel NOE • rtsp: Service is RTSP • sccp: Service is SCCP • sip: Service is SIP • sips: Service is Secure SIP • svp: Service is SVP • tftp: Service is TFTP • vocera: Service is VOCERA	

Usage Guidelines

Aliases can simplify configuration of session ACLs, as you can use an alias when specifying the network service. Once you configure an alias, you can use it in multiple session ACLs.

Example

The following command configures an alias for a network service:

```
(host) (config) #netservice HTTP tcp 80
```

Command History

Version	Modification
ArubaOS 3.0	Command introduced.
ArubaOS 6.0	The list parameter for defining non-contiguous ports was introduced.

network-printer [deprecated]

```
network-printer [max-clients <2-20> |  
    max-clients-per-host <1-20> |  
    max-jobs <1-1000>]
```

Description

This command allows you to configure client and print job for the USB printer connected to a W-600 Series controller.

Syntax

Parameter	Description
max-clients	Specify the maximum number of clients that can use the printer. Currently, the W-600 Series supports a maximum of 20 concurrent clients.
max-clients-per-host	Specify the maximum number of concurrent clients for a single host. Currently, the W-600 Series supports a maximum of 20 concurrent clients.
max-jobs	Specify the maximum number of jobs that can be saved in the memory. Currently, the W-600 Series controller will support a storage of 1000 jobs.

Usage Guidelines

Use this command in the config mode.

In the enable mode, you can use the `network-printer delete <printer-name> job <job-id>` command to delete print jobs in specific printer.

Command History

Release	Modification
ArubaOS 3.4	Command introduced.
ArubaOS 6.2	Command deprecated.

network-storage [deprecated]

```
network-storage [share <share-name>]
    share [usb: disk <disk-name> <filesystem-path> mode {read-only | read-write}
    no share
```

Description

This command allows you to perform the following operation on a network share:

- Configure a file system path for the share—This allows users to access the share from their computer.
- Remove the share access using the `no share` command.

Syntax

Parameter	Description
share	Enter a name for the share on the controller. After you enter this command, the CLI mode will shift to operations on that share.

Usage Guidelines

To access the share, you must create a filesystem path to the share. enter:

```
(host) (config-network-storage share)# share usb: disk <disk name> <filesystem path> mode
```

Where,

disk name is the name of the disk. You can also specify the disk alias instead of the disk name.

filesystem path is the path to access the share. This path contains the partition name and the shared folder name.

mode is the permission settings. You can either specify `read-only` or `read-write` modes.

Example

The following command associates a share to a file system path and configures the access mode.

```
(host) (config-network-storage share)#share usb: disk Maxtor1TB Maxtor-Basics_Desktop-2HBADMJ4_p1/documents mode read-write
```

```
(host) (config-network-storage share)#show network-storage shares
```

NAS Shares

Disk Name	Partition Name	Folder Name	Share Name	Share Path	Share Mode	Status

ntp authenticate

ntp authenticate

Description

This command enables or disables NTP authentication.

Syntax

No parameters.

Usage Guidelines

Network Time Protocol (NTP) authentication enables the controller to authenticate the NTP server before synchronizing local time with server. This helps identify secure servers from fraudulent servers. This command has to be enabled for NTP authentication to work.

Example

The following command configures an NTP server:

```
(host) (config) #ntp authenticate
```

Command History

Release	Modification
ArubaOS 6.1	Command introduced

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Config mode on master controllers

ntp authentication-key

```
ntp authentication-key <key-id> md5 <keyvalue>
```

Description

This command configures a key identifier and secret key and adds them into the database. NTP authentication works with a symmetric key configured by user. The key is shared by the client (Dell controller) and an external NTP server.

Syntax

Parameter	Description	Default
<key-id>	The key identifier is a string that is shared by the client (Dell controller) and an external NTP server. This value is added into the database.	—
md5 <keyvalue>	The key value is a secret string, which along with the key identifier, is used for authentication. This is added into the database.	—

Usage Guidelines

NTP authentication works with a symmetric key configured by user. The key is shared by the client (Dell controller) and an external NTP server. This command adds both the key identifier and secret string into the database.

Example

The following command configures the NTP authentication key. The key identifier is 12345 and the shared secret is 67890. Both key identifier and shared secret:

```
(host) (config) #ntp authentication-key 12345 md5 67890
```

Command History

Release	Modification
ArubaOS 6.1	Command introduced

Command Information

All platforms	Base operating system	Config mode on master controllers

ntp server

```
#ntp server {<IPv4/IPv6 Address>| [iburst] [key]}
```

Description

This command configures a Network Time Protocol (NTP) server.

Syntax

Parameter	Description	Default
IPv4/IPv6 Address	IPv4/IPv6 Address of the Peer.	—
iburst	(Optional) This parameter causes the controller to send up to ten queries within the first minute to the NTP server. This option is considered “aggressive” by some public NTP servers.	disabled
key <key-id>	This is the key identifier used to authenticate the NTP server. This needs to match the key identifier configured in the ntp authentication-key command.	—

Usage Guidelines

You can configure the controller to set its system clock using NTP by specifying one or more NTP servers.

Example

The following command configures an NTP server using the **iburst** optional parameter and using a key identifier “123456.”

```
(host) (config) #ntp server 10.1.1.245 iburst key 12345
```

Command History

Release	Modification
ArubaOS 1.0	Command introduced
ArubaOS 3.0	The iburst parameter was introduced
ArubaOS 6.1	The key parameter was introduced
ArubaOS 6.4	The IPv6 parameter was introduced.

ntp trusted-key

ntp trusted-key <keyid>

Description

This command configures an additional subset of trusted keys which can be used for NTP authentication.

Syntax

Parameter	Description	Default
<keyid>	An additional trusted string that can be used for authentication	—

Usage Guidelines

You can configure additional subset of keys which are trusted and can be used for NTP authentication.

Example

The following command configures an additional trusted key(84956) which can be used for NTP authentication.

```
(host) (config) #ntp trusted-key 84956
```

Command History

Release	Modification
ArubaOS 6.1	Command introduced

packet-capture

packet-capture

```
controlpath [interprocess {all | <ports>}] [other] [sysmsg {all | <opcodes>}] [tcp
{all | <ports>}] [udp {all | <ports>}]
copy-to-flash {controlpath-pcap | datapath-pcap}
datapath {ipsec <peer-ip>} [wifi-client <mac-address> {decrypted | encrypted | all}]
destination [interface <slot/port>] [ip-address <ip-address>] [local-filesystem]
no
reset-pcap {controlpath-pcap | datapath-pcap}
```

Description

Use this command to enable or disable packet capturing and set packet capturing options for a single packet capture session.

Syntax

Parameter	Description	Default
controlpath	Enables controlpath packet capture. Captured packets are stored in <code>/var/log/oslog/filter.pcap</code> . NOTE: Only capture to local-filesystem is supported for controlpath capture.	Disabled
interprocess	Enables or disables interprocess packet capturing. . Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all ports. All CLI ports, which are TCP, are always skipped.	Disabled
other	Enable or disable all other types of packets.	Disabled
sysmsg	Enable or disable internal messaging packets. Specify up to ten comma-separated opcodes to capture; use <code>all</code> to sniff all opcodes. All CLI ports, which are TCP, are always skipped.	Disabled
tcp	Enable or disable TCP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all TCP ports. All CLI ports, which are TCP, are always skipped.	Disabled
udp	Enable or disable UDP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all UDP ports. All CLI ports, which are TCP, are always skipped.	Disabled
copy-to-flash	Copies captured packets to the flash.	—
controlpath-pcap	Copies controlpath captures. They are saved as controlpath-pcap.tar.gz .	—

Parameter	Description	Default
datapath-pcap	Copies datapath captures. They are saved as datapath-pcap.tar.gz .	—
datapath	Enables datapath packet capture. Captured packets are stored in /var/log/oslog/datapath.pcap or mirrored out of the controller.	Disabled
ipsec <peer-ip>	Enable or disable IPSec packet capturing. Enter the IPSec peer IP address to specify a given peer. NOTE: Capture to local-filesystem is not supported with this option.	Disabled
wifi-client <mac-address> {decrypted encrypted all}	Enable or disable packet capturing from a wifi client. Specify the client device by entering the device's MAC address. Additionally, you can specify what type of traffic captured: decrypted, encrypted, or all.	Disabled
destination	Configures the capture destination.	—
interface <slot/port> or <slot/module/port>	Sends packet captures to a specific interface on the controller. Specify the interface using the slot/port format or <slot/module/port> for the W-7200 Series controllers.	—
ip-address <ip-address>	Sends packet captures to a specific IP address.	—
local-filesystem	Stores captured packets on the controller in pcap files.	—
no	Negates any configured parameter.	
reset-pcap	Deletes old pcap files and restarts the active capture.	—
controlpath-pcap	Deletes old controlpath pcap files and restarts the active controlpath capture.	—
datapath-pcap	Deletes old datapath pcap files and restarts the active datapath capture.	—

Usage Guidelines

The packet-capture command can perform two types of packet capture: controlpath and datapath. Controlpath only captures packet destined for the controller. Datapath captures packets that are being forwarded by the controller, such as packets from a wifi client.

Packets can be retrieved through the **tar logs** command; look for the filter.pcap or datapath.pcap file. This command activates packet capture options on the current session. They are not saved and applied across all reboots.

If you do want to enable a packet capture session without setting values that can be saved and used for another session, use the command [packet-capture](#). The related command [packet-capture-defaults](#) lets you define a set of packet capture options and save them in the configuration file. These setting will be

automatically enabled when the controller boots up. Any settings defined using the command [packet-capture](#) will override [packet-capture-defaults](#).

Example

The following command enables packet capturing for debugging a wireless WEP station doing VPN. This example uses the following parameters and values:

- Station up/down: sysmsg opcode 30
- WEP key plumbing: sysmsg opcode 29
- DHCP: sysmsg opcode 90
- IKE: UDP port 500 and 4500
- Layer 2 Tunneling Protocol (L2TP): UDP port 1701

```
(host) #packet-capture sysmsg 30,29,90
```

```
(host) #packet-capture udp 500,4500,1701,1812,1645
```

Command History

This command was introduced in ArubaOS 2.3.

Release	Modification
ArubaOS 2.3	Command introduced
ArubaOS 6.3	The following parameters were added: • controlpath • copy-to-flash • datapath ipsec and datapath wifi-client • destination • reset-pcap • no parameter has replaced disable The following parameters were moved under the controlpath parameter: • interprocess • other • sysmsg • tcp • udp

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system	Enable mode on master and local controllers

packet-capture-defaults

packet-capture

```
controlpath [interprocess {all | <ports>}] [other] [sysmsg {all | <opcodes>}] [tcp  
{all | <ports>}] [udp {all | <ports>}]  
datapath {ipsec <peer-ip>} [wifi-client <mac-address> {decrypted | encrypted | all}]  
destination [interface <slot/port>] [ip-address <ip-address>] [local-filesystem]  
no
```

Description

Use this command to enable or disable packet capturing and define a set of default packet capturing options on the control path for debugging purposes.

Syntax

Parameter	Description	Default
controlpath	Enables controlpath packet capture. Captured packets are stored in /var/log/oslog/filter.pcap. NOTE: Only capture to local-filesystem is supported for controlpath capture.	Disabled
interprocess	Enables or disables interprocess packet capturing. . Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all ports. All CLI ports, which are TCP, are always skipped.	Disabled
other	Enable or disable all other types of packets.	Disabled
sysmsg	Enable or disable internal messaging packets. Specify up to ten comma-separated opcodes to capture; use <code>all</code> to sniff all opcodes. All CLI ports, which are TCP, are always skipped.	Disabled
tcp	Enable or disable TCP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all TCP ports. All CLI ports, which are TCP, are always skipped.	Disabled
udp	Enable or disable UDP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all UDP ports. All CLI ports, which are TCP, are always skipped.	Disabled
datapath	Enables datapath packet capture. Captured packets are stored in /var/log/oslog/datapath.pcap or mirrored out of the controller.	Disabled
ipsec <peer-ip>	Enable or disable IPSec packet capturing. Enter the IPSec peer IP address to specify a given peer. NOTE: Capture to local-filesystem is not supported with this option.	Disabled

Parameter	Description	Default
wifi-client <mac-address> {decrypted encrypted all}	Enable or disable packet capturing from a wifi client. Specify the client device by entering the device's MAC address. Additionally, you can specify what type of traffic captured: decrypted, encrypted, or all.	Disabled
destination	Configures the capture destination.	—
interface <slot/port> or <slot/module/port>	Sends packet captures to a specific interface on the controller. Specify the interface using the slot/port format or <slot/module/port> for the W-7200 Series controllers.	—
ip-address <ip-address>	Sends packet captures to a specific IP address.	—
local-filesystem	Stores captured packets on the controller in pcap files.	—
no	Negates any configured parameter.	

Usage Guidelines

This command applies to control path packets; not datapath packets. Packets can be retrieved through the **tar log** command; look for the filter.pcap file. This command activates packet capture options on the current switch. They are not saved and applied across switches.

Example

The following command sets the default packet capture values to debug a wireless WEP station doing VPN. Once these default settings are defined, you can use the [packet-capture](#) command to enable packet capturing with these values. This example uses the following parameters and values:

- Station up/down: sysmsg opcode 30
 - WEP key plumbing: sysmsg opcode 29
 - DHCP: sysmsg opcode 90
 - IKE: UDP port 500 and 4500
 - Layer 2 Tunneling Protocol (L2TP): UDP port 1701
- ```
packet-capture-defaults sysmsg 30,29,90 udp 500,4500,1701,1812,1645
```

Use the **show packet-capture** command to show the current action and the default values.

```
(host) show packet-capture
```

```
Current Active Packet Capture Actions(current switch)

## Command History

This command was introduced in ArubaOS 2.3.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## page

page <length>

### Description

This command sets the number of lines of text the terminal will display when paging is enabled.

### Syntax

| Parameter | Description                                      | Range    |
|-----------|--------------------------------------------------|----------|
| length    | Specifies the number of lines of text displayed. | 24 - 100 |

### Usage Guidelines

Use this command in conjunction with the **paging** command to specify the number of lines of text to display. For more information on the pause mechanism that stops the command output from printing continuously to the terminal, see [paging on page 673](#).

If you need to adjust the screen size, use your terminal application to do so.

### Example

The following command sets 80 as the number of lines of text displayed:

```
(host) (config) #page 80
```

### Command History

This command was introduced in ArubaOS 1.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Config and Enable mode on master controllers |

# paging

paging

## Description

This command stops the command output from printing continuously to the terminal.

## Syntax

No parameters

## Usage Guidelines

By default, paging is enabled.

With paging enabled, there is a pause mechanism that stops the command output from printing continuously to the terminal. If paging is disabled, the output prints continuously to the terminal. To disable paging, use the **no paging** command. You must be in enable mode to disable paging.

The paging setting is active on a per-user session. For example, if you disable paging from the CLI, it only affects that session. For new or existing sessions, paging is enabled by default.

You can also configure the number of lines of text displayed when paging is enabled. For more information, refer to the command [page on page 672](#).

If you need to adjust the screen size, use your terminal application to do so.

## Example

The following command enables paging:

```
(host) (config) #paging
```

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Config and Enable mode on master controllers |

## pan active-profile

```
pan active-profile
 profile <profile name>
```

### Description

This command makes a Palo Alto Network (PAN) profile active from a set of profiles.

### Syntax

| Parameter              | Description                                  |
|------------------------|----------------------------------------------|
| profile <profile name> | The name of the PAN profile to be activated. |

### Usage Guidelines

This command makes a PAN profile active from a set of profiles, if any. Only one PAN profile can be active at a time.

```
(host) (config) #pan active-profile
(host) (Palo Alto Networks Active Profile) #profile default
```

### Command History

|             | Modification        |
|-------------|---------------------|
| ArubaOS 6.4 | Command introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master or local controllers |

## pan profile

```
pan profile <profile-name>
 clone
 firewall host <host> port <port> username <username> passwd <password>
 no
```

### Description

This command configures a Palo Alto Networks (PAN) profile to allow a controller to communicate with a PAN firewall.

### Syntax

| Parameter           | Description                                                                           |
|---------------------|---------------------------------------------------------------------------------------|
| clone               | Name of an existing PAN profile configuration from which parameter values are copied. |
| firewall            | Configures the information for the associated PAN firewall.                           |
| host <host>         | IP address or hostname of the PAN firewall.                                           |
| port <port>         | Port number of the PAN firewall.                                                      |
| username <username> | The username of the PAN firewall.                                                     |
| passwd <password>   | The password of the PAN firewall.                                                     |
| no                  | Negates any configured parameter.                                                     |

### Usage Guidelines

This command is used to configure the PAN firewall that the controller will be communicating with. The username and password must match the name of the admin account configured on the PAN firewall.

```
(host) (config) #pan profile default
(host) (Palo Alto Networks Servers Profile "default") #firewall host 192.0.2.1 port 5642
username axde passwd ZAQ!2wsx
```

### Command History

|             | Modification        |
|-------------|---------------------|
| ArubaOS 6.4 | Command introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master or local controllers |

## panic

```
panic {clear | info {file <filename> <symbolfile>|nvram <symbolfile>} | list {file
<filename>|nvram} | save <filename>}
```

### Description

This command manages information created during a system crash.

### Syntax

| Parameter | Description                                                               |
|-----------|---------------------------------------------------------------------------|
| clear     | Removes panic information from non-volatile random access memory (NVRAM). |
| info      | Displays the content of specified panic files.                            |
| list      | Lists panic information in the specified file in flash or in NVRAM.       |
| save      | Saves panic information from NVRAM into the specified file in flash.      |

### Usage Guidelines

To troubleshoot system crashes, use the **panic save** command to save information from NVRAM into the specified file, then use the **panic clear** command to clear the information from NVRAM.

### Example

The following command lists panic information in NVRAM:

```
(host) #panic list nvram
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## pan-options

```
pan-options
 portal <IP-address>|<FQDN> cert <cert-name>
 no
```

### Description

This command configures options to integrate a branch controller with a Palo Alto Networks (PAN) firewall.

### Syntax

| Parameter    | Description                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <IP-address> | The IP address of the portal                                                                                                           |
| <FQDN>       | The fully qualified domain name (FQDN) of the portal                                                                                   |
| <cert-name>  | Specify the name of the self-signed or external certification authority (CA) certificate to establish an SSL connection to the portal. |

### Usage Guidelines

Issue this command on controllers configured as branch controllers to securely redirect internet inbound traffic from the controller into the PAN firewall. Although this configuration setting can be used on standalone or local controllers, this feature can only be used on controllers in these types of deployments when used in conjunction with the controller uplink VLAN manager feature. The uplink VLAN manager is enabled by default on branch controller uplinks. Master or local (non-branch) controllers using the PAN portal feature must enable the uplink VLAN manager using the [uplink](#) command in the controller command-line interface.

### Integration Workflow

The following steps describes the work flow to integrate a branch controller with a Palo Alto Networks LSVPN firewall.

1. The Palo Alto portal is configured with the MAC address of the branch controller(s) at each remote office site. This allows the branch controller to authenticate to the portal.
2. Once the branch controller is authenticated, the Palo Alto portal sends the branch controller a list of firewall gateways and priority levels.
3. The branch controller uses the gateway list and credentials from the portal to contact all gateways. Each gateway then sends the branch controller information that allows the controller to automatically generate and populate the ip nexthop list **pan-gp-ipsec-map-list**, and sends the branch controller the information that allows the branch controller to create an IPsec tunnel to that gateway.
4. Once the controller has established a functional IPsec tunnel to the first gateway that comes up, it begins routing traffic to that gateway, even if the controller has not yet contacted all gateways. Other gateways are added based upon the preemption policy in the nexthop list.

**Figure 1** Branch-office Controller and PAN Firewall Integration

## Configuration Prerequisites

The Palo Alto Networks Large-Scale VPN (LSVPN) framework can integrate with a branch-office controller by establishing an IPsec tunnels between the firewall and the controller. Integrating a Palo Alto Networks firewall with a W-7000 Series controller requires that all user traffic is routed, so it can be managed by a policy-based routing access control list. If PAN gateways are deployed across multiple datacenters, PAN devices must have a public IP or be behind a single NAT device so that reverse traffic comes back to the correct PAN gateway.

The following certificate requirements must be fulfilled before the cloud services controller can integrate with the Palo Alto Networks Large-Scale VPN (LSVPN) framework:

- The CA certificate used by the firewall portal must be installed on the master controller, so that it can be pushed down to the branch controllers.
- On the gateway devices, the **accept published routes** option must be enabled, and the devices must install the server certificates derived from the management portal root CA.

In deployments with multiple PAN firewalls, the PAN management portal needs to be configured with a list of gateways and the priorities for each gateway. Even if the PAN management portal uses serial number registration with preregistered serial numbers or MAC addresses, best practices is to configure LDAP, Radius, Kerberos or Local Database authentication as well. This allows a controller to authenticate to the portal even if the portal does not recognize the controller's MAC address.

## Examples

```
(host) (config)# pan-options
```

```
(host) (Configure Palo Alto Network options)# portal 192.0.2.3 cert MyServerCert
```

Next, create a policy-based routing access control list (ACL) and apply that ACL to all the roles that need redirection. Best practices is to define a default rule at the end of the policy-based routing ACL that redirects all non-corporate traffic to the PAN firewalls in the predefined next-hop list.

If you use the predefined nexthop list **pan-gp-ipsec-map-list** in your policy-based routing ACL, multiple branch controllers can use the same ACL configuration.

```
(host) (config)# ip access-list route my_PBR_policy
```

```
(host) (config-route-my_PBR_policy)# any network 192.0.2.0 255.255.255.0 any forward
```

```
(host) (config-route-my_PBR_policy)# any any any route nexthop-list pan-gp-ipsec-map-list
```

## perf-test

perf-test

```
server start|stop controller|{ap [ap-name <name>]}|{ip-addr <ip>}|{ip6-addr <ip6>} [tcp|udp]
client start|stop controller|{ap [ap-name <name>]}|{ip-addr <ip>}|{ip6-addr <ip6>}<host-ip>
tcp|udp
duration <duration>
parallel <parallel>
window
bandwidth <value>
port open|close
```

### Description

Use this command under the guidance of Dell technical support to launch or halt an Iperf throughput test between the controller and the AP.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server              | Run Iperf tests in server mode.                                                                                                                                                                                                                   |
| start stop          | Start or stop the iperf test. Tests run in server mode must be manually stopped using the command perf-test server stop.                                                                                                                          |
| ap-name <ap-name>   | Name of the AP.                                                                                                                                                                                                                                   |
| ip-addr <ip-addr>   | IPv4 address of the AP.                                                                                                                                                                                                                           |
| ip6-addr <ip6-addr> | IPv6 address of the AP.                                                                                                                                                                                                                           |
| TCP                 | Run Iperf tests using the TCP protocol.                                                                                                                                                                                                           |
| UDP                 | Run Iperf tests using the UDP protocol.                                                                                                                                                                                                           |
| client              | Run Iperf tests in client mode by specifying the IPV4 or IPv6 address of the host. Tests run in client mode automatically stop when they are complete, although they can also be manually stopped using the <b>perf-test client stop</b> command. |
| host <ip> <ip6>     |                                                                                                                                                                                                                                                   |
| start stop          | Start or stop the iperf test. Tests run in server mode must be manually stopped using the command perf-test server stop.                                                                                                                          |
| ap-name <ap-name>   | Name of the AP.                                                                                                                                                                                                                                   |
| ip-addr <ip-addr>   | IPv4 address of the AP.                                                                                                                                                                                                                           |

| Parameter           | Description                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ip6-addr <ip6-addr> | IPv6 address of the AP.                                                                                                                                                                                       |
| TCP                 | Run Iperf tests using the TCP protocol.                                                                                                                                                                       |
| UDP                 | Run Iperf tests using the UDP protocol.                                                                                                                                                                       |
| bandwidth <value>   | Rate at which the Iperf test data should be sent, in bits/sec. The default value is 1 Mbit/sec. This parameter supports the suffixes <b>K</b> (to represent Kbits/sec) and <b>M</b> (to represent Mbits/sec.) |
| duration            | Number of seconds for which the test runs. The supported range is 10-120 seconds, and the default value is 10 seconds.                                                                                        |
| parallel            | Number of parallel clients threads to run.                                                                                                                                                                    |
| window              | TCP window size. This parameter supports the suffixes <b>K</b> (to represent Kbit-s/sec) and <b>M</b> (to represent Mbits/sec.)                                                                               |
| port open close     | Use this command under the guidance of Dell technical support to open port 5001 to allow Iperf throughput tests between the controller and the AP.                                                            |

## Usage Guidelines

Only W-AP130 Series, W-AP220 Series, and W-AP105 access points connected to a W-7200 Series or W-6000M3 controller support this feature. The report generated by an Iperf throughput test can be viewed by issuing the command .

## pcap (deprecated)

```
pcap {raw-start <ipaddr> <target-ipaddr> <target-port> <format> [bssid <bssid>] [channel <number>] [maxlen <maxlen>]}|{interactive <am-ip> <filter> <target-ipaddr> <target-port> [bssid <bssid>] [channel <number>]}|{clear|pause|resume|stop <am-ip> <id> [bssid <bssid>]}
```

### Description

These commands manage packet capture (PCAP) on Dell air monitors.

### Syntax

| Parameter       | Description                                                                                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| raw-start       | Stream raw packets to an external viewer.                                                                                                                                                                                                                                  |
| <ipaddr>        | IP address of the air monitor collecting packets.                                                                                                                                                                                                                          |
| <target-ipaddr> | IP address of the client station running Wildpacket's AiroPeek monitoring application.                                                                                                                                                                                     |
| <target-port>   | UDP port number on the client station where the captured packets are sent.                                                                                                                                                                                                 |
| <format>        | Specify a number to indicate one of the following formats for captured packets: <ul style="list-style-type: none"><li>• <b>0</b> : pcap</li><li>• <b>1</b> : peek</li><li>• <b>2</b> : airmagnet</li><li>• <b>3</b> : pcap+radio header</li><li>• <b>4</b> : ppi</li></ul> |
| bssid           | (Optional) BSSID of the Air Monitor interface for the PCAP session.                                                                                                                                                                                                        |
| <bssid>         | BSSID of the Air Monitor Interface, which is usually its MAC address.                                                                                                                                                                                                      |
| channel         | (Optional) Number of a radio channel to tune into to capture packets                                                                                                                                                                                                       |
| maxlen          | (Optional) Limit the length of 802.11 frames to include in the capture to a specified maximum.                                                                                                                                                                             |
| <maxlen>        | (Optional) Maximum number of packets to be captured.                                                                                                                                                                                                                       |
| interactive     | Start an interactive packet capture session.                                                                                                                                                                                                                               |
| <am-ip>         | IP address of the air monitor collecting packets.                                                                                                                                                                                                                          |
| <filter-spec>   | Packet Capture filter specification.                                                                                                                                                                                                                                       |

| Parameter       | Description                                                                     |
|-----------------|---------------------------------------------------------------------------------|
| <target-ipaddr> |                                                                                 |
| <target-port>   |                                                                                 |
| bssid           | (Optional) Specify the BSSID of the Air Monitor interface for the PCAP session. |
| <bssid>         | BSSID of the Air Monitor Interface, which is usually its MAC address.           |
| channel         | (Optional) Number of a radio channel to tune into to capture packets            |
| clear           | Clears the packet capture session.                                              |
| pause           | Pause a packet capture session.                                                 |
| resume          | Resume a packet capture session.                                                |
| start           | Start a new packet capture session.                                             |
| stop            | Stop a packet capture session.                                                  |
| <am-ip>         | IP address of the air monitor collecting packets.                               |
| <id>            | ID of the PCAP session.                                                         |
| bssid           | (Optional) Specify the BSSID of the Air Monitor interface for the PCAP session. |
| <bssid>         | BSSID of the Air Monitor Interface, which is usually its MAC address.           |

## Usage Guidelines

These commands direct a Dell air monitor to send packet captures to the Wildpacket's AiroPeek monitoring application on a remote client. The AiroPeek application listens for packets sent by the air monitor.

The following pcap commands are available:

| Command | Description                         |
|---------|-------------------------------------|
| clear   | Clears the packet capture session.  |
| pause   | Pause a packet capture session.     |
| resume  | Resume a packet capture session.    |
| start   | Start a new packet capture session. |
| stop    | Stop a packet capture session.      |

Before using these commands, you need to start the AiroPeek application on the client and open a capture window for the air monitor. The AiroPeek application cannot be used to control the flow or type of packets sent from Dell air monitors.

The AiroPeek application processes all packets, however, you can apply display filters on the capture window to control the number and type of packets being displayed. In the capture window, the time stamp displayed corresponds to the time that the packet is received by the client and is not synchronized with the time on the Dell air monitor.

## Example

The following command starts a raw packet capture session for the air monitor at 10.100.100.1 and sends the packets to the client at 192.168.22.44 on port 604 with pcap format:

```
(host) (config) #pcap raw-start 10.100.100.1 192.168.22.44 604 0
```

## Command History

|-------------|-------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command Introduced                                                                        |
| ArubaOS 3.4 | The <b>maxlen</b> parameter was introduced, and the <b>pcap start</b> command deprecated. |
| ArubaOS 6.2 | Functionality with 2 new parameters, now subsumed by the ap packet capture command.       |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

# phonehome

phonehome

https <from\_addr>

## Description

This command configures the PhoneHome auto reporting feature.

## Syntax

| Parameter         | Description                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| https <from_addr> | Configure controllers running ArubaOS 6.4 send PhoneHome reports to an Activate server using HTTPS. Earlier versions of ArubaOS allow the PhoneHome feature to send reports to an SMTP server only. The <from-addr> email address is used to properly identify the user sending the report. |

## Command History

| Version     | Description                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| ArubaOS 6.0 | Command Introduced                                                                                                  |
| ArubaOS 6.4 | The <b>https</b> parameter was introduced to allow the controller to send reports to Dell support through Activate. |

|---------------|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| All platforms | Base operating system | The <b>phonehome now</b> command must be issued in enable mode. All other PhoneHome commands require config mode. |

## ping

```
ping <ipaddress> | ipv6 {<global-address> | interface vlan <vlanid> <linklocal-address>}
 count
 df-flag
 packet-size
 source
```

### Description

This command sends five ICMP echo packets to the specified ip address. You can also ping the specified IPv6 address.

### Syntax

| Parameter                                                                   | Description                                                                                                                                                                                                   | Default   | Range     |

| ipv6<br>• <global-address><br>• interface vlan <vlanid> <linklocal-address> | Specify this parameter to ping an IPv6 address.<br><ul style="list-style-type: none"><li>Specify the IPv6 global address.</li><li>Specify the IPv6 link local address of a specific VLAN interface.</li></ul> | —         | —         |
| count                                                                       | The number of ping packets sent to the target IP address.                                                                                                                                                     | 5         | 1 - 100   |
| df-flag                                                                     | Sets the Don't Fragment flag.                                                                                                                                                                                 | —         | —         |
| packet-size                                                                 | The size, in bytes, of a ping datagram                                                                                                                                                                        | 100 bytes | 10 - 2000 |
| source                                                                      | Sets the source interface for a ping datagram. The source can be a valid <b>VLAN ID</b> or a <b>Management Interface</b> .                                                                                    | —         | —         |

### Usage Guidelines

You can send five ICMP echo packets to a specified IP address. The controller times out after two seconds. You can also ping the specified IPv6 address.

### Examples

The following example pings 10.10.10.5.

```
(host) #ping 10.10.10.5
```

The sample controller output is:

```
Press 'q' to abort.
Sending 5, 100-byte ICMP Echos to 10.10.10.5, timeout is 2 seconds:!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 0.408/0.5434/1.073 ms
```

The following example pings the specified IPv6 global address:

```
(host) #ping ipv6 2005:d81f:f9f0:1001::14
```

The sample controller output is:

```
Press 'q' to abort.
Sending 5, 100-byte ICMPv6 Echos to 2005:d81f:f9f0:1001::14, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 0.309/0.3726/0.463 ms
```

## Command History

| Release     | Modification                                                                                                                                          |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 1.0 | Command introduced                                                                                                                                    |
| ArubaOS 6.1 | Introduced <b>ipv6</b> parameter to provide support for IPv6.                                                                                         |
| ArubaOS 6.3 | Introduced the following parameters: <ul style="list-style-type: none"><li>• count</li><li>• df-flag</li><li>• packet-size</li><li>• source</li></ul> |

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | User, Enable, and Config modes on master controllers |

## pkt-trace

```
pkt-trace acl <acl-name> {enable|disable} [trace {cptrace|pktrace} [trace-mask <tmask>]]]
```

### Description

Enable packet tracing in the datapath. Use this feature only under the supervision of Dell technical support.

### Syntax

| Parameter         | Description                                                                    |
|-------------------|--------------------------------------------------------------------------------|
| <acl-name>        | Enable packet tracing for the specified access-control list.                   |
| enable            | Enable packet tracing for the ACL.                                             |
| disable           | Disable packet tracing for the ACL.                                            |
| cptrace           | Send packet trace data into the Control Processor.                             |
| pktrace           | Write packet trace data in the packet.                                         |
| tracemask <tmask> | Specify the trace mask. This value will be provided by Dell technical support. |

### Example

The following example enables packet tracing for the traffic matching the acl **stateful-dot1x**.

```
(host) #pkt-trace acl stateful-dot1x enable trace cptrace trace-mask <val>
```

### Command History

This command was introduced in ArubaOS 3.4.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## pkt-trace-global

`pkt-trace-global {enable|disable} [trace-mask <tmask>]`

### Description

Enable global packet tracing in the datapath. Use this feature only under the supervision of Dell technical support.

### Syntax

| Parameter         | Description                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------|
| <acl-name>        | Enable packet tracing for the specified access-control list.                                 |
| enable            | Enable global packet tracing for the ACL.                                                    |
| disable           | Disable global packet tracing for the ACL.                                                   |
| tracemask <tmask> | Specify a trace mask. Use this feature only under the supervision of Dell technical support. |

### Example

The following command enables the global packet tracing for all traffic.

```
(host) (config) #pkt-trace-global enable
```

### Command History

This command was introduced in ArubaOS 3.4.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## policer-profile (deprecated)

```
policer-profile <profile-name>
 cbs {k | m | g}
 cir <cir>
 clone <source>
 ebs [k | m | g]
 exceed-action drop | permit | remark
 exceed-profile <policerProfile>
 no..
 violate-action drop | permit
 violate-profile <profile-name>
```

### Description

This command configures a Policer profile to manage the transmission rate of a class of traffic based on user-defined criteria.

### Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.2 | Command deprecated. |

## pptp ip local pool

```
pptp ip local pool <pool> <ipaddr> [<end-ipaddr>]
```

### Description

This command configures an IP address pool for VPN users using Point-to-Point Tunneling Protocol (PPTP).

### Syntax

| Parameter    | Description                             |
|--------------|-----------------------------------------|
| <pool>       | User-defined name for the address pool. |
| <ipaddr>     | Starting IP address for the pool.       |
| <end-ipaddr> | Ending IP address for the pool.         |

### Usage Guidelines

If VPN is used as an access method, you specify the pool from which the user's IP address is assigned when the user negotiates a PPTP session. Use the **show vpdn pptp local** command to see the used and free addresses in the pool.

PPTP is an alternative to IPsec that is supported by various hardware platforms. PPTP is considered to be less secure than IPsec but also requires less configuration. You configure PPTP with the **vpdn** command.

### Example

The following command configures an IP address pool for PPTP VPN users:

```
(host) (config) #pptp ip local pool pptp-pool1 172.16.18.1 172.16.18.24
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## priority-map

```
priority-map <name>
 dot1p <priority> high
 dscp <priority> high
 no ...
```

### Description

This command configures the Type of Service (ToS) and Class of Service (CoS) values used to map traffic into high priority queues.

### Syntax

| Parameter | Description                                                                                             | Range |
|-----------|---------------------------------------------------------------------------------------------------------|-------|
| <name>    | User-defined name of the priority map.                                                                  | —     |
| dot1p     | IEEE 802.1p priority value, or a range of values separated by a dash (-).                               | 0-7   |
| dscp      | Differentiated Services Code Point (DSCP) priority value, or a range of values separated by a dash (-). | 0-63  |
| no        | Negates any configured parameter.                                                                       | —     |

### Usage Guidelines

This command allows you to prioritize inbound traffic that is already tagged with 802.1p and/or IP ToS in hardware queues. You apply configured priority maps to ports on the controller (using the **interface fastethernet** or **interface gigabitethernet** command). This causes the controller to inspect inbound traffic on the port; when a matching QoS tag is found, the packet or flow is mapped to the specified queue.

### Example

The following commands configure a priority map and apply it to a port:

```
(host) (config) #priority-map pri1
 dscp 4-20 high
 dscp 60 high
 dot1p 4-7 high
interface gigabitethernet 1/24
 priority-map pri1
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

# process monitor

process monitor log|restart|

## Description

The process monitor validates the integrity of processes every 120 seconds. If a process does not respond during three consecutive 120-second timeout intervals, that process is flagged as nonresponsive and the process monitor will create a log message, restart the process or reboot the controller

## Syntax

| Parameter | Description                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log       | The process monitor creates a log message when a process fails to responding properly. This is the default behavior for the process monitor                                    |
| restart   | This parameter enables strict behavior for runtime processes.<br><br>When you enable this option, the process monitor will restart processes that fail to responding properly. |

## Usage Guidelines

The CLI command **process monitor log** enables logging for process monitoring. By default, whenever a process does not update a required file or send a heartbeat pulse within the required time limit, the process monitor records a critical log message, but does not restart any process. If you want the configure watchdog to restart a process once it fails to respond, use the CLI **command process monitor restart**.

## Example

The following changes the default process monitor behavior, so the process monitor restarts nonresponsive processes.

```
(host) #process monitor restart
```

## Related Commands

The show **process monitor statistics** command displays the current status of all the processes running under the process monitor watchdog. A partial example of the output of this command is shown below:

```
host) (config) #show process monitor statistics
```

### Process Monitor Statistics

# prompt

prompt <prompt>

## Description

This command changes the prompt text.

## Syntax

| Parameter | Description                                  | Range | Default    |
|-----------|----------------------------------------------|-------|------------|
| prompt    | The prompt text displayed by the controller. | 1-64  | <hostname> |

## Usage Guidelines

You can use any alphanumeric character, punctuation, or symbol character. To use spaces, plus symbols (+), question marks (?), or asterisks (\*), enclose the text in quotes.

You cannot alter the parentheses that surround the prompt text, or the greater-than (>) or hash (#) symbols that indicate user or enable CLI mode.

## Example

The following example changes the prompt text to "It's a new day!".

```
(host) (config) #prompt "It's a new day!"
(It's a new day!) (config) #
```

## Command History

This command was introduced in ArubaOS 1.0.

|                   | <p>This setting allows you to select how the modem should operate.</p> <ul style="list-style-type: none"> <li>• <b>auto</b> (default): In this mode, the modem firmware will control the cellular network service selection; so the cellular network service failover and fallback is not interrupted by the remote AP (RAP).</li> <li>• <b>3g_only</b>: Locks the modem to operate only in 3G.</li> <li>• <b>4g_only</b>: Locks the modem to operate only in 4G.</li> <li>• <b>advanced</b>: The RAP controls the cellular network service selection based on the Received Signal Strength Indication (RSSI) threshold-based approach. Initially the modem is set to the default auto mode. This allows the modem firmware to select the available network. The RAP determines the RSSI value for the available network type (for example 4G), checks whether the RSSI is within required range, and if so, connects to that network. If the RSSI for the modem's selected network is not within the required range, the RAP will then check the RSSI limit of an alternate network (for example, 3G), and reconnect to that alternate network. The RAP will repeat the above steps each time it tries to connect using a 4G multimode modem in this mode.</li> </ul> |           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Range |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| Longitude | <p>Longitude coordinates of the AP. Use the DMS format.</p> <p>For example: 122 02 00 W</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |
| master    | Name or IP address of the master controller.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |       |
| mesh-role | <p>Configure the AP to operate as a mesh node. You assign one of three roles: <b>mesh portal</b>, <b>mesh point</b> or <b>remote mesh point</b>. If you select “none,” the AP operates as a thin AP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |
| mesh-sae  | <p>Enable or disable Simultaneous Authentication of Equals (SAE) on a mesh network. This option offers enhanced security over the default wpa2-psk-aes mesh security setting, and provides secure, attack-resistant authentication using a pre-shared key. SAE supports simultaneous initiation of a key exchange, allowing either party to initiate an exchange or both parties to initiate a key exchange simultaneously.</p> <p>To use the SAE feature, you must enable this parameter on all mesh nodes (points and portals) in the network, to prevent mesh link connectivity issues.</p> <p><b>NOTE:</b> This is a Beta feature only. This parameter should be kept “disabled” for this release.</p> |       |
| netmask   | Netmask for the IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                           | Range |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| no                | Negates any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                                     |       |
| pap-password      | Password Authentication Protocol (PAP) password for the AP.<br>You can use special characters in the PAP password. Following are the restrictions: <ul style="list-style-type: none"> <li>• You cannot use double-byte characters</li> <li>• You cannot use a tilde (~)</li> <li>• You cannot use a tick (')</li> <li>• If you use quotes (single or double), you must use the backslash (\) before and after the password</li> </ul> |       |
| pap-user          | PAP username for the AP.                                                                                                                                                                                                                                                                                                                                                                                                              |       |
| pkcs12-passphrase | Passphrase in PKCS12 format.                                                                                                                                                                                                                                                                                                                                                                                                          |       |

| Parameter         | Description                                                        | Range |
|-------------------|--------------------------------------------------------------------|-------|
| pppoe-chap-secret | PPPoE CHAP secret key for the AP.                                  | —     |
| pppoe-password    | Point-to-Point Protocol over Ethernet (PPPoE) password for the AP. | —     |

| Parameter          | Description                                                                                                                              | Range |

| pppoe-service-name | PPPoE service name for the AP.                                                                                                           | —     |
| pppoe-user         | PPPoE username for the AP.                                                                                                               | —     |
| read-bootinfo      | Retrieves current provisioning parameters of the specified AP.<br><b>NOTE:</b> This parameter can only be used on the master controller. | —     |

| Parameter        | Description                                                                                                                                                                                                                                                                                                             | Range |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| reprovision      | <p>Provisions one or more APs with the values in the provisioning-params workspace. To use <b>reprovision</b>, you must use <b>read-bootinfo</b> to retrieve the current values of the APs into the provisioning-ap-list.</p> <p><b>NOTE:</b> This parameter can only be used on the master controller.</p>             | —     |
| reset-bootinfo   | <p>Restores factory default provisioning parameters to the specified AP.</p> <p><b>NOTE:</b> This parameter can only be used on the master controller.</p>                                                                                                                                                              | —     |
| sch-mode-radio-0 | <p>If you are provisioning an 802.11n-capable AP, you can issue the sch-mode-radio-0 command to enable single-chain mode for the selected radio. AP radios in single-chain mode will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This setting is disabled by default.</p> |       |

| Parameter        | Description                                                                                                                                                                                                                                                                                                      | Range |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| sch-mode-radio-1 | If you are provisioning an 802.11n-capable AP, you can issue the sch-mode-radio-1 command to enable single-chain mode for the selected radio. AP radios in single-chain mode will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This setting is disabled by default. |       |
| server-ip        | IP address of the controller from which the AP boots.                                                                                                                                                                                                                                                            |       |
| server-name      | DNS name of the controller from which the AP boots.                                                                                                                                                                                                                                                              |       |

| Parameter              | Description                                                     | Range |
|------------------------|-----------------------------------------------------------------|-------|
| set-ike-psk-by-address | Set a IKE preshared key to correspond to a specific IP address. |       |
| syslocation            | User-defined description of the location of the AP.             |       |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                            | Range |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| uplink-vlan <uplink-vlan> | <p>If you configure an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink.</p> <p>By default, an AP has an uplink vlan of 0, which disables this feature.</p> <p><b>NOTE:</b> If an AP is provisioned with an uplink VLAN, it <i>must be connected to a trunk mode port</i> or the AP's frames will be dropped.</p> |       |
| usb-devicev               | The USB device identifier, if the device is not already supported.                                                                                                                                                                                                                                                                                                                                     |       |
| usb-dial                  | The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.                                                                                                                                                                                                                                                                                     |       |

| p-<br>a-<br>r-<br>a-<br>m-<br>e-<br>t-<br>e-<br>r | Description                                                                                                                                                                                                                                                                                                                                                                                                   | R<br>a<br>n<br>g<br>e |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
|                                                   | <p>USB cellular devices on remote APs typically register as modems, but may occasionally register as a mass-storage device. If a remote AP cannot recognize its USB cellular modem, use the <b>usb-modeswitch</b> command to specify the parameters for the hardware model of the USB cellular data-card.</p> <p><b>NOTE:</b> You must enclose the entire modeswitch parameter string in quotation marks.</p> |                       |

| Parameter    | Description                                                                                                                  | Range |
|--------------|------------------------------------------------------------------------------------------------------------------------------|-------|
| usb-init     | The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct. |       |
| usb-password | A PPP password, if provided by the cellular service provider                                                                 |       |

| Parameter                                     | Description                                                                                                          | Range |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------|-------|
| usb-power-mode<br> <br>enable<br> <br>disable | Set the USB power mode to control the power to the USB port.                                                         |       |
| usb-tty                                       | The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct. |       |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Range |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| usb-tty-control | The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |
| usb-type        | <p>Specify the USB driver type.</p> <ul style="list-style-type: none"> <li>● <b>acm</b>: Use ACM driver</li> <li>● <b>airprime</b>: Use Airprime driver</li> <li>● <b>beceem-wimax</b>: Use Beceem driver for 4G-WiMAX</li> <li>● <b>ether</b>: Use CDC Ether driver for direct IP 4G device</li> <li>● <b>hso</b>: Use HSO driver for newer Option</li> <li>● <b>none</b>: Disable 3G or 2G network on USB</li> <li>● <b>option</b>: Use Option driver</li> <li>● <b>pantech-3g</b>: Same as "pantech-uml290" - to support upgrade</li> <li>● <b>pantech-uml290</b>: Use Pantech USB driver for UML290 device</li> <li>● <b>ptumlnet</b>: Use Pantech USB driver for 4G device</li> <li>● <b>rndis</b>: Use a RNDIS driver for a 4G device</li> <li>● <b>sierra-evdo</b>: Use EVDO Sierra Wireless driver</li> <li>● <b>sierra-gsm</b>: Use GSM Sierra Wireless driver</li> <li>● <b>sierrausbnet</b>: Use SIERRA Direct IP driver for 4G device</li> <li>● <b>storage</b>: Use USB flash as storage device for storing RAP certificates</li> </ul> |       |

| Parameter | Description                                                | Range |
|-----------|------------------------------------------------------------|-------|
|           |                                                            |       |
| usb-user  | The PPP username provided by the cellular service provider |       |

## Usage Guidelines

You do not need to provision APs before installing and using them.

The exceptions are outdoor APs, which have antenna gains that you must provision before they can be used, and APs configured for mesh. You must provision the AP before you install it as a mesh node in a mesh deployment.

Users less familiar with this process may prefer to use the **Provisioning** page in the WebUI to provision an AP.

Provisioned or reprovisioned values do not take effect until the AP is rebooted. APs reboot automatically after they are successfully reprovisioned.

In order to enable cellular uplink for a remote AP (RAP), the RAP must have the device driver for the USB data card and the correct configuration parameters. ArubaOS includes device drivers for the most common hardware types, but you can use the **usb** commands in this profile to configure a RAP to recognize and use an unknown USB modem type.

## Provisioning a Single AP

To provision a single AP:

1. Use the **read-bootinfo** option to read the current information from the deployed AP you wish to reprovision.
2. Use the **show provisioning-ap-list** command to see the AP to be provisioned.
3. Use the **copy-provisioning-params** option to copy the AP's parameter values to the provisioning-params workspace.
4. Use the provision-ap options to set new values. Use the **show provisioning-params** command to display parameters and values in the provisioning-params workspace. Use the **clear provisioning-params** command to reset the workspace to default values.
5. Use the **reprovision** option to provision the AP with the values in provisioning-params workspace. The AP automatically reboots.

## Provisioning Multiple APs at a Time

You can change parameter values for multiple APs at a time, however, note the following:

- You cannot provision the following AP-specific options on multiple APs:

- ap-name
- ipaddr
- pap-user
- pap-passwd
- ikepsk

If any of these options are already provisioned on the AP, their values are retained when the AP is reprovisioned.

- The values of the server-name, a-ant-gain, or g-ant-gain options are retained if they are not reprovisioned.
- All other values in the provisioning-params workspace are copied to the APs.

To provision multiple APs at the same time:

1. Use the **read-bootinfo** to read the current information from each deployed AP that you wish to provision.

---

The AP parameter values are written to the provisioning-ap-list. To reprovision multiple APs, the APs must be present in the provisioning-ap-list. Use the **show provisioning-ap-list** command to see the APs that will be provisioned. Use the **clear provisioning-ap-list** command to clear the provisioning-ap-list.

---

2. Use the **copy-provisioning-params** option to copy an AP's parameter values to the provisioning-params workspace.
3. Use the provision-ap options to set new values. Use the **show provisioning-params** command to display parameters and values in the provisioning-params workspace. Use the **clear provisioning-params** command to reset the workspace to default values.
4. Use the **reprovisionall** option to provision the APs in the provisioning-ap-list with the values in provisioning-params workspace. All APs in the provisioning-ap-list automatically reboot.

The following are useful commands when provisioning one or more APs:

- **show|clear provisioning-ap-list** displays or clears the APs that will be provisioned.
- **show|clear provisioning-params** displays or resets values in the provisioning-params workspace.
- **show ap provisioning** shows the provisioning parameters an AP is currently using.

## Example

The following commands change the IP address of the master controller on the AP:

```
(host) (config) #provision-ap
read-bootinfo ap-name lab103
show provisioning-ap-list
copy-provisioning-params ap-name lab103
master 10.100.102.210
reprovision ap-name lab103
```

## Command History

| Release     | Modification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ArubaOS 3.2 | Introduced support for the mesh parameters, additional antenna parameters, and AP location parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ArubaOS 3.4 | Introduced support for the following parameters: <ul style="list-style-type: none"> <li>• installation</li> <li>• mesh-sae</li> <li>• set-ikepsk-by-addr</li> <li>• usb-dev</li> <li>• usb-dial</li> <li>• usb-init</li> <li>• usb-passwd</li> <li>• usb-tty</li> <li>• usb-type</li> <li>• usb-user</li> <li>• link-priority-cellular</li> <li>• link-priority-ethernet</li> </ul>                                                                                                                                                   |
| ArubaOS 5.0 | The mesh-sae parameter no longer has the <b>sae-default</b> option. Use the <b>sae-disable</b> option to return this parameter to its default disabled setting.                                                                                                                                                                                                                                                                                                                                                                       |
| ArubaOS 6.0 | The <b>uplink-vlan</b> parameter was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ArubaOS 6.1 | The following new parameters were introduced for provisioning IPv6 APs: <ul style="list-style-type: none"> <li>• <b>dns-server-ip6</b></li> <li>• <b>ip6addr</b></li> <li>• <b>ip6prefix</b></li> <li>• <b>gateway6</b></li> </ul>                                                                                                                                                                                                                                                                                                    |
| ArubaOS 6.2 | <p>The following new parameters provision APs in single-chain mode:</p> <ul style="list-style-type: none"> <li>• <b>sch-mode-radio-0</b></li> <li>• <b>sch-mode-radio-1</b></li> </ul> <p>The following new parameters provision APs for 802.1X authentication:</p> <ul style="list-style-type: none"> <li>• <b>apdot1x-passwd</b></li> <li>• <b>apdot1x-username</b></li> </ul> <p>The following new parameters provision Remote APs using USB modems:</p> <ul style="list-style-type: none"> <li>• <b>usb-modeswitch</b></li> </ul> |

| Release         | Modification                                                                                                                                                                                                             |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <ul style="list-style-type: none"> <li>• <b>4g-usb-type</b></li> </ul>                                                                                                                                                   |
| ArubaOS 6.2.1.0 | The <b>cellular_nw_preference</b> parameter was introduced for provisioning multi-mode modems, and the <b>4g-usb-type</b> parameter was deprecated. Specify a 2/3G or 4G modem type using the <b>usb-type</b> parameter. |
| ArubaOS 6.3     | The <b>sierrausbnet</b> and <b>storage</b> usb-type parameters were introduced.                                                                                                                                          |
| ArubaOS 6.3.1   | the <b>rndis</b> usb-type parameter was introduced.                                                                                                                                                                      |
| ArubaOS 6.4.2.0 | The <b>service-tag</b> parameter was introduced under <b>reprovision</b> parameter.                                                                                                                                      |

## qos-profile (deprecated)

```
qos-profile <profile-name>
 clone <source>
 dot1p <priority>
 drop-precedence {high | low}
 dscp <rewrite-value>
 no
 traffic-class <traffic-class-value>
```

### Description

This command configures a QoS profile to assign TC/DP, DSCP, and 802.1p values to an interface or policer profile.

### Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.2 | Command deprecated. |

## reload-peer-sc (deprecated)

reload-peer-sc

### Description

This command performs a reboot of the W-6000M3 controller module.

### Command History

| Version     | Description        |
|-------------|--------------------|
| ArubaOS 1.0 | Command Introduced |
| ArubaOS 6.1 | Command deprecated |

# reload

reload

## Description

This command performs a reboot of the controller.

## Syntax

No parameters.

## Usage Guidelines

Use this command to reboot the controller if required after making configuration changes or under the guidance of Dell Networks customer support. The **reload** command powers down the controller, making it unavailable for configuration. After the controller reboots, you can access it via a local console connected to the serial port, or through an SSH, Telnet, or WebUI session. If you need to troubleshoot the controller during a reboot, use a local console connection.

After you use the **reload** command, the controller prompts you for confirmation of this action. If you have not saved your configuration, the controller returns the following message:

```
Do you want to save the configuration (y/n):
```

- Enter **y** to save the configuration.
- Enter **n** to not save the configuration.
- Press [Enter] to exit the command without saving changes or rebooting the controller.

If your configuration has already been saved, the controller returns the following message:

```
Do you really want to reset the system(y/n):
```

- Enter **y** to reboot the controller.
- Enter **n** to cancel this action.

The command will timeout if you do not enter y or n.

## Example

The following command assumes you have already saved your configuration and you must reboot the controller:

```
(host) (config) #reload
```

The controller returns the following messages:

```
Do you really want to reset the system(y/n): y
System will now restart!
...
Restarting system.
```

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                  |
|---------------|-----------------------|-----------------------------------------------|
| All platforms | Base operating system | Enable and Config modes on master controllers |

# rename

rename <filename> <newfilename>

## Description

This command renames an existing system file.

## Syntax

| Parameter   | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| filename    | An alphanumeric string that specifies the current name of the file on the system. |
| newfilename | An alphanumeric string that specifies the new name of the file on the system.     |

## Usage Guidelines

Use this command to rename an existing system file on the controller. You can use a combination of numbers, letters, and punctuation (periods, underscores, and dashes) to rename a file. The new name takes affect immediately.

Make sure the renamed file uses the same file extension as the original file. If you change the file extension, the file may be unrecognized by the system. For example, if you have an existing file named `upgrade.log`, the new file must include the `.log` file extension.

You cannot rename the active configuration currently selected to boot the controller. If you attempt to rename the active configuration file, the controller returns the following message:

```
Cannot rename active configuration file
```

To view a list of system files, and for more information about the directory contents, see [dir on page 362](#).

## Example

The following command changes the file named **test\_configuration** to **deployed\_configuration**:

```
(host) (config) #rename test_configuration deployed_configuration
```

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                  |
|---------------|-----------------------|-----------------------------------------------|
| All platforms | Base operating system | Eanble and Config modes on master controllers |

## restore

restore flash

### Description

This command restores flash directories backed up to the flashbackup.tar.gz file.

### Syntax

| Parameter | Description                                                  |
|-----------|--------------------------------------------------------------|
| flash     | Restores flash directories from the flashbackup.tar.gz file. |

### Usage Guidelines

Use the **backup flash** command to tar and compress flash directories to the flashbackup.tar.gz file.

### Example

The following command restores flash directories from the flashbackup.tar.gz file:

```
(host) #restore flash
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## rf am-scan-profile

```
<profile-name>
 clone <profile>
 dwell-time-active-channel
 dwell-time-other-reg-domain-channel
 dwell-time-rare-channel
 dwell-time-reg-domain-channel
 no
 scan-mode
```

### Description

Configure an Air Monitor (AM) scanning profile.

### Syntax

| Parameter                           | Description                                                         | Range           | Default |
|-------------------------------------|---------------------------------------------------------------------|-----------------|---------|
| <profile-name>                      | Name of this instance of the profile.                               | 1-63 characters | —       |
| clone <profile>                     | Copy data from another AM scanning profile                          | —               | —       |
| dwell-time-active-channel           | Dwell time (in ms) for channels where there is wireless activity.   | 100-32768 ms    | 500 ms  |
| dwell-time-other-reg-domain-channel | Dwell time (in ms) for channels not in the APs regulatory domain.   | 100-32768 ms    | 250 ms  |
| dwell-time-rare-channel             | Dwell time (in ms) for rare channels.                               | 100-32768 ms    | 100 ms  |
| dwell-time-reg-domain-channel       | Dwell time (in ms ) for AP's Regulatory domain channels             | 100-32768 ms    | 250 ms  |
| no                                  | Delete the command                                                  | —               | —       |
| scan-mode                           | Set the scanning mode for the radio.                                | —               | —       |
| all-reg-domain                      | Scan channels in all regulatory domain                              | —               | —       |
| rare                                | Scan <i>all</i> channels (all regulatory domains and rare channels) | —               | —       |
| reg-domain                          | Scan channels in the APs regulatory domain                          | —               | —       |

## Usage Guidelines

Channels are categorized into the following types:

- **Active Channel:** This qualifier indicates that wireless activity (for example, a probe request) is detected on this channel by the presence of an AP or other 802.11 activity.
- **All Regulatory Domain Channels:** A valid non-overlapping channel that is in the regulatory domain of at least one country.
- **Rare Channels:** Channels that fall into a frequency range outside of the regulatory domain; 2484 MHz and 4900MHz-4995MHz (J-channels), and 5000-5100Mhz.
- **Regulatory Domain Channels:** A channel that belongs to the regulatory domain of the country in which the AP is deployed. The set of channels that belong to this group is a subset of the channels in all-reg-domain channel group.

## Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.0 | Command introduced |

## Command Information

| Platforms     | Licensing | Command Mode                |
|---------------|-----------|-----------------------------|
| All Platforms | RFProtect | Configuration Mode (config) |

## rft

```
rft test profile antenna-connectivity ap-name <name> [dest-mac <macaddr> [phy {a|g}| radio {0|1}]]
```

```
rft test profile link-quality {ap-name <name> dest-mac <macaddr> [phy {a|g}| radio {0|1}] | bssid <bssid> dest-mac <macaddr> | ip-addr <ipaddr> dest-mac <macaddr> [phy {a|g}|radio {0|1}]}
```

```
rft test profile raw {ap-name <name> dest-mac <macaddr> [phy {a|g}|radio {0|1}] | bssid <bssid> dest-mac <macaddr> | ip-addr <ipaddr> dest-mac <macaddr> [phy {a|g}|radio {0|1}]}
```

## Description

This command is used for RF troubleshooting.

## Syntax

| Parameter | Description                                  | Range |
|-----------|----------------------------------------------|-------|
| ap-name   | Name of the AP that performs the test.       | —     |
| dest-mac  | MAC address of the client to be tested.      | —     |
| phy       | 802.11 type, either a or g.                  | a   g |
| radio     | Radio ID, either 0 or 1.                     | 0   1 |
| bssid     | BSSID of the AP that performs the test.      | —     |
| ip-addr   | IP address of the AP that performs the test. |       |

## Usage Guidelines

This command can run predefined test profiles for antenna connectivity, link quality, or raw testing. You should only run these commands when directed to do so by a Dell support representative.

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## rf arm-rf-domain-profile

```
rf arm-rf-domain profile
 arm-rf-domain-key <arm-rf-domain-key>
```

### Description

This profile holds a non-editable key defined by the master controller, and used to sign over-the air (OTA) ARM updates exchanged between APs.

### Syntax

| Parameter           | Description            |
|---------------------|------------------------|
| <arm-rf-domain-key> | Non-editable key value |

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.2 | Command introduced |

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

### Description

This command configures the Adaptive Radio Management (ARM) profile.

## Syntax

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                        | Range                      | Default   |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|-----------|
| <profile>                 | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                                                                                                                                                            | —                          | “default” |
| 40MHz-allowed- bands      | The specified setting allows ARM to determine if 40 MHz mode of operation is allowed on the 5 GHz or 2.4 GHz frequency band only, on both frequency bands, or on neither frequency band.                                                                                                                                                                           | All/None/<br>a-only/g-only | a-only    |
| All                       | Allows 40 MHz channels on both the 5 GHz (802.11a) and 2.4 GHz (802.11b/g) frequency bands.                                                                                                                                                                                                                                                                        | —                          | —         |
| None                      | Disallows use of 40 MHz channels.                                                                                                                                                                                                                                                                                                                                  | —                          | —         |
| a-only                    | Allows use of 40 MHz channels on the 5 GHz (802.11a) frequency band only.                                                                                                                                                                                                                                                                                          | —                          | —         |
| g-only                    | Allows use of 40 MHz channels on the 2.4 GHz (802.11b/g) frequency band only.                                                                                                                                                                                                                                                                                      | —                          | —         |
| 80MHz-support             | If enabled, 80 MHz channels can be used in the 5 GHz frequency band on APs that support 802.11ac.                                                                                                                                                                                                                                                                  | —                          | enabled   |
| acceptable-coverage-index | The minimal coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be.<br><br>This setting applies to multi-band implementations only.                                                                                                                                                               | 1-6                        | 4         |
| active-scan               | When active-scan is enabled, an AP initiates active scanning via probe request. This option elicits more information from nearby APs, but also creates additional management traffic on the network. This feature is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Dell Technical Support.<br><br>Default: disabled | —                          | disabled  |
| aggressive-scan           | When this feature is enabled, an AP radio with no clients will scan channels every second.                                                                                                                                                                                                                                                                         | —                          | enabled   |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                       | Range    | Default                              |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|--------------------------------------|
| assignment                | Activates one of four ARM channel/power assignment modes.                                                                                                                                                                                                                                                                                                                                                                         | —        | single-band (new installations only) |
| disable                   | Disables ARM channel/power assignments.                                                                                                                                                                                                                                                                                                                                                                                           | —        | —                                    |
| maintain                  | Maintains existing channel assignments.                                                                                                                                                                                                                                                                                                                                                                                           | —        | —                                    |
| multi-band                | Computes ARM assignments for both 5 GHz (802.11a) and 2.4 GHz (802.11b/g) frequency bands.                                                                                                                                                                                                                                                                                                                                        | —        | —                                    |
| single-band               | Computes ARM assignments for a single band.                                                                                                                                                                                                                                                                                                                                                                                       | —        | —                                    |
| backoff-time              | Time, in seconds, an AP backs off after requesting a new channel or power.                                                                                                                                                                                                                                                                                                                                                        | 120-3600 | 240 seconds                          |
| cellular-handoff-assist   | When both the client match and cellular handoff assist features are enabled, the cellular handoff assist feature can help a dual-mode, 3G/4G-capable Wi-Fi device such as an iPhone, iPad, or Android client at the edge of Wi-Fi network coverage switch from Wi-Fi to an alternate 3G/4G radio that provides better network access. This feature is disabled by default, and is recommended only for Wi-Fi hotspot deployments. | —        | disabled                             |
| channel-quality-aware-arm | Base ARM changes on channel quality and noise floor values. If this parameter is disabled, only noise-floor values will be used to change channels. Default: Disabled                                                                                                                                                                                                                                                             | —        | disabled                             |
| channel-quality-threshold | Channel quality percentage below which ARM initiates a channel change.                                                                                                                                                                                                                                                                                                                                                            | 0-100    | 70                                   |
| channel-quality-wait-time | If channel quality is below the specified channel quality threshold for this wait time period, ARM initiates a channel change.                                                                                                                                                                                                                                                                                                    | 1-3600   | 120                                  |

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Range         | Default |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------|
| client-aware                                | If the Client Aware option is enabled, the AP does not change channels if there is active client traffic on that AP. If Client Aware is disabled, the AP may change to a more optimal channel, but this change may also disrupt current client traffic.                                                                                                                                                                                                                                                                                                                                                  | —             | enabled |
| client match                                | <p>The client match feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless client's probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Dell AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is enabled by default</p> | —             | enabled |
| clone                                       | Name of an existing ARM profile from which parameter values are copied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | —             | —       |
| cm-band-a-min-signal <cm-band-a-min-signal> | Minimum signal level required for the targeted A band radio in a Client Match band steer move (-dBm).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | —             | 75      |
| cm-band-g-max-signal <cm-band-g-max-signal> | Maximum signal level of the G band radio that can trigger a Client Match band steer move (-dBm)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | —             | 45      |
| cm-dot11v                                   | Client Match steers using 802.11v BSS Transition Management.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | —             | enabled |
| cm-lb-client-thresh <#-of-clients>          | If an AP radio has fewer clients than the client match load balancing threshold defined by this parameter, the AP will not participate in load balancing.                                                                                                                                                                                                                                                                                                                                                                                                                                                | 0-100 clients | 30      |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Range          | Default |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|---------|
| cm-lb-signal-delta                 | Client match will not move a client to a new radio if the signal strength of the target AP is this dB value lower than the radio to which the client is currently associated. This parameter works differently than the cm-lb-snr-thresh value, which imposes a definite value on the target AP's signal-to-noise ratio. The cm-lb-signal-delta imposes a <i>relative</i> constraint based upon the signal strength of the radio to which the client is currently associated.                                                                                                                                    | 0-20 dB        | 5 dB    |
| cm-lb-snr-thresh <dB>              | Clients must detect a SNR from an underutilized AP radio at or above this threshold before the client match feature considers load balancing a client to that radio.                                                                                                                                                                                                                                                                                                                                                                                                                                             | 0-100 dB       | 25      |
| cm-lb-thresh<br><%-of-clients>     | When the client match feature is enabled, clients may be steered from a highly utilized channel on an AP to a channel with fewer clients. If a channel on an AP radio has this percentage fewer clients than another channel supported by the client, the client match feature may move clients from the busier channel to the channel with fewer clients.                                                                                                                                                                                                                                                       | 0-100 %        | 20      |
| cm-max-steer-fails<br><#-of-fails> | The controller keeps track of the number of times the client match feature failed to steer a client to a different radio, and the reason that each steer attempt was triggered. If the client match feature attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as unsteerable for that specific trigger.<br><br>This parameter defines the maximum allowed number of client match steering fails with the same trigger before the client is marked as unsteerable for that trigger. | 0-100 failures | 5       |
| cm-report-interval <secs>          | This interval defines how often an AP sends an updated client probe report to the controller. Each client probe report contains a list of MAC addresses for clients that have been active in the last two minutes, and the AP radio SNR values seen by those clients.                                                                                                                                                                                                                                                                                                                                            | 0-255 secs     | 30      |

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Range            | Default  |

| cm-stale-age <secs>             | <p>The controller maintains client match data for up to clients showing the detected SNR values for up to 16 candidate APs per client. This table is periodically updated as APs send client probe reports to the controller. This parameter defines the amount of time that the controller should retain client match data from each client probe report.</p> <p>Different controller types support varying numbers of clients.</p> <ul style="list-style-type: none"> <li>• W-650 : 4096 clients</li> <li>• W-3000 Series: 4096 clients</li> <li>• W-7005: 1024 client</li> <li>• W-7010: 2048 clients</li> <li>• W-7030: 4096 clients</li> <li>• W-7240: 32000 clients</li> <li>• W-7220: 24000 clients</li> <li>• W-7210: 16000 clients</li> <li>• W-6000M3 = 8000 clients</li> </ul> | 0- 65535 seconds | 900 secs |
| cm-steer-timeout                | When a client is steered from one AP to a more desirable AP, the steer timeout feature helps facilitate the move by defining the amount of time that any APs to which the client should NOT associate will not respond to the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 0-255 secs       |          |
| cm-sticky-check-interval <secs> | Frequency at which the AP checks for client's received SNR values. If the SNR value drops below the threshold defined by the <b>cm-sticky-snr</b> parameter for three consecutive check intervals, that client may be moved to an different AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0-255 secs       | 3 secs   |
| cm-sticky-min-signal <-dB>      | A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the candidate AP radio is at or higher than the minimum signal level defined by this parameter <i>and</i> the candidate radio has a higher signal strength than the radio to which the client is currently associated. (The required improvement in signal strength can be defined using the <b>cm-sticky-snr-delta</b> command.)                                                                                                                                                                                                                                                                                                                         | 0-255 (-dB)      | 65       |

| error-rate-threshold      | The percentage of errors in the channel that triggers a channel change. Recommended value is 50%. A value of 0% disables this feature.                                                                                                                                                                                                                                                                                         | 0-100                                        | 50%                  |
| error-rate-wait-time      | Time, in seconds, that the error rate has to be at least the error rate threshold to trigger a channel change.                                                                                                                                                                                                                                                                                                                 | 1-2,147,483,647<br>Recommended Values: 1-100 | 30 seconds           |
| free-channel-index        | The difference in the interference index between the new channel and current channel must exceed this value for the AP to move to a new channel. The higher this value, the lower the chance an AP will move to the new channel. Recommended value is 25.                                                                                                                                                                      | 10-40                                        | 25                   |
| ideal-coverage-index      | The coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be. Recommended value is 10.                                                                                                                                                                                                                                                                          | 2-20                                         | 10                   |
| load-aware-scan-threshold | Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high.<br><br>The Load Aware Scan Threshold is the traffic throughput level an AP must reach before it stops scanning. The supported range for this setting is 0-20000000 bytes/second. (Specify 0 to disable this feature.)                                                      | —                                            | 1250000 bytes/second |
| max-tx-power              | Maximum effective isotropic radiated power (EIRP) from 3 to 33 dBm in 3 dBm increments. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links. This value takes into account both radio transmit power and antenna gain.<br><br>Higher power level settings may be constrained by local regulatory requirements and AP capabilities. | 3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33, 127 | 127 dBm              |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Range                                                  | Default  |

| ps-aware-scan  | When enabled, the AP will not scan if Power Save is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                        | disabled       |
| rogue-ap-aware | When enabled, the AP will try to contain off-channel rogue APs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | —                        | disabled       |
| scan-interval  | <p>If scanning is enabled, the scan interval defines how often the AP will leave its current channel to scan other channels in the band. Off-channel scanning can impact client performance. Typically, the shorter the scan interval, the higher the impact on performance. If you are deploying a large number of new APs on the network, you may want to lower the Scan Interval to help those APs find their optimal settings more quickly. Raise the Scan Interval back to its default setting after the APs are functioning as desired.</p> <p><b>Recommended Values:</b> 0-30 seconds</p> | 0-2,147,483, 647 seconds | 10 seconds     |
| scan-mode      | <p>Select the scan mode for the AP:</p> <ul style="list-style-type: none"> <li>• <b>all-reg-domain:</b> The AP scans channels within all regulatory domains. This is the default setting.</li> <li>• <b>reg-domain:</b> Limit the AP scans to just the regulatory domain for that AP.</li> </ul>                                                                                                                                                                                                                                                                                                 | —                        | all-reg-domain |
| scanning       | <p>The Scanning checkbox enables or disables AP scanning across multiple channels. Disabling this option also disables the following scanning features:</p> <ul style="list-style-type: none"> <li>• Multi Band Scan</li> <li>• Rogue AP Aware</li> <li>• Voip Aware Scan</li> <li>• Power Save Scan</li> </ul> <p>Do not disable Scanning unless you want to disable ARM and manually configure AP channel and transmission power.</p>                                                                                                                                                          | —                        | enabled        |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Range | Default  |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| video-aware-scan | <p>As long as there is at least one video frame every 100 mSec the AP will reject an ARM scanning request. Note that for each radio interface, video frames must be defined in one of two ways:</p> <ul style="list-style-type: none"> <li>Classify the frame as video traffic via a session ACL.</li> <li>Enable WMM on the WLAN's SSID profile and define a specific DSCP value as a video stream. Next, create a session ACL to tag the video traffic with the that DSCP value.</li> </ul> | —     | enabled  |
| voip-aware-scan  | <p>Dell's VoIP Call Admission Control (CAC) prevents any single AP from becoming congested with voice calls. When you enable CAC, you should also enable <b>voip-aware-scan</b> parameter in the ARM profile, so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that <b>scanning</b> is also enabled.</p>                                                                                                            | —     | disabled |

## Usage Guidelines

Adaptive Radio Management (ARM) is a radio frequency (RF) resource allocation algorithm that allows each AP to determine the optimum channel selection and transmit power setting to minimize interference and maximize coverage and throughput. This command configures an ARM profile that you apply to a radio profile for the 5 GHz or 2.4 GHz frequency band (see [rf dot11 a-radio-profile on page 752](#) or [rf dot11 g-radio-profile on page 763](#)).

### Channel Quality

Hybrid APs and Spectrum Monitors determine channel quality by measuring channel noise, non-Wi-Fi (interferer) utilization and duty-cycles, and certain types of Wi-Fi retries. Regular APs using the ARM feature derive channel quality values by measuring the noise floor for that channel.

### Client Match

the ARM client match feature continually monitors a client's RF neighborhood to provide ongoing client bandsteering and load balancing, and enhanced AP reassignment for roaming mobile clients. This feature is recommended over the legacy bandsteering and spectrum load balancing features, which, unlike client match, do not trigger AP changes for clients already associated to an AP.

Legacy 802.11a/b/g devices do not support the client match feature. When client match is enabled on 802.11n-capable devices, the client match feature overrides any settings configured for the legacy bandsteering, station handoff assist or load balancing features. 802.11ac-capable devices do not support the legacy bandsteering, station hand off or load balancing settings, so these APs must be managed on using client match.

When this feature is enabled on an AP, that AP is responsible for measuring the RF health of its associated clients. The AP receives and collects information about clients in its neighborhood, and periodically sends this information to the controller. The controller aggregates information it receives from all APs using client match,

and maintains information for all associated clients in a database. The controller shares this database with the APs (for their associated clients) and the APs use the information to compute the client-based RF neighborhood and determine which APs should be considered candidate APs for each client. When the controller receives a client steer request from an AP, the controller identifies the optimal AP candidate and manages the client's relocation to the desired radio. This is an improvement from previous releases, where the ARM feature was managed exclusively by APs, without the larger perspective of the client's RF neighborhood.

The following client/AP mismatch conditions are managed by the client match feature:

- **Load Balancing:** Client match balances clients across APs on different channels, based upon the client load on the APs and the SNR levels the client detects from an underutilized AP. If an AP radio can support additional clients, the AP will participate in client match load balancing and clients can be directed to that AP radio, subject to predefined SNR thresholds.
- **Sticky Clients:** The client match feature also helps mobile clients that tend to stay associated to an AP despite low signal levels. APs using client match continually monitor the client's RSSI as it roams between APs, and move the client to an AP when a better radio match can be found. This prevents mobile clients from remaining associated to an APs with less than ideal RSSI, which can cause poor connectivity and reduce performance for other clients associated with that AP.
- **Band Steering/Band Balancing:** APs using the client match feature monitor the RSSI for clients that advertise a dual-band capability. If a client is currently associated to a 2.4 GHz radio and the AP detects that the client has a good RSSI from the 5 GHz radio, the controller will attempt to steer the client to the 5 GHz radio, as long as the 5 GHz RSSI is not significantly worse than the 2.4 GHz RSSI, and the AP retains a suitable distribution of clients on each of its radios.

## ARM Scanning

The default ARM scanning interval is determined by the **scan-interval** parameter in the ARM profile. If the AP does not have any associated clients (or if most of its clients are inactive) the ARM feature will dynamically readjust this default scan interval, allowing the AP obtain better information about its RF neighborhood by scanning non-home channels more frequently. Starting with ArubaOS 6.2, if an AP attempts to scan a non-home channel but is unsuccessful, the AP will make additional attempts to rescan that channel before skipping it and continuing on to other channels.

## Using Adaptive Radio Management (ARM) in a Mesh Network

When a mesh portal operates on a mesh network, the mesh portal determines the channel used by the mesh feature. When a mesh point locates an upstream mesh portal, it will scan the regulatory domain channels list to determine the channel assigned to it, for a mesh point always uses the channel selected by its mesh portal. However, if a mesh portal uses an ARM profile enabled with a single-band or multi-band channel/power assignment and the scanning feature, the mesh portal will scan the configured channel lists and the ARM algorithm will assign the proper channel to the mesh portal.

If you are using ARM in your network, it is important to note that mesh points, unlike mesh portals, do not scan channels. This means that once a mesh point has selected a mesh portal or an upstream mesh point, it will tune to this channel, form the link, and will not scan again unless the mesh link gets broken. This provides good mesh link stability, but may adversely affect system throughput in networks with mesh portals and mesh points. When ARM assigns optimal channels to mesh portals, those portals use different channels, and once the mesh network has formed and all the mesh points have selected a portal (or upstream mesh point), those mesh points will not be able to detect other portals on other channels that could offer better throughput. This type of suboptimal mesh network may form if, for example, two or three mesh points select the same mesh portal after booting, form the mesh network, and leave a nearby mesh portal without any mesh points. Again, this will not affect mesh functionality, but may affect total system throughput.

## Example

The following command configures VoIP-aware scanning for the arm-profile named "voice-arm:"

```
(config) (host) #rf arm-profile voice-arm
 voip-aware-scan
```

## Command History

```

### Description

This command configures AP radio settings for the 5 GHz frequency band, including the Adaptive Radio Management (ARM) profile and the high-throughput (802.11n) radio profile.

### Syntax

| Parameter                 | Description                                                                                          | Range | Default   |
|---------------------------|------------------------------------------------------------------------------------------------------|-------|-----------|
| <profile>                 | Name of this instance of the profile. The name must be 1-63 characters.                              | —     | "default" |
| am-scan-profile<br><name> | Configure an Air Monitor (AM) scanning profile                                                       | —     | "default" |
| arm-profile               | Configures Adaptive Radio Management (ARM) feature. See <a href="#">rf arm-profile on page 738</a> . | —     | "default" |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Range                        | Default          |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|------------------|
| beacon-period                                | Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 60 (minimum)                 | 100 milliseconds |
| beacon-regulate                              | Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | —                            | disabled         |
| cap-reg-eirp<br><cap-reg-eirp>               | Work around a known issue on Cisco 7921G telephones by specifying a cap for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1-31 dBm.                    |                  |
| cell-size-reduction<br><cell-size-reduction> | <p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. This value should only be changed if the network is experiencing performance issues. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p> <p>Values from 1 dB - 55 dB reduce the power level that the radio can hear by that amount. If you configure this feature to use a non-default value, you must also reduce the radio's transmission (Tx) power to match its new received (Rx) power level. Failure to match a device's Tx power level to its Rx power level can result in a configuration that allows the radio to send messages to a device that it cannot hear.</p> | 1-5 5dB                      | 0 dB             |
| channel                                      | <p>Channel number for the AP 802.11a/802.11n.802.11ac physical layer. The available channels depend on the regulatory domain (country). Channel number configuration options for 20 MHz, 40 MHz, and 80 Mhz modes:</p> <ul style="list-style-type: none"> <li>num: Entering a channel number disables 40 MHz mode and activates 20 MHz mode for the entered channel.</li> <li>num+: Entering a channel number with</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Depends on regulatory domain | —                |

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Range                          | Default |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|---------|
|               | <p>a plus (+) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by increasing the primary channel number by 4. Example: 157+ represents 157 as the primary channel and 161 as the secondary channel.</p> <ul style="list-style-type: none"> <li>num-: Entering a channel number with a minus (-) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by decreasing the primary channel number by 4. Example: 157- represents 157 as the primary channel and 153 as the secondary channel.</li> </ul> <p><b>NOTE:</b> 20 MHz clients are allowed to associate when a primary and secondary channel are configured; however, the client will only use the primary channel.</p>                                                                                                                                                                                                                  |                                |         |
| channel-reuse | <p>When you enable the channel reuse feature, it can operate in either of the following three modes; static, dynamic or disable. (This feature is disabled by default.)</p> <ul style="list-style-type: none"> <li>Static mode: This mode of operation is a coverage-based adaptation of the Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa.</li> <li>Dynamic mode: In this mode, the Clear Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client.</li> <li>Disable mode: This mode does not support the tuning of the CCA Detect Threshold.</li> </ul> | <p>enabled</p> <p>disabled</p> | enabled |

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Range                        | Default  |

| channel-reuse-threshold | <p>RX Sensitivity Tuning Based Channel Reuse Threshold, in - dBm.</p> <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (in -dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength.</p> <p>If the value is set to zero, the feature will automatically determine an appropriate threshold.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Depends on regulatory domain | —        |
| client-match            | <p>The ARM client match feature continually monitors a client's RF neighborhood to provide ongoing client bandsteering and load balancing, and enhanced AP reassignment for roaming mobile clients. This feature is recommended over the legacy bandsteering and spectrum load balancing features, which, unlike client match, do not trigger AP changes for clients already associated to an AP.</p> <p>When this feature is enabled on an AP, that AP is responsible for measuring the RF health of its associated clients. The AP receives and collects information about clients in its neighborhood, and periodically sends this information to the controller. The controller aggregates information it receives from all APs using client match, and maintains information for all associated clients in a database. The controller shares this database with the APs (for their associated clients) and the APs use the information to compute the client-based RF neighborhood and determine which APs should be considered candidate APs for each client. When the controller receives a client steer request from an AP, the controller identifies the optimal AP candidate and manages the client's relocation to the desired radio. This is an improvement from previous releases, where the ARM feature was managed exclusively by APs, the without the larger perspective of the client's RF neighborhood</p> | —                            | Disabled |
| clone                   | Name of an existing radio profile from which parameter values are copied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | —                            | —        |
| csa                     | Channel Switch Announcement (CSA), as defined by IEEE 802.11h, allows an AP to announce that it is switching to a new channel before it begins transmitting on that channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | —                            | disabled |

|                           | Clients must support CSA in order to track the channel change without experiencing disruption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |             |
| csa-count                 | Number of CSA announcements that are sent before the AP begins transmitting on the new channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 1-16               | 4           |
| disable-arm-wids-function | Disables Adaptive Radio Management (ARM) and Wireless IDS functions. These can be disabled if a small increase in packet processing performance is desired. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled irrespective of this option. CAUTION: Use carefully, since this effectively disables ARM and WIDS                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1-16               | 4           |
| dot11h                    | Enable advertisement of 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities. This parameter is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | —                  | disabled    |
| high-throughput-enable    | Enables high-throughput (802.11n) features on a radio using the 5 GHz frequency band.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | —                  | enabled     |
| ht-radio-profile          | Name of high-throughput radio profile to use for configuring high-throughput support on the 5 GHz frequency band. See <a href="#">rf ht-radio-profile on page 779</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | —                  | "default-a" |
| interference-immunity     | <p>Set a value for 802.11 Interference Immunity. The default setting for this parameter is level 2. When performance drops due to interference from non-802.11 interferers (such as DECT or Bluetooth devices), the level can be increased up to level 5 for improved performance. However, increasing the level makes the AP slightly "deaf" to its surroundings, causing the AP to lose a small amount of range.</p> <p>The levels for this parameter are:</p> <ul style="list-style-type: none"> <li>Level-0: no ANI adaptation.</li> <li>Level-1: noise immunity only.</li> <li>Level-2: noise and spur immunity. This is the default setting</li> <li>Level-3: level 2 and weak OFDM immunity.</li> <li>Level-4: level 3 and FIR immunity.</li> <li>Level-5: disable PHY reporting.</li> </ul> | Level-0 - Level-15 | Level-2     |

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Range                                                | Default                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|------------------------|
|                              | <b>NOTE:</b> Do not raise the noise immunity feature's default setting if the <a href="#">channel-reuse-threshold on page 755</a> feature is also enabled. A level-3 to level-5 Noise Immunity setting is not compatible with the Channel Reuse feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                      |                        |
| maximum-distance             | <p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.</p> <p>The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 5 GHz frequency band radio:</p> <ul style="list-style-type: none"> <li>20MHz mode: 58km</li> <li>40MHz mode: 27km</li> </ul> <p>Note that if you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600m will use default settings.</p> | 0-57km<br>(40MHz mode)<br><br>0-27km<br>(20MHz mode) | 0 meters               |
| mgmt-frame-throttle-interval | <p>Averaging interval for rate limiting management frames in seconds. Zero disables rate limiting.</p> <p>Note: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 0-60                                                 | 1 second interval      |
| mgmt-frame-throttle-limit    | <p>Maximum number of management frames allowed in each throttle interval.</p> <p><b>NOTE:</b> This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 0-999999                                             | 20 frames per interval |
| mode                         | One of the operating modes for the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                      | ap-mode                |
| ap-mode                      | Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | —                                                    | —                      |
| am-mode                      | Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | —                                                    | —                      |

| spectrum-load-balancing       | <p>The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Dell AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p>                                                                        | —                    | disabled |
| spectrum-monitoring           | <p>Issue this command to turn APs in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p> <p>For further details on using hybrid APs and spectrum monitors to examine the radio frequency (RF) environment in which the Wi-Fi network is operating, refer to the Spectrum Analysis chapter of the Dell Networking W-Series ArubaOS User Guide.</p> <p>For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the Dell Networking W-Dell Networking W-Series ArubaOS 6.4.x User Guide.</p> | —                    | default  |
| spectrum-profile<br><profile> | Specify the rf spectrum profile used by hybrid APs and spectrum monitors. This profile sets the spectrum band and device ageout times used by a spectrum monitor or hybrid AP radio. For details, see <a href="#">rf spectrum-profile on page 784</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                    | default  |
| tpc-power                     | The transmit power advertised in the TPC IE of beacons and probe responses.<br>Range: 0-51 dBm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 0-51 dBm             | 15 dBm   |

| very-high-throughput-enable | Enable or disable support for Very High Throughput (802.11ac) on the radio.                     | –     | Enabled |

## Usage Guidelines

This command configures radios that operate in the 5 GHz frequency band, which includes radios utilizing the IEEE 802.11a or IEEE 802.11n standard. Channels must be valid for the country configured in the AP regulatory domain profile (see [ap regulatory-domain-profile on page 217](#)). To view the supported channels, use the **show ap allowed-channels** command.

APs initially start up with default **ack-timeout**, **cts-timeout** and **slot-time** values. When you modify the **maximum-distance** parameter in an rf dot11a radio profile or rf dot11g radio profile, new **ack-timeout**, **cts-timeout** and **slot-time** values may be derived, but those values are never less than the default values for an indoor AP.

Mesh radios on outdoor APs have additional constraints, as mesh links may need to span long distances. For mesh radios on outdoor APs, the effect of the default **maximum-distance** parameter on the **ack-timeout**, **cts-timeout** and **slot-time** values depends on whether the APs are configured as mesh portals or mesh points. This is because mesh portals use a default **maximum-distance** value of 16,050 meters, and mesh points use, by default, the maximum possible **maximum-distance** value.

The **maximum-distance** value should be set correctly to span the largest link distance in the mesh network so that when a mesh point gets the configuration from the network it will apply the correct **ack-timeout**, **cts-timeout** and **slot-time** values. The values derived from the **maximum-distance** setting depend on the band and whether 20MHz/40MHz mode of operation is in use.

The following table indicates values for a range of distances:

| Timeouts[usec]         | --- 5GHz radio --- |     |      | --- 2.4GHz radio --- |     |      |
|------------------------|--------------------|-----|------|----------------------|-----|------|
| Distance[m]            | Ack                | CTS | Slot | Ack                  | CTS | Slot |
| 0 (outdoor:16050m)     | 128                | 128 | 63   | 128                  | 128 | 63   |
| 0 (indoor:600a,6450g)  | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 200 (==default)        | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 500                    | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 600                    | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 1050                   | 28                 | 28  | 13   | 64                   | 48  | 31   |
| 5100                   | 55                 | 55  | 26   | 64                   | 55  | 31   |

| 24750 (2.4G limit 40M) | –                  | –   | –    | 186                  | 186 | 92   |

## Examples

The following command configures APs to operate in AM mode for the selected dot11a-radio-profile named "samplea:"

```
(host) (config) #rf dot11a-radio-profile samplea mode am-mode
```

The following command configures APs to operate in high-throughput (802.11n) mode on the 5 GHz frequency band for the selected dot11a-radio profile named "samplea" and assigns a high-throughput radio profile named "default-a:"

```
(host) (config) #rf dot11a-radio-profile samplea
 high-throughput-enable
 ht-radio-profile default-a
```

The following command configures a primary channel number of 157 and a secondary channel number of 161 for 40 MHz mode of operation for the selected dot11a-radio profile named "samplea:"

```
(host) (config) #rf dot11a-radio-profile samplea
 channel <157+>
```

### Description

This command configures AP radio settings for the 2.4 GHz frequency band, including the Adaptive Radio Management (ARM) profile and the high-throughput (802.11n) radio profile.

### Syntax

| Parameter                      | Description                                                             | Range | Default   |
|--------------------------------|-------------------------------------------------------------------------|-------|-----------|
| <profile>                      | Name of this instance of the profile. The name must be 1-63 characters. | —     | “default” |
| am-scan-profile <profile-name> | Configure an Air Monitor (AM) scanning profile.                         | —     | —         |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Range        | Default          |

| arm-profile                               | Configures Adaptive Radio Management (ARM) feature. See <a href="#">rf arm-profile on page 738</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | —            | "default"        |
| beacon-period                             | Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 60 (minimum) | 100 milliseconds |
| beacon-regulate                           | Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | —            | disabled         |
| cap-reg-eirp<br><cap-reg-eirp>            | Work around a known issue on Cisco 7921G telephones by specifying a cap for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1–31 dBm.    |                  |
| cell-size-reduction <cell-size-reduction> | <p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. This value should only be changed if the network is experiencing performance issues. The possible range of values for this feature is 0–55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p> <p>Values from 1 dB - 55 dB reduce the power level that the radio can hear by that amount. If you configure this feature to use a non-default value, you must also reduce the radio's transmission (Tx) power to match its new received (Rx) power level. Failure to match a device's Tx power level to its Rx power level can result in a configuration that allows the radio to send messages to a device</p> | 1–5 5dB      | 0 dB             |

| channel-reuse           | <p>When you enable the channel reuse feature, it can operate in either of the following three modes; static, dynamic or disable. (This feature is disabled by default.)</p> <ul style="list-style-type: none"> <li>• <b>Static mode:</b> This mode of operation is a coverage-based adaptation of the Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa.</li> <li>• <b>Dynamic mode:</b> In this mode, the Clear Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client.</li> <li>• <b>Disable mode:</b> This mode does not support the tuning of the CCA Detect Threshold.</li> </ul> | <p>enabled</p> <p>disabled</p> | enabled |
| channel-reuse-threshold | <p>RX Sensitivity Tuning Based Channel Reuse Threshold, in -dBm.</p> <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (in -dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength.</p> <p>If the value is set to zero, the feature will automatically determine an appropriate threshold.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | depends on regulatory domain   | —       |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Range | Default     |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------|
| disable-arm-wids-function | Disables Adaptive Radio Management (ARM) and Wireless IDS functions. These can be disabled if a small increase in packet processing performance is desired. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled irrespective of this option. CAUTION: Use carefully, since this effectively disables ARM and WIDS                                                                                                                                   | 1-16  | 4           |
| dot11b-protection         | Enable or disable protection for 802.11b clients. This parameter is enabled by default. Disabling this feature may improve performance if there are no 802.11b clients on the WLAN.<br><br>WARNING: Disabling protection violates the 802.11 standard and may cause interoperability issues. If this feature is disabled on a WLAN with 802.11b clients, the 802.11b clients will not detect an 802.11g client talking and can potentially transmit at the same time, thus garbling both frames. | —     | enabled     |
| dot11h                    | Enable advertisement of 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities This parameter is disabled by default.                                                                                                                                                                                                                                                                                                                                            | —     | disabled    |
| high-throughput-enable    | Enables high-throughput (802.11n) features on a radio using the 2.4 GHz frequency band.                                                                                                                                                                                                                                                                                                                                                                                                          | —     | enabled     |
| ht-radio-profile          | Name of high-throughput radio profile to use for configuring high-throughput support on the 5 GHz frequency band. See <a href="#">rf ht-radio-profile on page 779</a> .                                                                                                                                                                                                                                                                                                                          | —     | "default-a" |

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Range                                                 | Default  |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|----------|
| interference-immunity | <p>Set a value for 802.11 Interference Immunity. The default setting for this parameter is level 2. When performance drops due to interference from non-802.11 interferers (such as DECT or Bluetooth devices), the level can be increased up to level 5 for improved performance. However, increasing the level makes the AP slightly “deaf” to its surroundings, causing the AP to lose a small amount of range.</p> <p>The levels for this parameter are:</p> <ul style="list-style-type: none"> <li>• Level-0: no ANI adaptation.</li> <li>• Level-1: noise immunity only.</li> <li>• Level-2: noise and spur immunity. This is the default setting</li> <li>• Level-3: level 2 and weak OFDM immunity.</li> <li>• Level-4: level 3 and FIR immunity.</li> <li>• Level-5: disable PHY reporting.</li> </ul> <p><b>NOTE:</b> Do not raise the noise immunity feature’s default setting if the <a href="#">channel-reuse-threshold on page 755</a> feature is also enabled. A level-3 to level-5 Noise Immunity setting is not compatible with the Channel Reuse feature.</p> | Level-0 - Level-5                                     | Level-2  |
| maximum-distance      | <p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.</p> <p>The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 2.4GHz frequency band radio:</p> <ul style="list-style-type: none"> <li>• 20MHz mode: 54km</li> <li>• 40MHz mode: 24km</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <p>0-24km (40MHz mode)</p> <p>0-54km (20MHz mode)</p> | 0 meters |

| Parameter                    | Description                                                                                                                                                                                                                                                                                                       | Range    | Default                |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|------------------------|
|                              | Note that if you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600m will use default settings.                                                                                                                                                    |          |                        |
| mgmt-frame-throttle-interval | Averaging interval for rate limiting management frames in seconds. Zero disables rate limiting.<br><br>Note: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.                                                                                                                            | 0-60     | 1 second interval      |
| mgmt-frame-throttle-limit    | Maximum number of management frames allowed in each throttle interval.<br><br><b>NOTE:</b> This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.                                                                                                                                              | 0-999999 | 20 frames per interval |
| mode                         | One of the operating modes for the AP.                                                                                                                                                                                                                                                                            |          | ap-mode                |
| ap-mode                      | Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.                                                                                                                                                                                           |          |                        |
| am-mode                      | Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.                                                                                                                                        |          |                        |
| spectrum-mode                | Device operates as a spectrum monitor, and can send spectrum analysis data to a desktop or laptop client.<br><br>For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the Dell Networking W-Dell Networking W-Series ArubaOS 6.4.x User Guide. |          |                        |
| no                           | Negates any configured parameter.                                                                                                                                                                                                                                                                                 | —        | —                      |

| very-high-throughput-rates-enable | <p>This feature enables Very High Throughput (VHT) rates on the 2.4 GHz band, providing 256-QAM modulation and encoding that allows for 600 Mbit/sec performance over 802.11n networks. Maximum data rates are increased on the 2.4 GHz band through the addition of VHT Modulation and Coding Scheme (MCS) values 8 and 9, which support the highly efficient modulation rates in 256-QAM. Starting with ArubaOS 6.4.2.0, VHT is supported on W-AP220 Series access points on both 20 and 40 MHz channels.</p> <p>Using the controller's CLI or WebUI, VHT MCS values 0-9 are enabled, overriding the existing high-throughput (HT) MCS values 0-7, which have a lower maximum data rate. However, this feature should be disabled if individual rate selection is required.</p> | —                 | disabled |

## Usage Guidelines

This command configures radios that operate in the 2.4 GHz frequency band, which includes radios utilizing the IEEE 802.11 b/g or IEEE 802.11 n standard. Channels must be valid for the country configured in the AP

regulatory domain profile (see [ap regulatory-domain-profile on page 217](#)). To view the supported channels, use the **show ap allowed-channels** command.

APs initially start up with default **ack-timeout**, **cts-timeout** and **slot-time** values. When you modify the **maximum-distance** parameter in an rf dot11a radio profile or rf dot11g radio profile, new **ack-timeout**, **cts-timeout** and **slot-time** values may be derived, but those values are never less than the default values for an indoor AP.

Mesh radios on outdoor APs have additional constraints, as mesh links may need to span long distances. For mesh radios on outdoor APs, the effect of the default **maximum-distance** parameter on the **ack-timeout**, **cts-timeout** and **slot-time** values depends on whether the APs are configured as mesh portals or mesh points. This is because mesh portals use a default **maximum-distance** value of 16,050 meters, and mesh points use, by default, the maximum possible **maximum-distance** value.

The **maximum-distance** value should be set correctly to span the largest link distance in the mesh network so that when a mesh point gets the configuration from the network it will apply the correct **ack-timeout**, **cts-timeout** and **slot-time** values. The values derived from the **maximum-distance** setting depend on the band and whether 20MHz/40MHz mode of operation is in use.

The following table indicates values for a range of distances:

| Timeouts[usec]         | --- 5GHz radio --- |     |      | --- 2.4GHz radio --- |     |      |
|------------------------|--------------------|-----|------|----------------------|-----|------|
| Distance[m]            | Ack                | CTS | Slot | Ack                  | CTS | Slot |
| 0 (outdoor:16050m)     | 128                | 128 | 63   | 128                  | 128 | 63   |
| 0 (indoor:600a,6450g)  | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 200 (==default)        | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 500                    | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 600                    | 25                 | 25  | 9    | 64                   | 48  | 9    |
| 1050                   | 28                 | 28  | 13   | 64                   | 48  | 31   |
| 5100                   | 55                 | 55  | 26   | 64                   | 55  | 31   |

| 27450 (5G limit 40M)   | 204                | 204 | 101  | -                    | -   | -    |
| 24750 (2.4G limit 40M) | -                  | -   | -    | 186                  | 186 | 92   |

## Examples

The following command configures APs to operate in AM mode for the selected dot11g-radio-profile named "sampleg:"

```
rf dot11g-radio-profile sampleg
mode am-mode
```

The following command configures APs to operate in high-throughput (802.11n) mode on the 2.4 GHz frequency band for the selected dot11g-radio profile named "sampleg" and assigns a high-throughput radio profile named "default-g:"

```
rf dot11g-radio-profile sampleg
high-throughput-enable
ht-radio-profile default-g
```

The following command configures a primary channel number of 1 and a secondary channel number of 5 for 40 MHz mode of operation for the selected dot11g-radio profile named "sampleg:"

```
rf dot11g-radio-profile sampleg
channel <1+>
```

|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced                                                                                                                                                                                                                                                          |
| ArubaOS 3.3.2   | Introduced protection for 802.11b clients and support for the high-throughput IEEE 802.11n standard.                                                                                                                                                                        |
| ArubaOS 3.4     | Support for the following parameters: <ul style="list-style-type: none"><li>• Spectrum load balancing</li><li>• Spectrum load balancing domain</li><li>• RX Sensitivity Tuning Based Channel Reuse</li><li>• RX Sensitivity Threshold</li><li>• ARM/WIDS Override</li></ul> |
| ArubaOS 3.4.1   | The <b>maximum-distance</b> parameter was introduced.                                                                                                                                                                                                                       |
| ArubaOS 3.4.2   | The <b>beacon-regulate</b> parameter was introduced.                                                                                                                                                                                                                        |
| ArubaOS 6.0     | The following parameters were introduced <ul style="list-style-type: none"><li>• am-scan-profile</li><li>• cap-reg-eirp</li><li>• slb-mode</li><li>• slb-update-interval</li></ul>                                                                                          |
| ArubaOS 6.1     | The <b>spectrum-monitoring</b> and <b>slb-threshold</b> parameters were introduced.                                                                                                                                                                                         |
| ArubaOS 6.1.3.2 | The <b>cell-size-reduction</b> parameter was introduced.                                                                                                                                                                                                                    |
| ArubaOS 6.4.2.0 | The <b>very-high-throughput-rates-enable</b> parameter was introduced.                                                                                                                                                                                                      |

### Description

This command configures the event thresholds profile.

### Syntax

| Parameter                   | Description                                                                                                                                                                                                                                                                  | Range | Default   |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------|
| <profile>                   | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                                                                      | —     | “default” |
| bwr-high-wm                 | If bandwidth in an AP exceeds this value, a bandwidth exceeded condition exists. The value represents the percentage of maximum for a given radio. (For 802.11b, the maximum bandwidth is 7 Mbps. For 802.11 a and g, the maximum is 30 Mbps.) The recommended value is 85%. | 0-100 | 0%        |
| bwr-low-wm                  | After a bandwidth exceeded condition exists, the condition persists until bandwidth drops below this value. The recommended value is 70%.                                                                                                                                    | 0-100 | 0%        |
| clone                       | Name of an existing radio profile from which parameter values are copied.                                                                                                                                                                                                    | —     | —         |
| detect-frame-rate-anomalies | Enable or disables detection of frame rate anomalies.                                                                                                                                                                                                                        | —     | disabled  |

| Parameter    | Description                                                                                                                                                                                                   | Range | Default |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| fer-high-wm  | If the frame error rate (as a percentage of total frames in an AP) exceeds this value, a frame error rate exceeded condition exists. The recommended value is 16%.                                            | 0-100 | 0%      |
| fer-low-wm   | After a frame error rate exceeded condition exists, the condition persists until the frame error rate drops below this value. The recommended value is 8%.                                                    | 0-100 | 0%      |
| ffr-high-wm  | If the frame fragmentation rate (as a percentage of total frames in an AP) exceeds this value, a frame fragmentation rate exceeded condition exists. The recommended value is 16%.                            | 0-100 | 16%     |
| ffr-low-wm   | After a frame fragmentation rate exceeded condition exists, the condition persists until the frame fragmentation rate drops below this value. The recommended value is 8%.                                    | 0-100 | 8%      |
| flsr-high-wm | If the rate of low-speed frames (as a percentage of total frames in an AP) exceeds this value, a low-speed rate exceeded condition exists. This could indicate a coverage hole. The recommended value is 16%. | 0-100 | 16%     |
| flsr-low-wm  | After a low-speed rate exceeded condition exists, the condition persists until the percentage of low-speed frames drops below this value. The recommended value is 8%.                                        | 0-100 | 8%      |
| fnur-high-wm | If the non-unicast rate (as a percentage of total frames in an AP) exceeds this value, a non-unicast rate exceeded condition exists. This value depends upon the applications used on the network.            | 0-100 | 0%      |
| fnur-low-wm  | After a non-unicast rate exceeded condition exists, the condition persists until the non-unicast rate drops below this value.                                                                                 | 0-100 | 0%      |
| frer-high-wm | If the frame receive error rate (as a percentage of total frames in an AP) exceeds this value, a frame receive error rate exceeded condition exists. The recommended value is 16%.                            | 0-100 | 16%     |
| frer-low-wm  | After a frame receive error rate exceeded condition exists, the condition persists until the frame receive error rate drops below this value. The recommended value is 8%.                                    | 0-100 | 8%      |

| Parameter   | Description                                                                                                                                                        | Range | Default |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| frr-high-wm | If the frame retry rate (as a percentage of total frames in an AP) exceeds this value, a frame retry rate exceeded condition exists. The recommended value is 16%. | 0-100 | 16%     |
| frr-low-wm  | After a frame retry rate exceeded condition exists, the condition persists until the frame retry rate drops below this value. The recommended value is 8%.         | 0-100 | 8%      |
| no          | Negates any configured parameter.                                                                                                                                  | —     | —       |

## Usage Guidelines

The event threshold profile configures Received Signal Strength Indication (RSSI) metrics. When certain RF parameters are exceeded, these events can signal excessive load on the network, excessive interference, or faulty equipment. This profile and many of the detection parameters are disabled (value is 0) by default.

## Example

The following command configures an event threshold profile:

```
(host) (config) #rf event-thresholds-profile et1
detect-frame-rate-anomalies
```

## Command History

This command was introduced in ArubaOS 3.0

## rf ht-radio-profile

```
rf ht-radio-profile <profile>
 40MHz-intolerance
 clone <profile>
 diversity-spreading-workaround
 honor-40MHz-intolerance
 no
```

### Description

This command configures high-throughput AP radio settings. High-throughput features use the IEEE 802.11n standard.

### Syntax

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Range | Default                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------------------------------|

| clone                   | Name of an existing high-throughput radio profile from which parameter values are copied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | —     | —                                 |
| honor-40MHz-intolerance | When enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —     | enabled                           |
| no                      | Negates any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | —     | —                                 |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                    | Range | Default  |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| diversity-spreading-workaround | <p>When this feature is enabled, all legacy transmissions will be sent using a single antenna. This enables interoperability for legacy or high-throughput stations that cannot decode 802.11n cyclic shift diversity (CSD) data.</p> <p>This feature is disabled by default and should be kept disabled unless necessary.</p> |       | disabled |

## Usage Guidelines

The ht-radio-profile configures high-throughput settings for networks utilizing the IEEE 802.11n standard, which supports 40 MHz channels and operates in both the 2.4 GHz and 5 GHz frequency bands.

Most transmissions to high throughput (HT) stations are sent through multiple antennas using cyclic shift diversity (CSD). When you enable the single-chain-legacydisable-diversity-spreadingparameter, CSD is disabled and only one antenna transmits data, even if they are being sent to high-throughput stations. Use this feature to turn off antenna diversity when the AP must support legacy clients such as Cisco 7921g VoIP phones, or older 802.11g clients (e.g. Intel Centrino clients). Note, however, that enabling this feature can reduce overall throughput rates.

The ht-radio-profile you wish to use must be assigned to a dot11a and/or dot11g-radio-profile. You can assign the same profile or different profiles to the 2.4 GHz and 5 GHz frequency bands. See [rf dot11a-radio-profile on page 752](#) and [rf dot11g-radio-profile on page 763](#).

## Example

The following command configures an ht-radio-profile named “default-g” and enables 40MHz-intolerance:

```
(host) (config) #rf ht-radio-profile default-g
40MHz-intolerance
```

## rf optimization-profile

```
rf optimization-profile <profile-name>
 clone <profile>
 handoff-assist
 low-rssi-threshold <number>
 no ...
 rssi-check-frequency <number>
 rssi-falloff-wait-time <number>
```

### Description

This command configures the RF optimization profile.

### Syntax

| Parameter                       | Description                                                                                                                                                                              | Range | Default   |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-----------|
| <profile-name>                  | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                  | —     | "default" |
| clone                           | Name of an existing optimization profile from which parameter values are copied.                                                                                                         | —     | —         |
| handoff-assist                  | Allows the controller to force a client off an AP when the RSSI drops below a defined minimum threshold.                                                                                 | —     | disabled  |
| low-rssi-threshold              | Minimum RSSI, above which deauth should never be sent.                                                                                                                                   | 1-255 | 10        |
| no                              | Negates any configured parameter.                                                                                                                                                        | —     | —         |
| rssi-check-frequency            | Interval, in seconds, to sample RSSI.                                                                                                                                                    | 9-255 | 3 seconds |
| rssi-falloff-wait-time <number> | Number of times the detected client RSSI level must fall below the minimum RSSI threshold the before the AP sends a deauthorization message to the client. The maximum value is 8 times. | 0-8   | 4         |

### Example

The following command configures an RF optimization profile:

```
(host) (config) #rf optimization-profile Angela1
(host) (RF Optimization Profile "Angela1") #rssi-falloff-wait-time 3
(host) (RF Optimization Profile "Angela1") #rssi-check-frequency 2
```

## Command History

```

### Description

Define the device ageout times used by a spectrum monitor, or hybrid AP radio.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                      | Range           | Default |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|---------|
| age-out             | Use the <b>age-out</b> parameter to define the number of seconds for which a specific device type must stop sending a signal before the spectrum monitor considers that device no longer active on the network.                                                                                                                                                                                                                  |                 |         |
| audio               | Some audio devices such as wireless speakers and microphones also use fixed frequency to continuously transmit audio. These devices are classified as Fixed Frequency (Audio).                                                                                                                                                                                                                                                   | 5-65535 seconds | 10 sec  |
| bluetooth           | Bluetooth devices. Note that this setting is applicable to 2.4GHz spectrum monitor radios only.                                                                                                                                                                                                                                                                                                                                  | 5-65535 seconds | 25 sec  |
| cordless-ff-phone   | Some cordless phones use a fixed frequency to transmit data (much like the fixed frequency video devices). These devices are classified as Fixed Frequency (Cordless Phones).                                                                                                                                                                                                                                                    | 5-65535 seconds | 10 sec  |
| cordless-fh-base    | Frequency hopping cordless phone base units transmit periodic beacon-like frames at all times. When the handsets are not transmitting (i.e., no active phone calls), the cordless base is classified as Frequency Hopper (Cordless Base).                                                                                                                                                                                        | 5-65535 seconds | 240 sec |
| cordless-fh-network | When there is an active phone call and one or more handsets are part of the phone conversation, the device is classified as Frequency Hopper (Cordless Network). Cordless phones may operate in 2.4 GHz or 5 GHz bands. Some phones use both 2.4 GHz and 5 GHz bands (for example, 5 GHz for Base-to-handset and 2.4 GHz for Handset-to-base). These phones may be classified as unique Frequency Hopper devices on both bands.. | 5-65535 seconds | 60 sec  |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Range           | Default |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|---------|
| generic-ff         | All fixed frequency devices that do not fall into one of the other categories are classified as Fixed Frequency (Other). Note that the RF signatures of the fixed frequency audio, video and cordless phone devices are very similar and that some of these devices may be occasionally classified as Fixed Frequency (Other).                                                                                                                                                                                                                                                      | 5-65535 seconds | 10 sec  |
| generic-fh         | When the classifier detects a frequency hopper that does not fall into one of the above categories, it is classified as Frequency Hopper (Other). Some examples include IEEE 802.11 FHSS devices, game consoles and cordless/hands-free devices that do not use one of the known cordless phone protocols.                                                                                                                                                                                                                                                                          | 5-65535 seconds | 25 sec  |
| generic-interferer | Any non-frequency hopping device that does not fall into one of the other categories described in this table is classified as a Generic Interferer. For example a Microwave-like device that does not operate in the known operating frequencies used by the Microwave ovens may be classified as a Generic Interferer. Similarly wide-band interfering devices may be classified as Generic Interferers.                                                                                                                                                                           | 5-65535 seconds | 30 sec  |
| microwave          | Common residential microwave ovens with a single magnetron are classified as a Microwave. These types of microwave ovens may be used in cafeterias, break rooms, dormitories and similar environments. Some industrial, healthcare or manufacturing environments may also have other equipment that behave like a microwave and may also be classified as a Microwave device. Note that this setting is applicable to 2.4GHz spectrum monitor radios only.                                                                                                                          | 5-65535 seconds | 15 sec  |
| microwave-inverter | Some newer-model microwave ovens have the inverter technology to control the power output and these microwave ovens may have a duty cycle close to 100%. These microwave ovens are classified as Microwave (Inverter). Dual-magnetron industrial microwave ovens with higher duty cycle may also be classified as Microwave (Inverter). As in the Microwave category described above, there may be other equipment that behave like inverter microwaves in some industrial, healthcare or manufacturing environments. Those devices may also be classified as Microwave (Inverter). | 5-65535 seconds | 15 sec  |
| video              | Video transmitters that continuously transmit video on a single frequency are classified as Fixed Frequency (Video). These devices typically have close to a 100% duty cycle. These                                                                                                                                                                                                                                                                                                                                                                                                 | 5-65535 seconds | 60 sec  |

| Parameter      | Description                                                                                                                                                                                                            | Range           | Default |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|---------|
|                | types of devices may be used for video surveillance, TV or other video distribution, and similar applications.                                                                                                         |                 |         |
| wifi           | Wi-Fi devices.                                                                                                                                                                                                         | 5-65535 seconds | 600 sec |
| xbox           | The Microsoft Xbox device uses a frequency hopping protocol in the 2.4 GHz band. These devices are classified as Frequency Hopper (Xbox). Note that this setting is applicable to 2.4GHz spectrum monitor radios only. | 5-65535 seconds | 25 sec  |
| clone <source> | Make a copy of an existing spectrum profile.                                                                                                                                                                           |                 | 600 sec |
| no             | Remove a spectrum profile or negate a configured parameter.                                                                                                                                                            |                 |         |

## Usage Guidelines

The Spectrum Analysis software module provides visibility into RF coverage, allowing you to troubleshoot RF interference and identify the 802.11 devices on the network. APs that gather spectrum data are called Spectrum Monitors, or *SMs*, and reference a spectrum profile that determines the band monitored by that SM radio. Use this profile to modify default device ageout times for spectrum monitors and hybrid APs using this profile.

For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the Dell Networking W-Series ArubaOS 6.4.x User Guide.

## Example

The following command creates the spectrum profile **spectrum2**.

```
(host) (config) #rf spectrum-profile spectrum2
```

# router mobile

router mobile

## Description

This command enables Layer-3 (IP) mobility.

## Syntax

No parameters.

## Usage Guidelines

Use this command to enable IP mobility on a controller. IP mobility is disabled by default on the controller. This command must be executed on all controllers(master and local) that need to provide support for layer-3 roaming in a mobility domain. You can enable or disable IP mobility on a virtual AP profile with the **wlan virtual-ap** command (IP mobility is enabled by default in a virtual AP profile).

---

It is recommended to reboot the controller every time you enable or disable IP mobility.

---

## Example

This command enables IP mobility:

```
(host) (config) #router mobile
```

## router ospf

```
router ospf
 aggregate-route rapng-vpn <addr>
 area <area-id>
 default-cost <cost>
 nssa [default-information no-redistribution | no-summary]
 stub [no-summary]
 default-information originate always
 redistribute
 loopback
 rapng-vpn
 vlan [<vlan-ids> | add <vlan-ids> | remove <vlan-ids>]
 router-id <rtr-id>
 subnet exclude <addr> <mask>
```

### Description

Global OSPF configuration for the upstream router.

### Syntax

| Parameter                            | Description                                                                                                      |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------|
| aggregate-route                      | Enter the aggregate route information.                                                                           |
| area <area-id>                       | Enter the keyword area followed by the area identification, in dotted decimal format, to configure an OSPF area. |
| default-cost <cost>                  | Set the summary cost of a NSSA/stub area (in route metric)<br>Range: 0 to 16777215                               |
| nssa                                 | Set an area as a NSSA                                                                                            |
| default-information-originate        | Originate Type 7 default into the NSSA area                                                                      |
| no-redistribution                    | Set the NSSA area for no distribution into this NSSA area                                                        |
| no-summary                           | Do not send summary LSA into this NSSA area                                                                      |
| stub [no-summary]                    | Set an area as a Total Stub Area and optionally do not send summary LSA into this area                           |
| default-information originate always | Control distribution of default information by distributing a default route.                                     |
| redistribute                         | Redistributes the route.                                                                                         |
| loopback                             | Redistributes loopback addresses.                                                                                |
| rapng-vpn                            | Redistribute IAP-VPN addresses.                                                                                  |

| Parameter                    | Description                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| vlan <vlan-ids>              | Redistribute the vlan user subnet.                                                                                            |
| add <vlan-ids>               | Add the user VLANs to the list                                                                                                |
| remove <vlan-ids>            | Remove user VLANs to the list.                                                                                                |
| router-id <rtr-id>           | Enter the router ID in IP address format.                                                                                     |
| subnet exclude <addr> <mask> | Specify the subnet that OSPF will <i>not</i> advertise. Enter the subnet and mask address in dotted decimal format (A.B.C.D). |

## Usage Guidelines

OSPFv2 is a dynamic Interior Gateway routing Protocol (IGP) based on IETF RFC 2328. The ArubaOS implementation of OSPF allows controllers to deploy effectively in a Layer 3 topology. For more detailed information, refer to the OSPF Chapter in the *Dell Networking W-Series ArubaOS User Guide*.

## Example

By default OSPF will advertise all the user VLAN subnet addresses in the router LSA (Link-State Advertisement). To control the OSPF advertisement, execute the following command:

```
(host) (config) # router ospf subnet exclude 75.1.1.0 255.255.0.0
```

With the above command, any user VLAN subnet matching 75.1/16 will not be advertised in the router LSA. To return to the default advertisement, execute the command:

```
(host) (config) # no router ospf subnet exclude 75.1.1.0 255.255.0.0
```

# routing-policy-map

routing-policy-map role <user-role> access-list <route-acl>

## Description

This command associates a routing access control list (ACL) with a user role.

## Syntax

| Parameter                  | Description                                                            |
|----------------------------|------------------------------------------------------------------------|
| role <user-role>           | Name of the user role to be associated with the specified routing ACL. |
| access-list<br><route-acl> | Name of the route ACL to be associated to the specified user role.     |

## Usage Guidelines

The commands to associate an access list to a user role vary, depending upon the type of access list being associated to that role. User roles are applied globally across all controllers, so Ethertype, MAC and session ACLs can be applied to global user roles. However, routing access lists may vary between locations, so they are mapped to a user role in a local configuration setting.

## Example

The following example maps a user role to a routing ACL.

```
(host) (config) #routing-policy-map
role employee access-list branch1
```

To associate the user role with an ethertype, MAC or session ACL, use the command **user-role <role> access-list eth|mac|session <acl>**.

## service

service [dhcp] [dhcpv6] [network-storage] [print-server]

### Description

This command enables the DHCP server on the controller.

### Syntax

| Parameter       | Description                 | Default  |
|-----------------|-----------------------------|----------|
| dhcp            | Enables the DHCP server     | disabled |
| dhcpv6          | Enables the DHCPv6 server   | disabled |
| network-storage | Enables the NAS service     | disabled |
| print-server    | Enables the printer service | disabled |

### Usage Guidelines

You can enable and configure DHCP, DHCPv6, network-storage or print server in the controller to provide the following:

- DHCP: IP addresses to wireless clients if an external DHCP server is not available.
- DHCPv6: IPv6 addresses to wireless clients if an external DHCPv6 server is not available.
- Network-storage: To provide access to the storage devices attached to the controller.
- Printer-server: To provide access to printers attached to the controller.

### Example

The following command enables the DHCP server in the controller:

```
(host) (config) #service dhcp
```

The following command enables the DHCPv6 server in the controller:

```
(host) (config) #service dhcpv6
```

The following command enables the NAS services in the controller:

```
(host) (config) #service network-storage
```

The following command enables the printer services in the controller:

```
(host) (config) #service print-server
```

## show aaa accounting tacacs

show aaa accounting tacacs

### Description

Show configuration information for TACACS+ accounting servers.

### Usage Guidelines

This command displays TACACS+ data for your controller if you have previously configured a TACACS+ server and server group. The output includes the current TACACS+ accounting mode (enabled or disabled), and the name of the TACACS+ server group.

### Example

The output of the **show aaa accounting tacacs** command displays configuration information for a TACACS+ accounting server. The output of this command includes the following parameters:

```
(host) #show aaa accounting tacacs
TACACS Accounting Configuration

Parameter Value

Mode Enabled
Commands configuration
Server-Group tacacs1
```

| Parameter    | Description                                                                                                                                                                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

# show aaa authentication all

show aaa authentication all

## Description

Show authentication statistics for your controller, including authentication methods, successes and failures.

## Usage Guidelines

This command displays a general overview of authentication statistics. To view authentication information for specific profiles such as a captive-portal, MAC or 801.x authentication profile, issue the commands specific to those features.

## Example

The output of this command displays an authentication overview for your controller, including the authentication methods used, and the numbers of successes or failures for each method. This example shows the numbers of authentication successes and failures for a controller using TACACS+ and RADIUS authentication methods.

```
(host) #show aaa authentication all
```

```
Auth Method Statistics
```

```

```

```
Method Success Failures
```

```

```

```
tacacs 12
```

```
2Radius
```

```
9
```

## Command History

This command was introduced in ArubaOS 3.0.

## show aaa authentication captive-portal

show aaa authentication captive-portal [<profile-name>]

### Description

This command shows configuration information for captive portal authentication profiles.

### Syntax

| Parameter      | Description                                                    |
|----------------|----------------------------------------------------------------|
| <profile-name> | The name of an existing captive portal authentication profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the entire Captive Portal Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

If you do not yet have any captive portal authentication profiles defined, use the command [aaa authentication captive-portal](#) to configure your captive portal profiles.

### Examples

This first example shows that there are three configured captive portal profiles in the Captive Profile Authentication Profile List. The **References** column lists the number of other profiles with references to a captive portal authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication captive-portal
```

```
Captive Portal Authentication Profile List
```

| Name       | References | Profile Status |
|------------|------------|----------------|
| c-portal   | 2          |                |
| remoteuser |            | 1              |
| portall    |            | 1              |

```
Total: 4
```

Include a captive portal profile name to display a complete list of configuration settings for that profile. The example below shows settings for the captive portal profile portall.

```
Captive Portal Authentication Profile "portall"
```

| Parameter           | Value    |
|---------------------|----------|
| Default Role        | guest    |
| Default Guest Role  | guest    |
| Server Group        | default  |
| Redirect Pause      | 10 sec   |
| User Login          | Enabled  |
| Guest Login         | Disabled |
| Logout popup window | Enabled  |

```

Use HTTP for authentication Disabled
Logon wait minimum wait 5 sec
Logon wait maximum wait 10 sec
logon wait CPU utilization threshold 60 %
Max Authentication failures 0
Show FQDN Disabled
Authentication Protocol PAP
Login page /auth/index.
Welcome page /auth/welcom
Show Welcome Page Yes
Add switch IP address in the redirection URL Disabled
Adding user vlan in redirection URL Disabled
Add a controller interface in the redirection URL N/A
Allow only one active user session Disabled
White List N/A
Black List N/A
Show the acceptable use policy page Disabled
User idle timeout N/A
Redirect URL N/A
Bypass Apple Captive Network Assistant Disabled
URL Hash Key *****

```

The output of this command includes the following parameters:

| Parameter           | Description                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Role        | Role assigned to the captive portal user upon login.                                                                                                                                                              |
| Default Guest Role  | Guest role assigned to the captive portal user upon login.                                                                                                                                                        |
| Server Group        | Name of the group of servers used to authenticate captive portal users.                                                                                                                                           |
| Redirect Pause      | Time, in seconds, that the system remains in the initial welcome page before redirecting the user to the final web URL. If set to 0, the welcome page displays until the user clicks on the indicated link.       |
| User Login          | Shows whether the profile has enabled or disabled captive portal with authentication of user credentials.                                                                                                         |
| Guest Login         | Shows whether the profile has enabled or disabled captive portal guest login without authentication.                                                                                                              |
| Logout popup window | Shows whether the profile has enabled or disabled a pop-up window that allows a user to log out. If this is disabled, the user remains logged in until the user timeout period has elapsed or the station resets. |

| Parameter                                         | Description                                                                                                                                                                                                                                                                   |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use HTTP for authentication                       | Shows whether the profile has enabled or disabled the ability to use the HTTP protocol to redirect users to the captive portal page.                                                                                                                                          |
| Logon wait minimum wait                           | Minimum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high.                                                                                                                                                                    |
| Logon wait maximum wait                           | Maximum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high.                                                                                                                                                                    |
| logon wait CPU utilization threshold              | CPU utilization percentage above which the logon wait interval is applied when directing a captive portal user with the logon page.                                                                                                                                           |
| Max Authentication failures                       | Maximum number of authentication failures before the user is blacklisted.                                                                                                                                                                                                     |
| Show FQDN                                         | If enabled, the user can see and select the fully-qualified domain name (FQDN) on the captive portal login page.                                                                                                                                                              |
| Authentication Protocol                           | This parameter specifies the type of authentication required by this profile, PAP is the default authentication type                                                                                                                                                          |
| Login page                                        | URL of the page that appears for the user logon.                                                                                                                                                                                                                              |
| Welcome page                                      | URL of the page that appears after logon and before the user is redirected to the web URL.                                                                                                                                                                                    |
| Add controller IP address in the redirection URL  | If enabled, this option sends the controller's IP address in the redirection URL when external captive portal servers are used. An external captive portal server can determine the controller from which a request originated by parsing the 'switchip' variable in the URL. |
| Adding user vlan in redirection URL               | Shows the user's VLAN ID sent in the redirection URL, if enabled                                                                                                                                                                                                              |
| Add a controller interface in the redirection URL | Shows the IP address of a controller interface added to the redirection URL, if enabled.                                                                                                                                                                                      |

| Parameter                           | Description                                                                                                                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Allow only one active user session  | If enabled, only one active user session is allowed at any time. This feature is disabled by default.                                                                                                                               |
| White List                          | Shows the configured white list on an IPv4 or IPv6 network destination. The white list contains authenticated websites that a guest can access.                                                                                     |
| Black List                          | Shows the configured black list on an IPv4 or IPv6 network destination. The black list contains websites (unauthenticated) that a guest cannot access.                                                                              |
| Show the acceptable use policy page | If enabled, the captive portal page will show the acceptable use policy page before the user logon page. This feature is disabled by default.                                                                                       |
| User Idle Timeout                   | The user idle timeout for this profile. The valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used. |
| redirect-url <url>                  | URL to which an authenticated user will be directed.                                                                                                                                                                                |
| URL hash key                        | If this value is set, the redirection URL is hashed using the defined hash key. The characters in the hash key are hidden in the output of this command                                                                             |

## show aaa authentication captive-portal customization

show aaa authentication captive-portal customization <profile-name>

### Description

Display customization settings for a captive portal profile

### Syntax

| Parameter      | Description                                                    |
|----------------|----------------------------------------------------------------|
| <profile-name> | The name of an existing captive portal authentication profile. |

### Usage Guidelines

The this command shows how a captive portal profile has been customized with non-default configuration settings. If you do not yet have any captive portal authentication profiles defined, use the command [aaa authentication captive-portal](#) to configure your captive portal profiles

### Example

The output of the following command shows how the captive portal profile *c-portal* has been customized. If an individual parameter has not been changed from its default settings, its value entry will be blank.

```
(host) #show aaa authentication captive-portal customization c-portal
Captive-Portal Customization

Parameter Value

Login page design theme 3
Login page logo image
Login page text URL /flash/upload/custom/ssu-guest-cp/logintext.html
Login policy text URL /upload/custom/ssu-guest-cp/acceptableusepolicy.html
Custom page background color
Custom page background image /upload/custom/default/auth-slider-1.gif
```

The output of this command includes the following parameters:

| Parameters              | Description                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Login page design theme | Indicates whether the controller is using one of the two predefined login page designs ( <b>1</b> or <b>2</b> ) or has a custom background ( <b>3</b> ). |
| Login page logo image   | Path and filename for a custom captive portal logo. This option is only available if the controller has a predefined login design.                       |
| Login page text         | Path and filename of the page that appears for the user logon.                                                                                           |
| Login policy text       | Path and filename of the page that displays user policy text.                                                                                            |

| Parameters                   | Description                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Custom page background color | Hexadecimal value for a custom background color. This option is only available if the controller has a custom login page design theme.                     |
| Custom page background image | Path and filename for a custom JPEG captive portal background image. This option is only available if the controller has a custom login page design theme. |

## show aaa authentication dot1x

```
show aaa authentication dot1x [<profile-name>|countermeasures]
```

### Description

This command shows information for 802.1X authentication profiles.

### Syntax

| Parameter       | Description                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <profile-name>  | The name of an existing 802.1X authentication profile.                                                                                                                          |
| countermeasures | Reports if WPA/WPA2 Countermeasures have been enabled for 802.1X profiles. If enabled, the AP scans for message integrity code (MIC) failures in traffic received from clients. |

### Usage Guidelines

Issue this command without the **<profile-name>** or **countermeasures** options to display the entire 802.1X Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed dot1x authentication configuration information for that profile. The **countermeasures** option indicates whether the 802.1X profiles have been configured for WPA/WPS2 countermeasures. If countermeasures have not been configured, the output for this command will be blank.

### Examples

The following example lists all dot1x authentication profiles. The **References** column lists the number of other profiles with references to a 802.1X authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined 802.1X profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication dot1x

802.1X Authentication Profile List

Name References Profile Status

default 2
default-psk 1 Predefined (editable)
dot1x 5
dot1xtest 0

Total:4
```

To display a complete list of parameters for an individual profile, include the <profile> parameter. The example below displays some of the profile details for the authentication profile pDot1x.

```
(host) #show aaa authentication dot1x pDot1x

802.1X Authentication Profile "pDot1x"

Parameter Value

Max authentication failures 0
```

|                                               |           |
|-----------------------------------------------|-----------|
| Enforce Machine Authentication                | Disabled  |
| Machine Authentication: Default Machine Role  | guest     |
| Machine Authentication Cache Timeout          | 24 hrs    |
| Blacklist on Machine Authentication Failure   | Disabled  |
| Machine Authentication: Default User Role     | guest     |
| Interval between Identity Requests            | 30 sec    |
| Quiet Period after Failed Authentication      | 30 sec    |
| Reauthentication Interval                     | 86400 sec |
| Use Server provided Reauthentication Interval | Disabled  |
| Multicast Key Rotation Time Interval          | 1800 sec  |
| Unicast Key Rotation Time Interval            | 900 sec   |
| ...                                           |           |

The output of the **show aaa authentication dot1x** command includes the following parameters:

| Parameter                                    | Value                                                                                                                                                                                                                                       |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max authentication failures                  | Number of times a user can try to login with wrong credentials after which the user is blacklisted as a security threat. Blacklisting is disabled if this parameter is set to 0.                                                            |
| Enforce Machine Authentication               | Shows if machine authentication is enabled or disabled for Windows environments. If enabled, If enabled, either the machine-default-role or the user-default-role is assigned to the user, depending on which authentication is successful. |
| Machine Authentication: Default Machine Role | Default role assigned to the user after completing only machine authentication.                                                                                                                                                             |
| Machine Authentication Cache Timeout         | The timeout period, in hours, for machine authentication. After this period passes, the use will have to re-authenticate.                                                                                                                   |
| Blacklist on Machine Authentication Failure  | If enabled, the client is blacklisted if machine authentication fails.                                                                                                                                                                      |
| Machine Authentication: Default User Role    | Default role assigned to the user after 802.1X authentication.                                                                                                                                                                              |

| Parameter                                     | Value                                                                                   |
|-----------------------------------------------|-----------------------------------------------------------------------------------------|
| Interval between Identity Requests            | Interval, in seconds, between identity request retries                                  |
| Quiet Period after Failed Authentication      | Interval, in seconds, following failed authentication.                                  |
| Reauthentication Interval                     | Interval, in seconds, between reauthentication attempts.                                |
| Use Server provided Reauthentication Interval | If enabled, 802.1X authentication will use the server-provided reauthentication period. |
| Multicast Key Rotation Time Interval          | Interval, in seconds, between multicast key rotations.                                  |
| Unicast Key Rotation Time Interval            | Interval, in seconds, between unicast key rotations.                                    |
| Authentication Server Retry Interval          | Server group retry interval, in seconds.                                                |
| Authentication Server Retry Count             | The number of server group retries.                                                     |
| Framed MTU                                    | Shows the framed MTU attribute sent to the authentication server.                       |
| Number of times ID-Requests are retried       | Maximum number of times ID requests are sent to the client.                             |
| Maximum Number of Reauthentication Attempts   | Maximum number of reauthentication attempts.                                            |

| Parameter                                                 | Value                                                                                                                                                                                                                      |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximum number of times Held State can be bypassed        | Number of consecutive authentication failures which, when reached, causes the controller to not respond to authentication requests from a client while the controller is in a held state after the authentication failure. |
| Dynamic WEP Key Message Retry Count                       | Number of times unicast/multicast EAPOL key messages are sent to the client.                                                                                                                                               |
| Dynamic WEP Key Size                                      | Dynamic WEP key size, either 40 or 128 bits.                                                                                                                                                                               |
| Interval between WPA/WPA2 Key Messages                    | Interval, in milliseconds, between each WPA key exchange. The allowed range of values is 1000-5000 msec, and the default value is 1000 msec.                                                                               |
| Delay between EAP-Success and WPA2 Unicast Key Exchange   | Show the delay interval between EAP-Success and unicast key exchanges, in msec.<br><br>Range: 0-2000msec.<br>Default: 0 (no delay).                                                                                        |
| Delay between WPA/WPA2 Unicast Key and Group Key Exchange | Interval, in milliseconds, between unicast and multicast key exchanges.                                                                                                                                                    |
| Time interval after which the PMKSA will be deleted       | Show the PMKSA cache interval. Time interval in Hours. Range: 1-2000. Default: 8 hrs.                                                                                                                                      |
| Delete Keycache upon user deletion Enabled                | If enabled, the controller deletes the key cache entry when the user entry is deleted.                                                                                                                                     |
| WPA/WPA2 Key Message Retry Count                          | Number of times WPA/WPA2 key messages are retried.                                                                                                                                                                         |

| Parameter                 | Value                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multicast Key Rotation    | Shows if multicast key rotation is enabled or disabled.                                                                                                                                                                                                                                                                                                                     |
| Unicast Key Rotation      | Shows if unicast key rotation is enabled or disabled.                                                                                                                                                                                                                                                                                                                       |
| Reauthentication          | If enabled, this option forces the client to do a 802.1X reauthentication after the expiration of the default timer for reauthentication. (The default value of the timer is 24 hours.)                                                                                                                                                                                     |
| Opportunistic Key Caching | If enabled, a cached pairwise master key (PMK) is derived with a client and an associated AP and used when the client roams to a new AP.                                                                                                                                                                                                                                    |
| Validate PMKID            | Shows if the <b>Validate PMKID</b> feature is enabled or disabled. When this option is enabled, the client must send a PMKID in the associate or reassociate frame to indicate that it supports OKC; otherwise, full 802.1X authentication takes place. (This feature is optional, since most clients that support OKC do not send the PMKID in their association request.) |
| Use Session Key           | If enabled, the controller will use a RADIUS session key as the unicast WEP key.                                                                                                                                                                                                                                                                                            |
| Use Static Key            | If enabled, the controller will use a static key as the unicast/multicast WEP key.                                                                                                                                                                                                                                                                                          |
| xSec MTU                  | Shows the size of the MTU for xSec.                                                                                                                                                                                                                                                                                                                                         |
| Termination               | Shows if 802.1X termination is enabled or disabled on the controller.                                                                                                                                                                                                                                                                                                       |

| Parameter                                                     | Value                                                                                                                                                                           |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Termination EAP-Type                                          | Shows the current Extensible Authentication Protocol (EAP) method, either EAP-PEAP or EAP-TLS.                                                                                  |
| Termination Inner EAP-Type                                    | When EAP-PEAP is the EAP method, this parameter displays the inner EAP type.                                                                                                    |
| Enforce Suite-B 128 bit or more security level Authentication | Shows if Suite-B 128 bit or more security level authentication enforcement is enabled or disabled.                                                                              |
| Enforce Suite-B 192 bit security level Authentication         | Shows if Suite-B 192 bit or more security level authentication enforcement is enabled or disabled.                                                                              |
| Token Caching                                                 | If this feature enabled (and EAP-GTC is configured as the inner EAP method), token caching allows the controller to cache the username and password of each authenticated user. |
| Token Caching Period                                          | Timeout period, in hours, for the cached information.                                                                                                                           |
| CA-Certificate                                                | Name of the CA certificate for client authentication loaded in the controller.                                                                                                  |
| Server-Certificate                                            | Name of the Server certificate used by the controller to authenticate itself to the client.                                                                                     |
| TLS Guest Access                                              | Shows if guest access for valid EAP-TLS users is enabled or disabled.                                                                                                           |
| TLS Guest Role                                                | User role assigned to EAP-TLS guest.                                                                                                                                            |

| Parameter                                              | Value                                                                                                                                              |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Ignore EAPOL-START after authentication                | If enabled, the controller ignores EAPOL-START messages after authentication.                                                                      |
| Handle EAPOL-Logoff                                    | Shows if handling of EAPOL-LOGOFF messages is enabled or disabled.                                                                                 |
| Ignore EAP ID during negotiation                       | If enabled, the controller will ignore EAP IDs during negotiation.                                                                                 |
| WPA-Fast-Handover                                      | Shows if WPA-fast-handover is enabled or disabled. This feature is only applicable for phones that support WPA.                                    |
| Disable rekey and reauthentication for clients on call | Shows if the rekey and reauthentication features for voice-over-WLAN clients has been enabled or disabled.                                         |
| Check certificate common name against AAA server       | If enabled, this parameter verifies that the certificate's common name exists in the server. This parameter is disabled by default dot1x profiles. |

## show aaa authentication mac

```
show aaa authentication mac [<profile-name>]
```

### Description

This command shows information for MAC authentication profiles. Issue this command without the **<profile-name>** option to display the entire MAC Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed MAC authentication configuration information for that profile.

### Syntax

| Parameter      | Description                                         |
|----------------|-----------------------------------------------------|
| <profile-name> | The name of an existing MAC authentication profile. |

### Examples

The output of the example below shows two MAC authentication profiles, **default** and **macProfile1**, which are referenced three times by other profiles. the **Profile Status** columns are blank, indicating that these profiles are both user-defined. (If a profile is predefined, the value **Predefined** appears in the Profile Status column.)

```
(host) #show aaa authentication dot1x pDot1x

802.1X Authentication Profile "pDot1x"

Parameter Value

Max authentication failures 0
Enforce Machine Authentication Disabled
Machine Authentication: Default Machine Role guest
Machine Authentication Cache Timeout 24 hrs
Blacklist on Machine Authentication Failure Disabled
Machine Authentication: Default User Role guest
Interval between Identity Requests 30 sec
Quiet Period after Failed Authentication 30 sec
Reauthentication Interval 86400 sec
Use Server provided Reauthentication Interval Disabled
Multicast Key Rotation Time Interval 1800 sec
Unicast Key Rotation Time Interval 900 sec
...
```

The following example displays configuration details for the MAC authentication profile "MacProfile1," including the delimiter and case used in the authentication request, and the maximum number of times a client can fail to authenticate before it is blacklisted.

```
(host) #show aaa authentication mac MacProfile1
MAC Authentication Profile "MacProfile1"

Parameter Value

Delimiter colon
Case upperMax Authentication failures 3
```

## show aaa authentication mgmt

```
show aaa authentication mgmt
```

### Description

This command displays administrative user authentication information, including management authentication roles and servers.

### Usage Guidelines

Issue this command to identify the default management role assigned to authenticated administrative users, and the name of the group of servers used to authenticate these users.

### Example

The output of the following example displays management authentication information for your controller.

```
(host) #show aaa authentication mgmt
```

```
Management Authentication Profile
```

```

```

```
Parameter Value

Default Role root
Server Group ServerGroup1
Enable Enabled
```

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Role | This parameter shows which of the following roles the controller uses for authentication management. <ul style="list-style-type: none"><li>● <b>root</b>, the super user role (default).</li><li>● <b>guest-provisioning</b>, guest provisioning role.</li><li>● <b>network-operations</b>, network operator role.</li><li>● <b>read-only</b>, read only role.</li><li>● <b>location-api-mgmt</b>, location API management role.</li><li>● <b>no-access</b>, no commands are accessible.</li></ul> |
| Server Group | The name of a server group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Enable       | The <b>Enable</b> parameter indicates whether or not this feature is enabled or disabled.                                                                                                                                                                                                                                                                                                                                                                                                          |

The output of the **show aaa authentication mgmt** command includes the following parameters:

## show aaa authentication stateful-dot1x

```
show aaa authentication stateful-dot1x [config-entries]
```

### Description

This command displays configuration settings for 802.1X authentication for clients on non-Dell APs.

### Syntax

| Parameter      | Description                                           |
|----------------|-------------------------------------------------------|
| config-entries | Display details for the AP Server configuration list. |

### Usage Guidelines

Issue this command to identify the default role assigned to the 802.1X user group, name of the group of RADIUS servers used to authenticate the 802.1X users, and the 802.1X authentication timeout period, in seconds.

### Example

The output of the following example displays 802.1X authentication information for your controller.

```
(host) #show aaa authentication stateful-dot1x
```

```
Stateful 802.1X Authentication Profile
```

```

```

| Parameter    | Value     |
|--------------|-----------|
| Default Role | guest     |
| Server Group | newgroup2 |
| Timeout      | 10 sec    |
| Mode         | Enabled   |

| Parameter    | Description                                                                               |
|--------------|-------------------------------------------------------------------------------------------|
| Default Role | This parameter shows which role the controller uses for 802.1X authentication management. |
| Server Group | The name of a server group.                                                               |
| Timeout      | Timeout period for an authentication request, in seconds.                                 |
| Mode         | The <b>Mode</b> parameter indicates whether or not this feature is enabled or disabled.   |

The output of this command includes the following parameters:

When you include the **config-entries** parameter, the output shows the AP - Server Configuration List.

```
(host) #show aaa authentication stateful-dot1x config-entries
```

#### AP-Server Configuration List

```

Cfg-Name AP-IP Server Shared-Secret

cfg22 10.3.14.6 RADIUS1 secret-pwd
```

| Parameter     | Description                        |
|---------------|------------------------------------|
| Cfg-Name      | is a auto-generated name           |
| AP-IP         | IP address of the AP.              |
| Server        | Name of the authentication server. |
| Shared-Secret | Shared authentication secret.      |

The output of this command includes the following parameters:

## show aaa authentication stateful-ntlm

show aaa authentication stateful-ntlm

### Description

This command displays configuration settings for the Stateful NTLM Authentication profile. Issue this command without the **<profile-name>** option to display the entire Stateful NTLM Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed Stateful NTLM authentication configuration information for that profile.

### Syntax

| Parameter      | Description                                                   |
|----------------|---------------------------------------------------------------|
| <profile-name> | The name of an existing Stateful NTLM authentication profile. |

### Usage Guidelines

Issue this command to identify the default role assigned to users who have successfully authenticated using the NT LAN Manager (NTLM) authentication protocol, the name of the group of windows servers used to authenticate these users, and the NTLM authentication timeout period, in seconds.

### Examples

The output of the example below shows two stateful NTLM authentication profiles, **default** and **NTLMprofile1**, which are each referenced one time by other profiles. the **Profile Status** columns are blank, indicating that these profiles are both user-defined. (If a profile is predefined, the value **Predefined** appears in the Profile Status column.)

```
(host) #show aaa authentication stateful-ntlm

Stateful NTLM Authentication Profile List

Name References Profile Status
---- -
default 1
NTLMprofile1 1

Total:2
```

The following example displays configuration details for the stateful NTLM authentication profile "default".

```
(host) #show aaa authentication stateful-ntlm default

Stateful NTLM Authentication Profile "default"

Parameter Value

Default Role guest
Server Group default
Mode Disabled
Timeout 10 sec
```

| Parameter    | Description                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------|
| Default Role | This parameter shows the role assigned to NTLM authenticated users.                                    |
| Server Group | The name of a windows server group.                                                                    |
| Mode         | The <b>Mode</b> parameter indicates whether or not this authentication profile is enabled or disabled. |
| Timeout      | Timeout period for an authentication request, in seconds.                                              |

The output of this command includes the following parameters:

## show aaa authentication via auth-profile

```
show aaa authentication via auth-profile [<profile-name>]
```

### Description

This command displays configuration settings for the VIA Authentication profile. Issue this command without the **<profile-name>** option to display the entire VIA Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed VIA authentication configuration information for that profile.

### Syntax

| Parameter      | Description                                         |
|----------------|-----------------------------------------------------|
| <profile-name> | The name of an existing VIA authentication profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the entire VIA Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

If you do not yet have any VIA authentication profiles defined, use the command [aaa authentication via auth-profile](#) to configure your VIA authentication profiles.

### Examples

This first example shows that there are three configured captive portal profiles in the Captive Profile Authentication Profile List. The **References** column lists the number of other profiles with references to a VIA authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication via auth-profile
```

```
VIA Authentication Profile List

Name References Profile Status
---- -
default 0
via1 2
via2 1

Total:3
```

Include a VIA authentication profile name to display a complete list of configuration settings for that profile. The example below shows settings for the VIA authentication profile via1.

```
VIA Authentication Profile "via1"

Parameter Value

Default Role default-via-role
Server Group internal
Max Authentication failures 2
```

The output of this command includes the following parameters:

| Parameter                   | Description                                                               |
|-----------------------------|---------------------------------------------------------------------------|
| Default Role                | Role assigned to the captive portal user upon login.                      |
| Server Group                | Name of the group of servers used to authenticate captive portal users.   |
| Max Authentication failures | Maximum number of authentication failures before the user is blacklisted. |
| Description                 | Description of the VIA authentication profile.                            |

## Related Commands

| Command                                             | Description                                                                                                                       | Mode        |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|-------------|
| <a href="#">aaa authentication via auth-profile</a> | Use <a href="#">aaa authentication via auth-profile</a> to configure the parameters displayed in the output of this show command. | Config mode |

## Command History

This command was introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show aaa authentication via connection-profile

```
show aaa authentication via connection-profile [<profile-name>]
```

### Description

This command displays configuration settings for the VIA connection profile. Issue this command without the **<profile-name>** option to display the entire VIA Connection profile list, including profile status and the number of references to each profile. Include a profile name to display detailed VIA connection configuration information for that profile.

### Syntax

| Parameter      | Description                                     |
|----------------|-------------------------------------------------|
| <profile-name> | The name of an existing VIA connection profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the entire VIA connection profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

If you do not yet have any VIA connection profiles defined, use the command [aaa authentication via connection-profile](#) to configure your VIA connection profiles.

### Examples

This first example shows that there are three configured connection profiles in the Captive Profile Authentication Profile List. The **References** column lists the number of other profiles with references to a VIA connection profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication via connection-profile
```

```
VIA Connection Profile List
```

```

Name References Profile Status
---- -
connection_1 3
connection_2 1
default 0
```

```
Total:3
```

Include a connection profile name to display a complete list of configuration settings for that profile. The example below shows settings for the captive portal profile connection\_1.

```
VIA Connection Profile "default"
```

```

Parameter Value

VIA Servers N/A
Client Auto-Login Enabled
VIA Authentication Profiles to provision N/A
```

|                                                                                    |                                |
|------------------------------------------------------------------------------------|--------------------------------|

| VIA servers       | <p>Displays the following information about the VIA server:</p> <ul style="list-style-type: none"> <li>• <i>Controller Hostname/IP Address</i>: This is the public IP address or the DNS hostname of the VIA controller. Users will connect to remote server using this IP address or the hostname.</li> <li>• <i>Controller Internal IP Address</i>: This is the IP address of any of the VLAN interface IP addresses belongs to this controller.</li> <li>• <i>Controller Description</i>: This is a human-readable description of the controller.</li> </ul> |
| Client Auto-Login | <p>Enable or disable VIA client to auto login and establish a secure connection to the controller.</p> <p>Default: Enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                | Description                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VIA Authentication Profiles to provision | This is the list of VIA authentication profiles that will be displayed to users in the VIA client.                                                                                                                                                                                                                 |
| Allow client to auto-upgrade             | Enable or disable VIA client to automatically upgrade when an updated version of the client is available on the controller.<br>Default: Enabled                                                                                                                                                                    |
| VIA tunneled networks                    | A list of network destination (IP address and netmask) that the VIA client will tunnel through the controller. All other network destinations will be reachable directly by the VIA client.                                                                                                                        |
| Enable split-tunneling                   | Enable or disable split tunneling. <ul style="list-style-type: none"> <li>• If enabled, all traffic to the VIA tunneled networks will go through the controller and the rest is just bridged directly on the client.</li> <li>• If disabled, all traffic will flow through the controller.</li> </ul> Default: off |
| Allow client-side logging                | Enable or disable client side logging. If enabled, VIA client will collect logs that can be sent to the support email-address for troubleshooting.<br>Default: Enabled                                                                                                                                             |
| VIA Client WLAN profiles                 | A list of VIA client WLAN profiles that needs to be pushed to the client machines that use Windows Zero Config (WZC) to configure or manage their wireless networks.                                                                                                                                               |
| VIA IKEv2 Policy                         | A list of IPsec crypto maps that the VIA client uses to connect to the controller. These IPsec Crypto Maps are configured in the CLI using the <code>crypto-local ipsec-map &lt;ipsec-map-name&gt;</code> command.                                                                                                 |
| VIA IKE Policy                           | List of IKE policies that the VIA Client has to use to connect to the controller.                                                                                                                                                                                                                                  |
| Use Windows Credentials                  | Enable or disable the use of the Windows credentials to login to VIA. If enabled, the SSO (Single Sign-on) feature can be utilized by remote users to connect to internal resources.<br>Default: Enabled                                                                                                           |
| Enable IKEv2                             | Select this option to enable or disable the use of IKEv2 policies for VIA.                                                                                                                                                                                                                                         |
| Use Suite B Cryptography                 | Select this option to use Suite B cryptography methods. You must install the Advanced Cryptography license to use the Suite B cryptography.                                                                                                                                                                        |
| IKEv2 Authentication method              | List of all IKEv2 authentication methods.                                                                                                                                                                                                                                                                          |
| VIA IPSec V2 Crypto Map                  | List of all IPSec V2 that the VIA client uses to connect to the controller.                                                                                                                                                                                                                                        |

| Parameter                           | Description                                                                                                                                                                                                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VIA IPsec Crypto Map                | List of IPsec Crypto Map that the VIA client uses to connect to the controller. These IPsec Crypto Maps are configured in CLI using the <code>crypto-local ipsec-map &lt;ipsec-map-name&gt;</code> command.                                                         |
| Allow user to save passwords        | Enable or disable users to save passwords entered in VIA.<br>Default: Enabled                                                                                                                                                                                       |
| Enable Supplicant                   | If enabled, VIA starts in bSec mode using L2 suite-b cryptography. This option is disabled by default.                                                                                                                                                              |
| Enable FIPS Module                  | Shows if the VIA (Federal Information Processing Standard) FIPS module is enabled, so VIA checks for FIPS compliance during startup. This option is disabled by default.                                                                                            |
| Auto-Launch Supplicant              | Select this option to automatically connect to a configured WLAN network.                                                                                                                                                                                           |
| Lockdown All Settings               | If enabled, all user options on the VIA client are disabled.                                                                                                                                                                                                        |
| Domain Suffix in VIA Authentication | Enables a domain suffix on VIA Authentication, so client credentials are sent as <i>domainname\username</i> instead of just <i>username</i> .                                                                                                                       |
| Enable Controllers Load Balance     | This option allows the VIA client to failover to the next available selected randomly from the list as configured in the VIA Servers option. If disabled, VIA will failover to the next in the sequence of ordered list of VIA Servers.                             |
| Enable Domain Pre-Connect           | This option allows users with lost or expired passwords to establish a VIA connection to corporate network. This option authenticates the user's device and establishes a VIA connection that allows users to reset credentials and continue with corporate access. |
| VIA Banner Reappearance Timeout     | The maximum time (in minutes) allowed before the VIA login banner reappears. Default: 1440 min                                                                                                                                                                      |
| VIA Client Network Mask             | The network mask that has to be set on the client after the VPN connection is established.<br>Default: 255.255.255.255                                                                                                                                              |
| Validate Server Certificate         | Enable or disable VIA from validating the server certificate presented by the controller.<br>Default: Enabled                                                                                                                                                       |
| VIA Client DNS Suffix List          | The DNS suffix list (comma separated) that has be set on the client once the VPN connection is established.<br>Default: None.                                                                                                                                       |
| VIA max session timeout             | The maximum time (minutes) allowed before the VIA session is disconnected.<br>Default: 1440 min                                                                                                                                                                     |

| Parameter                            | Description                                                                                                                                                                           |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VIA Logon Script                     | Name of the logon script that must be executed after VIA establishes a secure connection. The logon script must reside in the client computer.                                        |
| VIA Logoff Script                    | Name of the log-off script that must be executed after the VIA connection is disconnected. The logoff script must reside in the client computer.                                      |
| VIA Support E-mail Address           | The support e-mail address to which VIA users will send client logs.<br>Default: None.                                                                                                |
| Maximum reconnection attempts        | The maximum number of re-connection attempts by the VIA client due to authentication failures.<br>Default: 3                                                                          |
| VIA external download URL            | End users will use this URL to download VIA on their computers.                                                                                                                       |
| Allow user to disconnect VIA         | Enable or disable users to disconnect their VIA sessions.<br>Default: Enabled                                                                                                         |
| Comma Separated List of HTTP Ports   | Traffic from the specified ports will be verified by the content security service provider.                                                                                           |
| Keep VIA window minimized            | Enable this option to minimize the VIA client to system tray during the connection phase. Applicable to VIA client installed in computers running Microsoft Windows operating system. |
| Block traffic until VPN tunnel is up | If enabled, this feature will block network access until the VIA VPN connection is established.                                                                                       |
| Block traffic rules                  | Specify a hostname or IP address and network mask to define a whitelist of users to which the <b>Block traffic until VPN tunnel is up</b> setting will not apply.                     |

This command was introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show aaa authentication via web-auth

```
show aaa authentication via web-auth [default]
```

### Description

A VIA web authentication profile contains an ordered list of VIA authentication profiles. The web authentication profile is used by end users to login to the VIA download page (<https://<server-IP-address>/via>) for downloading the VIA client. Only one VIA web authentication profile is available. If more than one VIA authentication profile is configured, users can view this list and select one during the client login.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to view the authentication profiles associated with the default web authentication profile. Use it without the profile name to see the list of authentication profiles.

### Examples

```
(host) #show aaa authentication via web-auth
```

```
VIA Web Authentication List
```

```

Name References Profile Status
---- -
default 2
```

```
Total:1
```

```
(host) #show aaa authentication via web-auth default
```

```
VIA Web Authentication "default"
```

```

Parameter Value

VIA Authentication Profiles via1
```

The output of this command includes the following parameters:

| Parameter                   | Description                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VIA Authentication Profiles | This is the name of the VIA authentication profile. The value column displays the order of priority in which the profiles are displayed in the VIA client login. |

## show aaa authentication vpn

```
show aaa authentication vpn [default|default-cap|default-rap]
```

### Description

This command displays VPN authentication settings, including authentication roles and servers.

### Usage Guidelines

Issue this command to identify the default role assigned to VPN users, the name of the group of servers used to authenticate the VPN users, and the maximum number of authentication failures allowed before the user is blacklisted.

### Example

The following example displays configuration details for the VPN authentication profile **default**, **default-cap** and **default-rap**.

```
(host) #show aaa authentication vpn default
```

```
VPN Authentication Profile "default"
```

```

Parameter Value

Default Role default-vpn-role
Server Group default
Max Authentication failures 2
```

```
(TechPubs) #show aaa authentication vpn default-cap
```

```
VPN Authentication Profile "default-cap" (Predefined)
```

```

Parameter Value

Default Role ap-role
Server Group internal
Max Authentication failures 0
```

```
(TechPubs) #show aaa authentication vpn default-rap
```

```
VPN Authentication Profile "default-rap" (Predefined (changed))
```

```

Parameter Value

Default Role default-vpn-role
Server Group default
Max Authentication failures 0
```

| Parameter    | Description                                                    |
|--------------|----------------------------------------------------------------|
| Default Role | The default role to be assigned to VPN users.                  |
| Server Group | The name of the server group that performs the authentication. |

| Parameter                   | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| Max Authentication failures | Number of times a user attempted to authenticate, but failed. |

## show aaa authentication wired

show aaa authentication wired

### Description

View wired authentication settings for a client device that is directly connected to a port on the controller.

### Usage Guidelines

This command displays the name of the AAA profile currently used for wired authentication.

### Example

The following example shows the current wired profile for the controller is a profile named "secure\_profile\_3."

```
(host) #show aaa authentication wired
Wired Authentication Profile

Parameter Value

AAA Profile Secure_profile_3
```

## show aaa authentication wispr

show aaa authentication wispr <profile-name>

### Description

This command shows information for a WISPr authentication profiles. Issue this command without the **<profile-name>** option to display the entire WISPr Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed WISPr authentication configuration information for that profile.

| Parameter      | Description                                         |
|----------------|-----------------------------------------------------|
| <profile-name> | The name of an existing MAC authentication profile. |

### Examples

The output of the example below shows two WISPr authentication profiles, **default** and **WISPr1**, which are referenced two times by other profiles. the **Profile Status** columns are blank, indicating that these profiles are both user-defined. (If a profile is predefined, the value **Predefined** appears in the Profile Status column.)

```
(host) #show aaa authentication wispr

WISPr Authentication Profile List

Name References Profile Status

default 2
WISPr1 2

Total:2

(host) #show aaa authentication wispr WISPr1
WISPr Authentication Profile "WISPr1"

Parameter Value

Default Role guest
Server Group default
Logon wait minimum wait 5 sec
Logon wait maximum wait 10 sec
logon wait CPU utilization threshold 60 %
WISPr Location-ID ISO Country Code US
WISPr Location-ID E.164 Country Code 1
WISPr Location-ID E.164 Area Code 408
WISPr Location-ID SSID/Zone Corp1
WISPr Operator Name MyCompany
WISPr Location Name Sunnyvale
```

The following example displays configuration details for the WISPr authentication profile "WISPr1".

```
(host) #show aaa authentication wispr WISPr1
WISPr Authentication Profile "WISPr1"

```

| Parameter                            | Value     |
|--------------------------------------|-----------|
| -----                                | -----     |
| Default Role                         | guest     |
| Server Group                         | default   |
| Logon wait minimum wait              | 5 sec     |
| Logon wait maximum wait              | 10 sec    |
| logon wait CPU utilization threshold | 60 %      |
| WISPr Location-ID ISO Country Code   | US        |
| WISPr Location-ID E.164 Country Code | 1         |
| WISPr Location-ID E.164 Area Code    | 408       |
| WISPr Location-ID SSID/Zone          | Corp1     |
| WISPr Operator Name                  | MyCompany |
| WISPr Location Name                  | Sunnyvale |

The output of this command includes the following parameters:

| Parameter                              | Description                                                                                                                                                                                                                                                                              |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Role                           | The default role to be assigned to users that have completed WISPr authentication.                                                                                                                                                                                                       |
| Server Group                           | The name of the server group that performs the authentication.                                                                                                                                                                                                                           |
| Logon wait minimum wait                | If the controller's CPU utilization has surpassed the <b>Logon wait CPU utilization threshold value</b> , the <b>Logon wait minimum wait</b> parameter defines the minimum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 5 seconds. |
| Logon wait maximum wait                | If the controller's CPU utilization has surpassed the logon <b>wait CPU utilization threshold</b> value, the <b>Logon wait maximum wait</b> parameter defines the maximum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 10 seconds. |
| WISPr Location-ID E.164 Area Code      | The E.164 Area Code in the WISPr Location ID.                                                                                                                                                                                                                                            |
| WISPr Location-ID E.164 Country Code 1 | The 1-3 digit E.164 Country Code in the WISPr Location ID.                                                                                                                                                                                                                               |
| WISPr Location-ID ISO Country Code     | The ISO Country Code in the WISPr Location ID.                                                                                                                                                                                                                                           |
| WISPr Location-ID SSID/Zone            | The SSID/network name in the WISPr Location ID.                                                                                                                                                                                                                                          |
| WISPr Location Name                    | A name identifying the hotspot location. If no name is defined, the default ap-name is used.                                                                                                                                                                                             |
| WISPr Operator Name                    | A name identifying the hotspot operator.                                                                                                                                                                                                                                                 |

## show aaa authentication-server all

```
show aaa authentication-server all
```

### Description

View authentication server settings for both external authentication servers and the internal controller database.

### Usage Guidelines

The output of this command displays statistics for the Authentication Server Table, including the name and address of each server, server type and configured authorization and accounting ports.

### Examples

The following command shows information for the internal Authentication server, and another RADIUS server named RADIUS-1.

```
(host) #show aaa authentication-server all
```

Auth Server Table

| Name     | Type   | FQDN  | IP addr     | AuthPort | AcctPort | Status  | Requests |
|----------|--------|-------|-------------|----------|----------|---------|----------|
| Internal | Local  | n/a   | 10.4.62.11  | n/a      | n/a      | Enabled | 0        |
| server   | Ldap   | n/a   | 0.0.0.0     | 389      | n/a      | Enabled | 0        |
| server   | Radius | SRVR1 | 127.9.9.61  | 1812     | 1813     | Enabled | 0        |
| default  | Tacacs | n/a   | 127.9.10.61 | 49       | n/a      | Enabled | 0        |

The following data columns appear in the output of this command:

| Parameter | Description                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name      | Name of the authentication server.                                                                                                                                                                            |
| Type      | The type of authentication server. ArubaOS supports LDAP, RADIUS and TACACS+ servers, in addition to its own local, internal authentication server.                                                           |
| FQDN      | The Fully-Qualified Domain Name of the server, if configured.                                                                                                                                                 |
| IP addr   | IP address of the server, in dotted-decimal format.                                                                                                                                                           |
| AuthPort  | Port number used for authentication. An LDAP server uses port 636 for LDAP over SSL, and port 389 for SSL over LDAP, Start TLS operation and clear text. The default RADIUS authentication port is port 1812. |
| AcctPort  | Accounting port on the server. The default RADIUS accounting port is port 1813.                                                                                                                               |

| Parameter | Description                                                    |
|-----------|----------------------------------------------------------------|
| AcctPort  | Accounting port on the server.                                 |
| Status    | Shows whether the Authentication server is enable or disabled. |
| Requests  | Number of authentication requests received by the server.      |

## show aaa authentication-server internal

```
show aaa authentication-server internal [statistics]
```

### Description

View authentication server settings for the internal controller database.

### Examples

The output of the command below shows that the internal authentication server has been disabled

```
(host) #show aaa authentication-server internal

Internal Server

Host IP addr Retries Timeout Status

Internal 10.168.254.221 3 5 Disabled
```

The following data columns appear in the output of this command:

| Parameter | Description                                                                             |
|-----------|-----------------------------------------------------------------------------------------|
| Host      | Name of the internal authentication server.                                             |
| IP addr   | Address of the internal server, in dotted-decimal format.                               |
| Retries   | Number of retries allowed before the server stops attempting to authenticate a request. |
| Timeout   | Timeout period, in seconds.                                                             |
| Status    | Shows if the server is enabled or disabled                                              |

Include the **statistics** parameter to display additional details for the internal server.

```
(host) #show aaa authentication-server internal statistics

Internal Database Server Statistics

PAP Requests 8
PAP Accepts 8
PAP Rejects 0
MSCHAPv2 Requests 0
MSCHAPv2 Accepts 0
MSCHAPv2 Rejects 0

```

The following data columns appear in the output of this command:

| Parameter           | Description                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| PAP Requests        | Number of PAP requests received by the internal server.                                                          |
| PAP Accepts         | Number of PAP requests accepted by the internal server.                                                          |
| PAP Rejects         | Number of PAP requests rejected by the internal server.                                                          |
| MSCHAPv2 Requests   | Number of MSCHAPv2 requests received by the internal server.                                                     |
| MSCHAPv2 Accepts    | Number of MSCHAPv2 requests accepted by the internal server.                                                     |
| MSCHAPv2 Rejects    | Number of MSCHAPv2 requests rejected by the internal server.                                                     |
| Mismatch Response   | Number of times the server received an authentication response to a request after another request had been sent. |
| Users Expired       | Number of users that were deauthenticated because they stopped responding.                                       |
| Unknown Response    | Number of times the server did not recognize the response, possibly due to internal errors.                      |
| Timeouts            | Number of times that the controller timed out an authentication request.                                         |
| AvgRespTime (ms)    | Time it takes the server to respond to an authentication request, in seconds.                                    |
| Uptime (d:h:m)      | Time elapsed since the last server reboot.                                                                       |
| SEQ first/last/free | This internal buffer counter keeps track of the requests to the authentication server.                           |

## show aaa authentication-server ldap

show aaa authentication-server ldap [<ldap\_server\_name>]

### Description

Display configuration settings for your LDAP servers.

### Syntax

| Parameter          | Description                          |
|--------------------|--------------------------------------|
| <ldap_server_name> | Name that identifies an LDAP server. |

### Examples

The output of the example below displays the LDAP server list with the names of all the LDAP servers. The **References** column lists the number of other profiles that reference an LDAP server, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #aaa authentication-server ldap
```

```
LDAP Server List
```

```

```

```
Name References Profile Status
```

```

```

```
ldap1 5
ldap2 3
ldap3 1
```

```
Total:3
```

Include the <ldap\_server\_name> parameter to display additional details for an individual server.

```
(host) #show aaa authentication-server ldap ldap1
```

```
LDAP Server "ldap1"
```

```

```

| Parameter                 | Value                                 |
|---------------------------|---------------------------------------|
| -----                     | -----                                 |

| Admin-DN                  | cn=corp,cn=Users,dc=1m,dc=corp,dc=com |
| Admin-Password            | *****                                 |
| Allow Clear-Text          | Disabled                              |
| Auth Port                 | 389                                   |
| Base-DN                   | cn=Users,dc=1m,dc=corp,dc=com         |
| Filter                    | (objectclass=*)                       |
| Key Attribute             | sAMAccountName                        |
| Timeout                   | 20 sec                                |
| Mode                      | Enabled                               |
| Preferred Connection Type | ldap-s                                |

The output of this command includes the following parameters:

| Parameter                 | Description                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host                      | IP address of the LDAP server                                                                                                                                              |
| Admin-DN                  | Distinguished name for the admin user who has read/search privileges across all of the entries in the LDAP database.                                                       |
| Admin Passwd              | Password for the admin user.                                                                                                                                               |
| Allow Clear-Text          | If enabled, this parameter allows clear-text (unencrypted) communication with the LDAP server.                                                                             |
| Auth Port                 | Port number used for authentication. Port 636 will be attempted for LDAP over SSL, while port 389 will be attempted for SSL over LDAP, Start TLS operation and clear text. |
| Base-DN                   | Distinguished Name of the node which contains the required user database.                                                                                                  |
| Filter                    | Filter that should be applied to search of the user in the LDAP database (default filter string is: <code>!(objectclass=*)</code> ).                                       |
| Key attribute             | Attribute that should be used as a key in search for the LDAP server.                                                                                                      |
| Timeout                   | Timeout period of a LDAP request, in seconds.                                                                                                                              |
| Mode                      | Shows whether this server is <b>Enabled</b> or <b>Disabled</b> .                                                                                                           |
| Preferred Connection Type | Preferred type of connection to the server. Possible values are <ul style="list-style-type: none"> <li>• Clear text</li> <li>• LDAP-S</li> <li>• START-TLS</li> </ul>      |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

## show aaa authentication-server radius

```
show aaa authentication-server radius [<rad_server_name>|statistics]
```

### Description

Displays the configuration settings of your RADIUS servers.

### Syntax

| Parameter         | Description                                     |
|-------------------|-------------------------------------------------|
| <rad_server_name> | Name that identifies a RADIUS server.           |
| statistics        | Displays the statistics for all RADIUS servers. |

### Usage Guidelines

Timeouts information in the output of this command includes RADIUS accounting requests. Timeouts are kept track for every request the controller sends to the RADIUS server, so each retry is counted towards a timeout.

### Examples

The output of the example below displays the RADIUS server list with the names of all the RADIUS servers. The **References** column lists the number of other profiles that reference a RADIUS server, and the **Profile Status** column indicates whether the profile is predefined. User-defined servers will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication-server radius
```

```
RADIUS Server List
```

```

Name References Profile Status
---- -
myserver 3
radius 0
servername 0
```

```
Total:3
```

Include the <rad\_server\_name> parameter to display additional details for an individual server.

```
(host) #show aaa authentication-server radius radsec
```

```
RADIUS Server "radsec"
```

```

Parameter Value

Host 10.15.28.101
Key *****
CPPM credentials ade/*****
Auth Port 1812
Acct Port 1813
Radsec Port 2083
Retransmits 3
Timeout 5 sec
NAS ID N/A
```

|                                       |                       |
|---------------------------------------|-----------------------|
| NAS IP                                | N/A                   |

| Service-type of FRAMED-USER           | Disabled              |
| Radsec                                | Enabled               |
| Radsec Trusted CA Name                | can-new               |
| Radsec Server Cert Name               | N/A                   |
| Radsec Client Cert                    | client-new            |
| called-station-id                     | macaddr colon disable |

The output of this command includes the following information:

| Parameter        | Description                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------|
| host             | IP address of the RADIUS server                                                                                        |
| Key              | Shared secret between the controller and the authentication server.                                                    |
| CPPM credentials | Setting this parameter allows the controller to use configurable username and password instead of a support password.  |
| Auth port        | Authentication port on the server.                                                                                     |
| Acct Port        | Accounting port on the server.                                                                                         |
| Radsec Port      | Displays the Radsec port for RADIUS data transport.                                                                    |
| Retransmits      | Maximum number of retries sent to the server by the controller before the server is marked as down.                    |
| Timeout          | Maximum time, in seconds, that the controller waits before timing out the request and resending it.                    |
| NAS ID           | Network Access Server (NAS) identifier to use in RADIUS packets.                                                       |
| NAS IP           | NAS IP address to send in RADIUS packets. If you do not configure a server-specific NAS IP, the global NAS IP is used. |
| Enable IPv6      | Shows if the RADIUS server is enabled in IPv6 mode.                                                                    |
| NAS IPv6         | IPv6 address for the global NAS IP which the controller uses to communicate with all the RADIUS servers.               |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source Interface                      | The source interface VLAN ID number.                                                                                                                                                                                                                                                                                                                      |
| Use MD5                               | If enabled, the RADIUS server will use a MD5 hash of cleartext password.                                                                                                                                                                                                                                                                                  |
| Use IP address for calling station ID | If enabled, the RADIUS server will use an IP address instead of a MAC address for calling station IDs.                                                                                                                                                                                                                                                    |
| Mode                                  | Shows whether this server is <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                                                                                                                                                          |
| Lowercase MAC addresses               | If this feature is enabled, the server will send MAC addresses in lowercase letters.                                                                                                                                                                                                                                                                      |
| MAC address delimiter                 | The character used as a MAC address delimiter. If no character is specified, the RADIUS server will use a colon (:) by default.                                                                                                                                                                                                                           |
| Service-type of FRAMED-USER           | If this option is enabled, the server sends the service-type as FRAMED-USER instead of LOGIN-USER. This option is disabled by default                                                                                                                                                                                                                     |
| Radsec                                | Displays the status of the Radsec server.                                                                                                                                                                                                                                                                                                                 |
| Radsec Trusted CA                     | Displays the Certificate Authority to sign Radsec certificates.                                                                                                                                                                                                                                                                                           |
| Radsec Server Cert Name               | Displays the trusted Radsec server certificate.                                                                                                                                                                                                                                                                                                           |
| Radsec Client Cert                    | Displays the Radsec client certificate on the RADIUS server that identifies and authenticates clients.                                                                                                                                                                                                                                                    |
| called-station-id                     | <p>Configure this parameter to be sent with the RADIUS attribute Called Station ID for authentication and accounting requests.</p> <p>The <b>called-station-id</b> parameter can be configured to include AP group, AP MAC address, AP name, controller IP, controller MAC address, or user vlan.</p> <p>The default value is controller MAC address.</p> |

Include the optional **statistics** parameter in this command to display the following statistics for all RADIUS servers:

| Parameter | Description                |
|-----------|----------------------------|
| Server    | Name of the RADIUS server. |

| Parameter    | Description                                                                                                                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Acct Rq      | Accounting requests. This reports of the number of accounting messages (for example, start/stop/interim update) sent by the controller to a RADIUS server. This counter increments whenever the controller sends one of these messages.                                                                                   |
| Raw Rq       | Raw requests. Number of raw authentication requests the controller sent to a RADIUS server.                                                                                                                                                                                                                               |
| PAP Rq       | Pap Requests. Number of PAP authentication requests the controller sent to a RADIUS server.                                                                                                                                                                                                                               |
| CHAP Rq      | CHAP requests. Number of CHAP authentication requests the controller sent to a RADIUS server.                                                                                                                                                                                                                             |
| MSCHAP Rq    | MSCHAP requests. Number of MS-CHAP authentication requests the controller sent to a RADIUS server.                                                                                                                                                                                                                        |
| MSCHAPv2 Rq  | MSCHAPv2 requests. Number of MS-CHAPv2 requests the controller sent to a RADIUS server.                                                                                                                                                                                                                                   |
| Mismatch Rsp | Mismatch responses. Number of responses from a RADIUS server for which the controller does not have the proper request context.                                                                                                                                                                                           |
| Bad Auth     | Bad authenticator. Number of responses from the RADIUS server with an invalid secret or bad reply digest.                                                                                                                                                                                                                 |
| Acc          | Access accept. Number of responses from the RADIUS server with invalid secret or bad reply digest.                                                                                                                                                                                                                        |
| Rej          | Access reject. Number of responses from the RADIUS server that indicate that client authentication failed.                                                                                                                                                                                                                |
| Acct Rsp     | Accounting response. Number of responses sent from the RADIUS server in response to accounting requests sent from the controller.                                                                                                                                                                                         |
| Chal         | Access challenge. Number of responses from the RADIUS server containing a challenge for the client (to complete authentication).                                                                                                                                                                                          |
| Ukn Rsp      | Unknown Response code. Number of responses from the RADIUS server that were not understood by the controller due to the purpose or type of the response                                                                                                                                                                   |
| Tmout        | Timeouts. Number of messages sent by the controller for which the controller did not receive a response before the message timed out.<br><b>NOTE:</b> Timeouts include RADIUS accounting requests. Every request controller sends to the RADIUS server is monitored for a timeout, so each retry increments this counter. |
| AvgRspTme    | Average response time. Time taken, on an average, for the RADIUS server to respond to a message from the controller.                                                                                                                                                                                                      |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tot Rq    | Total errors. This counter reflects the total number of requests sent to the RADIUS server (auth and accounting requests).                                                                                                                                                                                                                                                                                                                                |
| Tot Rsp   | This counter reflects the total number of responses received by the RADIUS server (auth and accounting responses).                                                                                                                                                                                                                                                                                                                                        |
| Rd Err    | Read errors. This counter reflects the total number of errors encountered while reading off socket corresponding to that RADIUS server.                                                                                                                                                                                                                                                                                                                   |
| Uptime    | Amount of for which the RADIUS server has been active/up. The RADIUS server is considered to have an UP status if the server is active and serving requests. The RADIUS server is considered to be DOWN if the server is not responding. For example, if the RADIUS server does not respond for (<no of retries> * <timeout>) seconds, the controller takes the RADIUS server down. It brings the radius server back into service after the dead timeout. |
| SEQ       | Information corresponding to the sequence number of requests. <b>SEQ total</b> corresponds to the total number of sequence numbers that can be used to communicate with the RADIUS server. <b>SEQ free</b> corresponds to the free/available/not in use sequence numbers for a particular RADIUS server.                                                                                                                                                  |

```
(host) #show aaa authentication-server radius <servername> dsec radsec status
Radius Server "radsec" Radsec Status

Radsec Server Attribute Value

In Service Yes
Connected Sockets 1
```

The output of this command includes the following information:

| Parameter         | Description                                                 |
|-------------------|-------------------------------------------------------------|
| In Service        | Shows the status of the Radsec RADIUS server.               |
| Connected Sockets | Shows the number of TLS connections with the RADIUS server. |

## Command History

| Version     | Description                                                                                |
|-------------|--------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced.                                                                        |
| ArubaOS 6.1 | The <b>Source Interface</b> parameter was introduced.                                      |
| ArubaOS 6.3 | The <b>enable-ipv6</b> and <b>nas-ip6</b> fields were added to the output of this command. |

| Version         | Description                                                                                                                                                                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 6.4     | The <b>called-station-id</b> and <b>cppm credentials</b> parameter was added to the output of this command.                                                                                                                                                                                     |
| ArubaOS 6.4.2.5 | The <b>CPPM credentials</b> parameter was introduced.                                                                                                                                                                                                                                           |
| ArubaOS 6.4.3.0 | <p>The following parameters were introduced:</p> <ul style="list-style-type: none"> <li>• <b>enable-radsec</b></li> <li>• <b>radsec-client-cert-name</b></li> <li>• <b>radsec-port</b></li> <li>• <b>radsec-trusted-cacert-name</b></li> <li>• <b>radsec-trusted-servercert-name</b></li> </ul> |

| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show aaa authentication-server tacacs

```
show aaa authentication-server tacacs [<tacacs_server_name>]|statistics
```

### Description

Display configuration settings for your TACACS+ servers.

### Syntax

| Parameter            | Description                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------|
| <tacacs_server_name> | Name that identifies an TACACS+ server.                                                                       |
| statistics           | Displays accounting, authorization, and authentication request and response statistics for the TACACS server. |

### Examples

The output of the example below displays the TACACS+ server list with the names of all the TACACS+ servers. The **References** column lists the number of other profiles that reference a TACACS+ server, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #aaa authentication-server tacacs
```

```
TACACS Server List
```

```

```

| Name    | References | Profile Status |
|---------|------------|----------------|
| ----    | -----      | -----          |
| LabAuth | 5          |                |
| TACACS1 | 3          |                |

```
Total:2
```

Include the <tacacs\_server\_name> parameter to display additional details for an individual server

```
(host) #show aaa authentication-server tacacs tacacs1
```

```
TACACS Server "tacacs1"
```

```

```

| Parameter   | Value     |
|-------------|-----------|
| -----       | -----     |
| Host        | 10.1.1.16 |
| Key         | *****     |
| TCP Port    | 49        |
| Retransmits | 3         |
| Timeout     | 20 sec    |
| Mode        | Enabled   |

| Parameter | Description                      |
|-----------|----------------------------------|
| host      | IP address of the TACACS+ server |

| Parameter   | Description                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------|
| Key         | Shared secret between the controller and the authentication server.                                 |
| TCP Port    | TCP port used by the server.                                                                        |
| Retransmits | Maximum number of retries sent to the server by the controller before the server is marked as down. |
| Timeout     | Maximum time, in seconds, that the controller waits before timing out the request and resending it. |
| Mode        | Shows whether this server is <b>Enabled</b> or <b>Disabled</b> .                                    |

The output of this command includes the following parameters:

## Command History

| Release     | Modification                                    |
|-------------|-------------------------------------------------|
| ArubaOS 3.0 | Command introduced                              |
| ArubaOS 6.0 | The <b>Statistics</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show aaa authentication-server windows

show aaa authentication-server windows [<windows\_server\_name>]

### Description

Display configuration settings for your Windows servers.

### Syntax

| Parameter             | Description                            |
|-----------------------|----------------------------------------|
| <windows_server_name> | Name that identifies a Windows server. |

### Examples

The output of the example below displays the Windows server list with the names of all the Windows servers used for NTLM authentication. The **References** column lists the number of other profiles that reference a Windows server, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #aaa authentication-server tacacs
```

```
Windows Server List
```

```

Name References Profile Status
---- -
NTLM 1
Windows2 1
```

```
Total:2
```

Include the <windows\_server\_name> parameter to display additional details for an individual server.

```
(host) #show aaa authentication-server windows Windows2
```

```
Windows Server "windows"
```

```

Parameter Value

Host 172.21.18.170
Mode Enabled
Windows Domain MyCompanyDomain
```

The output of this command includes the following parameters:

| Parameter      | Description                                                      |
|----------------|------------------------------------------------------------------|
| host           | IP address of the Windows server                                 |
| Mode           | Shows whether this server is <b>Enabled</b> or <b>Disabled</b> . |
| Windows Domain | Name of the Windows domain to which this server is assigned.     |

## Command History

This command was introduced in ArubaOS 3.4.1.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show aaa bandwidth-contracts

```
show aaa bandwidth-contracts [<bwname>]
```

### Description

This command shows the contract names, ID numbers and Rate limits for your bandwidth contracts.

### Syntax

| Parameter | Description                              |
|-----------|------------------------------------------|
| <bwname>  | (Optional) Name of a bandwidth contract. |

### Example

Specify a bandwidth contract name to view information for a specific bandwidth contract, or omit that parameter to view information for all configured bandwidth contracts. The output of the following command shows that the bandwidth contract **VLAN** has a configured rate of 6 Mbps, and the contract **User** has a rate of 2048 Kbps.

```
(host) #show aaa bandwidth-contracts VLAN
```

```
Bandwidth ContractInstances
```

```

```

```
Contract Id Rate (bits/second)
```

```

```

```
VLAN 1 6000000
```

```
User 2 2048000
```

```
Total contracts = 2
```

```
Per-user contract total = 4096
```

```
Per-user contract usage = 0
```

## show aaa debug

```
show aaa debug
 age {dev-id-cache [mac <A:B:C:D:E:F>]|key-cache [mac <A:B:C:D:E:F>]|pmk-cache [mac
 <A:B:C:D:E:F>]}
 pmk bss-table [<A:B:C:D:E:F>]
 role user {ip <A.B.C.D>|ipv6 <ipv6addr>|mac <A:B:C:D:E:F>}
 vlan user {ip <A.B.C.D>|ipv6 <ipv6addr>|mac <A:B:C:D:E:F>}
```

### Description

Displays AAA related debug information.

### Syntax

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| age<br>dev-id-cache<br>key-cache<br>pmk-cache | Displays the age of the GSM entry since the previous refresh (in seconds) based on: <ul style="list-style-type: none"><li>• <b>dev-id-cache</b>—Device ID information in memory.</li><li>• <b>key-cache</b>—Key cache information in memory.</li><li>• <b>pmk-cache</b>—Pairwise Master Key (PMK) cache information in memory.</li></ul> |
| pmk bss-table                                 | Displays PMK related debug information based on the BSSID address.                                                                                                                                                                                                                                                                       |
| role user<br>ip<br>ipv6<br>mac                | Displays role derivation related debug information based on: <ul style="list-style-type: none"><li>• <b>ip</b>—IPv4 address of the client.</li><li>• <b>ipv6</b>—IPv6 address of the client.</li><li>• <b>mac</b>—MAC address of the client.</li></ul>                                                                                   |
| vlan user<br>ip<br>ipv6<br>mac                | Displays VLAN derivation related debug information based on: <ul style="list-style-type: none"><li>• <b>ip</b>—IPv4 address of the client.</li><li>• <b>ipv6</b>—IPv6 address of the client.</li><li>• <b>mac</b>—MAC address of the client.</li></ul>                                                                                   |

### Example

The output of the example below displays the VLAN derivation debug information of an user with IPv4 address.

```
(host) #show aaa debug vlan user ip 192.0.2.1
```

```
VLAN types present for this User
=====
Default VLAN : 3
Initial Role Contained : 1
User Dot1x Role Contained : 5
Dot1x Server Rule : 5

VLAN Derivation History
=====
VLAN Derivation History Index : 8
```

1. VLAN 1 for Default VLAN
2. VLAN 1 for Current VLAN updated
3. VLAN 0 for Reset VLANs for Station up
4. VLAN 3 for Default VLAN
5. VLAN 1 for Initial Role Contained
6. VLAN 5 for Dot1x Server Rule
7. VLAN 5 for User Dot1x Role Contained
8. VLAN 5 for Current VLAN updated

Current VLAN : 5 (Dot1x Server Rule)

## show aaa derivation-rules

show aaa derivation-rules [server-group <group-name>|user <name>]

### Syntax

| Parameter    | Description               |
|--------------|---------------------------|
| <group-name> | Name of a server group    |
| <name>       | Name of a user rule group |

### Description

Show derivation rules based on user information or configured for server groups.

### Example

The output of the following command shows that the server group group1 has the internal database configured as its authentication server, and that there is a single rule assigned to that group. You can omit the **<group-name>** parameter to show a table of all your server groups.

```
(host) #show aaa derivation-rules server-group group1
```

Server Group

| Name     | Inservice | trim-FQDN | match-FQDN |
|----------|-----------|-----------|------------|
| Internal | Yes       | No        |            |

Server Rule Table

| Priority | Attribute | Operation | Operand  | Action   | Value | Total Hits | New Hits |
|----------|-----------|-----------|----------|----------|-------|------------|----------|
| 1        | Filter-Id | equals    | nsFilter | set vlan | 111   | 24         |          |

Rule Entries: 1

The following data columns appear in the output of this command:

| Parameter  | Description                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------|
| Name       | Name of the authentication server assigned to this server group                                               |
| Inservice  | Specifies if the server is in service or out-of-service.                                                      |
| trim-FQDN  | If enabled, user information in an authentication request is edited before the request is sent to the server. |
| match-FQDN | If enabled, the authentication server is associated with a specified domain.                                  |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Priority   | The priority in which the rules are applied. Rules at the top of the list are applied before rules at the bottom.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Attribute  | This is the attribute returned by the authentication server that is examined for <b>Operation</b> and <b>Operand</b> match                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Operation  | <p>This is the match method by which the string in <b>Operand</b> is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> <li>• <b>contains</b> – The rule is applied if and only if the attribute value contains the string in parameter <b>Operand</b>.</li> <li>• <b>starts-with</b> – The rule is applied if and only if the attribute value returned starts with the string in parameter <b>Operand</b>.</li> <li>• <b>ends-with</b> – The rule is applied if and only if the attribute value returned ends with the string in parameter <b>Operand</b>.</li> <li>• <b>equals</b> – The rule is applied if and only if the attribute value returned equals the string in parameter <b>Operand</b>.</li> <li>• <b>not-equals</b> – The rule is applied if and only if the attribute value returned is not equal to the string in parameter <b>Operand</b>.</li> <li>• <b>value-of</b> – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied.</li> </ul> |
| Operand    | This is the string to which the value of the returned attribute is matched.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Action     | This parameter identifies whether the rule sets a server group role ( <b>set role</b> ) or a VLAN ( <b>set vlan</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Value      | Sets the user role or VLAN ID to be assigned to the client if the condition is met.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Total Hits | Number of times the rule has been applied since the last server reboot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| New Hits   | Number of times the rule has been applied since the <b>show aaa derivation-rules</b> command was last issued.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

To display derivation rules for a user group, include the **user <name>** parameter. You can also display a table of all user rules by including the **user** parameter, but omitting the **<name>** parameter

```
(host) #show aaa derivation-rules user user44
```

```
User Rule Table
```

```

```

| Priority    | The priority in which the rules are applied. Rules at the top of the list are applied before rules at the bottom.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Attribute   | This is the attribute returned by the authentication server that is examined for <b>Operation</b> and <b>Operand</b> match.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Operation   | <p>This is the match method by which the string in <b>Operand</b> is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> <li>• <b>contains</b> – The rule is applied if and only if the attribute value contains the string in parameter <b>Operand</b>.</li> <li>• <b>starts-with</b> – The rule is applied if and only if the attribute value returned starts with the string in parameter <b>Operand</b>.</li> <li>• <b>ends-with</b> – The rule is applied if and only if the attribute value returned ends with the string in parameter <b>Operand</b>.</li> <li>• <b>equals</b> – The rule is applied if and only if the attribute value returned equals the string in parameter <b>Operand</b>.</li> <li>• <b>not-equals</b> – The rule is applied if and only if the attribute value returned is not equal to the string in parameter <b>Operand</b>.</li> <li>• <b>value-of</b> – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied.</li> </ul> |
| Operand     | This is the string to which the value of the returned attribute is matched.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Action      | This parameter identifies whether the rule sets a server group role ( <b>set role</b> ) or a VLAN ( <b>set vlan</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Value       | Sets the user role or VLAN ID to be assigned to the client if the condition is met.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Total Hits  | Number of times the rule has been applied since the last server reboot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| New Hits    | Number of times the rule has been applied since the <b>show aaa derivation-rules</b> command was last issued.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description | This optional parameter describes the rule. If no description was configured then it does not appear when you view the User Table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## show aaa dns-query-interval

```
show aaa dns-query-interval <minutes>
```

### Description

View the configured interval between DNS requests sent from the controller to the DNS server.

### Syntax

No parameters

### Usage Guidelines

If you define a RADIUS server using the FQDN of the server rather than its IP address, the controller will periodically generate a DNS request and cache the IP address returned in the DNS response. By default, DNS requests are sent every 15 minute, but the interval can be changed using the `aaa dns-query-period` command. Issue the **show aaa dns-query-period** command to view the current DNS query interval.

### Example

This command shows that the controller will send a DNS query every 30 minutes

```
(host) # show aaa dns-query-period
DNS Query Interval = 30 minutes
```

### Related Commands

To configure the DNS query interval, issue the command [aaa dns-query-interval](#).

### Command History

This command was available in ArubaOS 6.0.

|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show aaa fqdn-server-names

show aaa fqdn-server-names

### Description

Show a table of IP addresses that have been mapped to fully qualified domain names (FQDNs).

### Syntax

No parameters.

### Usage Guidelines

If you define a RADIUS server using the FQDN of the server rather than its IP address, the controller will periodically generate a DNS request and cache the IP address returned in the DNS response. Issue this command to view the IP addresses that currently correlate to each RADIUS server FQDN.

### Example

The output of this command shows the IP addresses for two RADIUS servers.

```
(host) #show aaa fqdn-server-names

Auth Server FQDN names

FQDN IP Address IPv6 Address Refcount
---- -
myhost1.example.com 192.0.2.3
2myhost2.example.com 192.0.2.5 3
```

### Related Commands

To configure a RADIUS authentication server using that server's fully qualified domain name, use the command [aaa authentication-server radius](#).

### Command History

This command was available in ArubaOS 6.0.

|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show aaa load-balance statistics

```
show aaa load-balance statistics server-group <sg_name>
```

### Description

Display the load balancing statistics for RADIUS servers.

### Syntax

| Parameter | Description               |
|-----------|---------------------------|
| <sg_name> | Name of the server group. |

### Example

```
(host) #show aaa load-balance statistics server-group dot1x-test-apsim
Statistics for Radius Servers in Server Group
```

```

| Parameter    | Description                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server       | Name of the RADIUS server.                                                                                                                                                                                                           |
| Acct Rq      | Accounting requests. This reports the number of accounting messages (for example, start/stop/interim update) sent by the controller to a RADIUS server. This counter increments whenever the controller sends one of these messages. |
| Raw Rq       | Raw requests. Number of raw authentication requests the controller sent to a RADIUS server.                                                                                                                                          |
| PAP Rq       | PAP Requests. Number of PAP authentication requests the controller sent to a RADIUS server.                                                                                                                                          |
| CHAP Rq      | CHAP requests. Number of CHAP authentication requests the controller sent to a RADIUS server.                                                                                                                                        |
| MSCHAP Rq    | MSCHAP requests. Number of MS-CHAP authentication requests the controller sent to a RADIUS server.                                                                                                                                   |
| MSCHAPv2 Rq  | MSCHAPv2 requests. Number of MS-CHAPv2 requests the controller sent to a RADIUS server.                                                                                                                                              |
| Mismatch Rsp | Mismatch responses. Number of responses from a RADIUS server for which the controller does not have the proper request context.                                                                                                      |
| Bad Auth     | Bad authenticator. Number of responses from the RADIUS server with an invalid                                                                                                                                                        |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | secret or bad reply digest.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Acc               | Access accept. Number of responses from the RADIUS server with invalid secret or bad reply digest.                                                                                                                                                                                                                                                                                                                                                        |
| Rej               | Access reject. Number of responses from the RADIUS server that indicate that client authentication failed.                                                                                                                                                                                                                                                                                                                                                |
| Acct Rsp          | Accounting response. Number of responses sent from the RADIUS server in response to accounting requests sent from the controller.                                                                                                                                                                                                                                                                                                                         |
| Chal              | Access challenge. Number of responses from the RADIUS server containing a challenge for the client (to complete authentication).                                                                                                                                                                                                                                                                                                                          |
| Ukn Rsp           | Unknown Response code. Number of responses from the RADIUS server that were not understood by the controller due to the purpose or type of the response                                                                                                                                                                                                                                                                                                   |
| Tmout             | Timeouts. Number of messages sent by the controller for which the controller did not receive a response before the message timed out.<br><br><b>NOTE:</b> Timeouts include RADIUS accounting requests. Every request controller sends to the RADIUS server is monitored for a timeout, so each retry increments this counter.                                                                                                                             |
| AvgRspTme         | Average response time. Time taken, on an average, for the RADIUS server to respond to a message from the controller.                                                                                                                                                                                                                                                                                                                                      |
| Tot Rq            | Total errors. This counter reflects the total number of requests sent to the RADIUS server (auth and accounting requests).                                                                                                                                                                                                                                                                                                                                |
| Tot Rsp           | This counter reflects the total number of responses received by the RADIUS server (auth and accounting responses).                                                                                                                                                                                                                                                                                                                                        |
| Rd Err            | Read errors. This counter reflects the total number of errors encountered while reading off socket corresponding to that RADIUS server.                                                                                                                                                                                                                                                                                                                   |
| Uptime            | Amount of for which the RADIUS server has been active/up. The RADIUS server is considered to have an UP status if the server is active and serving requests. The RADIUS server is considered to be DOWN if the server is not responding. For example, if the RADIUS server does not respond for (<no of retries> * <timeout>) seconds, the controller takes the RADIUS server down. It brings the radius server back into service after the dead timeout. |
| SEQ               | Information corresponding to the sequence number of requests. <b>SEQ total</b> corresponds to the total number of sequence numbers that can be used to communicate with the RADIUS server. <b>SEQ free</b> corresponds to the free/available/not in use sequence numbers for a particular RADIUS server.                                                                                                                                                  |
| Outstanding Auths | This value keeps track of the number of clients that are currently getting authenticated against this authentication server, i.e. clients for which the controller has sent Access-Request but has not yet received Access-Accept or Access-Reject and also the Access-Request has not timed out completely.                                                                                                                                              |

## Command History

| Version     | Description                                                                                |
|-------------|--------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced.                                                                        |
| ArubaOS 6.1 | The <b>Source Interface</b> parameter was introduced.                                      |
| ArubaOS 6.3 | The <b>enable-ipv6</b> and <b>nas-ip6</b> fields were added to the output of this command. |
| ArubaOS 6.4 | The <b>Outstanding Auths</b> parameter was added to the output of this command.            |

## show aaa main-profile

```
show aaa main-profile summary
```

### Description

Show a summary of all AAA profiles.

### Example

The output of the **show aaa main-profile summary** command shows roles, server group settings, and wire-to-wireless-roaming statistics for each AAA profile.

```
(host) #show aaa main-profile summary
```

```
AAA Profile summary
```

```

Name role mac-auth dot1x- rad- XML-api RFC3576 UDR- ww- enforce
----- ----- ----- ----- ----- ----- ----- ----- ----- -----

```

The following data columns appear in the output of this command:

| Parameter  | Description                                                                                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name       | Name of the AAA profile.                                                                                                                                                                                                                                |
| role       | Role for unauthenticated users.                                                                                                                                                                                                                         |
| mac-auth   | Name of the server group used for MAC authentication.                                                                                                                                                                                                   |
| dot1x-auth | Name of the server group used for dot1x authentication.                                                                                                                                                                                                 |
| rad-act    | Name of the server group used for RADIUS authentication.                                                                                                                                                                                                |
| XML-api    | IP address of a configured XML API server.                                                                                                                                                                                                              |
| RFC3576    | IP address of a RADIUS server that can send user disconnect, session timeout and change-of-authorization messages, as described in RFC 3576.                                                                                                            |
| UDR-group  | Name of the user derivation rule profile.                                                                                                                                                                                                               |
| ww-roam    | Shows if wired-to-wireless roaming is enabled or disabled.                                                                                                                                                                                              |
| devtype    | Shows if the device identification feature is enabled or disabled. When devtype-classification parameter is enabled, the output of the show user and show user-table commands shows each client's device type, if that client device can be identified. |

| Parameter    | Description                                                                                                                                                                                                                                                                              |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enforce-dhcp | When this option is enabled, clients must complete a DHCP exchange to obtain an IP address. Best practices are to enable this option when you use the <b>aaa derivation-rules</b> command to create a rule with the <b>DHCP-Option</b> rule type. This parameter is disabled by default. |

## show aaa password-policy mgmt

show aaa password-policy mgmt [statistics]

### Description

Show the current password policy for management users.

### Syntax

| Parameter  | Description                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------|
| statistics | Include this optional parameter to show the numbers of failed login attempts and any lockout periods for management user accounts. |

### Examples

The output of the **show aaa password-policy mgmt** command below shows that the current password policy requires a management user to have a password with a minimum of 9 characters, including one numeric character and one special character

```
(host) #show aaa password-policy mgmt

Mgmt Password Policy

Parameter Value

Enable password policy Yes
Minimum password length required 9
Minimum number of Upper Case characters 0
Minimum number of Lower Case characters 0
Minimum number of Digits 1
Minimum number of Special characters (!, @, #, $, %, ^, &, *, <, >, {, }, [,], :, ., comma, |, +, ~, `) 1
Username or Reverse of username NOT in Password No
Maximum Number of failed attempts in 3 minute window to lockout user 0
Time duration to lockout the user upon crossing the "lock-out" threshold 3
Maximum consecutive character repeats 0
```

The following data columns appear in the output of this command:

| Parameter                               | Description                                                                                                                                                                                           |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable password policy                  | Shows if the defined policy has been enabled                                                                                                                                                          |
| Minimum password length required        | Minimum number of characters required for a management user password. The default setting is 6 characters.                                                                                            |
| Minimum number of Upper Case characters | The maximum number of uppercase letters required for a management user password. By default, there is no requirement for uppercase letters in a password, and the parameter has a default value of 0. |

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Minimum number of Lower Case characters                                  | The maximum number of lowercase letters required for a management user password. By default, there is no requirement for lowercase letters in a password, and the parameter has a default value of 0.                                                                                             |
| Minimum number of Digits                                                 | Minimum number of numeric digits required in a management user password. By default, there is no requirement for digits in a password, and the parameter has a default value of 0.                                                                                                                |
| Minimum number of Special characters                                     | Minimum number of special characters required in a management user password. By default, there is no requirement for special characters in a password, and the parameter has a default value of 0.                                                                                                |
| Username or Reverse of username NOT in Password                          | If <b>Yes</b> , a management user's password cannot be the user's username or the username spelled backwards. If <b>No</b> , the password can be the username or username spelled backwards.                                                                                                      |
| Maximum Number of failed attempts in 3 minute window to lockout user     | Number of times a user can unsuccessfully attempt to log in to the controller before that user gets locked out for the time period specified by the <b>lock-out threshold</b> below. By default, the password lockout feature is disabled, and the default value of this parameter is 0 attempts. |
| Time duration to lockout the user upon crossing the "lock-out" threshold | Amount of time a management user will be "locked out" and prevented from logging into the controller after exceeding the maximum number of failed attempts setting show above. The default lockout time is 3 minutes.                                                                             |
| Maximum consecutive character repeats                                    | The maximum number of consecutive repeating characters allowed in a management user password.<br><br>By default, there is no limitation on the numbers of character that can repeat within a password, and the parameter has a default value of 0 characters.                                     |

```
(host) #show aaa password-policy mgmt statistics
```

Management User Table

```

USER ROLE FAILED_ATTEMPTS STATUS
---- -
admin14 root 1 Locked until 12/1/2009 22:28
```

Include the optional **statistics** parameter to show failed login statistics in the Management User table. The example below shows that a single failed login attempt locked out the root user **admin14**, and displays the time when that user can attempt to login to the controller again.

## show aaa profile

```
show aaa profile <profile-name>
```

### Description

Show configuration details for an individual AAA profile.

### Example

The output of the following command shows roles, servers and server group settings, and wire-to-wireless-roaming statistics for each AAA profile.

```
(host) #show aaa profile default
```

```
AAA Profile "default"

Parameter Value

Initial role guest
MAC Authentication Profile N/A
MAC Authentication Default Role guest
MAC Authentication Server Group default
802.1X Authentication Profile default
802.1X Authentication Default Role guest
802.1X Authentication Server Group N/A
Download Role from CPPM Disabled
L2 Authentication Fail Through Disabled
Multiple Server Accounting Disabled
User idle timeout N/A
RADIUS Accounting Server Group N/A
RADIUS Interim Accounting Disabled
XML API server N/A
RFC 3576 server N/A
User derivation rules N/A
Wired to Wireless Roaming Enabled
SIP authentication role N/A
Device Type Classification Enabled
Enforce DHCP Disabled
```

The following data columns appear in the output of this command:

| Parameter                       | Description                                                    |
|---------------------------------|----------------------------------------------------------------|
| Name                            | The name of the AAA profile.                                   |
| Initial Role                    | Role for unauthenticated users.                                |
| MAC Authentication Profile      | Name of the MAC authentication profile.                        |
| MAC Authentication Default Role | Configured role assigned to the user after MAC authentication. |
| MAC Authentication Server Group | Name of the server group used for MAC authentication.          |

| Parameter                          | Description                                                                                                                                                                                                                                                                    |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 802.1X Authentication Profile      | Name of the 802.1X authentication profile.                                                                                                                                                                                                                                     |
| 802.1X Authentication Default Role | Configured role assigned to the user after 802.1X authentication.                                                                                                                                                                                                              |
| 802.1X Authentication Server Group | Name of the server group used for 802.1X authentication.                                                                                                                                                                                                                       |
| Download Role from CPPM            | Status of role download from CPPM. If enabled, the controller downloads the role from ClearPass Policy Manager (CPPM) if not defined.                                                                                                                                          |
| L2 Authentication Fail Through     | To select the other authentication method if one fails.                                                                                                                                                                                                                        |
| Multiple Server Accounting         | Status of multiple server accounting. If enabled, the controller sends RADIUS accounting to all servers in RADIUS accounting server group.                                                                                                                                     |
| User idle timeout                  | The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. A value of 0, deletes the user immediately after disassociation from the wireless network. Valid range is 30-15300 in multiples of 30 seconds.                               |
| RADIUS Accounting Server Group     | Name of the server group used for RADIUS authentication.                                                                                                                                                                                                                       |
| RADIUS Interim Accounting          | By default, the RADIUS accounting feature sends only start and stop messages to the RADIUS accounting server. If RADIUS Interim Accounting is enabled, the controller to can also end Interim-Update messages with current user statistics to the server at regular intervals. |
| XML API server                     | IP address of a configured XML API server.                                                                                                                                                                                                                                     |
| RFC 3576 server                    | IP address of a RADIUS server hat can send user disconnect, session timeout and change-of-authorization messages, as described in RFC 3576.                                                                                                                                    |
| User derivation rules              | User attribute profile from which the user role or VLAN is derived.                                                                                                                                                                                                            |
| Wired to Wireless Roaming          | Shows whether Wired to Wireless Roaming is <b>Enabled</b> or <b>Disabled</b> .                                                                                                                                                                                                 |

| Parameter                  | Description                                                                                                                                                                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIP authentication role    | For controllers with an installed PEFNG license, this parameter displays the configured role assigned to a session initiation protocol (SIP) client upon registration.                                                                                                                   |
| Device Type Classification | Shows if the device identification feature is enabled or disabled. When devtype-classification parameter is enabled, the output of the show user and show user-table commands shows each client's device type, if that client device can be identified.                                  |
| Enforce DHCP               | When this option is enabled, clients must complete a DHCP exchange to obtain an IP address. Best practices are to enable this option when you use the <b>aaa derivation-rules</b> command to create a rule with the <b>DHCP-Option</b> rule type. This parameter is disabled by default. |

| Version       | Description                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0   | Command introduced.                                                                                                                                                                                                        |
| ArubaOS 3.4.1 | License requirements changed in ArubaOS 3.4.1, so the <b>sip-authentication-role</b> parameter required the Policy Enforcement Firewall license instead of the Voice Services Module license required in earlier versions. |
| ArubaOS 6.1   | The <b>radius-interim-accounting</b> , <b>devtype-classification</b> and <b>enforce-dhcp</b> parameters were introduced.                                                                                                   |
| ArubaOS 6.3   | The <b>user-idle-timeout</b> parameter was introduced.                                                                                                                                                                     |
| ArubaOS 6.4   | The <b>multiple-server-accounting</b> and <b>download-role</b> parameters were introduced.                                                                                                                                 |

| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show aaa radius-attributes

```
show aaa radius-attributes
```

### Description

Show RADIUS attributes recognized by the controller.

### Example

The output of the following command shows the name, currently configured value, type, vendor and RADIUS ID for each attribute.

```
(host) #show aaa radius-attributes
```

Dictionary

## show aaa rfc-3576-server

```
show aaa rfc-3576-server
<server-ip>
statistics
udp-port
```

### Description

Show configuration details for an RFC-3576 server, which is a RADIUS server that can send user disconnect, session timeout and change-of-authorization (CoA) messages, as described in RFC 3576.

### Syntax

| Parameter   | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| <server-ip> | IP address of an RFC-3576 server                                                  |
| statistics  | View detailed connection and authentication information for all RFC 3575 servers. |
| udp-port    | Show the configured RFC3576 server port. The default value is port 3799.          |

### Example

This first example shows that there are two configured servers in the RFC 3567 Server List. The **References** column lists the number of other profiles with references to the RFC 3567 server, and the **Profile Status** column indicates whether the server is predefined. User-defined servers will not have an entry in the **Profile Status** column.

```
(host) #show aaa rfc-3567-server
```

```
RFC 3576 Server List

Name References Profile Status
---- -
10.2.14.6 2
```

To view details for a specific server, include the IP address of that server in the command.

```
(host) #show aaa rfc-3576-server 192.0.2.31
RFC 3576 Server "192.0.2.31"

Parameter Value

Key *****
```

To view information for all RFC 3576 servers, include the **statistics** parameter.

```
(host) #show aaa rfc-3576-server statistics

RADIUS RFC 3576 Statistics

Statistics 10.1.2.3 10.1.2.34

Disconnect Requests 13 3
Disconnect Accepts 12 3
```

```

Disconnect Rejects 1 0
No Secret 0 0
No Session ID 0 0
Bad Authenticator 0 0
Invalid Request 0 0
Packets Dropped 0 2
Unknown service 0 0
CoA Requests 1 0
CoA Accepts 1 0
CoA Rejects 0 0
No permission 0 0

```

```

Packets received from unknown clients: 0
Packets received with unknown request: 0
Total RFC3576 packets Received : 0

```

The output of the **show aaa rfc-3576-server statistics** command includes the following parameters:

| Parameter           | Description                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------|
| Disconnect Requests | Number of disconnect requests sent by the server.                                                        |
| Disconnect Accepts  | Number of disconnect requests sent by the server that were accepted by the user.                         |
| Disconnect Rejects  | Number of disconnect requests sent by the server that were rejected by the user.                         |
| No Secret           | Number of authentication requests that did not contain a RADIUS secret.                                  |
| No Session ID       | Number of authentication requests that did not contain a session ID.                                     |
| Bad Authenticator   | Number of authentication requests that contained a missing or invalid authenticator field in the packet. |
| Invalid Request     | Number of invalid requests.                                                                              |
| Packets Dropped     | Number of packets dropped.                                                                               |
| Unknown service     | Number of requests for an unknown service type.                                                          |
| CoA Requests        | Number of requests for a Change of Authorization (CoA).                                                  |
| CoA Accepts         | Number of times a CoA request was accepted.                                                              |
| CoA Rejects         | Number of times a CoA request was rejected.                                                              |
| No permission       | Number of requests for a service that has been defined, but has not been administratively enabled.       |

## Related Commands

| Command                             | Description                      | Mode        |
|-------------------------------------|----------------------------------|-------------|
| <a href="#">aaa rfc-3576-server</a> | Define RFC 3576 server profiles. | Config mode |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |

## show aaa server-group

show aaa server-group [<group-name>|summary]

### Description

Show configuration details for your AAA server groups.

### Syntax

| Parameter    | Description                               |
|--------------|-------------------------------------------|
| <group-name> | The name of an existing AAA server group. |

### Usage Guidelines

Issue this command without the **><group-name>** or **summary** options to display the entire server group list, including profile status and the number of references to each profile. The **References** column lists the number of other profiles that reference a server group, and the **Profile Status** column indicates whether the server group is predefined. User-defined server groups will not have an entry in the Profile Status column. Examples

This first example shows that there are five configured server groups

```
(host) #show aaa server-group summary
```

```
Server Group List
```

```

```

| Name                  | References | Profile Status |
|-----------------------|------------|----------------|
| ----                  | -----      | -----          |
| auth-profile-2        | 1          |                |
| coltrane-server-group | 1          |                |
| default               | 25         |                |
| group1                | 0          |                |
| internal              | 0          | Predefined     |

```
Total:5
```

To view additional statistics for all server groups, include the **statistics** parameter.

```
(host) #show aaa server-group summary
```

```
Server Groups
```

```

```

| Name                  | Servers | Rules | hits | Out-of-service |
|-----------------------|---------|-------|------|----------------|
| ----                  | -----   | ----- | ---- | -----          |
| auth-profile-2        | 1       | 0     | 0    |                |
| coltrane-server-group | 1       | 0     | 0    |                |
| default               | 1       | 0     | 0    |                |
| group1                | 1       | 1     | 0    |                |
| internal              | 1       | 1     | 0    |                |

The output of the show aaa server-group summary command includes the following parameters:

| Parameter      | Description                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------|
| name           | Name of an existing AAA server group.                                                                                         |
| Servers        | Number of servers in the group.                                                                                               |
| Rules          | Number of rules configured for the server group.                                                                              |
| hits           | Number of hits for the server's rules.                                                                                        |
| Out-of-Service | Indicates whether the server is active, or out of service. Active servers may not have an entry in the Out-of-Service column. |

To display detailed authorization, role and vlan statistics for an individual server group, include the name of the group for which you want more information.

```
(host) #show aaa server-group summary group1
```

Fail Through:No

Auth Servers

-----

| Name | Server-Type | trim-FQDN | Match-Type | Match-Op | Match-Str |
|------|-------------|-----------|------------|----------|-----------|
| rad1 | Radius      | No        |            |          |           |
| rad3 | Radius      | No        |            |          |           |

Role/VLAN derivation rules

|----------|-----------|-----------|----------|--------|---------------|
| 1        |           | class     | contains | admin  | set role root |

The output of the show aaa server-group <group-name> command includes the following parameters:

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name        | Specifies if the server is in service or out-of-service.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Server-Type | If enabled, user information in an authentication request is edited before the request is sent to the server.                                                                                                                                                                                                                                                                                                                                                                                              |
| trim-FQDN   | If enabled, user information in an authentication request is edited before the request is sent to the server.                                                                                                                                                                                                                                                                                                                                                                                              |
| Match-Type  | <p>If the match type is <b>authstring</b> the authentication server associates with a match rule that the controller can compare with the user/client information in the authentication request.</p> <p>A <b>fdqn</b> match type associates the authentication server with a specified domain. An authentication request is sent to the server only if there is an exact match between the specified domain and the &lt;domain&gt; portion of the user information sent in the authentication request.</p> |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Match-Op  | <p>This is the match method by which the string in <b>Match-Str</b> is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> <li>• <b>contains</b> – The rule is applied if and only if the attribute value contains the string in parameter <b>Operand</b>.</li> <li>• <b>starts-with</b> – The rule is applied if and only if the attribute value returned starts with the string in parameter <b>Operand</b>.</li> <li>• <b>ends-with</b> – The rule is applied if and only if the attribute value returned ends with the string in parameter <b>Operand</b>.</li> <li>• <b>equals</b> – The rule is applied if and only if the attribute value returned equals the string in parameter <b>Operand</b>.</li> <li>• <b>not-equals</b> – The rule is applied if and only if the attribute value returned is not equal to the string in parameter <b>Operand</b>.</li> <li>• <b>value-of</b> – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied</li> </ul>                                   |
| Match-Str | This is the string to which the value of the returned attribute is matched.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Priority  | The priority in which role or VLAN derivation rules are applied. Rules at the top of the list are applied before rules at the bottom.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Attribute | For role or VLAN derivation rules, this is the attribute returned by the authentication server that is examined for <b>Operation</b> and <b>Operand</b> match.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Operation | <p>For role or VLAN derivation rules, this is the match method by which the string in <b>Operand</b> is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> <li>• <b>contains</b> – The rule is applied if and only if the attribute value contains the string in parameter <b>Operand</b>.</li> <li>• <b>starts-with</b> – The rule is applied if and only if the attribute value returned starts with the string in parameter <b>Operand</b>.</li> <li>• <b>ends-with</b> – The rule is applied if and only if the attribute value returned ends with the string in parameter <b>Operand</b>.</li> <li>• <b>equals</b> – The rule is applied if and only if the attribute value returned equals the string in parameter <b>Operand</b>.</li> <li>• <b>not-equals</b> – The rule is applied if and only if the attribute value returned is not equal to the string in parameter <b>Operand</b>.</li> <li>• <b>value-of</b> – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied.</li> </ul> |
| Operand   | For role or VLAN derivation rules, this is the string to which the value of the returned attribute is matched.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Action    | This parameter identifies whether the derivation rule sets a server group role ( <b>set role</b> ) or a VLAN ( <b>set vlan</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter | Description                                                                              |
|-----------|------------------------------------------------------------------------------------------|
| Value     | Sets the user role or VLAN ID to be assigned to the client if the rule condition is met. |

## show aaa state ap-group

show aaa state ap-group

### Description

Show the names and ID numbers of your AP groups

### Example

This first example shows that the selected controller has two defined AP groups.

```
(host) #show aaa state ap-group
```

AP Group Table

-----

Name    ID

-----

ap1                    1

ap2                    2

## show aaa state configuration

show aaa state configuration

### Description

Display authentication state configuration information, including the numbers of successful and failed authentications.

### Example

This example shows authentication settings and values for a controller with no current users.

```
(host) #show aaa state configuration
```

#### Authentication State

```

Name Value
---- -
Switch IP 10.6.2.253
Switch IPv6
Master IP 10.100.103.253
Switch Role local
Current/Max/Total IPv4 Users 0/6/14
Current/Max/Total IPv6 Users 0/1/1
Current/Max/Total User Entries 0/4/15
Current/Max/Total Stations 121/190/367550
Captive Portal Users 4
802.1x Users 119
VPN Users 0
MAC Users 0
Stateful 802.1x Users 0
Tunneled users 0
Configured user roles 21
Configured session ACL 41
Configured destinations 32
Configured services 77
Configured Auth servers 9
Auth server in service 9
Radius server timeouts 7062
```

#### Successful authentications

```

Web MAC VPN 802.1x Krb RadAcct SecureID Stateful-802.1x Management
--- --- --- --- --- --- --- --- ---
138 0 0 10117 0 0 0 0 0
```

#### Failed authentications

```

Web MAC VPN 802.1x Krb RadAcct SecureID Stateful-802.1x Management
--- --- --- --- --- --- --- --- ---
48 0 0 32235 0 0 0 0 0
```

```
Idled users = 3366
Mobility = Enabled
fast age = Disabled
per-user log = Disabled
Bandwidth contracts = 2/1
IP takeovers = 21
```

The output of the **show aaa state configuration** command includes the following parameters:

| Parameter                    | Description                                                                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Switch IP                    | IP address of the local controller.                                                                                                                                                                                                        |
| Master IP                    | IP address of the master controller.                                                                                                                                                                                                       |
| Switch Role                  | Role assigned to the controller on which you issued the <b>show aaa state</b> command.                                                                                                                                                     |
| Current/Max/Total IPv4 Users | Current number of IPv4 users on the controller/Maximum number of IPv4 users that can be assigned to the controller at any time/Total number of IPv4 users that have been assigned to the controller since the last controller reboot.      |
| Current/Max/Total IPv6 Users | Current number of IPv6 users on the controller/Maximum number of IPv6 users that can be assigned to the controller at any time/Total number of IPv6 users that have been assigned to the controller since the last controller reboot.      |
| Current/Max/Total Users      | Current number of users on the controller/Maximum number of users that can be assigned to the controller at any time/Total number of users that have been assigned to the controller since the last controller reboot.                     |
| Current/Max/Total Stations   | Current number of stations registered with the controller/Maximum number of stations that can be registered with the controller at any time/Total number of stations that have registered the controller since the last controller reboot. |
| Captive Portal Users         | Number of current users authenticated via captive portal.                                                                                                                                                                                  |
| 802.1x Users                 | Number of current users authenticated via 802.1X authentication.                                                                                                                                                                           |
| VPN Users                    | Number of current users authenticated via VPN authentication.                                                                                                                                                                              |
| MAC Users                    | Number of current users authenticated via MAC authentication.                                                                                                                                                                              |
| Stateful 802.1x Users        | Number of current users authenticated via stateful 802.1X authentication.                                                                                                                                                                  |
| Tunneled users               | Number of stations in tunneled forwarding mode, where 802.11 frames are tunneled to the controller using generic routing encapsulation (GRE).                                                                                              |
| Configured user roles        | Number of configured user roles.                                                                                                                                                                                                           |
| Configured session ACL       | Number of configured session ACLs.                                                                                                                                                                                                         |

| Parameter               | Description                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configured destinations | Number of destinations configured using the <a href="#">netdestination</a> command.                                                                                     |
| Configured services     | Number of service aliases configured using the <a href="#">netservice</a> command.                                                                                      |
| Configured Auth servers | Number of configured authentication servers.                                                                                                                            |
| Auth server in service  | Number of authentication servers currently in service.                                                                                                                  |
| Radius server timeouts  | Number of times the RADIUS server did not respond to the authentication request.                                                                                        |
| Web                     | Total number of captive portal authentications or authentication failures since the last controller reset.                                                              |
| MAC                     | Total number of MAC authentications or authentication failures since the last controller reset.                                                                         |
| VPN                     | Total number of VPN authentications or authentication failures since the last controller reset.                                                                         |
| 802.1x                  | Total number of 802.1X authentications or authentication failures since the last controller reset.                                                                      |
| Krb                     | Total number of Kerberos authentications or authentication failures since the last controller reset.                                                                    |
| RadAcct                 | Total number of RADIUS accounting verifications or accounting failures since the last controller reset.                                                                 |
| SecureID                | Number of authentication verifications or failures using methods which use one-time passwords. (For example, EAP-GTC being used as the inner EAP protocol of EAP-PEAP.) |
| Stateful-802.1x         | Total number of Stateful 802.1X authentications or authentication failures since the last controller reset.                                                             |
| Management              | Total number of Management user authentications or authentication failures since the last controller reset.                                                             |
| Idled users             | Total number of users that are not broadcasting data to an AP.                                                                                                          |
| Mobility                | Shows whether the IP mobility feature has been enabled or disabled on the controller.                                                                                   |

| Parameter                | Description                                                                                                                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fast age                 | When the <b>fast age</b> feature allows the controller actively sends probe packets to all users with the same MAC address but different IP addresses. The users that fail to respond are purged from the system. This parameter shows if fast aging of user table entries has been enabled or disabled. |
| Per-User Log             | Shows if a W-6000, W-3600 or W-7200 Series controller collects per-user log files for debugging.<br><b>NOTE:</b> This option is enabled using the <b>aaa log</b> command.                                                                                                                                |
| Bandwidth contracts      | Number of configured bandwidth contracts on the controller.                                                                                                                                                                                                                                              |
| IP takeovers             | Number of times a two different stations have attempted to use the same IP address (IP spoofing).                                                                                                                                                                                                        |
| Ping/SYN/Session attacks | Number of reported ping, SYN and session attacks.                                                                                                                                                                                                                                                        |

## Command History

| Release     | Modification                                                          |
|-------------|-----------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced.                                                   |
| ArubaOS 6.3 | The <b>per-user log</b> field was added to the output of this command |

This command was introduced in ArubaOS 3.0.

## show aaa state debug-statistics

show aaa state debug statistics

### Description

show debug statistics for controller authentication, authorization and accounting.

### Syntax

No parameters.

### Example

The following example displays debug statistics for a variety of authentication errors:

```
(host) #show aaa state debug-statistics
user miss: ARP=47, 8021Q=5216, non-IP=0, zero-IP=0, loopback=0
user miss: mac mismatch=0, spoof=269 (74), drop=390, ncfg=0
user miss: non-auth opcode=0, no-l2-user=0, l2tp=0, vrrp=0, special mac=0, iap 13 user=0
Idled users = 3376
Idled users due to MAC mismatch = 0
Idled users due to SOS: wireless tunnel=0 wireless dtunnel=0
Idled users due to SOS: wired tunnel=0 wired dtunnel=0
Idled users due to SOS: other=0
Idled users due STM deauth: tunnel=0 dtunnel=0
Idled users from STM timeout: tunnel=0 dtunnel=0
Idled users from STM: other=0
Current users with STM idle flag = 0
Idle messages: SOS=0 STM deauth=0 STM timeout=0
Logon lifetime iterations = 4501, entries deleted = 121
SIP authentication messages received 29227, dropped 29227
Missing auth user deletes: 0
Captive-portal forced user deletes: 1
Mobility Stats
 INTRA_MS 0, MAC mismatch 0, HA mismatch 0
 INTER_MS 0, MAC mismatch 0, HA mismatch 0
 MIP Update 0, Move 0, Del 0, TunAcl 0
 AAA Done 0, Del 2
 IPIP Loop forced Del: 0, Validate Visitor 0
Auth User rejects Received
L2 User:0, IPV4 :0, IPV6:0
Auth User rejects Processed
L2 User:0, IPV4 :0, IPV6:0
```

The output of this command includes the following parameters:

| Parameter | Description                                                                        |
|-----------|------------------------------------------------------------------------------------|
| User Miss |                                                                                    |
| ARP       | Number of ARP packets sent between the datapath and the controlpath.               |
| 8021q     | Number of 802.1q (VLAN tag) packets sent between the datapath and the controlpath. |

| Parameter                       | Description                                                                                                                                                    |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| non-ip                          | Number of non-IP type packets sent between the datapath and the controlpath.                                                                                   |
| zero-ip                         | Number of packets sent without an internet protocol (IP).                                                                                                      |
| loopback                        | If <b>1</b> , the controller has a defined loopback address. If <b>0</b> , a loopback address has not yet been configured.                                     |
| mac mismatch                    | Number of users that were not authenticated due to MAC mismatches.                                                                                             |
| spoof                           | Number of users that were not authenticated due to spoofed IP addresses.                                                                                       |
| drop                            | Number of user authentication attempts that were dropped.                                                                                                      |
| ncfg                            | Number of packets sent between datapath and controlpath, where the authentication module has not completed the initialization required to process the traffic. |
| Non-auth opcode                 | Number of packets whose opcode is non-auth opcode. This is a check to find if auth is responsible for processing received packet.                              |
| No-l2-user                      | Number of user packets dropped due to absence of an L2 entry for the user.                                                                                     |
| l2tp                            | Number of l2tp users.                                                                                                                                          |
| vrrp                            | Number of VRRP users.                                                                                                                                          |
| special mac                     | Number of users with a special MAC address.                                                                                                                    |
| iap                             | Number of instant AP users.                                                                                                                                    |
| idled users                     | Number of inactive stations that are not broadcasting data to an AP.                                                                                           |
| idled users due to MAC mismatch | For internal use only.                                                                                                                                         |
| Idled users due to SOS          |                                                                                                                                                                |
| wireless tunnel                 | Number of wireless users in tunnel forwarding mode that were aged out by the controller.                                                                       |
| wireless dtunnel                | Number of wireless users in decrypt tunnel forwarding mode that were aged out by the controller.                                                               |
| wired tunnel                    | Number of wired users in tunnel forwarding mode that were aged out by the controller.                                                                          |
| wired dtunnel                   | Number of wired users in decrypt tunnel forwarding mode that were aged out by the controller.                                                                  |
| Other                           | Number of users using modes other than tunneled or Decrypt tunneled aged out by the controller.                                                                |

| Parameter                          | Description                                                                                                                                                                                                      |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Idled users due STM deauth         |                                                                                                                                                                                                                  |
| tunnel                             | Number of users in tunnel forwarding mode that aged out after STM deauthentication, and timer expiration.                                                                                                        |
| dtunnel                            | Number of users in decrypt tunnel forwarding mode that aged out after STM deauthentication, and timer expiration.                                                                                                |
| Idled users from STM timeout       |                                                                                                                                                                                                                  |
| tunnel                             | Number of users in tunnel forwarding mode that aged out after the STM timer expired.                                                                                                                             |
| dtunnel                            | Number of users in decrypt tunnel forwarding mode that aged out after the STM timer expired.                                                                                                                     |
| Idled users from STM               |                                                                                                                                                                                                                  |
| other                              | Number of users in forwarding modes other than decrypt tunnel or tunnel mode that aged out after the STM timer expired.                                                                                          |
| Logon lifetime iteration           | Number of users deleted for lack of activity.                                                                                                                                                                    |
| SIP authentication message         | Number of session initiation protocol (SIP) authentication messages received.                                                                                                                                    |
| Missing auth user deletes          | Number of users removed from the datapath by the auth module, even without a mapping entry in control path. This counter can help identify problems with messages sent between the controlpath and the datapath. |
| Mobility Stats                     | Number of different messages exchanged between the mobile IP and the auth module.<br><b>NOTE:</b> This is used for troubleshooting purposes only.                                                                |
| Captive-portal forced user deletes | Number of idle users deleted after captive portal authentication.                                                                                                                                                |
| Auth User Rejects Received         |                                                                                                                                                                                                                  |
| L2 User                            | Number of authentication rejects received for L2 users from the datapath due to a failure of the operation.                                                                                                      |
| IPv4                               | Number of authentication rejects received for IPv4 users from the datapath due to a failure of the operation.                                                                                                    |
| IPv6                               | Number of authentication rejects received for IPv6 users from the datapath due to a failure of the operation.                                                                                                    |
| Auth User Rejects Processed        |                                                                                                                                                                                                                  |
| L2 User                            | Number of authentication rejects for L2 users that were processed after the reject was received.                                                                                                                 |
| IPv4                               | Number of authentication rejects for IPv4 users that were processed after the                                                                                                                                    |

| Parameter | Description                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------|
|           | reject was received.                                                                               |
| IPv6      | Number of authentication rejects for IPv6 users that were processed after the reject was received. |

## show aaa state log

show aaa state log [info]

### Description

Display global log files for AAA events.

### Syntax

| Parameter | Description                                                          |
|-----------|----------------------------------------------------------------------|
| info      | This parameter displays debugging information for internal use only. |

### Usage Guidelines

If you have enabled per-user logging using the [aaa log](#) command, the output of this command displays global AAA log files for events that are not triggered by individual user authentication, such as AP authentication and the initial pre-authentication processes that occur before a client authenticates to the controller.

To display log files for events triggered by a specific user, use the command [show user](#) or **show ipv6 user-table ip <ipv6-addr> log**.

### Example

The example below shows a partial list of the global log files displayed by the **show aaa state log** command..

```
(host) #show aaa state log
 1: At Thu Apr 11 10:41:27: [L] Type cert-downloaded * id 0 len 0, bssid
 00:00:00:00:00:00 | mac: 00:00:00:00:00:00
 2: At Thu Apr 11 10:43:17: [L] Type ap-up * id 0 len 0, bssid
 6c:f3:7f:5f:2c:b0 | mac: 00:00:00:00:00:00
 3: At Thu Apr 11 10:43:17: [L] Type ap-up * id 0 len 0, bssid
 6c:f3:7f:5f:2c:a0 | mac: 00:00:00:00:00:00
 4: At Thu Apr 11 10:43:50: [L] Type station-term-start * id 10 len 0, bssid
 6c:f3:7f:5f:2c:a0 | mac: 50:a4:c8:bd:be:41
 5: At Thu Apr 11 10:43:50: [L] Type station-data-ready_ack * id 10 len 0, bssid
 00:00:00:00:00:00 | mac: 50:a4:c8:bd:be:41
```

## show aaa state messages

### Description

Display numbers of authentication messages sent and received.

### Syntax

No parameters.

### Usage Guidelines

This command displays a general overview of authentication statistics. To view authentication information for specific profiles such as a captive-portal, MAC or 801.x authentication profile, issue the commands specific to those features.

### Example

The output of this command displays tables of statistics for PAPI, RAW socket and Sibyte messages.

```
(host) #show aaa state messages
```

```
PAPI Messages
```

```

```

| Msg ID | Name                   | Since last Read | Total |

## show aaa state station

show aaa state station <A:B:C:D:E:F>

### Description

Display AAA statistics for a station.

### Syntax

| Parameter     | Description               |
|---------------|---------------------------|
| <A:B:C:D:E:F> | MAC address of a station. |

### Example

The example below shows statistics for a station with four associated user IP addresses. The output of this command shows station data, the AAA profiles assigned to the station, and the station's authentication method.

```
(host) #show aaa state station 00:21:5c:85:d0:4b
Association count = 1, User count = 4

## show aaa state user

show aaa state user <A.B.C.D>

### Description

Display statistics for an authenticated user.

### Syntax

| Parameter | Description           |
|-----------|-----------------------|
| <A.B.C.D> | IP address of a user. |

### Example

The example below shows statistics for a user with the IP address 10.1.10.11. The output of this command shows user data, the user's authentication method, and statistics for assigned roles, timers and flags.

```
(host) #show aaa state user 10.1.10.11
Name: MYCOMPANY\tsenter, IP: 10.1.10.11, MAC: 00:21:5c:85:d0:4a, Role:employee, ACL:51/0, Age:

## show aaa tacacs-accounting

### Description

Show TACACS accounting configuration.

### Syntax

No parameters.

### Example

The example below shows that TACACS accounting has been enabled, and that the TACACS server is in the server group acct-server.

```
(host) #show aaa tacacs-accounting
TACACS Accounting Configuration

Parameter Value

Mode Enabled
Server-Group acct-server
```

The output of this command includes the following parameters:

| Parameter    | Description                                                  |
|--------------|--------------------------------------------------------------|
| Mode         | Shows if the TACACS accounting feature is enabled or disable |
| Server-Group | The server group that contains the active TACACS server.     |

### Command History

This command was introduced in ArubaOS 3.0.

|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show aaa timers

### Description

Show AAA timer values.

### Syntax

No parameters

### Example

The example below shows that the controller has all default timer values:

```
(host) #show aaa timers
User idle timeout = 6 minutes
Auth Server dead time = 10 minutes
Logon user lifetime = 5 minutes
```

| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show aaa web admin-port

```
show aaa web admin-port
```

### Description

Show the port numbers of HTTP and HTTPS ports used for web administration.

### Syntax

No parameters.

### Example

The example below shows that the controller is configured to use HTTPS on port 4343 or 443, and HTTP on port 8888.

```
(host) #show aaa web admin-port
https port = 4343
http port = 8888
```

### Command History

This command was introduced in ArubaOS 3.0.

## show aaa xml-api server

```
show aaa xml-api server [<server_ip>]
```

### Description

Show a list of XML servers used for authentication, authorization and accounting.

### Syntax

| Parameter   | Description                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| <server_ip> | IP address of an XML API server. Include this parameter to see if a secret key is configured for the specified server. |

### Example

The output of this command shows that the controller has two configured XML API servers that are each referenced by two different AAA profiles. Note that user-defined servers will not have an entry in the **Profile Status** column.

```
(host) #show aaa xml-api statistics
XML API Server List

Name References Profile Status
---- -
10.1.2.3 2
10.4.3.2 2
```

### Command History

This command was introduced in ArubaOS 3.0.

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show aaa xml-api statistics

show aaa xml-api statistics

### Description

Display statistics for an external XML API server.

### Syntax

| Parameter   | Description                   |
|-------------|-------------------------------|
| <server_ip> | IP address of XML API server. |

### Usage Guidelines

Issue this command to troubleshoot AAA problems and monitor usage on an XML server.

### Example

The example below shows AAA statistics for an external XML server with the IP address 10.1.2.3. This command shows the number of times that a particular event has occurred per client. The first number is the number of times this event occurred. The number of new events since the last time the counters were displayed is shown in parentheses.

```
(host) #show aaa xml-api statistics
Statistics 10.1.2.3

user_authenticate 0 (0)
user_add 0 (0)
user_delete 0 (0)
user_blacklist 0 (0)
user_query 0 (0)
unknown user 0 (0)
unknown role 0 (0)
unknown external agent 0 (0)
authentication failed 0 (0)
invalid command 0 (0)
invalid message authentication method 0 (0)
invalid message digest 0 (0)
missing message authentication 0 (0)
missing or invalid version number 0 (0)
internal error 0 (0)
client not authorized 0 (0)
Cant use VLAN IP 0 (0)
Invalid IP 0 (0)
Cant use Switch IP 0 (0)
missing MAC address 0 (0)
Packets received from unknown clients: 0 (0)
Packets received with unknown request: 0 (0)
Requests Received/Success/Failed : 0/0/0 (0/0/0)
```

The output of this command includes the following parameters:

| Parameter                             | Description                                                                                                |
|---------------------------------------|------------------------------------------------------------------------------------------------------------|
| user_authenticate                     | Number of users authenticated on the XML server since the last controller reboot.                          |
| user_add                              | Number of users added to the controller's user table.                                                      |
| user_delete                           | Number of users removed from the controller's user table.                                                  |
| user_blacklist                        | Number of denied user association requests.                                                                |
| user_query                            | Number of user queries performed.                                                                          |
| unknown user                          | Number of unknown users.                                                                                   |
| unknown role                          | Number of unknown user roles.                                                                              |
| unknown external agent                | Number of requests by an unknown external agent.                                                           |
| authentication failed                 | Number of failed authentication requests.                                                                  |
| invalid command                       | Number of invalid XML commands                                                                             |
| invalid message authentication method | Number of XML commands with an invalid authentication method (when a key is configured on the controller). |
| invalid message digest                | Number of XML commands with an invalid digest type (when a key is configured on the controller).           |
| missing message authentication        | Number of XML commands with an missing authentication method (when a key is configured on the controller). |
| missing or invalid version number     | Number of commands with a missing or invalid version number. The version number should always be 1.0.      |
| internal error                        | Number of internal server errors                                                                           |
| client not authorized                 | Number of unauthorized clients                                                                             |
| Cant use VLAN IP                      | Number of time a user IP is same as the VLAN IP.                                                           |
| Invalid IP                            | Number of XML commands with an invalid IP address.                                                         |
| Cant use Switch IP                    | Redirection to a IP failed, possibly because the source IP has been NATted.                                |

| Parameter                             | Description                                                                                   |
|---------------------------------------|-----------------------------------------------------------------------------------------------|
| missing MAC address                   | Number of XML commands with a missing MAC address.                                            |
| Packets received from unknown clients | Number of packets received from unknown clients.                                              |
| Packets received with unknown request | Number of packets received with unknown request                                               |
| Requests Received/Success /Failed     | Total number of requests received / number of successful requests / number of failed requests |

## Command History

## show acl ace-table

```
show acl ace-table {ace <0-1999>}|{acl <1-2700>}
```

### Description

Show an access list entry (ACE) table for an access control list (ACL).

### Syntax

| Parameter    | Description                            |
|--------------|----------------------------------------|
| ace <0-1999> | Show a single ACE entry.               |
| acl <1-2700> | Show all ACE entries for a single ACL. |

### Example

The following example shows that there are eighteen access control entries for ACL 1.

```
(host) #show acl ace-table acl 1
1020: any any 1 0-65535 0-65535 f80001:permit
1021: any any 17 0-65535 53-53 f80001:permit
1022: any any 17 0-65535 8211-8211 f80001:permit
1023: any any 17 0-65535 8200-8200 f80001:permit
1024: any any 17 0-65535 69-69 f80001:permit
1025: any any 17 0-65535 67-68 f80001:permit
1026: any any 17 0-65535 137-137 f80001:permit
1027: any any 17 0-65535 138-138 f80001:permit
1028: any any 17 0-65535 123-123 f80001:permit
1029: user 10.6.2.253 255.255.255.255 6 0-65535 443-443 f80001:permit
1030: user any 6 0-65535 80-80 d1f90,0000 f80021:permit dnat
1031: user any 6 0-65535 443-443 d1f91,0000 f80021:permit dnat
1032: any any 17 0-65535 500-500 f80001:permit
1033: any any 50 0-65535 0-65535 f80001:permit
1034: any any 17 0-65535 1701-1701 f80001:permit
1035: any any 6 0-65535 1723-1723 f80001:permit
1036: any any 47 0-65535 0-65535 f80001:permit
1037: any any 0 0-0 0-0 f180000:deny
```

### Related Commands

Configure ACLs using the command [ip access-list session](#).

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                 |

| All platforms | Base operating system | Enable and Config mode on master controllers |

## show acl acl-table

```
show acl acl-table <1-2700>
```

### Description

Display information for a specified access control list (ACL).

### Syntax

| Parameter          | Description                                                           |
|--------------------|-----------------------------------------------------------------------|
| acl-table <1-2700> | Specify the number of the ACL for which you want to view information. |

### Example

The following example displays the ACL table for the controller.

```
(host) #show acl acl-table acl 1

AcLTable

ACL Type ACE Index Ace Count Name Applied
--- --- -
1 role 1459 18 logon 0

Total free ACE entries = 3591
Free ACE entries at the bottom = 2552
Next ACE entry to use = 1480 (table 1)
Ace entries reused 622 times
ACL count 64, tunnel acl 0

Ace entries reused 373 times
ACL count 64, tunnel acl 0
```

The output of this command displays the following parameters:

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACL       | Number of the specified ACL                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Type      | Shows the ACL type: <ul style="list-style-type: none"><li>• <b>role</b>: Access list is used to define a user role.</li><li>• <b>mac</b>: MAC ACLs allow filtering of non-IP traffic. This ACL filters on a specific source MAC address or range of MAC addresses.</li><li>• <b>session</b>: Session ACLs define traffic and firewall policies on the controller.</li><li>• <b>ether-type</b>: This type of ACL filters on the Ethertype field in the Ethernet frame header, and is useful when filtering non-IP traffic on a physical port.</li><li>• <b>standard</b>: Standard ACLs are supported for compatibility with router</li></ul> |

| Parameter                      | Description                                                                                                                                                                                                            |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | software from other vendors. This ACL permits or denies traffic based on the source address of the packet.                                                                                                             |
| ACE Index                      | Starting index entry for the ACL's access control entries                                                                                                                                                              |
| ACE count                      | Number of access control entries in the ACL                                                                                                                                                                            |
| Name                           | Name of the access control list                                                                                                                                                                                        |
| Applied                        | Number of times the ACL was applied to a role.                                                                                                                                                                         |
| Total free ACE entries         | The total number of free ACE entries. This includes available ACE entries at the bottom of the list, as well as free ACE entries in the middle of the table from previous access list entries that were later removed. |
| Free ACE entries at the bottom | The total number of free ACE entries at the bottom of the list.                                                                                                                                                        |
| Next ACE entry to use          | Ace number of the first free entry at the bottom of the list.                                                                                                                                                          |
| ACE entries reused             | For internal use only.                                                                                                                                                                                                 |
| ACL count                      | Total number of defined ACLs                                                                                                                                                                                           |
| Tunnel ACL                     | Total number of defined tunnel ACLs.                                                                                                                                                                                   |

The following example displays the ACL table for ACL 1.

```
(host) #show acl ace-table acl 1
Acl Table

ACL Type ACE Index Ace Count Name Applied
--- --- ----- -
1 role 1020 18 logon 0

Total free ACE entries = 3591
Free ACE entries at the bottom = 2991
Next ACE entry to use = 1041 (table 1)
Ace entries reused 373 times

ACL count 64, tunnel acl 0
```

## Related Commands

Configure ACLs using the command [ip access-list session](#).

## show acl hits

show acl hits

### Description

Show internal ACL hit counters.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to see the number of times an access control list defined a user's role, or traffic and firewall policies for a user session.

### Example

In the example below, the output of the *User Role ACL Hits* table is shown in two separate tables to allow the output to fit on a single page of this document. In the actual controller command-line interface, the *User Role ACL Hits* table is shown in a single, wide table.

```
(host) #show acl ace-table acl 1
User Role ACL Hits
```

| Role    | Policy     | Src  | Dst            |
|---------|------------|------|----------------|
| ----    | -----      | ---  | ---            |
| logon   | control    | any  | any            |
| logon   | control    | any  | any            |
| logon   |            | any  | any            |
| visitor | vp-control | any  | any            |
| visitor | vp-control | any  | any            |
| visitor | vp-access  | any  | any            |
| visitor | vp-access  | user | mswitch-master |
| visitor | vp-access  | any  | any            |

| User Role ACL Hits----- |        |             |          |            |       |

| Parameter   | Description                                                              |
|-------------|--------------------------------------------------------------------------|
| Dest/Opcode | The datapath destination ID.                                             |
| New Hits    | Number of ACL hits that occurred since this command was last issued.     |
| Total Hits  | Total number of ACL hits recorded since the controller last reset.       |
| Index       | Index number of the ACL.                                                 |
| ACL         | ACL number                                                               |
| ACE         | ACE number                                                               |
| New Hits    | Number of times the ACL was applied since this command was last issued.  |
| Total Hits  | Number of times the ACL was applied since the controller was last reset. |
| Index       | Index number of the ACL.                                                 |

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master controllers |

## show activate-service-whitelist

show activate-service-whitelist

### Description

This command displays the profile that allows the controller to synchronize its remote AP whitelist with the Dell Activate cloud-based services.

### Syntax

No parameters.

### Usage Guidelines

Use this command to view the credentials the controller uses to synchronize the remote AP whitelist with an Activate server.

### Example

The following example displays the Activate whitelist service settings on the controller:

```
(host) (config) # show activate-service-whitelist
(host) (activate-service-whitelist) #username user2 password pA$$w0rd whitelist-enable
activate-service-whitelist

Parameter Value

Activate Whitelist Service Enabled
Activate Login Username Marin
Activate Login Password *****
Periodic Interval for WhiteList Download 1
Add-Only Operation Enabled
```

### Related Commands

| All platforms | Base operating system | Config or enable mode on master or local controllers |

## show adp config

show adp config

### Description

Show Aruba Discovery Protocol (ADP) configuration settings.

### Syntax

No parameters.

### Example

The following example shows that the controller has all default settings for ADP.

```
(host) #show adp config
ADP Configuration

key value
--- -
discovery enable
igmp-join enable
igmp-vlan 0
```

The output of this command includes the following parameters:

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| discovery | Dell APs send out periodic multicast and broadcast queries to locate the master controller. If the APs are in the same broadcast domain as the master controller and ADP is enabled on the controller, the controller automatically responds to the APs' queries with its IP address.<br><br>This command shows whether ADP is enabled or disabled on the controller. |
| igmp-join | Shows whether the controller has enabled or disabled the sending of Internet Group Management Protocol (IGMP) join requests.                                                                                                                                                                                                                                          |
| igmp-vlan | ID of the VLAN to which IGMP reports are sent. If this value is set to 0, the controller will use the default route VLAN used.                                                                                                                                                                                                                                        |

### Command History

This command was available in ArubaOS 3.0.

## show adp counters

show adp counters

### Description

Show Aruba Discovery Protocol (ADP) counters.

### Syntax

No parameters.

### Example

The following example shows the ADP counter table for the controller.

```
(host) #show adp counters

IGMP Join Tx 1
IGMP Drop Tx 0
ADP Tx 0
ADP Rx 0
```

The output of this command includes the following parameters:

| Parameter    | Description                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------|
| IGMP Join Tx | Number of Internet Group Management Protocol (IGMP) join requests sent by the controller.           |
| IGMP Drop Tx | Number of Internet Group Management Protocol (IGMP) drop requests sent by the controller.           |
| ADP Tx       | Number of ADP responses sent to APs.                                                                |
| ADP Rx       | Number of multicast and broadcast queries received from APs trying to locate the master controller. |

### Command History

This command was available in ArubaOS 3.0.

| vlan                             | This command displays the status of all the disallowed AirGroup VLANs.<br>For more information, see <a href="#">show airgroup vlan on page 952</a>                                                                                                                                                                                                       |

## Example

Access the controller's command-line interface and use the following command to display the current status of the AirGroup configuration and AirGroup services configured on the controller:

```
(host) #show airgroup status
```

```
AirGroup Feature

Status

Enabled
AirGroup- MDNS Feature

Status

Enabled
AirGroup- DLNA Feature

Status

Enabled
AirGroup Location Discovery

Status

Enabled
AirGroup Active Wireless Discovery

Status

Disabled
AirGroup Enforce Registration

```

```

Status

Enabled
AirGroup IPV6 Support

Status

Disabled
AirGroup Service Information

Service Status

airplay Enabled
airprint Enabled
itunes Disabled
remotemgmt Disabled
sharing Disabled
chat Disabled
googlecast Disabled
DIAL Enabled
DLNA Media Enabled
DLNA Print Disabled
allowall Disabled

```

Use the following command to display the IP address of all the controllers participating in an AirGroup multi controller environment:

```

(host) #show airgroup domain

AirGroup Domains

Name Description IP-Address
---- -
Campus1 AirGroup_campus1 10.10.10.1
 11.11.11.1
Campus2 AirGroup_campus2 9.9.9.1
 8.8.8.1

Num domains:2

```

Use the following command to displays a list of AirGroup active-domains configured on the controller:

```

(host) #show airgroup active-domains

AirGroup Active-Domains

Domain Name Status

Campus1 Included
Campus2 Included

Num active-domains:2

```

## show airgroup active-domains

show airgroup active-domains

### Description

This command displays a list of AirGroup active-domains configured.

### Syntax

No parameters.

### Example

The following example displays a list of AirGroup active-domains configured:

```
(host) #show airgroup active-domains
```

```
AirGroup Active-Domains
```

```

```

```
Domain Name Status
```

```

```

```
Campus1 Included
```

```
Campus2 Included
```

```
Num active-domains:2
```

The output of this command includes the following parameters:

| Column      | Description                                                                |
|-------------|----------------------------------------------------------------------------|
| Domain Name | Displays the name of the domain.                                           |
| Status      | Displays the status of the domain if it is part of the active-domain list. |

### Command History:

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode          |
|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

## show airgroup blocked-queries

```
show airgroup blocked-queries [mdns|dlna]
```

### Description

This command displays the service ID that was queried but not available in the AirGroup service table.

### Syntax

| Parameter | Description                         | Range | Default |
|-----------|-------------------------------------|-------|---------|
| mdns      | Specifies the mDNS blocked queries. | —     | —       |
| dlna      | Specifies the DLNA blocked queries. | —     | —       |

### Example

The following example displays the service ID that was queried but not available in the AirGroup service table:

```
(host) #show airgroup blocked-queries
AirGroup dropped Query IDs

Service ID #query-hits

urn:schemas-upnp-org:device:InternetGatewayDevice:1 744
urn:schemas-microsoft-com:nhed:presence:1 9

10.15.121.240.in-addr.arpa 6
10.15.121.240.in-addr.arpa 3
Num dropped Query IDs:15
```

The output of this command includes the following parameters:

| Parameter   | Description                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service ID  | Displays the service ID that was queried but not available in the AirGroup service table. An AirGroup service ID is the name of a DLNA or mDNS service. |
| #query-hits | Displays the number of query hits for a service blocked by AirGroup.                                                                                    |

## Command History:

| ArubaOS 6.3 | Command introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode          |
|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

## show airgroup blocked-service-id

show airgroup blocked-service-id [mdns|dlna]

### Description

This command displays the list of blocked services.

### Syntax

| Parameter | Description                          | Range | Default |
|-----------|--------------------------------------|-------|---------|
| mdns      | Specifies the mDNS blocked services. | —     | —       |
| dlna      | Specifies the DLNA blocked services. | —     | —       |

### Example

The **airgroup service <servicename> disable** command disables an AirGroup service by blocking the service IDs for that service. When you enable an AirGroup service, service IDs of that service are enabled automatically. The following example displays the list of blocked services:

```
(host) (config) #show airgroup blocked-service-id
AirGroup Blocked Service IDs

Origin Service ID #response-hits

10.15.121.240 urn:schemas-upnp-org:service:RenderingControl:1 3196
10.15.121.240 urn:schemas-upnp-org:service:ContentDirectory:1 7048
10.15.121.240 urn:schemas-upnp-org:service:ConnectionManager:1 7082
10.15.121.240 _sleep-proxy._udp 34
10.15.121.240 _touch-able._tcp 12

10.15.121.240 _apple-mobdev._tcp 83
10.15.121.240 _workstation._tcp 8
10.15.121.240 _LifeLineDevice._tcp 8
10.15.121.240 _daap._tcp 16
10.15.121.240 _adisk._tcp 16
10.15.121.240 urn:schemas-emc-com:device:sohodevice:1 1007
10.15.121.240 urn:schemas-emc-com:service:sohoOSabout:1 1006
Num Blocked Service-ID:13
```

The output of this command includes the following parameters:

| Parameter      | Description                                                                         |
|----------------|-------------------------------------------------------------------------------------|
| Origin         | Displays the source IP address of the AirGroup server that advertises this service. |
| Service ID     | Displays the blocked service ID of the server.                                      |
| #response-hits | Displays the number of response messages received for this service ID.              |

## Command History:

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode          |
|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

## show airgroup cache entries

show airgroup cache <entries> [mdns|dlna|static]

### Description

This command displays the AirGroup mDNS and DLNA resource records in cache in a controller:

### Syntax

| Parameter | Description                                                        | Range | Default |
|-----------|--------------------------------------------------------------------|-------|---------|
| <entries> | Displays the AirGroup mDNS and DLNA resource records in the cache. | —     | —       |
| mdns      | Displays the mDNS cache entries.                                   | —     | —       |
| dlna      | Displays the DLNA cache entries.                                   | —     | —       |
| static    | Displays static cache entries.                                     | —     | —       |

### Example

The following example displays the AirGroup mDNS and DLNA resource records in cache in a controller:

```
(host) #show airgroup cache entries
```

Cache Entries

```

The output of this command includes the following parameters:

| Column      | Description                                                       |
|-------------|-------------------------------------------------------------------|
| Name        | Displays the name of the Service ID.                              |
| Type        | Displays the type of mDNS or DLNA record.                         |
| Class       | Displays the class of the record. This is usually IN.             |
| TTL         | Displays the time to live value of the service ID in seconds.     |
| Origin      | Displays the source IP of the AirGroup server.                    |
| Expiry      | Displays the expiry period of the mDNS or DLNA record in seconds. |
| Last Update | Displays the time stamp of the last cache update.                 |

### Command History:

| Release     | Modification        |

## show airgroup cppm

```
show airgroup cppm {<entries>|<server-group>}
```

### Description

This command displays the information for devices registered in ClearPass Policy Manager.

### Syntax

| Parameter      | Description                                 | Range | Default |
|----------------|---------------------------------------------|-------|---------|
| <entries>      | Displays the CPPM registration information. | —     | —       |
| <server-group> | Displays the Server Group information.      | —     | —       |

### Example

The following example displays the information for devices registered in ClearPass Policy Manager:

```
(host) #show airgroup cppm entries

ClearPass Guest Device Registration Information

Device device-owner shared location-id AP-name shared location-id AP-FQDN
shared location-id AP-group shared user-list shared group-list shared role-list CPPM-Req
CPPM-Resp

 Chemistry
 Biology
 1 1

Num CPPM Entries:3
```

The following example displays the server group information:

```
(host) (config) #show airgroup cppm server-group
Airgroup AAA Server Group

Name Inservice trim-FQDN match-FQDN
---- -
cppm Yes No
```

The output of this command includes the following parameters:

| Column                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device                      | Displays the MAC address of the AirGroup device.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| device-owner                | Displays the user name of the AirGroup device.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| shared location-id AP-name  | Displays the location ID based on an AP name.<br><b>NOTE:</b> The geographical location of AirGroup device can be tracked with respect to its RF neighbors. AirGroup devices connected to APs can be located based on nearby APs. In this case, an AirGroup user's AP could be any of the APs in AirGroup server's neighbor AP list, in addition to the server's own associated AP to receive the service advertisements from the corresponding AirGroup server. |
| shared location-id AP-FQLN  | Displays the location ID based on the Fully Qualified Location Name (FQLN) value of an AP.<br>AP FQLN is configured in the format<br><b>apname&gt;.&lt;floor&gt;.&lt;building&gt;.&lt;campus&gt;</b>                                                                                                                                                                                                                                                             |
| shared location-id AP-group | Displays the location ID based on the name of an AP group.                                                                                                                                                                                                                                                                                                                                                                                                       |
| shared user-list            | Displays one or more primary login IDs of an AirGroup user.                                                                                                                                                                                                                                                                                                                                                                                                      |
| shared group-list           | Displays one or more primary login IDs of an AirGroup user group.                                                                                                                                                                                                                                                                                                                                                                                                |
| shared role-list            | Displays the name of the controller role.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| CPPM-Req                    | Displays the number of requests sent by the controller to CPPM server to populate the policy details for the given client.                                                                                                                                                                                                                                                                                                                                       |
| CPPM-Resp                   | Displays the number of responses received from the CPPM server for policy details of the given client.                                                                                                                                                                                                                                                                                                                                                           |

## show airgroup cppm-server

```
show airgroup cppm-server {<aaa>|<query-interval>|radius <statistics>|rfc3576 <statistics>}
```

### Description

This command displays the information for devices registered in ClearPass Policy Manager.

### Syntax

| Parameter            | Description                                                                                                                                             | Range        | Default  |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------|
| cppm-server          | Displays the ClearPass Policy Manager server information.                                                                                               | —            | —        |
| <aaa>                | Displays the data for the ClearPass Policy Manager servers.                                                                                             | —            | —        |
| <query-interval>     | Specifies the value in which the AirGroup ClearPass Policy Manager query interval refreshes the ClearPass Policy Manager entries at periodic intervals. | 1 - 24 hours | 10 hours |
| radius <statistics>  | Displays the AirGroup RADIUS server statistics.                                                                                                         | —            | —        |
| rfc3576 <statistics> | Displays the AirGroup RFC3576 server statistics.                                                                                                        | —            | —        |

### Example

The following example displays the information for devices registered in ClearPass Policy Manager:

```
(host) #show airgroup cppm entries

ClearPass Guest Device Registration Information

Device device-owner shared location-id AP-name shared location-id AP-FQDN
shared location-id AP-group shared user-list shared group-list shared role-list CPPM-Req
CPPM-Resp

cc:3a:61:b1:4a:cc lecturer
 lecturer2 1 1
c4:85:08:a2:15:1b N/A
 DEPT1 1 1
00:1e:65:2d:ae:44 N/A
 Physics 1 1
 Chemistry
 Biology

Num CPPM Entries:3
```

The following example displays the server group information:

```
(host) (config) #show airgroup cppm server-group
Airgroup AAA Server Group

Name Inservice trim-FQDN match-FQDN
---- -

```

cppm Yes No

The output of this command includes the following parameters:

| Column                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device                      | Displays the MAC address of the AirGroup device.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| device-owner                | Displays the user name of the AirGroup device.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| shared location-id AP-name  | Displays the location ID based on an AP name.<br><b>NOTE:</b> The geographical location of AirGroup device can be tracked with respect to its RF neighbors. AirGroup devices connected to APs can be located based on nearby APs. In this case, an AirGroup user's AP could be any of the APs in AirGroup server's neighbor AP list, in addition to the server's own associated AP to receive the service advertisements from the corresponding AirGroup server. |
| shared location-id AP-FQLN  | Displays the location ID based on the Fully Qualified Location Name (FQLN) value of an AP.<br>AP FQLN is configured in the format<br><b>apname&gt;.&lt;floor&gt;.&lt;building&gt;.&lt;campus&gt;</b>                                                                                                                                                                                                                                                             |
| shared location-id AP-group | Displays the location ID based on the name of an AP group.                                                                                                                                                                                                                                                                                                                                                                                                       |
| shared user-list            | Displays one or more primary login IDs of an AirGroup user.                                                                                                                                                                                                                                                                                                                                                                                                      |
| shared group-list           | Displays one or more primary login IDs of an AirGroup user group.                                                                                                                                                                                                                                                                                                                                                                                                |
| shared role-list            | Displays the name of the controller role.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| CPPM-Req                    | Displays the number of requests sent by the controller to ClearPass Policy Manager server to populate the policy details for the given client.                                                                                                                                                                                                                                                                                                                   |
| CPPM-Resp                   | Displays the number of responses received from the ClearPass Policy Manager server for policy details of the given client.                                                                                                                                                                                                                                                                                                                                       |

## Command History:

| Release     | Modification                                           |
|-------------|--------------------------------------------------------|
| ArubaOS 6.3 | Command introduced.                                    |
| ArubaOS 6.4 | The <b>shared group-list</b> parameter was introduced. |

## Command Information

|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

## show airgroup domain

show airgroup domain

### Description

This command displays a list of AirGroup domains configured.

### Syntax

No parameters.

### Example

Use this command to view a list of AirGroup domains configured:

```
(host) #show airgroup domain
```

AirGroup Domains

```

Name Description IP-Address
---- -
Campus1 AirGroup_campus1 10.15.121.240
 11.11.11.1
Campus2 AirGroup_campus2 9.9.9.1
 8.8.8.1
```

Num domains:2

The output of this command includes the following parameters:

| Column      | Description                                 |
|-------------|---------------------------------------------|
| Name        | Displays the name of the AirGroup domain.   |
| Description | Displays a short description of the domain. |
| IP-Address  | Displays the controller or VRRP IP address. |

### Command History:

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode          |
|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

## show airgroup internal-state statistics

show airgroup internal-state <statistics> [mdns|dlna]

### Description

This command displays the statistics of packets sent and received per second by a controller:

### Syntax

| Parameter  | Description                             | Range | Default |
|------------|-----------------------------------------|-------|---------|
| statistics | Displays the Packets sent and received. | —     | —       |
| dlna       | Displays the DLNA statistics.           | —     | —       |
| mdns       | Displays the mDNS statistics.           | —     | —       |

### Example

The following example displays the packets sent and received per second by the controller:

```
(host) (config) #show airgroup internal-state statistics
```

#### PAPI Messages

## show airgroup global-credits

show airgroup global credits

### Description

This command displays the current and user configured global tokens assigned to query and response packets.

### Syntax

No parameters.

### Example

In an AirGroup network, AirGroup devices generate excess mDNS query and response packets. Using airgroup global-credits command, the AirGroup controller restricts these packets by assigning tokens. The controller processes these mDNS packets based on this token value. The controller rejects any packets beyond this token limit. The token renews every 15 seconds. The renewal interval is not a configurable parameter.

In the following example, the AirGroup controller restricts the number of query packets to 450 and response packets to 90 from AirGroup devices in a time frame of 15 seconds.

```
(host)(config) #airgroup global-credits 450 90
```

The following command displays tokens assigned to query and response packets. It displays the current and user configured global tokens.

```
(host) #show airgroup global-credits
```

Global Credits - Default

| Type             | Value |
|------------------|-------|
| Query Packets    | 450   |
| Response Packets | 90    |

Global Credits - Current

| Type             | Value |
|------------------|-------|
| Query Packets    | 400   |
| Response Packets | 85    |

The output of this command includes the following parameters:

| Column | Description                            |
|--------|----------------------------------------|
| Type   | Displays the mDNS or DLNA packet type. |
| Value  | Displays the limit of the token.       |

## show airgroup multi-controller-table

```
show airgroup multi-controller-table [mdns|dlna] [verbose]
```

### Description

This command displays the IP address of all the controllers participating in an AirGroup multi-controller environment.

### Syntax

| Parameter | Description                                          | Range | Default |
|-----------|------------------------------------------------------|-------|---------|
| mdns      | Displays the mDNS statistics.                        | —     | —       |
| dlna      | Displays the DLNA statistics.                        | —     | —       |
| verbose   | Displays additional information in a tabular format. | —     | —       |

### Example

All controllers communicate with each other based on the multi-controller table in an AirGroup cluster. This table is a combination of controllers specified in each domain, as part of active-domains. Use the following command to view the IP address of all the controllers participating in an AirGroup multi-controller environment:

```
(host) (config) #show airgroup multi-controller-table
```

```
AirGroup Multi-Controller-Table
```

```

IP-Address Type Request with Tag Tx Unicast Response with tag Tx Raw Response Tx
Request with Tag Rx Unicast Response with tag Rx Raw Response Rx

10.15.121.240 mDNS 43 0 0
0 0 0 0
10.15.121.240 mDNS 43 0 0
0 0 0 0
Num IP-Address:2
```

The output of this command includes the following parameters:

**Table 7:** *show airgroup multi-controller-table*

| Column                       | Description                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP-Address                   | Displays the IP address of all the controllers participating in an AirGroup multi-controller environment.                                                               |
| Type                         | Displays the type of record.                                                                                                                                            |
| Request with Tag Tx          | Displays the number of AirGroup multi-controller queries transmitted with meta-tag information by the controller to other controllers in its multi-controller domain.   |
| Unicast Response with tag Tx | Displays the number of AirGroup multi-controller responses transmitted with meta-tag information by the controller to other controllers in its multi-controller domain. |
| Raw Response Tx              | Displays the number of mDNS or DLNA responses transmitted by the controller in response to multi-controller queries from other controllers in the domain.               |
| Request with Tag Rx          | Displays the number of AirGroup multi-controller queries received with meta-tag information by the controller from other controllers in its multi-controller domain.    |
| Unicast Response with tag Rx | Displays the number of AirGroup multi-controller responses received with meta-tag information by the controller from other controllers in its multi-controller domain.  |
| Raw Response Rx              | Displays the number of mDNS or DLNA responses received by the controller in response to multi-controller queries sent by the controller.                                |

## show airgroup servers

show airgroup servers [mdns|dlna] [verbose]

### Description

This command displays the status of the AirGroup server (Apple TV, AirPrint Printer, Google ChromeCast, and so on) in a controller:

### Syntax

| Parameter | Description                                          | Range | Default |
|-----------|------------------------------------------------------|-------|---------|
| mdns      | Displays the mDNS servers.                           | —     | —       |
| dlna      | Displays the DLNA servers.                           | —     | —       |
| verbose   | Displays additional information in a tabular format. | —     | —       |

### Example

The following example displays the status of the AirGroup server (Apple TV, AirPrint Printer, Google ChromeCast, and so on) in a controller:

```
(host) (config) #show airgroup servers
AirGroup Servers

MAC IP Type Host Name Service VLAN Wired/Wireless Role
Group Username AP-Name
--- --
00:25:11:3c:a3:5a 10.15.121.240 mDNS nandan allowall 64 N/A
00:25:90:cc:6e:b3 10.15.121.240 DLNA allowall 64 N/A
d4:be:d9:1f:83:c9 10.15.121.240 DLNA allowall 1 N/A
DLNA Media
00:1e:65:2d:ae:44 10.15.121.240 DLNA allowall 3 wireless authenticated Mathematics user1 104_
AP105
DLNA Media
Num Servers: 4, Max Servers: 2000.
```

The output of this command includes the following parameters:

| Column    | Description                                      |
|-----------|--------------------------------------------------|
| MAC       | Displays the MAC address of the AirGroup server. |
| IP        | Displays the IP address of the AirGroup server.  |
| Type      | Displays the type of the device.                 |
| Host Name | Displays the host name of the AirGroup server.   |

| Column           | Description                                                                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service          | Displays the AirGroup service hosted by the server.                                                                                                                                                                                                                            |
| VLAN             | Displays the VLAN ID of the AirGroup server.                                                                                                                                                                                                                                   |
| Wired/Wireless   | Indicates if the AirGroup server is connected to a Wired LAN or Wireless LAN.<br><b>NOTE:</b> The column displays <b>Wired</b> when the server is connected to an untrusted wired port. When the server is connected to a trusted wired port, the column displays <b>N/A</b> . |
| Role             | Displays the user role of the AirGroup server.                                                                                                                                                                                                                                 |
| Group            | Displays the group of the AirGroup user.                                                                                                                                                                                                                                       |
| Username         | Displays the user name of the AirGroup server.                                                                                                                                                                                                                                 |
| AP-Name          | Displays the AP name to which the AirGroup server is connected.                                                                                                                                                                                                                |
| Rec-dropped      | Displays the number of queries dropped from the AirGroup server.                                                                                                                                                                                                               |
| Rec-filtered     | Displays the number of queries filtered as a result of the policies.                                                                                                                                                                                                           |
| Rec-responded    | Displays the number of queries responded from the AirGroup server.                                                                                                                                                                                                             |
| Last-query       | Displays the time stamp of the last query received.                                                                                                                                                                                                                            |
| CPPM-Req         | Displays the number of requests sent by the controller to the CPPM server to populate the policy details for the given AirGroup server.                                                                                                                                        |
| CPPM-Rsp         | Displays the number of responses received from the CPPM server for policy details of the given AirGroup server.                                                                                                                                                                |
| CoA              | Displays the number of Change of Authorization (CoA) requests sent by CPPM to notify the controller about the registered device.                                                                                                                                               |
| CPPM Dev-Added   | Displays the last time stamp the controller learned about the CPPM policy information.                                                                                                                                                                                         |
| CPPM Dev-Deleted | Displays the last time stamp when this device entry was deleted from the CPPM table.                                                                                                                                                                                           |

## show airgroup status

show airgroup status

### Description

This command displays the global settings of the AirGroup configuration and AirGroup services configured in the WLAN controller.

### Syntax

No parameters.

### Example

Issue this command to view the global settings of the AirGroup configuration and AirGroup services configured in the WLAN controller.

```
(host) #show airgroup status
```

```
AirGroup Feature

Status

Enabled
AirGroup- MDNS Feature

Status

Enabled
AirGroup- DLNA Feature

Status

Enabled
AirGroup Location Discovery

Status

Enabled
AirGroup Active Wireless Discovery

Status

Disabled
AirGroup Enforce Registration

Status

Disabled
AirGroup IPV6 Support

Status

Disabled
AirGroup Service Information

Service Status

airplay Enabled
airprint Enabled
itunes Disabled
```

```

remotemgmt Disabled
sharing Disabled
chat Disabled
googlecast Disabled
DIAL Enabled
DLNA Media Enabled
DLNA Print Disabled
allowall Enabled
test Enabled
airplay Enabled

```

The output of this command includes the following parameters:

| Column                               | Description                                                                                                                                                                                                                                    |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AirGroup Feature Status              | Displays the status of AirGroup in the controller.                                                                                                                                                                                             |
| AirGroup - MDNS Feature              | Displays the status of mDNS.                                                                                                                                                                                                                   |
| AirGroup - DLNA Feature              | Displays the status of DLNA.                                                                                                                                                                                                                   |
| AirGroup Location Discovery          | Displays the status of AirGroup location discovery.<br>If enabled, AirGroup user can see shared devices based on the user's proximity.                                                                                                         |
| AirGroup Active Wireless Discovery   | Displays the status of wireless AirGroup server discovery.<br>If enabled, AirGroup controller actively sends refresh requests to discover wireless servers. If disabled, the controller sends refresh requests to wired AirGroup servers only. |
| AirGroup Enforce Registration Status | Displays the status of AirGroup server registration with the CPPM server.                                                                                                                                                                      |

## show airgroup users

```
show airgroup users [mdns|dlna] [verbose]
```

### Description

This command displays the user table.

### Syntax

| Parameter | Description                                          | Range | Default |
|-----------|------------------------------------------------------|-------|---------|
| mdns      | Displays the mDNS users.                             | —     | —       |
| dlna      | Displays the DLNA users.                             | —     | —       |
| verbose   | Displays additional information in a tabular format. | —     | —       |

### Example

The following example displays the AirGroup users:

```
(host) (config) #show airgroup users
AirGroup Users

MAC IP Type Host Name VLAN Role Group Username AP-Name
--- --
d4:be:d9:1f:83:c9 10.15.121.240 DLNA 1
Num Users: 1, Max Users: 6000.
```

The output of this command includes the following parameters:

| Column    | Description                                                   |
|-----------|---------------------------------------------------------------|
| MAC       | Displays the MAC address of the AirGroup user.                |
| IP        | Displays the IP address of the AirGroup user.                 |
| Type      | Displays the type of the AirGroup device.                     |
| Host Name | Displays the host name of the AirGroup user.                  |
| VLAN      | Displays the VLAN ID of the AirGroup user.                    |
| Role      | Displays the user role of the AirGroup user.                  |
| Group     | Displays the group of the AirGroup user.                      |
| Username  | Displays the user name of the AirGroup user.                  |
| AP-Name   | Displays the AP name to which the AirGroup user is connected. |

| Column           | Description                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Rec-dropped      | Displays the number of queries dropped from the AirGroup user.                                                                          |
| Rec-filtered     | Displays the number of queries filtered as a result of the policies.                                                                    |
| Rec-responded    | Displays the number of queries responded from the AirGroup user.                                                                        |
| Last-query       | Displays the time stamp of the last query received.                                                                                     |
| CPPM-Req         | Displays the number of requests sent by the controller to the CPPM server to populate the policy details for the given AirGroup client. |
| CPPM-Rsp         | Displays the number of responses received from the CPPM server for policy details of the given AirGroup client.                         |
| CoA              | Displays the number of Change of Authorization (CoA) requests sent by CPPM to notify the controller about the registered device.        |
| CPPM Dev-Added   | Displays the last time stamp when the controller learned about the CPPM policy information.                                             |
| CPPM Dev-Deleted | Displays the last time stamp when this device entry was deleted from the CPPM table.                                                    |

### Command History:

## show airgroup vlan

show airgroup vlan

### Description

This command displays the status of the disallowed AirGroup VLANs.

### Syntax

No parameters.

### Example

The following example displays the status of the disallowed AirGroup VLANs:

```
(host) #show airgroup vlan
```

VLAN Table

-----

| Vlan-Id | IP-Address    | IPv6-Address        | Status     |
|---------|---------------|---------------------|------------|
| -----   | -----         | -----               | -----      |
| 1       | 10.15.121.240 | 2001:1:1:16::165/64 | Allowed    |
| 2       | 0.0.0.0       | 2002:1:1:17::165/64 | Disallowed |
| 3       | 10.15.121.240 | 2003:1:1:18::165/64 | Allowed    |
| 4       | 10.15.121.240 | 2004:1:1:19::165/64 | Allowed    |

Num Vlans:4

The output of this command includes the following parameters:

| Column       | Description                                                     |
|--------------|-----------------------------------------------------------------|
| Vlan-Id      | Displays the identification number of the AirGroup VLAN.        |
| IP-Address   | Displays the IP address of the VLAN interface.                  |
| IPv6-Address | Displays the IPv6 address of the VLAN interface.                |
| Status       | Displays the status of AirGroup access to devices for the VLAN. |

### Command History:

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

### Command Information

## show airgroupservice

```
show airgroupservice [dlna|mdns] [verbose]
```

### Description

This command displays the service details of all AirGroup services in the controller.

### Syntax

| Parameter       | Description                                                                           | Range | Default |
|-----------------|---------------------------------------------------------------------------------------|-------|---------|
| airgroupservice | This command displays the service details of all AirGroup services in the controller. | —     | —       |
| mdns            | Displays the mDNS services.                                                           | —     | —       |
| dlna            | Displays the DLNA services.                                                           | —     | —       |
| Verbose         | Displays additional services information in a tabular format.                         | —     | —       |

### Example

The following example displays the service details of all AirGroup services in the controller. In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, the output appears in a single, long table.

```
(host) (config) #show airgroupservice
```

```
AirGroupService Details
```

| Service                            | Description       | Status   | Disallowed-Role | Disallowed-VLAN | ID                                                                                           |

| voip-only           | Show AP information filtered by associated/active VoIP clients.                                                                                                                                                                                              |

## Usage Guidelines

This command displays details for all active APs on the controller. If an AP on your network *does not* appear in this table, it may have been classified as an inactive AP for any of the following reasons:

- The AP is configured with a missing or incorrect VLAN. (For example, the AP is configured to use a tunneled SSID of VLAN 2 but the controller doesn't have a VLAN 2.)
- The AP has an unknown AP group.
- The AP has a duplicate AP name.
- An AP with an external antenna is not provisioned with external antenna gain settings.
- Both radios on the AP are disabled.
- No virtual APs are defined on the AP.
- The AP has profile errors. Issue the command "show profile errors" for details.
- The GRE tunnel between the AP and the controller was blocked by a firewall after the AP became active.
- The AP is temporarily down while it is upgrading its software. The AP will become active again after upgrading.
- An AP has conflicting configuration settings. For example, if the AP system profile on a single radio dual-band AP configures the radio uses 802.11g, but the virtual AP profile on the AP is set to use 802.11a, the AP might not appear to be active.

## Example

The output of the command in the example below shows that the controller sees an active AP. In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it will appear in a single, long table.

```
(host)# show ap active
```

### Active AP Table

| Name    | Group   | IP Address  | 11g Clients | 11g Ch/EIRP/MaxEIRP | 11a Clients |
|---------|---------|-------------|-------------|---------------------|-------------|
| APname1 | default | 10.3.15.107 | 0           | AP:HT:1/15/21.5     | 0           |

| 11a Ch/EIRP/MaxEIRP | AP Type | Flags | Uptime | Outer IP |
|---------------------|---------|-------|--------|----------|
| AP:HT:44/15/21      | 125     | 1E2   | 5m:48s | N/A      |

Flags: 1 = 802.1x authenticated AP; 2 = Using IKE version 2;  
A = Enet1 in active/standby mode; B = Battery Boost On; C = Cellular;  
D = Disconn. Extra Calls On; E = Wired AP enabled; F = AP failed 802.1x authentication;  
H = Hotspot Enabled; K = 802.11K Enabled; L = Client Balancing Enabled; M = Mesh;  
N = 802.11b protection disabled; P = PPPOE; R = Remote AP;  
S = AP connected as standby; X = Maintenance Mode;  
a = Reduce ARP packets in the air; d = Drop Mcast/Bcast On; u = Custom-Cert RAP;  
i = Provisioned as Indoor; o = Provisioned as Outdoor;  
r = 802.11r Enabled  
Q = DFS CAC timer running

The output of this command includes the following information:

| Column              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | <ul style="list-style-type: none"> <li>• r = 802.11r Enabled</li> <li>• Q = DFS CAC timer running</li> </ul>                                                                                                                                                                                                      |
| Uptime   | Number of hours, minutes and seconds since the last controller reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .                                                                                                                                                                                  |
| Outer IP | The outer IP address of a remote AP (RAP) is used to establish an IPsec VPN tunnel to the terminating master controller. The RAP acquires an outer IP address from the locally connected network, usually via DHCP. (A RAP is typically behind a NAT device whose public IP is seen as the outer ip for the RAP). |

## Command History

### Syntax

| Parameter  | Description              |
|------------|--------------------------|
| <ap-group> | The name of an AP group. |

### Usage Guidelines

Issue this command without the optional **<ap-group>** parameter to display the entire AP group list, including profile status for each profile. Include an AP group name to display detailed configuration information for that AP group profile.

### Example

This first example shows that the controller has nine configured AP groups. The **Name** column lists the names of all configured AP groups. the **Profile Status** column indicates whether the AP group is predefined. (User-defined profiles will not have an entry in the **Profile Status** column.)

```
(host) #show ap-group
AP group List

Name Profile Status
---- -
corp-office
branch-office-am
corp
corp1
Corp1-AM
Corp1-AM-Ch11
Corp1-AM-Ch6
corp1-AP85
corp1-lab

Total: 9
```

Include an AP group name to display a complete list of configuration settings for that profile. The example below shows settings for the AP group **corp1**.

```
(host) #show ap-group corp1
AP group "corp1"

Parameter Value

Virtual AP corp1-guest
Virtual AP corp1-wpa2
802.11a radio profile default
802.11g radio profile profile1-g
Wired AP profile default
```

```

Ethernet interface 0 link profile default
Ethernet interface 1 link profile default
AP system profile corp1344
VoIP Call Admission Control profile default
802.11a Traffic Management profile N/A
802.11g Traffic Management profile N/A
Regulatory Domain profile corp1344-channel-profile
SNMP profile default
RF Optimization profile handoff-aggressive
RF Event Thresholds profile default
IDS profile ids-low-setting
Mesh Radio profile default
Mesh Cluster profile N/A

```

The output of this command includes the following parameters:

| Parameter                           | Description                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------|
| Virtual AP                          | Virtual AP profile that which configures a specified WLAN.                       |
| 802.11a radio profile               | Profile that defines 802.11a radio settings for the AP group.                    |
| 802.11g radio profile               | Profile that defines 802.11g radio settings for the AP group.                    |
| Wired AP profile                    | Profile that defines wired port settings for APs assigned to the AP group.       |
| Ethernet interface 0 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| Ethernet interface 1 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| AP system profile                   | Name of the AP system profile for the AP group.                                  |
| VoIP Call Admission Control profile | Name of the AP system profile for the AP group.                                  |
| 802.11a Traffic Management profile  | Name of the 802.11a WLAN traffic management profile for the AP group.            |
| 802.11g Traffic Management profile  | Name of the 802.11g WLAN traffic management profile for the AP group.            |
| Regulatory Domain profile           | Name of the regulatory domain profile for the AP group.                          |
| SNMP profile                        | Name of the SNMP profile for the AP group.                                       |
| RF Optimization profile             | Name of the RF optimization profile for the AP group.                            |
| RF Event Thresholds profile         | Name of the RF event thresholds profile for the AP group.                        |
| IDS profile                         | IDS profile for the AP group.                                                    |

| Parameter            | Description                                    |
|----------------------|------------------------------------------------|
| Mesh Radio profile   | Mesh radio profile assigned to the AP group.   |
| Mesh Cluster profile | Mesh cluster profile assigned to the AP group. |

## Related Commands

Configure AP group settings using the command [ap-group](#).

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap-name

show ap-name [<ap-name>]

### Description

Show a list of AP names. Include the **<ap-name>** parameter to display detailed configuration information for that AP.

### Syntax

| Parameter | Description        |
|-----------|--------------------|
| <ap-name> | The name of an AP. |

### Example

This first example shows that the controller has eight registered APs. The **Name** column lists the names of each registered AP. Note that APs are all user-defined, so they will not have an entry in the **Profile Status** column.

```
(host) #show ap-name
AP name List

Name Profile Status
---- -
mp3
sw-ad-W-AP124-11
sw-ad-W-AP125-13sw-ad-W-AP125-15sw-ad-W-AP125-17sw-ad-W-AP125-18sw-ad-W-AP125-19sw-ad-W-AP125-3
Total: 8
```

Include an AP name to display a complete list of configuration settings for that AP. If the AP has default settings, the value may appear as N/A. The AP in the example below has all default profile settings.

```
(host) #show ap-group corp1
AP name "mp3"

Parameter Value

Virtual AP N/A
Excluded Virtual AP N/A
802.11a radio profile N/A
802.11g radio profile N/A
Wired AP profile N/A
Ethernet interface 0 link profile N/A
Ethernet interface 1 link profile N/A
AP system profile N/A
VoIP Call Admission Control profile N/A
802.11a Traffic Management profile N/A
802.11g Traffic Management profile N/A
Regulatory Domain profile N/A
RF Optimization profile N/A
RF Event Thresholds profile N/A
IDS profile N/A
Mesh Radio profile N/A
Mesh Cluster profile N/A
Excluded Mesh Cluster profile N/A
```

The output of this command includes the following parameters:

| Parameter                           | Description                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------|
| Virtual AP                          | Virtual AP profile that which configures a specified WLAN.                       |
| Excluded Virtual AP                 | Excludes the specified mesh cluster profile from this AP.                        |
| 802.11a radio profile               | Profile that defines 802.11a radio settings for the AP.                          |
| 802.11g radio profile               | Profile that defines 802.11g radio settings for the AP.                          |
| Wired AP profile                    | Profile that defines wired port settings for APs assigned to the AP.             |
| Ethernet interface 0 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| Ethernet interface 1 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| AP system profile                   | Name of the AP system profile for the AP.                                        |
| VoIP Call Admission Control profile | Name of the AP system profile for the AP.                                        |
| 802.11a Traffic Management profile  | Name of the 802.11a WLAN traffic management profile for the AP group.            |
| 802.11g Traffic Management profile  | Name of the 802.11g WLAN traffic management profile for the AP.                  |
| Regulatory Domain profile           | Name of the regulatory domain profile for the AP.                                |
| RF Optimization profile             | Name of the RF optimization profile for the AP.                                  |
| RF Event Thresholds profile         | Name of the RF event thresholds profile for the AP.                              |
| IDS profile                         | IDS profile for the AP.                                                          |
| Mesh Radio profile                  | Mesh radio profile assigned to the AP.                                           |
| Mesh Cluster profile                | Mesh cluster profile assigned to the AP.                                         |
| Excluded Mesh Cluster profile       | Excludes the specified mesh cluster profile from this AP.                        |

## show ap allowed-channels

```
show ap allowed-channels
ap-name <ap-name>
country-code <country-code> [ap-type <ap-type>]
ip-addr <ip-addr>
```

### Description

This command shows the allowed channels on a specific AP or country code.

### Syntax

| Parameter                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>                                  | Name of an AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| country-code <country-code><br>[ap-type <ap-type>] | <p>Specify a country code to display allowed channels for that country. If you include the optional <b>ap-type &lt;ap-type&gt;</b> parameter, the output displays allowed channels for the specified AP type in that country code.</p> <p>The <b>&lt;ap-type&gt;</b> parameter is the two or three digit model number of the AP, such as <b>135</b> for the W-AP135, or <b>225</b> for the W-AP225. Remote APs, such as the W-IAP3WN, require that you enter the prefix RAP- before the model number. If the AP model number includes an alphabetic suffix, such as the W-AP175AC, you must enter the suffix after the model number. Note that this suffix may be case-sensitive.</p> |
| <ip-addr>                                          | IP address of an AP, in dotted-decimal format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Usage Guidelines

Specify the country code for your controller during initial setup. Changing the country code causes the valid channel lists to be reset to the defaults for that country.

### Examples

The output of this example shows all allowed channels for the country code **US**.

```
(host)# show ap allowed-channels US

Allowed Channels for Country Code "US"

PHY Type Allowed Channels

802.11g (indoor) 1 2 3 4 5 6 7 8 9 10 11
802.11a (indoor) 36 40 44 48 149 153 157 161 165
802.11g (outdoor) 1 2 3 4 5 6 7 8 9 10 11
802.11a (outdoor) 149 153 157 161 165
802.11g 40MHz (indoor) 1-5 2-6 3-7 4-8 5-9 6-10 7-11
802.11a 40MHz (indoor) 36-40 44-48 149-153 157-161
802.11g 40MHz (outdoor) 1-5 2-6 3-7 4-8 5-9 6-10 7-11
802.11a 40MHz (outdoor) 149-153 157-161
```

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show ap ap-group

```
show ap ap-group {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

### Description

Show the AP group settings for an individual AP.

### Syntax

| Parameter         | Description                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                     |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                |

### Usage Guidelines

Use this command to display the contents of an AP's group profile. If you know the name of the group whose profile settings you want to view, use the command **show ap-group <profile-name>**. To view a list of all configured AP groups on your controller, use the command **show ap-group**.

### Examples

In the example below, the output of this command lists the profiles associated with the AP group **Corp13**.

```
(host) #show ap ap-group AP2
AP group "corp13"

Parameter Value

Virtual AP corp13-guest
Virtual AP corp13-ether-wpa2
Virtual AP corp13-ether-voip
Virtual AP corp13-ether-comm
802.11a radio profile default
802.11g radio profile default
Wired AP profile default
Ethernet interface 0 link profile default
Ethernet interface 1 link profile default
AP system profile corp13
VoIP Call Admission Control profile default
802.11a Traffic Management profile N/A
802.11g Traffic Management profile N/A
Regulatory Domain profile corp13-channel-profile
SNMP profile default
RF Optimization profile handoff-aggressive
RF Event Thresholds profile default
IDS profile ids-low-setting
Mesh Radio profile default
Mesh Cluster profile N/A
```

## Related Commands

## show ap arm client-match history

```
show ap arm client-match history
 advanced
 client-mac <macaddr>
```

### Description

If the client match feature is enabled, the output of this command shows the history of AP association changes triggered by the client match feature.

### Syntax

| Parameter            | Description                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| advanced             | Provides additional client-match history information, including: <ul style="list-style-type: none"><li>• <b>Eff_Signal</b></li><li>• <b>EIRP</b></li><li>• <b>ESSID</b></li></ul> |
| client-mac <macaddr> | MAC address of a client for which you want to view a history of AP association changes triggered by the client match feature.                                                     |

### Example

The following command displays information on the Client Match history.

```
(AP-7010) # show ap arm client-match history
```

```
S: Source, T: Target, A: Actual
Unit of Roam Time: second
Unit of Signal: dBm
```

```
ARM Client match History
```

```

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap arm client-match neighbors

```
show ap arm client-match neighbors
 ap-name <name>
 ip-addr <ipaddr>
 ip6-addr <ipaddr>
```

### Description

If the client match feature is enabled, the output of this command displays the BSSID of other APs seen by clients in the select AP's RF neighborhood.

### Syntax

| Parameter         | Description                                                       |
|-------------------|-------------------------------------------------------------------|
| ap-name <name>    | View neighboring clients for an AP with a specified name          |
| ip-addr <ipaddr>  | View neighboring clients for an AP with a specified IP address.   |
| ip6-addr <ipaddr> | View neighboring clients for an AP with a specified IPv6 address. |

### Usage Guidelines

Issue this command to view a list of other APs seen by clients currently associated to the selected AP.

### Example

The example below indicates that the clients currently associated to the AP can detect signals from three other APs.

```
(host)#show ap arm client-match neighbors ap-name <ap-name>
```

Client View

```

BSSID Channel

d8:c7:c8:37:84:70 132
d8:c7:c8:88:b6:50 132
d8:c7:c8:37:84:10 124
Num Neighbors:3
```

The output of this command includes the following parameters:

| Parameter             | Description                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------|
| Client MAC            | AP name of the AP from which the client can detect a signal.                            |
| Signal                | Signal strength, in dBm, of the probe request received from Client                      |
| Assoc                 | A "Y" in this field indicates that the client is currently associated to that AP radio. |
| Sec since last heard  | Time elapsed since the AP radio heard from the client.                                  |
| Sec since last repor- | Time elapsed since the AP radio heard from the client.                                  |

| Parameter  | Description                                              |
|------------|----------------------------------------------------------|
| ted        |                                                          |
| Last heard | Date and time at which the AP last heard from the client |

## Related Commands

Use the following command to enable the client match feature:

- [rf arm-profile](#) client-match

The following commands display additional statistics for the client match feature:

- [show ap arm client-match probe-report](#)
- [show ap arm client-match restriction-table](#)
- [show ap arm virtual-beacon-report](#)
- [show ap arm client-match unsupported](#)
- [show ap arm client-match summary](#)
- [show ap arm client-match history](#)

## Command History

Introduced in ArubaOS 6.3.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap arm client-match probe-report

```
show ap arm client-match probe-report
 ap-name <name>
 ip-addr <ipaddr>
 ip6-addr <ip6-addr>
 assoc
 phy-type 802.11a|802.11b|80211g
```

### Description

If the client match feature is enabled, the output of this command displays the client probe report for the specified AP.

### Syntax

| Parameter           | Description                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <name>      | Name of the AP for which you want to view a client report.                                                                                        |
| ip-addr <ip-addr>   | IPv4 address of an AP for which you want to view a client probe report.                                                                           |
| ip6-addr <ip6-addr> | IPv6 address of an AP for which you want to view a client probe report.                                                                           |
| assoc               | Show information for associated clients only.                                                                                                     |
| phy-type            | Show information for one of the following phy types: <ul style="list-style-type: none"><li>• 802.11a</li><li>• 802.11b</li><li>• 80211g</li></ul> |

### Usage Guidelines

APs using the client match feature maintain a table of clients that have sent probe requests, and the signal-to-noise ratio (SNR) of the frame the AP received from the client. The AP sends these reports to the controller ever 30 seconds, and the controller uses the information in these reports to steer each client to its optimal AP.

### Example

```
(host)#show ap arm client-match probe-report ap-name <ap-name>
```

```
AP Client Probe Report for Wifi0
```

```

Client MAC Signal Assoc Sec since Sec since Last heard

```

The output of this command includes the following parameters:

| Parameter               | Description                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------|
| Client MAC              | AP name of the AP from which the client can detect a signal.                            |
| Signal                  | Signal strength, in dBm, of the probe request received from the client.                 |
| Assoc                   | A "Y" in this field indicates that the client is currently associated to that AP radio. |
| Sec since last heard    | Time elapsed since the AP radio heard from the client.                                  |
| Sec since last reported | Time elapsed since the AP radio heard from the client.                                  |
| Last heard              | Date and time at which the AP last heard from the client                                |

## Related Commands

Use the following command to enable the client match feature:

- [rf arm-profile client-match](#)

The following commands display additional statistics for the client match feature:

- [show ap arm client-match neighbors](#)
- [show ap arm client-match restriction-table](#)
- [show ap arm virtual-beacon-report](#)
- [show ap arm client-match unsupported](#)
- [show ap arm client-match summary](#)
- [show ap arm client-match history](#)

## Command History

Introduced in ArubaOS 6.3.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap arm client-match restriction-table

```
show ap arm client-match restriction-table
 ap-name <name>
 ip-addr <ipaddr>
 ip6-addr <ip6-addr>
```

### Description

If the client match feature is enabled, the output of this command displays the list of clients that the client match feature has restricted from the specified AP.

### Syntax

| Parameter           | Description                                                                      |
|---------------------|----------------------------------------------------------------------------------|
| ap-name <name>      | Name of the AP for which you want to view the list of restricted clients         |
| ip-addr <ipaddr>    | IPv4 address of the AP for which you want to view the list of restricted clients |
| ip6-addr <ip6-addr> | IPv6 address of the AP for which you want to view the list of restricted clients |

### Usage Guidelines

If the client match feature is enabled, the controller sends APs a list of clients that should not be allowed to associate to that AP. These lists of restricted clients help the client associate to the best AP, by preventing the client from associating with a sub-optimal AP radio. The output of this command shows a list of all clients that were ever blacklisted from the specified AP.

### Example

```
(host)#show ap arm client-match restriction-table ap-name <ap-name>
```

```
Client Restriction Table for Wifi0

Client MAC Time last restricted Restricted(Cur/Last)

24:77:03:32:88:ec Wed Apr 10 03:51:00 2014 0

PS deauth Probe(home/scan/bc_ssid) Auth(home/scan)

- 2/0/no 4/0

Time since last restriction(sec) Radio Bssid

18603 00:1a:1e:89:c0:d0

Client Restriction Table for Wifi1

Client MAC Time last restricted Restricted(Cur/Last)

24:77:03:32:7b:cc Wed Apr 10 03:47:16 2014 0

PS deauth Probe(home/scan/bc_ssid) Auth(home/scan)

0/0/no 0/0/no 0/0
```

```

Time since last restriction(sec) Radio Bssid

3866 00:1a:1e:89:c0:c0

```

The output of this command includes the following parameters:

| Parameter                  | Description                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Client MAC                 | Displays the MAC address of the client that Client Match is attempting to steer.                                                         |
| Time last restricted       | Displays the date and time at which the client was last steered in the vicinity of this radio.                                           |
| Restricted(Cur/Last)       | A "1" in this field indicates that the client is currently in the process of being steered to another radio.                             |
| PS deauth                  | Displays if the client is in power save mode when client match is attempting to steer the client.                                        |
| Probe(home/scan/bc_ssid)   | Displays the number of probe requests received on home channel, AP scanning, and SSID broadcast probe.                                   |
| Auth(home/scan)            | Displays the number of probe requests received on home channel and AP scanning for 802.11 authentication frames.                         |
| Time since last restricted | Display the time (in seconds) since the client was last steered in the vicinity of this radio.                                           |
| Radio Bssid                | Displays the unique hard-wireless MAC address of the AP. A unique BSSID applies to each frequency— 802.11a and 802.11g—used from the AP. |

## show ap arm client-match summary

show ap arm client-match summary [client-mac <macaddr>] [[advanced]

### Description

If the client match feature is enabled, the output of this command shows the history of AP association changes triggered by the client match feature.

### Syntax

| Parameter            | Description                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| client-mac <macaddr> | MAC address of a client for which you want to view a history of AP association changes triggered by the client match feature. |
| advanced             | Display advanced debugging information. Include this parameter only under the supervision of Dell support.                    |

### Example

The following command displays information on the Client Match summary.

```
(host) #show ap arm client-match summary
```

SM: Sticky Moves, BM: Bandsteer Moves, LM: Load Balance Moves, VM: VHTsteer Moves, T: Total, S: Success, R: Reject, TO: Timeout

Client Match Summary

```

## show ap arm client-match unsupported

```
show ap arm client-match unsupported
```

### Description

If the client match feature is enabled, the output of this command displays a list of clients that failed to be steered to a more optimal AP, and the reason the initial steering request was triggered,.

### Syntax

No parameters.

### Usage Guidelines

The controller also keeps track of the number of times the client match feature failed to steer a client to a different radio, and the reason that each steer attempt was triggered. If the client match feature attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as unsteerable for that specific trigger.

### Example

```
(host) #show ap arm client-match unsupported
```

```
Client Match Unsteerable Clients
```

```

MAC Unsteerable Flags Last Steer Time Expiry Time Total
steers/successful
--- -
--
S: Sticky L: Load Balance V: VHT steer B: Bandsteer I: IOS T: Temporary

Total Unsteerable Clients:0
```

The output of this command includes the following parameters:

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| MAC               | MAC address of the client that could not be steered to a different AP radio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Unsteerable Flags | <p>The client is marked unsteerable under specific client steer triggers. These triggers include:</p> <ul style="list-style-type: none"><li>• <b>Sticky:</b> A mobile roaming client was staying associated (sticking) to a sub-optimal AP for too long.</li><li>• <b>Band steer:</b> A dual-band capable client was steered toward a 5GHz radio on a dual-band AP.</li><li>• <b>Load Balance:</b> Client match moved the client to a different AP, based upon the load on APs in the client's RF neighborhood, and the SNR levels the client detected. from each underutilized AP.</li><li>• <b>IOS:</b> An IOS device is temporarily prevented from steering to avoid blacklisting the ESS.</li><li>• <b>Temporary:</b> A client is temporarily prevented from steering after undergoing a successful band steer, then reverting back to a 2.4GHz radio.</li></ul> |

| Parameter               | Description                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------|
| Last Steer Time         | Timestamp showing the date and time the client match feature failed to associate the client to a different AP radio. |
| Expiry Time             | The amount of time before a client steer attempt expires.                                                            |
| Total steers/successful | The total number of client steer attempts, and the number of successful client steer attempts.                       |

## Related Commands

Use the following commands to enable the client match feature:

- [rf arm-profile client-match](#)

The following commands display additional statistics for the client match feature:

- [show ap arm client-match probe-report](#)
- [show ap arm client-match neighbors](#)
- [show ap arm client-match restriction-table](#)
- [show ap arm virtual-beacon-report](#)
- [show ap arm client-match unsupported](#)
- [show ap arm client-match summary](#)
- [show ap arm client-match history](#)

## show ap arm history

```
show ap arm history {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}]
```

### Description

For each interface on an AP, show the history of channel and power changes due to Adaptive Radio Management (ARM).

### Syntax

| Parameter         | Description                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show ARM history for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show ARM history for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show ARM history for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                         |

### Examples

Adaptive Radio Management (ARM) can automatically change channel and power levels based on a number of factors such as noise levels and radio interference. The output of the **show ap arm history** command shows you an AP's channel and power changes over time, and the reason why those changes took place.

```
host)# (ethersphere-lms3) #show ap arm history ap-name AP-16
Interface :wifi0
ARM History
```

```

## show ap arm neighbors

```
show ap arm neighbors {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

### Description

Show the ARM settings for an AP's neighbors.

### Syntax

| Parameter         | Description                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                     |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                |

### Examples

The output of this command shows ARM neighbor information for AP name **ap70\_1**.

```
(host)# show ap arm neighbors ap-name ap70_1
```

```
BSSID: BSSID of discovered radio
ESSID: ESSID of discovered radio/Src BSSID through which the neighbor is discovered
Channel: Channel of operation of discovered radio
SNR: Signal to noise ratio of discovered radio
tx-power: Tx Power of discovered radio (if known)
PL: Path loss to discovered radio (using txpower and SNR)
AP Flags: Active: Discovered using OTA updates
 Passive: Discovered using passive scan
 Indirect: Two hop neighbors discovered using neighbors OTA update
Last Update: Timestamp when last OTA update was received (total OTA updates)
```

## show ap arm rf-summary

```
show ap arm rf-summary {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>} [verbose]
```

### Description

Show the state and statistics for all channels being monitored by an individual AP.

### Syntax

| Parameter         | Description                                                                                                                    |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show channel data for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show channel data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show channel data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                         |
| verbose           | (Optional) Include the channel quality history for all channels on the AP's radios in the output of this command.              |

### Examples

The output of this command shows detailed information for the individual channels being monitored and statistics for each AP interface. Use this command to verify an AP's RF health, or to determine why multiple APs in the same area are on the same channel.

```
(host) #show ap arm rf-summary ap-name W-AP125

## show ap arm scan-times

```
show ap arm scan-times {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

### Description

Shows channel scan times for an individual AP and information on the channel being scanned.

### Syntax

| Parameter         | Description                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show channel scan data for an AP with a specific name.                                                      |
| bssid <bssid>     | Show channel scan data for a specific Basic Service Set Identifier (BSSID) on an AP.                        |
| ip-addr <ip-addr> | Show channel scan data for an AP with a specific IP address. Enter the IP address in dotted-decimal format. |

### Examples

The output of this command shows scan times for every channel on W-AP225.

```
(host) #show ap arm scan-times ap-name W-AP225
```

Channel Scan Time

| channel           | assign-time(ms) | scans-attempted | scans-rejected | scans-deferred | dos-scans | flags  |

183591
```

The output of this command includes the following parameters:

| Parameter        | Description                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| channel          | Displays the channels in the group.                                                                                                                                  |
| assign-time (ms) | The cumulative time spent on the channel.                                                                                                                            |
| scans-attempted  | The number of times an AP attempted to scan a channel.                                                                                                               |
| scans-rejected   | The number of times an AP attempted to scan a channel, but was unable to scan because the scan was halted by the power save, VoIP aware, or load aware ARM features. |
| scans-deferred   | The number of times an AP deferred to scan a channel due to an event such as a radar detection.                                                                      |
| dos-scans        | The number of times an AP visited the channel to contain a rogue device.                                                                                             |
| flags            | Displays additional information about the channel. The flags key is displayed at the bottom of the Channel Scan Time table.                                          |
| group_width      | The channel width of the group.                                                                                                                                      |
| timer-tick       | The timer-tick of the last scan.                                                                                                                                     |

## show ap arm split-scan-history

```
show ap arm split-scan-history {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

### Description

Show scanning information for a "split-scan", where ARM performs an additional scans on each channel within a 40 MHz channel pair or 80 MHz channel set.

### Syntax

| Parameter         | Description                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show scan data for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show scan data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show scan data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                         |

### Usage Guidelines

Starting with ArubaOS 6.3.1, if ARM reports a high noise floor on a channel within a 40 MHz channel pair or 80 MHz channel set, ARM performs an additional 20 MHz scan on each channel within that channel pair or set, to determine the actual noise floor of each affected channel. This allows ARM to avoid assigning the overutilized channel, while still allowing channel assignments to the other unaffected channels in that channel pair or set.

### Examples

The output of this command shows information about one split-scan performed on channel 161E.

```
(host)# show ap arm split-scan-history ap-name 1242-ac
Interface :wifi0
Split Scan History

Time of setup Channel scan Number of Split scans Noise Floor

2013-10-08 03:11:40 161E 4 69
Interface :wifi1
```

The output of this command includes the following parameters:

| Parameter             | Description                                                                          |
|-----------------------|--------------------------------------------------------------------------------------|
| Time of setup         | Timestamp showing the date and time the scan was performed                           |
| Channel Scan          | The channel pair or channel set scanned                                              |
| Number of Split Scans | The number of times ARM performed an additional split scan.                          |
| Noise Floor           | Noise floor recorded on the primary channel within that channel pair or channel set. |

## Command History

Introduced in ArubaOS 6.3.1

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap arm state

```
show ap arm state [ap-name <ap-name>|dot11a|dot11g|ip-addr <ip-addr>]
```

### Description

Display Adaptive Radio Management (ARM) information for an individual AP's neighbors, or show all available data for any neighboring AP using an 802.11a or 802.11g radio type.

### Syntax

| Parameter         | Description                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show aggregate ARM Neighbor Information for a specific AP.                                                                       |
| dot11a            | Show aggregate ARM Neighbor Information for all APs using an 802.11a radio.                                                      |
| dot11g            | Show aggregate ARM Neighbor Information for all APs using an 802.11g radio.                                                      |
| ip-addr <ip-addr> | Show aggregate ARM Neighbor Information for a AP with a specific IP address by entering its IP address in dotted-decimal format. |

### Usage Guidelines

The output of the **show ap arm state** command shows 802.11a and 802.11g information for all APs. Include an AP name or IP address to show data for just a single AP, or use the **dot11a** or **dot11g** keywords to show data for all APs using that radio type.

### Examples

The output of this command shows 802.11a information for all neighboring APs.

```
(host)# show ap arm state
```

```
show ap arm state ap-name AP49
```

```
AP-1249:10.100.139.233:52:21:26-Edge:disable : Client Density:13
```

```
Neighbor Data
```

```

```

| Name | IP Address     | SNR | Assignment | Neighbor Density |
|------|----------------|-----|------------|------------------|
| AP42 | 10.100.139.249 | 41  | 52/21      | 13/17/100/76     |
| AP09 | 10.100.139.224 | 22  | 56/21      | 3/5/23/60        |
| AP48 | 10.100.139.241 | 36  | 60/21      | 9/11/69/81       |

The output of this command includes the following information:

| Column     | Description          |
|------------|----------------------|
| Name       | Name of an AP.       |
| IP address | IP address of an AP. |

| Column           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SNR              | Signal-to-noise (SNR) ratio. SNR is the power ratio between an information signal and the level of background noise.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Assignment       | The AP's current channel assignment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Neighbor Density | <p>The neighborhood density for the specified AP is listed with the values A/B/C/D, where:</p> <ul style="list-style-type: none"> <li>• A= Number of the AP's clients heard in the AP neighbor's client list</li> <li>• B= Number of clients in AP neighbor's client list</li> <li>• C= Density percentage, (AP clients heard in in the AP neighbor client list / AP client density * 100).</li> <li>• D= Density Percentage (AP clients heard in the AP neighbor's client list / neighbor client density * 100)</li> </ul> |

## Command History

## show ap arm status

```
show ap arm status {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

### Description

Issue this command under the supervision of Dell support to display detailed debugging Adaptive Radio Management (ARM) information and ARM status counters for an individual AP.

### Syntax

| Parameter         | Description                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show ARM status for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show ARM status for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show ARM status for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                         |

### Usage Guidelines

The output of the **show ap arm status** command shows internal ARM status counters that can be used by Dell support for debugging purposes.

### Command History

| Version     | Description        |
|-------------|--------------------|
| ArubaOS 6.3 | Command introduced |

### Command Information

| Platforms     | Licensing             | Command Mode                                |

## show ap arm virtual-beacon-report

```
show ap arm virtual-beacon-report
 ap-name <name>
 ip-addr <ipaddr>
 ip6-addr <ip6-addr>
 phy-type 80211a|80211b|80211g
```

### Description

If the client match feature is enabled, the output of this command displays the virtual beacon report for an AP with a specific IP or MAC address.

### Syntax

| Parameter          | Description                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <name>     | Name of an AP for which you want to view a virtual beacon report.                                                                                                                  |
| ip-addr <ipaddr>   | IPv4 address of an AP for which you want to view a virtual beacon report.                                                                                                          |
| ip6-addr <ip6addr> | IPv6 address of an AP for which you want to view a virtual beacon report.                                                                                                          |
| phy-type           | Display virtual beacon report data for an AP radio with one of the following phy types: <ul style="list-style-type: none"><li>• 80211a</li><li>• 80211b</li><li>• 80211g</li></ul> |

### Usage Guidelines

If the client match feature is enabled, the controller sends APs a list of clients that should not be allowed to associate to that AP.

### Example

```
(host) #show ap arm virtual-beacon-report ap-name 1263-ac
```

```
Interface:wifi0
Rx VBR Reports:683
```

```
Client MAC:24:77:03:cf:fa:5c
Dual band:Yes
Active Voice:No
Steerable:Yes
Dual network capable:No
Current Association:6c:f3:7f:e7:5a:b0
```

```
Virtual Beacon Report
```

```

## show ap association

```
show ap association [ap-name <ap-name>|ap-group <ap-group>|bssid <bssid>|channel
<channel>|client-mac <client-mac>|essid <essid>|ip-addr <ip-addr> |ip6-addr <ip-addr>|phy
{a|b|g}|voip-only]
```

### Description

Show the association table for an AP group or for an individual AP.

### Syntax

| Parameter               | Description                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group>     | Show AP associations for a specific AP group. You can also include the <b>channel</b> , <b>essid</b> or <b>voip-only</b> keywords to further filter the output of this command.                                                                                 |
| ap-name <ap-name>       | Show AP associations for a specific AP. You can also include the <b>essid</b> , <b>phy</b> or <b>voip-only</b> keywords to further filter the output of this command.                                                                                           |
| bssid <bssid>           | Show the AP associations for an specific AP Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                                                                     |
| channel <channel>       | Show AP associations for an individual channel by specifying the channel for which you want to view information.                                                                                                                                                |
| client-mac <client-mac> | Show the AP associations for a specific MAC address by entering the MAC address of a client for which you want to view association information.                                                                                                                 |
| essid <essid>           | Show AP associations for an Extended Service Set Identifier (ESSID). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |
| ip-addr <ip-addr>       | Show AP associations for a specific AP by entering an IP address in dotted-decimal format. You can also include the <b>essid</b> , <b>phy</b> or <b>voip-only</b> keywords to further filter the output of this command.                                        |
| ip6-addr <ip-addr>      | Ahow AP association for a specific AP by entering an IPv6 address.                                                                                                                                                                                              |
| phy                     | Include the <b>phy</b> [ <b>a</b>   <b>b</b>   <b>g</b> ] keywords to show associations for a specific 802.11 radio type, either 802.11a, 802.11b or 802.11g.                                                                                                   |
| voip-only               | Show VoIP client information only.                                                                                                                                                                                                                              |

### Usage Guidelines

Use this command to check if user is connected to an AP. This command validates whether the client is associated and indicates the last AP to which it was connected. If the flags column shows an 'A', the client is

currently associated with that AP. Alternately, if the client is not currently associated, the AP with the smallest value of association time is the last AP used by the client.

## Example

Use the **show ap association client-mac** command to verify that a user has associated with an AP, or to determine last AP to which the client was connected. The output of this command in the example below shows the association table for the client with the MAC address 00:13:fd:5c:7c:59. If the flags column in the output of this command shows an 'A', the client associated last to that AP. Alternately, the AP with the smallest value of association time is the last AP to which the client had associated.

In the example below, the output of this command has been broken into two separate tables to better fit this page. In the actual output of the command, this information is shown in a single, wide table.

```
(host) #show ap association client-mac 00:13:fd:5c:7c:59

Flags: W: WMM client, A: Active, R: RRM client
PHY Details: HT: High throughput; 20: 20MHz; 40: 40MHzss: spatial streams

The output of this command includes the following information:

| Column | Description                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------|
| Name   | Name of an AP                                                                                                                            |
| bssid  | The AP Basic Service Set Identifier (BSSID)                                                                                              |
| mac    | MAC address of the AP                                                                                                                    |
| auth   | This column displays a <b>y</b> if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an <b>n</b> . |
| assoc  | This column displays a <b>y</b> if the AP has been configured for 802.11 association frame types. Otherwise, it displays an <b>n</b> .   |
| aid    | 802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.                                     |

| Column      | Description                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| l-int       | Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second. |
| essid       | Name that uniquely identifies the AP's Extended Service Set Identifier (ESSID).                                                                                       |
| vlan-id     | Identification number of the AP's VLAN.                                                                                                                               |
| tunnel-id   | Identification number of the AP's tunnel.                                                                                                                             |
| assoc. time | Amount of time the client has associated with the AP, in the format <i>hours:minutes:seconds</i> .                                                                    |
| num assoc   | Number of clients associated with the AP.                                                                                                                             |
| flags       | This column displays any flags for this AP. The list of flag abbreviations is included in the output of the <b>show ap association</b> command.                       |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap association remote

```
show ap association remote [ap-name <ap-name>|ap-group <ap-group>|bssid <bssid>|channel <channel>|essid <essid>
```

### Description

Display the association table for an individual AP or group of APs in bridge mode.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show AP associations for a specific remote AP.                                                                                                                                                                                                                         |
| ap-group <ap-group> | Show AP associations for a specific group of remote APs.                                                                                                                                                                                                               |
| bssid <bssid>       | Show the AP associations for an specific AP Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                                                                            |
| channel <channel>   | Show remote AP associations for a specific channel.                                                                                                                                                                                                                    |
| essid <essid>       | Show remote AP associations for an Extended Service Set Identifier (ESSID). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |

### Examples

The output of the command below shows the association table for clients in the AP group **group1**.

```
show ap association remote ap-group group1
```

Flags: W: WMM client, A: Active, R: RRM client

PHY Details: HT: High throughput; 20: 20MHz; 40: 40MHz ss: spatial streams

1

The output of this command includes the following information:

| Column | Description   |
|--------|---------------|
| Name   | Name of an AP |

| Column      | Description                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid       | The AP Basic Service Set Identifier (BSSID)                                                                                                                           |
| mac         | MAC address of the AP                                                                                                                                                 |
| auth        | This column displays a <b>y</b> if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an <b>n</b> .                              |
| assoc       | This column displays a <b>y</b> if the AP has been configured for 802.11 association frame types. Otherwise, it displays an <b>n</b> .                                |
| aid         | 802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.                                                                  |
| l-int       | Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second. |
| essid       | Name that uniquely identifies the AP's Extended Service Set Identifier (ESSID).                                                                                       |
| vlan-id     | Identification number of the AP's VLAN.                                                                                                                               |
| tunnel-id   | Identification number of the AP's tunnel.                                                                                                                             |
| phy         | The RF band in which the AP should operate:<br><b>g</b> = 2.4 GHz<br><b>a</b> = 5 GHz                                                                                 |
| assoc. time | Amount of time the client has associated with the AP, in the format <i>hours:minutes:seconds</i> .                                                                    |
| num assoc   | Number of clients associated with the AP.                                                                                                                             |
| flags       | This column displays any flags for this AP. The list of flag abbreviations is included in the output of the <b>show ap association remote</b> command.                |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap authorization-profile

show ap authorization-profile [<profile-name>]

### Description

This command shows information for AP authorization profiles.

### Syntax

| Parameter      | Description                                          |
|----------------|------------------------------------------------------|
| <profile-name> | The name of an an existing AP authorization profile. |

### Usage Guidelines

The AP authorization profile specifies which configuration should be assigned to a remote AP that has been provisioned but not yet authenticated at the remote site. By default, these yet-unauthorized APs are put into the temporary AP group **authorization-group** and assigned the predefined profile **NoAuthApGroup**. This configuration allows the user to connect to an unauthorized remote AP via a wired port then enter a corporate username and password. Once a valid user has authorized the AP and the remote AP will be marked as authorized on the network. The remote AP will then download the configuration assigned to that AP by it's permanent AP group.

Issue this command without the **<profile-name>** option to display the entire AP authorization profile list, including profile status and the number of references to each profile. Include a profile name to display the authorization group defined for that profile.

### Examples

The following example lists all AP authorization profiles. The **References** column lists the number of other profiles with references to that authorization profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined AP authorization profiles will not have an entry in the **Profile Status** column.

```
(host) #show ap authorization-profile
```

```
AP Authorization profile List
```

```

```

```
Name References Profile Status
```

```

```

```
Noauthprofile 1
```

```
default 2 Predefined (editable)
```

```
Total:2
```

To display the authentication group for an individual profile, include the <profile> parameter. The example below shows the profile details for the AP authorization profile **Default**.

```
(host) #show ap authorization-profile default
```

```
AP Authorization profile "default" (Predefined (editable))
```

```

```

```
Parameter Value
```

```

```

```
AP authorization group NoAuthApGroup
```

The output of the **show ap authorization** command includes the following parameters:

| Parameter              | Value                                                                                |
|------------------------|--------------------------------------------------------------------------------------|
| AP authorization group | Name of a configuration profile to be assigned to the group unauthorized remote APs. |

## show ap blacklist-clients

show ap blacklist-clients

### Description

Show a list of clients that have been denied access.

### Usage Guidelines

Use the [stm](#) CLI command to add or remove users from a blacklist. Additionally, the **dot1x authentication**, **VPN authentication** and **MAC authentication** profiles allow you to automatically blacklist a client if machine authentication fails.

### Examples

The output of this command shows that the controller has a single user-defined blacklisted client.

```
(host)# show ap blacklist-clients
```

Blacklisted Clients

```

STA reason block-time(sec) remaining time(sec)
--- -
00:1E:37:CB:D4:52 user-defined 45 3555
```

The output of this command includes the following information:

| Column | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## show ap bss-table

```
show ap bss-table [ap-name <ap-name>|bssid <bssid>|counters|essid <essid>|ip-addr <ip-addr>|ip6-addr <ip-addr>|port <port>\<slot>|standby>]
```

### Description

Show an AP's Basic Service Set (BSS).

### Syntax

| Parameter          | Description                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>  | Show the BSS table for a specific AP.                                                                                                                                                                                                                         |
| bssid <bssid>      | Show the BSS table for an specific AP Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                                                                         |
| counters           | Show the BSS table for a specific AP by providing the counter.                                                                                                                                                                                                |
| essid <essid>      | Show the BSS table for an Extended Service Set Identifier (ESSID). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |
| ap-name            | Filters by AP name.                                                                                                                                                                                                                                           |
| ip-addr            | Filters by IP address.                                                                                                                                                                                                                                        |
| ip6-addr           | Filters by IPv6 address.                                                                                                                                                                                                                                      |
| port               | Filter on port in <slot>/<module>/<port> format.                                                                                                                                                                                                              |
| ip-addr <ip-addr>  | Show the BSS table for a specific AP by entering an IP address in dotted-decimal format.                                                                                                                                                                      |
| ip6-addr <ip-addr> | Show the BSS table for a specific AP by providing the IPv6 address.                                                                                                                                                                                           |
| port <port>/<slot> | Show the BSS table for a specific port and slot on an AP. The slot and port numbers should be separated by a forward slash (/).                                                                                                                               |
| standby            | Show the BSS table for a specific AP in standby mode.                                                                                                                                                                                                         |

### Usage Guidelines

The output of the **show ap bss-table** command shows the Dell AP BSS table for all APs. To filter this information and view BSS table data for an individual AP or a specific port and slot number, include the **ap-name**, **bssid**, **essid**, **ip-addr** or **port** keywords.

### Example

The output of this command shows the BSS table for the seven active APs using the controller.

```
(host) #show ap bss-table
```

fm (forward mode): T-Tunnel, S-Split, D-Decrypt Tunnel, B-Bridge (s-standard, p-persistent, b-backup, a-always), n-anyspot

Aruba AP BSS Table

```

bss ess port ip phy type ch/EIRP/max-EIRP cur-cl ap

Num Associations:2

The output of this command includes the following information:

| Column           | Description                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bss              | The AP Basic Service Set Identifier (BSSID). This is usually the MAC address of the AP                                                                                                             |
| ess              | The AP Extended Service Set Identifier (ESSID).                                                                                                                                                    |
| s/p              |                                                                                                                                                                                                    |
| ip               | IP address of an AP.                                                                                                                                                                               |
| phy              | An AP radio type. Possible values are: <ul style="list-style-type: none"> <li>a—802.11a</li> <li>a-HT—802.11a high throughput</li> <li>g— 802.11g</li> <li>g-HT—802.11g high throughput</li> </ul> |
| type             | Shows whether the AP is working as an access point (AP) or air monitor (AM).                                                                                                                       |
| ch/EIRP/max-EIRP | Radio channel used by the AP/current effective Isotropic Radiated Power (EIRP) /maximum EIRP.                                                                                                      |
| cur-cl           | Current number of clients on the AP.                                                                                                                                                               |
| ap name          | Name of the AP.                                                                                                                                                                                    |

| Column    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in-t (s)  | Number of seconds that an AP has been inactive.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| tot-t     | An AP's total active time, in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| mtu       | Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.                                                                                                                                                                                                                                                                                                                        |
| acl-state | <p>An access control list (ACL) can enable or disable an AP during specific time ranges.</p> <ul style="list-style-type: none"> <li>• <b>Disabled:</b> An ACL with time restrictions is currently <b>disabled</b> (so the AP is enabled).</li> <li>• <b>Enabled:</b> An ACL with time restrictions is currently <b>enabled</b> (so the AP is disabled).</li> <li>• This data column will display a dash (-) if no ACLs are currently configured for the AP.</li> </ul> |
| acl       | The access control list (ACL) id is displayed based on the role set.                                                                                                                                                                                                                                                                                                                                                                                                   |
| fm        | <p>Listed below are the forwarding modes available:</p> <ul style="list-style-type: none"> <li>• <b>T-Tunnel</b></li> <li>• <b>S-Split</b></li> <li>• <b>D-Decrypt Tunnel</b></li> <li>• <b>B-Bridge</b> (s-standard, p-persistent, b-backup, a-always)</li> </ul> <p><b>NOTE:</b> If anyspot is enabled for a particular BSSID, then it is represented as <b>n</b> in the <b>Forwarding Mode</b> parameter.</p>                                                       |

| ArubaOS 3.0     | Command introduced.                                                                                                                                                                                                                                            |
| ArubaOS 6.2     | <p>Introduced support for the following parameters:</p> <ul style="list-style-type: none"> <li>• <b>essid &lt;ap-name&gt;</b></li> <li>• <b>essid &lt;ip-addr&gt;</b></li> <li>• <b>essid &lt;ip6-addr&gt;</b></li> <li>• <b>essid &lt;port&gt;</b></li> </ul> |
| ArubaOS 6.4.3.0 | The <b>n-anyspot</b> forwarding-mode flag was introduced.                                                                                                                                                                                                      |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap bw-report

```
show ap bw-report {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

### Description

Show the bandwidth reporting table for a specific AP.

### Syntax

| Parameter         | Description                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show bandwidth data for an AP with a specific name.                                                                                                         |
| bssid <bssid>     | Show bandwidth data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show bandwidth data for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                                |

### Examples

The output of the following command shows the Dell AP bandwidth table for an AP with the IP address 192.0.2.170.

```
show ap bw-report ip-addr 192.0.2.170
```

```
Bandwidth report for AP "AL16" radio 0
```

```

Virtual AP Allocated Share Actual Share Offered Load Delivered Load

corp1344-guest 0% 0% 0 kbps 0 kbps
corp1344-ethersphere-wpa2 0% 0% 0 kbps 0 kbps
Average Throughput:0 kbps
```

```
Bandwidth report for AP "AL16" radio 1
```

```

Virtual AP Allocated Share Actual Share Offered Load Delivered Load

corp1344-guest 0% 0% 0 kbps 0 kbps
corp1344-ethersphere-voip 0% 0% 0 kbps 0 kbps
corp1344-ethersphere-vocera 0% 0% 0 kbps 0 kbps
Average Throughput:0 kbps
```

The output of this command includes the following information for all radios on the AP:

| Column             | Description                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual AP         | Name of a Virtual AP                                                                                                                                |
| Allocated Share    | Maximum percentage of total bandwidth available to that Virtual AP.                                                                                 |
| Actual Share       | Actual percentage of total bandwidth used by a Virtual AP.                                                                                          |
| Offered Load       | Attempted throughput for the Virtual AP, in kbps.                                                                                                   |
| Delivered Load     | Actual throughput for the Virtual AP, in kbps. This value may be less than the offered load if the Virtual AP has used all its allocated bandwidth. |
| Average Throughput | Average throughput for the virtual AP, in kbps.                                                                                                     |

## Command History

## show ap client status

```
show ap client status <client-mac>
```

### Description

Show the current status of a specific client.

### Syntax

| Parameter    | Description             |
|--------------|-------------------------|
| <client-mac> | MAC address of a client |

### Examples

The output of the command shows the status of an individual client in the STA (station) table.

```
(host) #show ap client status 00:13:fd:42:32:38
```

STA Table

```

bssid auth assoc aid l-int essid vlan-id tunnel-id

00:1a:1e:a3:02:c9 y y 7 10 corp-wpa2 65 0x10c0
State Hash Table

```

```
bssid state reason

00:1a:1e:a3:02:c9 auth-assoc 0
```

The output of this command includes the following information:

| Column | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid  | Basic Service Set ID (BSSID) of the client.                                                                                                                           |
| auth   | This column displays a <b>y</b> if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an <b>n</b> .                              |
| assoc  | This column displays a <b>y</b> if the AP has been configured for 802.11 association frame types. Otherwise, it displays an <b>n</b> .                                |
| aid    | Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second. |
| l-int  | Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second. |
| ssid   | Extended Service Set ID (ESSID) of the client.                                                                                                                        |

| Column    | Description                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vlan-id   | VLAN ID of the VLAN used by the client                                                                                                                                                       |
| tunnel-id | Identification number for the tunnel                                                                                                                                                         |
| state     | If the client has been both authorized and associated, this data column will display <b>auth-assoc</b> . If the client has only been authorized, this data column will display <b>auth</b> . |
| Reason    | If the client failed to authenticate, this data column lists the reason code for 802.11 authentication failure                                                                               |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap client trail-info

show ap client trail-info [<client-mac>]

### Description

Use this command to show client activity for debugging purposes.

### Syntax

| Parameter    | Description                |
|--------------|----------------------------|
| <client-mac> | MAC address of the client. |

### Usage Guidelines

Use this command to view client activity, including reasons for client deauthentication, the history of how that client moved between different APs, and any alerts or errors encountered by that client. Include the optional **<client-mac>** parameter to show additional details for that specific client.

Client-trail information may be available for clients that are no longer active, as the controller saves a limited amount of client data in a buffer. The maximum number of clients for which trail-information is saved is determined by the controller platform. Each controller saves client trail information for twice the number of active clients supported by that controller platform.

### Examples

The following example shows client-trail information for all clients associated with the controller.

```
(host) #show ap client trail-info
```

Client Trail Info

| MAC               | BSSID             | ESSID | AP-name | VLAN | Deauth-reason | Alert        |
|-------------------|-------------------|-------|---------|------|---------------|--------------|
| 00:11:22:33:44:55 | 00:0b:86:11:22:33 | corp  | ap1     | 10   | AP-Down       | Auth-failure |
| 00:12:32:43:54:65 | 00:0b:86:11:22:34 | corp  | ap2     | 10   | AP-Down       | Auth-failure |
| 00:31:42:53:64:75 | 00:0b:86:11:22:35 | corp  | ap3     | 10   | AP-Down       | Auth-failure |

This example shows client-trail information for a specific user that includes information about AP alerts and mobility trails.

```
(host) #show ap client trail-info 00:11:22:33:44:55
```

| MAC               | BSSID                | ESSID | AP-name              | VLAN | Deauth-reason | Alert        |
|-------------------|----------------------|-------|----------------------|------|---------------|--------------|
| -----             | -----                | ----- | -----                | ---- | -----         | -----        |
| 00:11:22:33:44:55 | 00:0b:86:11:22:33    | corp  | ap1                  | 10   | AP-down       | Auth-failure |
| Deauth Reason     |                      |       |                      |      |               |              |
| Reason            | Timestamp            |       |                      |      |               |              |
| -----             | -----                |       |                      |      |               |              |
| AP-Down           | Apr-12-2013 08:12:34 |       |                      |      |               |              |
| Alert             |                      |       |                      |      |               |              |
| Reason            | Timestamp            |       |                      |      |               |              |
| -----             | -----                |       |                      |      |               |              |
| Auth-Failure      | Apr-10-2013 03:45:11 |       |                      |      |               |              |
| Mobility Trail    |                      |       |                      |      |               |              |
| AP-name           | BSSID                | ESSID | Timestamp            |      |               |              |
| -----             | -----                | ----- | -----                |      |               |              |
| Ap1               | 00:0b:86:11:11:11    | corp  | Apr-10-2013 03:45:11 |      |               |              |
| AP2               | 00:0b:86:22:22:22    | abc   | Apr-10-2013 03:45:11 |      |               |              |

The output of these commands include the following information:

| Column         | Description                                                                                                                                                                                                            |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAC            | MAC address of the client                                                                                                                                                                                              |
| BSSID          | BSSID of the client                                                                                                                                                                                                    |
| ESSID          | ESSID to which the client associated                                                                                                                                                                                   |
| AP-name        | Name of the AP to which the client associated                                                                                                                                                                          |
| VLAN           | VLAN ID of the VLAN to which the client associated.                                                                                                                                                                    |
| Deauth-reason  | Reason why the client was deauthorized.                                                                                                                                                                                |
| Alert          | Reason why alerts were triggered by the client                                                                                                                                                                         |
| Timestamp      | If you include the optional <client-mac> parameter, the output will include a timestamp that indicates the time each alert or deauthorization was triggered.                                                           |
| Mobility-Trail | If you include the optional <client-mac> parameter, the output will include the AP name, BSSID and ESSID of the APs to which the client connected, as well as a timestamp showing when the connections were initiated. |

## Command History

Introduced in ArubaOS 6.3.

## Command Information

| Platforms            | Licensing             | Command Mode                               |
|----------------------|-----------------------|--------------------------------------------|
| W-6000M3 controllers | Base operating system | Enable mode on master or local controllers |

## show ap config

```
show ap config {ap-group <ap-group>}|{ap-name <ap-name>}|{essid <essid>}
```

### Description

Show a large list of configuration settings for an ap-group or an individual AP.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group> | Display configuration settings for an AP group.                                                                                                                                                                                                                                              |
| ap-name <ap-name>   | Display configuration settings for an AP with a specific name.                                                                                                                                                                                                                               |
| essid <essid>       | Display configuration settings for an AP with a specific Extended Service Set Identifier (ESSID). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |

### Examples

The example output below shows just some of the configuration settings displayed in the output of this command.

```
show ap config ap-group apgroup14
```

| Parameter                    | 802.11g  | 802.11a  | Source            |
|------------------------------|----------|----------|-------------------|
| -----                        | -----    | -----    | -----             |
| LMS IP                       | N/A      | N/A      | ap system-profile |
| "default"                    |          |          |                   |
| Backup LMS IP                | N/A      | N/A      | ap system-profile |
| "default"                    |          |          |                   |
| LMS Preemption               | Disabled | Disabled | ap system-profile |
| "default"                    |          |          |                   |
| LMS Hold-down Period         | 600 sec  | 600 sec  | ap system-profile |

The output of this command includes the following parameters.

| Parameter | Description                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LMS IP    | The IPv4 address of the local management switch (LMS)—the Dell controller which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. |

| Parameter               | Description                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LMS IPv6                | The IPv6 address of the local management switch (LMS)—the Dell controller which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network.                              |
| Backup LMS IP           | For multi-controller networks, this parameter displays the IPv4 address of a backup to the IP address specified with the lms-ip parameter.                                                                                             |
| Backup LMS IP           | For multi-controller networks, this parameter displays the IPv6 address of a backup to the IP address specified with the lms-ip parameter.                                                                                             |
| LMS Preemption          | When this parameter is enabled, the local management switch automatically reverts to the primary LMS IP address when it becomes available.                                                                                             |
| LMS Hold-down Period    | Time, in seconds, that the primary LMS must be available before an AP returns to that LMS after failover.                                                                                                                              |
| Number of IPsec retries | Shows the number of times the AP will attempt to recreate an IPsec tunnel with the master controller before the AP will reboot. The supported range is 0-1000 retries, and the default value is 360. A value of 0 disables the reboot. |
| LED operation mode      | The operating mode for the LEDs (11n APs only) <ul style="list-style-type: none"> <li>normal: Normal mode</li> <li>off: All LEDs off</li> </ul>                                                                                        |

| Parameter                    | Description                                                                                                                                                                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master controller IP address | For multi-controller networks, this parameter displays the IP address of the master controller.                                                                                                                                                                                                     |
| RF Band                      | For dual-band radios, this parameter displays the RF band in which the AP should operate: <ul style="list-style-type: none"> <li>• <b>g</b> = 2.4 GHz</li> <li>• <b>a</b> = 5 GHz</li> </ul>                                                                                                        |
| Double Encrypt               | This parameter applies only to remote APs. Double encryption is used for traffic to and from a wireless client that is connected to a tunneled SSID. When enabled, all traffic is re-encrypted in the IPsec tunnel. When disabled, the wireless frame is only encapsulated inside the IPsec tunnel. |
| Native VLAN ID               | Native VLAN for bridge mode virtual APs (frames on the native VLAN are not tagged with 802.1q tags).                                                                                                                                                                                                |
| SAP MTU                      | Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.                                                                                                                                                     |
| Bootstrap threshold          | Number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots. On the controller, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.        |

| Parameter                  | Description                                                                                                                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Request Retry Interval     | Interval, in seconds, between the first and second retries of AP-generated requests. If the configured interval is less than 30 seconds, the interval for subsequent retries is increased up to 30 seconds.                      |
| Maximum Request Retries    | Maximum number of times to retry AP-generated requests, including keepalive messages. After the maximum number of retries, the AP either reboots or tries the IP address specified by the backup LMS IP address (if configured). |
| Keepalive Interval         | Time, in seconds, between keepalive messages from the AP                                                                                                                                                                         |
| Dump Server                | (For debugging purposes.) Displays the server to receive the core dump generated if an AP process crashes.                                                                                                                       |
| Telnet                     | Reports whether telnet access the AP is enabled or disabled.                                                                                                                                                                     |
| SNMP sysContact            | SNMP system contact information.                                                                                                                                                                                                 |
| AeroScout RTLS Server      | Displays whether or not the AP will send RFID tag information to an AeroScout real-time asset location (RTLS) server.                                                                                                            |
| RTLS Server configuration  | Displays whether or not the AP will send RFID tag information to an RTLS server.                                                                                                                                                 |
| Remote-AP DHCP Server VLAN | Shows the VLAN ID of the remote-AP DHCP server used when controller is unreachable.                                                                                                                                              |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote-AP DHCP Server Id         | Shows the IP Address of the DHCP DNS Server.                                                                                                                                                                                                                                                                               |
| Remote-AP DHCP Default Router    | Shows the IP Address of the DHCP Default Router.                                                                                                                                                                                                                                                                           |
| Remote-AP DHCP Pool Start        | Shows the IP Address used as start of DHCP Pool.                                                                                                                                                                                                                                                                           |
| Remote-AP DHCP Pool End          | Shows the IP Address used as end of DHCP Pool.                                                                                                                                                                                                                                                                             |
| Remote-AP DHCP Pool Netmask      | Shows the netmask of DHCP Pool.                                                                                                                                                                                                                                                                                            |
| Remote-AP DHCP Lease Time        | Shows the length of leases, in days (0 means infinite).                                                                                                                                                                                                                                                                    |
| Remote-AP uplink total bandwidth | This is the total reserved uplink bandwidth (in Kilobits per second)                                                                                                                                                                                                                                                       |
| Remote-AP bw reservation         | Session ACLs with uplink bandwidth reservation in kilobits per second. You can specify up to three session ACLs to reserve uplink bandwidth.                                                                                                                                                                               |
| Heartbeat DSCP                   | DSCP value of AP heartbeats (0-63).                                                                                                                                                                                                                                                                                        |
| Session ACL                      | Shows the access control list (ACL) applied on the uplink of a remote AP.                                                                                                                                                                                                                                                  |
| Maintenance Mode                 | Shows if Maintenance mode is enabled or disabled. If enabled, APs stop flooding unnecessary traps and syslog messages to network management systems or network operations centers when deploying, maintaining, or upgrading the network. The controller still generates debug syslog messages if debug logging is enabled. |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote-AP Local Network Access | Enable or disable local network access across VLANs in a Remote-AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Radio enable                   | Shows if the AP's radio is enabled or disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Mode                           | <p>Shows the operating modes for the AP.</p> <ul style="list-style-type: none"> <li>● <b>ap-mode:</b> Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.</li> <li>● <b>am-mode:</b> Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.</li> <li>● <b>spectrum-mode:</b> Device behaves as a spectrum monitor, sending spectrum analysis data to the controller. Spectrum monitors do not serve clients.</li> </ul> |
| High throughput enable (radio) | Shows if high-throughput (802.11n) features on the 2.4 GHz frequency band are enabled or disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Channel                        | Shows the channel number for the AP's 802.11a/802.11n physical layer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Beacon Period                  | Shows the time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Beacon Regulate                            | Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Transmit EIRP                              | Shows the current transmission power level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Advertise 802.11d and 802.11h Capabilities | This column reports whether or not the AP will advertise its 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TPC Power                                  | The transmit power advertised in the TPC IE of beacons and probe responses. Range: 0-51 dBm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Spectrum Load Balancing                    | <p>The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Dell AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p> |
| Spectrum Load Balancing mode               | Spectrum Load Balancing Mode allows control over how to balance clients. Select one of the following options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                    | <p>weak OFDM immunity.</p> <ul style="list-style-type: none"> <li>• Level-4: level 3 and FIR immunity.</li> <li>• Level-5: disable PHY reporting.</li> </ul>                                                              |
| Enable CSA                         | Displays whether or not the AP has enabled channel switch announcements (CSAs) for 802.11h.                                                                                                                               |
| CSA Count                          | Number of channel switch announcements that must be sent before the AP will switch to a new channel.                                                                                                                      |
| Management Frame Throttle interval | Average interval that rate limiting management frames are sent from this radio, in seconds. If this column displays a zero ( <b>0</b> ) rate limiting is disabled for this AP.                                            |
| Management Frame Throttle Limit    | Maximum number of management frames that can come from this radio in each throttle interval.                                                                                                                              |
| ARM/WIDS Override                  | Shows if Adaptive Radio Management (ARM) and Wireless IDS functions are enabled or disabled. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled, regardless of this option. |
| Protection for 802.11b Clients     | Displays whether or not protection for 802.11b clients is enabled or disabled.                                                                                                                                            |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximum Distance                 | <p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.</p> <p>The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 2.4GHz frequency band radio:</p> <ul style="list-style-type: none"> <li>• 20MHz mode: 54km</li> <li>• 40MHz mode: 24km</li> </ul> <p>Iff you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600m will use default settings.</p> |
| Spectrum Monitoring              | <p>When this parameter is enabled, it turns an AP in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Assignment                       | <p>Displays whether or not ARM channel and power assignment has been enabled or disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Allowed bands for 40MHz channels | <p>Forty MHz channels may be used on the specified radio bands (802.11a or 802.11g).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Client Aware                     | <p>Shows if the client aware feature has been enabled or disabled for this AP. If enabled, AP will not change channels when there are active clients.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max Tx Power    | Maximum transmission power for this AP, in dBm.                                                                                                                                                                                                                                                                                              |
| Min Tx Power    | Minimum transmission power for this AP, in dBm.                                                                                                                                                                                                                                                                                              |
| Multi Band Scan | Shows if the multi-band scan feature has been enabled or disabled on this AP. If enabled, single-radio APs will try to scan across bands for Rogue AP detection                                                                                                                                                                              |
| Rogue AP Aware  | Shows if the rogue AP awareness feature has been enabled or disabled on this AP. If enabled, the AP will try to contain off-channel Rogue APs                                                                                                                                                                                                |
| Scan Interval   | This column indicates, in seconds, how often the AP will leave its current channel to scan other channels in the band if scanning is enabled                                                                                                                                                                                                 |
| Active Scan     | <p>Displays whether or not the active scan feature is enabled.</p> <p><b>NOTE:</b> This option elicits more information from nearby APs, but also creates additional management traffic on the network. <b>Active Scan</b> is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Dell Support.</p> |
| Scanning        | <p>Shows if scanning is enabled or disabled for this AP. If this option is disabled, the following other options will also be disabled:</p> <ul style="list-style-type: none"> <li>• Multi Band Scan</li> <li>• Rogue AP Aware</li> <li>• Voip Aware Scan</li> <li>• Power Save Scan</li> </ul>                                              |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                               |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan Time                 | The amount of time, in milliseconds, an AP will drift out of the current channel to scan another channel. The supported range for this setting is 0-2,147,483,647 seconds. Best practices are to configure a scan time between 50-200 msec.                                                                               |
| VoIP Aware Scan           | Shows if VoIP aware scanning is enabled or disabled. If you use voice handsets in the WLAN, <b>VoIP Aware Scan</b> should be enabled in the ARM profile so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that <b>Scanning</b> is also enabled.  |
| Power Save Aware Scan     | Shows if the power save aware scan is enabled or disabled. If enabled, the AP will not scan a different channel if it has one or more clients and is in power save mode.<br><br>Default: enabled                                                                                                                          |
| Ideal Coverage Index      | The Dell coverage index metric is a weighted calculation based on the RF coverage for all DellAPs and neighboring APs on a specified channel. The <b>Ideal Coverage Index</b> specifies the ideal coverage that an AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be. |
| Acceptable Coverage Index | For multi-band implementations, the <b>Acceptable Coverage Index</b> specifies the minimal coverage an AP it should achieve on its channel. The denser the AP deployment, the lower this value should be.                                                                                                                 |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Free Channel Index   | <p>The current free channel index value. The Dell Interference index metric measures interference for a specified channel and its surrounding channels. This value is calculated and weighted for all APs on those channels (including 3rd-party APs).</p> <p>An AP will only move to a new channel if the new channel has a lower interference index value than the current channel.</p> <p><b>Free Channel Index</b> specifies the required difference between the two interference index values before the AP moves to the new channel. The lower this value, the more likely it is that the AP will move to the new channel.</p> |
| Backoff Time         | After an AP changes channel or power settings, it waits for this backoff time interval before it asks for a new channel/power setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Error Rate Threshold | The minimum percentage of PHY errors and MAC errors in the channel that will trigger a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Error Rate Wait Time | Minimum time in seconds the error rate on the AP has to exceed its defined error rate threshold before it triggers a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Noise Threshold      | Maximum level of noise in a channel that triggers a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Noise Wait Time      | Minimum time in seconds the noise level has to exceed the Noise Threshold before it triggers a channel change on the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Minimum Scan Time         | Minimum number of times a channel must be scanned before it is considered for assignment. Best practices are to configure a <b>Minimum Scan Time</b> between 1-20 scans.                                                                                                                                                                                                                                                 |
| Load aware Scan Threshold | The <b>Load Aware Scan Threshold</b> is the traffic throughput level an AP must reach before it stops scanning. Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high.                                                                                                                                                      |
| Mode Aware Arm            | Shows if the mode-aware ARM feature has been enabled or disabled for this AP. If enabled, ARM will turn the AP into an Air Monitors (AMs) if it detects higher coverage levels than necessary. This helps avoid higher levels of interference on the WLAN. Although this setting is disabled by default, you may want to enable this feature if your APs are deployed in close proximity (e.g. less than 60 feet apart). |
| Scan mode                 | Identifies the scan mode for the AP. <ul style="list-style-type: none"> <li>● <b>all-reg-domain:</b> The AP scans channels within all regulatory domains. This is the default setting.</li> <li>● <b>reg-domain:</b> Limit the AP scans to just the regulatory domain for that AP.</li> </ul>                                                                                                                            |

| Parameter                 | Description                                                                                                                                                                                                               |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 40 MHz intolerance        | The specified setting allows ARM to determine if 40 MHz mode of operation is allowed on the 5 GHz or 2.4 GHz frequency band only, on both frequency bands, or on neither frequency band.                                  |
| Honor 40 MHz intolerance  | Shows if 40 MHz intolerance is enabled or disabled. If enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.                                |
| Legacy station workaround | Shows if interoperability for misbehaving legacy stations is enabled or disabled.                                                                                                                                         |
| SSID enable               | Shows if the SSID is enabled or disabled                                                                                                                                                                                  |
| ESSID                     | Name that uniquely identifies the Extended Service Set Identifier (SSID).                                                                                                                                                 |
| Encryption                | Encryption type used on this AP.                                                                                                                                                                                          |
| DTIM Interval             | Shows the interval, in milliseconds, between the sending of Delivery Traffic Indication Messages (DTIMs) in the beacon. This is the maximum number of beacon cycles before unacknowledged network broadcasts are flushed. |
| Basic Rates               | Lists supported 802.11a rates, in Mbps, that are advertised in beacon frames and probe responses from this AP.                                                                                                            |

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transmit Rates        | Lists 802.11a rates at which the AP is allowed to send data. The actual transmit rate depends on what the client is able to handle, based on information sent at the time of association and on the current error/loss rate of the client.                                                                                                                                                                                                               |
| Station Ageout Time   | Time, in seconds, that a client is allowed to remain idle before being aged out.                                                                                                                                                                                                                                                                                                                                                                         |
| Max Transmit Attempts | Maximum number of retries allowed for the AP to send a frame                                                                                                                                                                                                                                                                                                                                                                                             |
| RTS Threshold         | Wireless clients transmitting frames larger than this threshold must issue Request to Send (RTS) and wait for the AP to respond with Clear to Send (CTS). This helps prevent mid-air collisions for wireless clients that are not within wireless peer range and cannot detect when other wireless clients are transmitting.                                                                                                                             |
| Short Preamble        | Shows if a short preamble for 802.11b/g radios is enabled or disabled for this AP. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using short preamble. To use only long preamble, disable short preamble. Legacy client devices that use only long preamble generally can be updated to support short preamble. |

| Parameter                                        | Description                                                                                                                                                         |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max Associations                                 | Maximum number of wireless clients allowed to associate to the AP                                                                                                   |
| Wireless Multimedia (WMM)                        | Shows if Wireless Multimedia (WMM) is enabled or disabled for this AP. WMM provides prioritization of specific traffic relative to other traffic in the network     |
| Wireless Multimedia U-APSD (WMM-UAPSD) Powersave | Shows if Wireless Multimedia (WMM) UAPSD powersave is enabled or disabled.                                                                                          |
| WMM TSPEC Min Inactivity Interval                | Displays the minimum inactivity time-out threshold of WMM traffic for this AP.                                                                                      |
| DSCP mapping for WMM voice AC                    | Displays the DSCP value used to map WMM voice traffic.                                                                                                              |
| DSCP mapping for WMM video AC                    | Displays the DSCP value used to map WMM video traffic.                                                                                                              |
| DSCP mapping for WMM best-effort AC              | Displays the DSCP value used to map WMM best-effort traffic                                                                                                         |
| DSCP mapping for WMM background AC               | Displays the DSCP value used to map WMM background traffic.                                                                                                         |
| 902il Compatibility Mode                         | Shows if 902 il compatibility mode is enabled or disabled. (This parameter only needs to be enabled for APs with associated clients using NTT DoCoMo 902iL phones.) |
| Hide SSID                                        | Shows if the feature to hide a SSID name in beacon frames is enabled or disabled.                                                                                   |

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deny_Broadcast Probes        | When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID.                                                                                       |
| Local Probe Response         | Shows if local probe response is enabled or disabled on the AP. If this option is enabled, the AP is responsible for sending 802.11 probe responses to wireless clients' probe requests. If this option is disabled, then the controller sends the 802.11 probe responses                                                                                                                                               |
| Disable Probe Retry          | If disabled, the AP will not resend probes if it does not get a response.                                                                                                                                                                                                                                                                                                                                               |
| Battery Boost                | Shows if the battery boost feature is enabled or disabled for the AP. If enabled, this feature converts multicast traffic to unicast before delivery to the client, thus allowing you to set a longer DTIM interval. The longer interval keeps associated wireless clients from activating their radios for multicast indication and delivery, leaving them in power-save mode longer and thus lengthening battery life |
| Drop Broadcast and Multicast | If this feature is enabled on an AP, it drops all downstream broadcast or multicast traffic to increase battery life.                                                                                                                                                                                                                                                                                                   |
| WEP Key 1                    | Displays the static WEP key (1 of 4).                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WEP Key 2                                     | Displays the static WEP key (2 of 4).                                                                                                                                                                                                                                                                                       |
| WEP Key 3                                     | Displays the static WEP key (3 of 4).                                                                                                                                                                                                                                                                                       |
| WEP Key 4                                     | Displays the static WEP key (4 of 4).                                                                                                                                                                                                                                                                                       |
| WEP Transmit Key Index                        | Displays the key index that specifies which static WEP key is to be used.                                                                                                                                                                                                                                                   |
| WPA Hexkey                                    | Displays the WPA pre-shared key (PSK).                                                                                                                                                                                                                                                                                      |
| WPA Passphrase                                | Displays the WPA passphrase with which the AP generates a pre-shared key (PSK).                                                                                                                                                                                                                                             |
| Maximum Transmit Failures                     | Display the maximum number of transmission failures allowed before the client gives up.                                                                                                                                                                                                                                     |
| BC/MC Rate Optimization                       | Shows if the AP has enabled or disabled scanning of all active stations currently associated to that AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate. |
| Rate Optimization for delivering EAPOL frames | Shows if the AP has enabled or disabled rate optimization for delivering EAPOL frames.                                                                                                                                                                                                                                      |
| Strict Spectralink Voice Protocol (SVP)       | Shows if strict Spectralink Voice Protocol (SVP) is enabled or disabled.                                                                                                                                                                                                                                                    |

| Parameter                     | Description                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 802.11g Beacon Rate           | Sets the beacon rate for 802.11g for APs use a Distributed Antenna System (DAS). Using this parameter in normal operation may cause connectivity problems. |
| 802.11a Beacon Rate           | Sets the beacon rate for 802.11a for APs use a Distributed Antenna System (DAS). Using this parameter in normal operation may cause connectivity problems. |
| Advertise QBSS Load IE        | Shows if the AP has enabled or disabled the advertising of QBSS in the load IE.                                                                            |
| High throughput enable (SSID) | Shows if the AP has enabled or disabled the use of its high-throughput SSID in 40 MHz mode.                                                                |
| 40 MHz channel usage          | Determines if this high-throughput SSID allows high-throughput (802.11n) stations to associate.                                                            |
| MPDU Aggregation              | Shows if the AP has enabled or disabled MAC protocol data unit (MPDU) aggregation.                                                                         |
| Max transmitted A-MPDU size   | Shows the maximum size, in bytes, of an A-MPDU that can be sent on the AP's high-throughput SSID.                                                          |
| Max received A-MPDU size      | Shows the maximum size, in bytes, of an Aggregated-MAC Packet Data Unit (A-MPDU) that can be received on the AP's high-throughput SSID.                    |
| Min MPDU start spacing        | Displays the minimum time between the start of adjacent MDPUs within an aggregate MPDU, in microseconds.                                                   |

| Parameter                                                      | Description                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Supported MCS set                                              | Comma-separated list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this high-throughput SSID.                                                                                                                                                                                       |
| Short guard interval in 20 MHz mode                            | Shows if the AP has enabled or disabled use of short guard interval in 20 MHz mode of operation.                                                                                                                                                                                                                      |
| Short guard interval in 40 MHz mode                            | Shows if the AP has enabled or disabled use of short guard interval in 40 MHz mode of operation.                                                                                                                                                                                                                      |
| Maximum number of spatial streams usable for STBC transmission | Controls the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the W-AP90, W-AP130 Series, W-AP175, W-AP68 and W-AP105 only. The configured value will be adjusted based on AP capabilities.) |
| Minimum number of spatial streams usable for STBC transmission | Controls the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the W-AP90, W-AP130 Series, W-AP175, W-AP68 and W-AP105 only. The configured value will be adjusted based on AP capabilities.)       |
| Legacy stations                                                | Shows if the AP has enabled or disabled the legacy stations option, which controls whether or not legacy (non-HT) stations are allowed to associate with the AP's SSID. By default, legacy stations are allowed to associate.<br><b>NOTE:</b> This setting has no                                                     |

| Parameter             | Description                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | effect on a BSS in which HT support is not available.                                                                                                                                                                                                                                                        |
| Allow weak encryption | <p>Shows if the AP has enabled or disabled the weak encryption option.</p> <p>The use of TKIP or WEP for unicast traffic forces the use of legacy transmissions rates. Disabling this mode prevents the association of stations using TKIP or WEP for unicast traffic. This mode is disabled by default.</p> |
| Virtual AP enable     | Wireless LAN profiles configure WLANs in the form of virtual AP profiles. This parameter shows if the AP has enabled or disabled virtual APs.                                                                                                                                                                |
| Allowed band          | <p>Shows the band(s) on which to use the virtual AP:</p> <ul style="list-style-type: none"> <li>• a—802.11a band only (5 GHz)</li> <li>• g—802.11b/g band only (2.4 GHz)</li> <li>• all—both 802.11a and 802.11b/g bands (5 GHz and 2.4 GHz)</li> </ul>                                                      |
| VLAN                  | Shows the VLAN(s) into which users are placed in order to obtain an IP address.                                                                                                                                                                                                                              |
| Forward mode          | Shows the current forward mode (tunnel, bridge, split-tunnel, or decrypt-tunnel) for the virtual AP.                                                                                                                                                                                                         |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p>This parameter controls whether 802.11 frames are tunneled to the controller using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the controller, and Internet access remains local).</p> <p>When an AP is configured to use the decrypt-tunnel forwarding mode, that AP decrypts and decapsulates all 802.11 frames from a client and sends the 802.3 frames through the GRE tunnel to the controller, which then applies firewall policies to the user traffic. When the controller sends traffic to a client, the controller sends 802.3 traffic through the GRE tunnel to the AP, which then converts it to encrypted 802.11 and forwards to the client.</p> <p>Only 802.1X authentication is supported when configuring bridge or split tunnel mode.</p> |
| Deny time range | Shows the time range for which the AP will deny access for a virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Mobile IP       | Shows if IP mobility has been enabled or disabled for the virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HA Discovery on-association | <p>If enabled, home agent discovery is triggered on client association instead of home agent discovery based on traffic from client. Mobility on association can speed up roaming and improve connectivity for clients that do not send many uplink packets to trigger mobility (VoIP clients). Best practices is to keep this parameter disabled, as it increases IP mobility control traffic between controllers in the same mobility domain. Enable this parameter only when voice issues are observed in VoIP clients.</p> <p><b>NOTE:</b> <code>ha-disc-onassoc</code> parameter works only when IP mobility is enabled and configured on the controller.</p> |
| DoS Prevention              | Shows the status of the Dos Prevention option. If enabled, virtual APs ignore deauthentication frames from clients. This prevents a successful deauth attack from being carried out against the AP. This does not affect third-party APs.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Station Blacklisting        | Shows if the virtual AP has enabled or disabled detection of denial of service (DoS) attacks, such as ping or SYN floods, that are not spoofed deauth attacks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Blacklist Time              | Shows the number of seconds that a client will be quarantined from the network after being blacklisted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authentication Failure Blacklist Time | Shows the time, in seconds, a client is blocked if it fails repeated authentication. If the virtual AP shows a value of 0, a blacklisted client is blocked indefinitely.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Fast Roaming                          | Shows if the AP has enabled or disabled fast roaming.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Strict Compliance                     | If enabled, the virtual AP denies client association requests if the AP and client station have no common rates defined. Some legacy client stations which are not fully 802.11-compliant may not include their configured rates in their association requests. Such non-compliant stations may have difficulty associating with APs unless strict compliance is disabled.                                                                                                                                                                                                                                      |
| VLAN Mobility                         | Shows if a virtual AP has enabled or disabled VLAN (Layer-2) mobility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Remote-AP Operation                   | Shows when the virtual AP operates on a remote AP: <ul style="list-style-type: none"> <li>• <b>always</b>—Permanently enables the virtual AP (Bridge Mode only). This option can be used for non-802.1X bridge VAPs.</li> <li>• <b>backup</b>—Enables the virtual AP if the remote AP cannot connect to the controller (Bridge Mode only). This option can be used for non-802.1X bridge VAPs.</li> <li>• <b>persistent</b>—Permanently enables the virtual AP after the remote AP initially <b>connects</b> to the controller (Bridge Mode only). This option can be used for any (Open/PSK/802.1X)</li> </ul> |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | <p>bridge VAPs.</p> <ul style="list-style-type: none"> <li>● <b>standard</b>—Enables the virtual AP when the remote AP connects to the controller. This option can be used for any (bridge/split-tunnel/tunnel/d-tunnel) VAPs.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Convert Broadcast ARP requests to unicast | <p>If this option is enabled, all broadcast ARP requests are converted to unicast and sent directly to the client. You can check the status of this option using the <b>show ap active</b> and the <b>show datapath tunnel</b> command. If enabled, the output will display the letter <b>a</b> in the flags column.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Band Steering                             | <p>Shows if band-steering has been enabled or disabled for a virtual AP.</p> <p>ARM's band steering feature encourages dual-band capable clients to stay on the 5GHz band on dual-band APs. This frees up resources on the 2.4GHz band for single band clients like VoIP phones.</p> <p>Band steering reduces co-channel interference and increases available bandwidth for dual-band clients, because there are more channels on the 5GHz band than on the 2.4GHz band. Dual-band 802.11n-capable clients may see even greater bandwidth improvements, because the band steering feature will automatically select between 40MHz or 20MHz channels in 802.11n networks. This feature is disabled by default, and must be enabled in a Virtual AP profile.</p> |

| Parameter                                          | Description                                                                                                                                                                                                                       |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VoIP Call Admission Control                        | Shows if WiFi VoIP Call Admission Control features are enabled or disabled.                                                                                                                                                       |
| VoIP Bandwidth based CAC                           | Shows the maximum bandwidth that can be handled by one radio, in kbps.                                                                                                                                                            |
| VoIP Call Capacity                                 | Show the number of simultaneous calls that can be handled by one radio.                                                                                                                                                           |
| VoIP Bandwidth Capacity (kbps)                     | Shows the maximum bandwidth that can be handled by one radio, in kbps.                                                                                                                                                            |
| VoIP Call Handoff Reservation                      | Shows the percentage of call capacity reserved for mobile VoIP clients on call.                                                                                                                                                   |
| VoIP Send SIP 100 Trying                           | If enabled, the AP sends SIP 100 - trying messages to a call originator to indicate that the call is proceeding. This is useful when the SIP invite may be redirected through a number of servers before reaching the controller. |
| VoIP Disconnect Extra Call                         | If enabled, the AP disconnects calls that exceed the high capacity threshold by sending a deauthentication frame.                                                                                                                 |
| VOIP TSPEC Enforcement                             | Shows if validation of TSPEC requests for call admission controls is enabled or disabled.                                                                                                                                         |
| VOIP TSPEC Enforcement Period                      | Displays the maximum time for the station to start a call after the TSPEC request.                                                                                                                                                |
| VoIP Drop SIP Invite and send status code (client) | Displays the status code sent to the client when a SIP Invite is dropped.                                                                                                                                                         |

| Parameter                                          | Description                                                                                                                                                                                                                                                                                           |

Use the commands displayed in the column to the left to configure these parameters. | Enable and Config modes |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap coverage-holes (deprecated)

show ap coverage holes

### Description

Show information for APs that have detected coverage holes in the wireless network.

### Command History

| Version     | Description        |
|-------------|--------------------|
| ArubaOS 2.0 | Command introduced |
| ArubaOS 6.1 | Command deprecated |

## show ap database

```
show ap database {flags|group <group>|inactive|indoor|local|long|outdoor|{page <page>}} |
sensors [disconnected]|sort-by [ap-flags|ap-group|ap-ip|
ap-mac|ap-name|ap-serial|ap-type|fqln|provisioned|status {up|down}|switch-ip]|sort-direction
[ascending|descending]|start <start> |status {up|down}|switch <switch-ip-
addr>|unprovisioned|usb}
```

### Description

Show the list of access points in the controller's database.

### Syntax

| Parameter     | Description                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags         | Show only APs with flags set [LUDINRCC12ME] .                                                                                                                                                   |
| group <group> | Show data for a specified AP group.                                                                                                                                                             |
| inactive      | Show only local APs with no active BSSIDs or wired AP interfaces.                                                                                                                               |
| indoor        | Show only APs that have an installation mode set to "indoor."                                                                                                                                   |
| local         | Show only APs connected to this controller.                                                                                                                                                     |
| long          | Display the following additional data columns: <ul style="list-style-type: none"><li>• Wired MAC Address,</li><li>• Serial #</li><li>• Slot/Port</li><li>• FQLN</li><li>• Service Tag</li></ul> |
| outdoor       | Show only APs that have an installation mode set to "outdoor."                                                                                                                                  |
| page <page>   | Display a limited number of APs by entering the number of APs to be displayed in the output of this command.                                                                                    |
| disconnected  | Show only disconnected RFprotect sensors.                                                                                                                                                       |
| sort-by       | Sort the output of this command by a specific data column.                                                                                                                                      |
| ap-flags      | Sort by AP flags.                                                                                                                                                                               |
| ap-group      | Sort by AP group name.                                                                                                                                                                          |

| Parameter               | Description                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-ip                   | Sort by AP group name.                                                                                                                                                                                                 |
| ap-mac                  | Sort by AP wired MAC address .                                                                                                                                                                                         |
| ap-name                 | Sort by AP name .                                                                                                                                                                                                      |
| ap-serial               | Sort by AP serial number.                                                                                                                                                                                              |
| ap-type                 | Sort by AP model.                                                                                                                                                                                                      |
| fqln                    | Sort by Fully Qualified Location Name (FQLN).                                                                                                                                                                          |
| provisioned             | Sort by provisioning statistics.                                                                                                                                                                                       |
| status up down          | If used with the <b>sort-by</b> keyword, <b>status</b> sorts the output of the command by status type ( <b>up</b> or <b>down</b> .) Otherwise, use the <b>status</b> keyword to display APs with the specified status. |
| switch-ip               | Sort by controller IP address.                                                                                                                                                                                         |
| uptime                  | Sort by AP uptime.                                                                                                                                                                                                     |
| sort-direction          | Choose sort direction of AP list:.                                                                                                                                                                                     |
| ascending               | Sort AP list in ascending order by name.                                                                                                                                                                               |
| descending              | Sort AP list in descending order by name.                                                                                                                                                                              |
| start <start>           | Start showing the AP index at the specified index number.                                                                                                                                                              |
| status                  | Show only APS with a given status as active or inactive.                                                                                                                                                               |
| down                    | Show only APs that are inactive.                                                                                                                                                                                       |
| up                      | Show only APs that are active.                                                                                                                                                                                         |
| switch <switch-ip-addr> | Show only APs registered with a specified controller by entering a controller IP address.                                                                                                                              |
| unprovisioned           | Show only unprovisioned APs (using modifiers).                                                                                                                                                                         |
| usb                     | Show USB related parameters.                                                                                                                                                                                           |

## Usage Guidelines

Many of the parameters in this command can be used together to filter a large database of information down to just the AP data you want to see. For example, you can issue the **command show ap database group**

**<group> local status up** to view a list of local APs within a specific AP group that are reporting an **up** status. Include the **sort-by** and **sort-direction** keywords to specify how the data is sorted in the output of this command.

## Examples

The output of the command **show ap database** shows the controller's database of information for APs in the group **default**. The output also includes a description of the flag types that may appear in the **Flags** column.

```
show ap database group default
AP Database
```

| Name              | Group   | AP Type | IP Address    | Status           | Flags | Switch IP    | Standby IP |

## show ap database-summary

show ap database-summary

### Description

Show a general summary of access point information for this controller.

### Usage Guidelines

Use this command to show the current number of active APs and Air Monitors. This command is also useful for determining how many unprovisioned APs or duplicate APs are on the network. For full details on each AP registered to a controller, use the command `show ap database`.

### Examples

The output of this command shows that this controller can detect a total of five APs, four up, and one down.

AP Database Summary

| AP Mode             | Total Up       | Total Down | Total Upgrading* | Total Rebooting* | RAP Up | RAP |
|---------------------|----------------|------------|------------------|------------------|--------|-----|
| Down RAP Upgrading* | RAP Rebooting* |            |                  |                  |        |     |
| Access Points       | 4              | 1          | 0                | 0                | 0      | 0   |
| 0                   | 0              |            |                  |                  |        |     |
| Air Monitors        | 0              | 0          | 0                | 0                | 0      | 0   |
| 0                   | 0              |            |                  |                  |        |     |

| 0                   | 0              |            |                  |                  |        |     |
| Mesh Points         | 0              | 0          | 0                | 0                | 0      | 0   |
| 0                   | 0              |            |                  |                  |        |     |
| Spectrum Monitors   | 1              | 1          | 0                | 0                | 0      | 0   |
| 0                   | 0              |            |                  |                  |        |     |

\*Upgrading and Rebooting counts only reflect APs registered on this controller.

The output of this command includes the following information:

| Column     | Description                                               |
|------------|-----------------------------------------------------------|
| Total Up   | Total number of APs with an <i>up</i> status.             |
| Total Down | Total number of APs with a <i>down</i> status.            |
| IPSEC Up   | Total number of APs with an active (up) IPsec tunnel.     |
| IPSEC Down | Total number of APs with an inactive (down) IPsec tunnel. |

### Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|

## show ap debug association-failure (deprecated)

```
show ap debug association-failure [{ap-name <ap-name>}|{bssid <bssid>}|{client-mac <client-mac>}|{ssid <ssid>}|{ip-addr <ip-addr>}]
```

### Description

Display association failure information that can be used to troubleshoot problems on an AP.

### Command History

| Platforms   | Licensing          |
|-------------|--------------------|
| ArubaOS 3.0 | Command introduced |
| ArubaOS 5.0 | Command deprecated |

## show ap debug bandwidth-management

```
show ap debug bandwidth-management [ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]
```

### Description

This command shows bandwidth management information for clients.

### Syntax

| Parameter           | Description                      |
|---------------------|----------------------------------|
| ap-name <ap-name>   | Name of the access point.        |
| ip-addr <ip-addr>   | IP address of the access point.  |
| ip6-addr <ip6-addr> | IPv6 address of the access point |

### Examples

The output of this command shows interface and shaping and interface policy for this AP.

```
(host) #show ap debug bandwidth-management ap-name amit-ap-105
Interface :wifi0
Shaping policy:Default-access (no stats)
Interface :wifil
Shaping policy:Default-access (no stats)
```

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug bss-config

```
show ap debug bss-config [ap-name <ap-name>|bssid <bssid>|essid <essid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>|port <port>/<slot>]
```

### Description

Show the configuration for each BSSID of an AP. This information can be used to troubleshoot problems on an AP.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Filter the AP Config table by AP name.                                                                                                                                                                                          |
| bssid <bssid>       | Filter the AP Config table by BSSID. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                                                                                  |
| essid <essid>       | Filter the AP Config table by ESSID. An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |
| ip-addr <ip-addr>   | Filter the AP Config table by IP address by entering an IP address in dotted-decimal format.                                                                                                                                    |
| ip6-addr <ip6-addr> | Filter the AP Config table by IP address by entering an IPv6 IP address in dotted-decimal format.                                                                                                                               |
| port <port>/<slot>  | Filter the AP Config table by port and slot numbers. The slot and port numbers should be separated by a forward slash (/).                                                                                                      |

### Examples

The output of this command shows the AP configuration table for a specific BSSID.

```
(host) #show ap debug bss-config
Dell AP Config Table

The output of this command includes the following information:

| Column   | Description                                                                                                                                                                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bss      | Basic Service Set (BSS) identifier, which is usually the AP's MAC address.                                                                                                                                                                                                |
| ess      | Extended Service Set (ESS) identifier; a user-defined name for a wireless network.                                                                                                                                                                                        |
| vlan     | The BSSID's VLAN number.                                                                                                                                                                                                                                                  |
| IP       | The AP's IP address.                                                                                                                                                                                                                                                      |
| phy      | One of the following 802.11 types <ul style="list-style-type: none"><li>• a</li><li>• a-HT (high-throughput)</li><li>• g</li><li>• g-HT (high-throughput)</li></ul>                                                                                                       |
| type     | This column shows if the BSSID is for an access point ( <b>ap</b> ) or an air monitor ( <b>am</b> ).                                                                                                                                                                      |
| fw-mode  | The configured forward mode for the AP's virtual AP profile. <ul style="list-style-type: none"><li>• <b>bridge</b>: Bridge locally</li><li>• <b>split-tunnel</b>: Tunnel to controller or NAT locally</li><li>• <b>tunnel</b>: Tunnel to controller</li></ul>             |
| max-cl   | The maximum number of clients allowed for this BSSID.                                                                                                                                                                                                                     |
| preamble | Shows if short preambles are enabled for 802.11b/g radios. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using a short preamble. |
| MTU      | Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.                                                                                                                           |
| status   | Shows if this BSSID is enabled or disabled.                                                                                                                                                                                                                               |
| wmm      | Shows if the BSSID has enabled or disabled WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF) WMM provides prioritization of specific traffic relative to other traffic in the network.                                                   |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug bss-stats

show ap debug bss-stats [bssid <bssid>]

### Description

Show debug and troubleshooting statistics from a specific BSSID of an AP.

### Syntax

| Parameter     | Description                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid> | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |

### Examples

The example below shows part of the output of the command **show ap debug bss-stats bssid <bssid>**.

```
(host) #show ap debug bss-stats bssid 00:1a:1e:11:5f:11
```

```
BSSID Stats
```

```

```

```
BSSID Stats
```

```

```

| Parameter                     | Value     |

The output of this command includes the following information:

| Parameter                   | Description                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------|
| Tx Frames Rcvd              | Number of transmitted frames that were received.                                                      |
| Tx Bcast Frames Rcvd        | Number of transmitted broadcast frames that were received.                                            |
| Tx Frames Dropped           | Number of transmitted frames that were dropped.                                                       |
| Tx Bcast Frames Dropped     | Number of transmitted broadcast frames that were dropped.                                             |
| Tx Frames Transmitted       | Number of frames successfully transmitted.                                                            |
| Tx Bytes Rcvd               | Number of transmitted bytes received.                                                                 |
| Tx Bytes Transmitted        | Number of transmitted bytes.                                                                          |
| Tx Time Frames Rcvd         | Number of times transmitted frames were received.                                                     |
| Tx Time Frames Dropped      | Number of times transmitted frames were dropped.                                                      |
| Tx Time Frames Transmitted  | Number of times frames were transmitted.                                                              |
| Tx Success With Retry       | Number of frames that were successfully transmitted after being retried.                              |
| Tx Multiple retries         | Number of frames that were successfully transmitted after being retried multiple times.               |
| Tx Mgmt Frames              | Number of management frames transmitted.                                                              |
| Tx Beacons Transmitted      | Number of beacons transmitted.                                                                        |
| Tx Probe Responses          | Number of transmitted probe responses.                                                                |
| Tx Data Transmitted Retried | Number of retried data frames.                                                                        |
| Tx Data Transmitted         | Number of transmitted data frames.                                                                    |
| Tx Data Frames              | Number of transmitted data frames.                                                                    |
| Tx Broadcast Data Frames In | Number of broadcast data frames received by the AP from wired interface to be transmitted in the air. |
| Tx Data Bytes Transmitted   | Total data bytes received by an AP from its wired interface to be transmitted over the air.           |
| Tx Data Bytes               | Total data bytes transmitted by the AP over the air.                                                  |
| Tx Time BC/MC Data          | Total time spent transmitting broadcast/multicast frames.                                             |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tx Time Data dropped          | Total time spent transmitting dropped frames.                                                                                                                                                                                                                                                                                                        |
| Tx Time Data                  | Total time spent sending frames received for transmission, including the frames that were dropped after retrying.                                                                                                                                                                                                                                    |
| Tx Broadcast Data Frames Sent | Broadcast data frames transmitted by the AP.                                                                                                                                                                                                                                                                                                         |
| Tx Multicast Data Frames      | Multicast data frames transmitted by the AP.                                                                                                                                                                                                                                                                                                         |
| Tx DMO Multicast              | <b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.                                                                                                                             |
| Tx DMO Invalid                | <b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.                                                                                                                             |
| Tx DMO Converted              | <b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.                                                                                                                             |
| Tx DMO Replicated             | <b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.                                                                                                                             |
| Tx DMO Dropped                | <b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.                                                                                                                             |
| Tx DMO No Client              | Number of times no client was found for an association-ID indicated by the frame. (This value is typically normally 0.)<br><b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APs in bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion. |
| Tx DMO No BSSID               | Number of times the BSSID indicated by the frame was not found. (This value is typically normally 0.)<br><b>NOTE:</b> This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.                    |
| Tx Unicast Data Frames        | Number of transmitted unicast data frames.                                                                                                                                                                                                                                                                                                           |
| Tx RTS Success                | Number of Ready To Send (RTS) frames successfully transmitted.                                                                                                                                                                                                                                                                                       |
| Tx RTS Failed                 | Number of Ready To Send (RTS) frames that were not successfully transmitted                                                                                                                                                                                                                                                                          |
| Tx CTS Frames                 | Number of Clear-to-Send (CTS) frames transmitted.                                                                                                                                                                                                                                                                                                    |
| Tx Dropped After Retry        | Number of frames dropped after an attempted retry.                                                                                                                                                                                                                                                                                                   |
| Tx Dropped No Buffer          | Number of frames dropped because the AP's buffer was full.                                                                                                                                                                                                                                                                                           |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tx Missed ACKs                | Number of retries triggered because an acknowledgement was not received.                                                                                                                                                                                                                                                                                                                          |
| Tx EAPOL Frames               | Number of EAPOL frames transmitted                                                                                                                                                                                                                                                                                                                                                                |
| TX STBC Frames                | Number of transmitted frames with Space-time block coding (STBC) enabled.                                                                                                                                                                                                                                                                                                                         |
| TX LDPC Frames                | Number of transmitted frames with Low Density Parity Check (LDPC) enabled.                                                                                                                                                                                                                                                                                                                        |
| Tx WMM                        | <p>Number of Wi-fi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <ul style="list-style-type: none"> <li>• Tx WMM [BE]: Best Effort</li> <li>• Tx WMM [BK]: Background</li> <li>• Tx WMM [VO]: VoIP</li> <li>• Tx WMM [VI]: Video</li> </ul> |
| Tx Data <value> Mbps          | Number of frames transmitted at the specified rate, (Mbps).                                                                                                                                                                                                                                                                                                                                       |
| Tx Data Bytes<br><value> Mbps | Number of bytes of data transmitted at the specified rate, (Mbps).                                                                                                                                                                                                                                                                                                                                |
| UAPSD OverflowDrop            | Number of packets dropped due to Unscheduled Automatic Power Save Delivery (U-APSD) overflow.                                                                                                                                                                                                                                                                                                     |
| Tx Mgmt Bytes                 | Total management frame bytes transmitted.                                                                                                                                                                                                                                                                                                                                                         |
| Tx Beacons Bytes              | Total number of Beacon frame bytes transmitted.                                                                                                                                                                                                                                                                                                                                                   |
| Tx AMSDU pkt count            | Total number of AMSDU bytes transmitted.                                                                                                                                                                                                                                                                                                                                                          |
| Rx Last SNR                   | The last recorded signal-to-noise ratio.                                                                                                                                                                                                                                                                                                                                                          |
| Rx Last SNR CTL0              | The signal-to-noise ratio for the last received data packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.                                                                                                                                                                                                                                |
| Rx Last SNR CTL1              | The signal-to-noise ratio for the last received data packet on the secondary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.                                                                                                                                                                                                                              |
| Rx Last SNR CTL2              | The signal-to-noise ratio for the last received data packet on the secondary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.                                                                                                                                                                                                                              |
| Rx Last ACK SNR               | Signal-to-noise ratio for the last received ACK packet.                                                                                                                                                                                                                                                                                                                                           |
| Rx Last ACK SNR CTL0          | Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.                                                                                                                                                                                                                                     |

| Parameter                | Description                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Rx Last ACK SNR CTL1     | Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.                                 |
| Rx Last ACK SNR CTL2     | Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.                                 |
| Rx Frames Received       | Number of frames received.                                                                                                                                                                    |
| Rx retry frames          | Number of retried frames received.                                                                                                                                                            |
| Rx data frames retried   | Number of retried data frames received.                                                                                                                                                       |
| Rx Data Frames           | Number of data frames received.                                                                                                                                                               |
| Rx Data Bytes            | Number of data bytes received.                                                                                                                                                                |
| Rx Time Data             | Total time spent on frames successfully received.                                                                                                                                             |
| Rx Duplicate Frames      | Number of duplicate frames received.                                                                                                                                                          |
| Rx Broadcast Data Frames | Number of broadcast frames received.                                                                                                                                                          |
| Rx Multicast Data Frames | Number of multicast frames received.                                                                                                                                                          |
| Rx Unicast Data Frames   | Number of unicast frames received.                                                                                                                                                            |
| Rx Null Data Frames      | Number of null data frames received.                                                                                                                                                          |
| Rx Mgmt Frames           | Number of management frames received.                                                                                                                                                         |
| Control Frames           | Number of control frames received.                                                                                                                                                            |
| Frames To Me             | Number of frames received that are addressed to the specified BSSID.                                                                                                                          |
| Bytes To Me              | Number of bytes received that are addressed to the specified BSSID.                                                                                                                           |
| Time To Me               | Total time spent receiving frames sent to a specified BSSID.                                                                                                                                  |
| Rx Probe Requests        | Number of probe requests received.                                                                                                                                                            |
| RX PS Poll Frames        | Power-Save Poll (PS-Poll) frames received. When a client exits a power-saving mode, it transmits a PS-Poll frame to the AP to retrieve any frames buffered while it was in power-saving mode. |
| RX STBC Frames           | Number of received frames with STBC enabled.                                                                                                                                                  |
| RX LDPC Frames           | Number of received frames with LDPC enabled.                                                                                                                                                  |

| Parameter                     | Description                                                     |
|-------------------------------|-----------------------------------------------------------------|
| Rx Data <value> Mbps          | Number of frames received at the specified rate, (Mbps).        |
| Rx Data Bytes<br><value> Mbps | Number of bytes of data received at the specified rate, (Mbps). |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug client-deauth-reason-counters

show ap debug client-deauth-reason-counters

### Description

Shows the aggregate client deauth reason counters

### Examples

The output of the command below shows client deauth reason counters.

```
(host) #show ap debug client-deauth-reason-counters
Deauth Reason Counters

Name Value

```

### Command History

Introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug client-mgmt-counters

```
show ap debug client-mgmt-counters
```

### Description

Show the numbers of each type of message from an AP's clients. This information can be used to troubleshoot problems on an AP.

### Examples

The output of the command below shows client management counters.

```
(host)#show ap debug client-mgmt-counters
```

```
Counters

| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug client-stats

show ap debug client-stats <client-mac>

### Description

Show detailed statistics about a client.

### Example

The command below displays statistics for packets received from and transmitted to the specified client.

```
(host) #show ap debug client-stats 00:19:7e:89:fa:e7
```

```
Station Stats

Parameter Value

The output of this command includes the following information:

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frames Rcvd For TX  | Number of frames received for transmission.                                                                                                                                                                                                                                                                                                                         |
| Tx Frames Dropped   | Number of transmission frames that were dropped.                                                                                                                                                                                                                                                                                                                    |
| Frames Transmitted  | Number of frames successfully transmitted.                                                                                                                                                                                                                                                                                                                          |
| Success With Retry  | Number of frames that were transmitted after being retried.                                                                                                                                                                                                                                                                                                         |
| Tx Mgmt Frames      | Number of management frames transmitted.                                                                                                                                                                                                                                                                                                                            |
| Tx Probe Responses  | Number of transmitted probe responses.                                                                                                                                                                                                                                                                                                                              |
| Tx Data Frames      | Number of transmitted data frames.                                                                                                                                                                                                                                                                                                                                  |
| Tx CTS Frames       | Number of clear-to-send (CTS) frames transmitted.                                                                                                                                                                                                                                                                                                                   |
| Dropped After Retry | Number of frames dropped after an attempted retry.                                                                                                                                                                                                                                                                                                                  |
| Dropped No Buffer   | Number of frames dropped because the AP's buffer was full.                                                                                                                                                                                                                                                                                                          |
| Missed ACKs         | Number of missed acknowledgements (ACKs)                                                                                                                                                                                                                                                                                                                            |
| Long Preamble       | Number of frames sent with a long preamble.                                                                                                                                                                                                                                                                                                                         |
| Short Preamble      | Number of frames sent with a short preamble.                                                                                                                                                                                                                                                                                                                        |
| Tx EAPOL Frames     | Number of Extensible Authentication Protocol over LAN (EAPOL) frames transmitted.                                                                                                                                                                                                                                                                                   |
| Tx <n> Mbps         | Number of frames transmitted at <n> Mbps, where <n> is a value between 6 and 300.                                                                                                                                                                                                                                                                                   |
| Tx WMM              | <p>Number of Wifi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <p><b>Tx WMM [BE]:</b> Best Effort</p> <p><b>Tx WMM [BK]:</b> Background</p> <p><b>Tx WMM [VO]:</b> VoIP</p> <p><b>Tx WMM [VI]:</b> Video</p> |

| Parameter          | Description                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UAPSD OverflowDrop | Number of packets dropped due to Unscheduled Automatic Power Save Delivery (U-APSD) overflow.                                                                        |
| Last SNR           | The last recorded signal-to-noise ratio.                                                                                                                             |
| Last SNR CTL0      | The signal-to-noise ratio for the last received data packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.   |
| Last SNR CTL1      | The signal-to-noise ratio for the last received data packet on the secondary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode. |
| Last SNR CTL2      | The signal-to-noise ratio for the last received data packet on the secondary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode. |
| Last ACK SNR       | Signal-to-noise ratio for the last received ACK packet.                                                                                                              |
| Last ACK SNR CTL0  | Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.        |
| Last ACK SNR CTL1  | Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.        |
| Last ACK SNR CTL2  | Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.        |
| Last ACK SNR EXT0  | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Last ACK SNR EXT1  | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Frames Received    | Number of frames received.                                                                                                                                           |
| Rx Data Frames     | Number of data frames received.                                                                                                                                      |
| Null Data Frames   | Number of null data frames received.                                                                                                                                 |
| Rx Mgmt Frames     | Number of management frames received.                                                                                                                                |
| PS Poll Frames     | Number of power save poll frames received.                                                                                                                           |
| Rx <n> Mbps        | Number of frames received at <n> Mbps, where <n> is a value between 6 and 300.                                                                                       |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tx WMM    | <p>Number of Wifi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <p><b>Tx WMM [BE]:</b> Best Effort</p> <p><b>Tx WMM [BK]:</b> Background</p> <p><b>Tx WMM [VO]:</b> VoIP</p> <p><b>Tx WMM [VI]:</b> Video</p> |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug client-table

```
show ap debug client-table [ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]
```

### Description

Show clients associated to an AP.

### Syntax

| Parameter           | Description                                                                        |
|---------------------|------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Filter the client table by AP name.                                                |
| bssid <bssid>       | Filter the client table by BSSID. This will print clients on top from given BSSID. |
| ip-addr <ip-addr>   | Filter the client table by AP IP address.                                          |
| ip6-addr <ip6-addr> | Filter the client table by AP IPv6 address.                                        |

### Usage Guidelines

The **Tx\_Rate**, **Rx\_Rate**, **Last\_ACK\_SNR**, and **Last\_Rx\_SNR** columns shown in the output of this command display valuable troubleshooting information for clients trying to connect to a specific AP. Use this command to verify that the transmit (Tx\_Rate) and receive (Rx\_Rate) rates are not too low, and that the signal-to-noise (SNR) ratio is acceptable.

### Examples

The example below the AP configuration table for a specific BSSID. In this example, the output is divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it appears in a single, long table.

```
(host) #show ap debug client-table ap-name apname1
```

Client Table

| Sun Jul 21 11:05:50 2013 | (0,0)            | 119       | 90/90               |

UAPSD: (VO,VI,BK,BE,Max SP,Q Len)

HT Flags: A - LDPC Coding; W - 40MHz; S - Short GI 40; s - Short GI 20

D - Delayed BA; G - Greenfield; R - Dynamic SM PS

Q - Static SM PS; N - A-MPDU disabled; B - TX STBC  
b - RX STBC; M - Max A-MSDU; I - HT40 Intolerant  
VHT Flags: C - 160MHz; c - 80MHz; V - Short GI 160; v - Short GI 80  
E - Beamformee; e - Beamformer  
HT\_State shows client's original capabilities (not operational capabilities)

The output of this command includes the following information:

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAC         | MAC address of a client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ESSID       | Extended Service Set identifier (ESSID) used by the client. An ESSID is a user-defined name for a wireless network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| BSSID       | Basic Service Set identifier for the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Assoc_State | The associated state column shows whether or not the client is currently authorized and/or associated with the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| HT_State    | Shows information about the client's high-throughput or very-high throughput transmission type. The description for each of the flags that can appear in this column follows the output of the command. <ul style="list-style-type: none"> <li>• A - LDPC Coding</li> <li>• W - 40MHz</li> <li>• S - Short GI 40</li> <li>• s - Short GI 20</li> <li>• D - Delayed BA</li> <li>• G - Greenfield</li> <li>• R - Dynamic SM PS</li> <li>• Q - Static SM PS</li> <li>• N - A-MPDU disabled</li> <li>• B - TX STBC</li> <li>• b - RX STBC</li> <li>• M - Max A-MSDU</li> <li>• I - HT40 Intolerant</li> <li>• C - 160MHz</li> <li>• c - 80MHz</li> <li>• V - Short GI 16</li> <li>• v - Short GI 80</li> <li>• E - Beamformee</li> <li>• e - Beamformer</li> </ul> |
| AID         | 802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Rx_rate      | Rate at which last packet was received from client (in Mbps)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Last_ACK_SNR | Signal-to-Noise ratio of the last acknowledge packet sent by client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Last_Rx_SNR  | Signal-to-Noise ratio of the last data packet received from the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| TX_Chains    | <p>The first digit in this value indicates the number of transmission chains on the radio currently in use, and the number in brackets shows which of the chains are active.</p> <p>The current status of each chain is indicated by a single-digit binary number; <b>1</b> if the chain is active, and <b>0</b> if it is inactive. In the example output above (<b>2 [0x5]</b>), two chain are active; chain one and chain three.</p> <ul style="list-style-type: none"> <li>chain one: <b>1</b> (active)</li> <li>chain two: <b>0</b> (inactive)</li> <li>chain three: <b>1</b> (active)</li> </ul> <p>In the example above, the chain would generate the value <b>101</b>, which translates to the hexadecimal number <b>5</b>. If all three chain were active, it would generate the value <b>111</b>, (the hexadecimal number <b>7</b>), and would appear in the CLI output as <b>3 [0x7]</b>.</p>                                                                                                                                                                                                         |

| Idle Time     | Number of seconds elapsed since a packet was received from the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Client Health | <p>This column shows the client health of the client and the AP radio, in the format &lt;client_health&gt;/&lt;AP-health&gt;. These values report the quality of link between the client and radio,</p> <p>An AP's client health is the efficiency at which that AP transmits downstream traffic to a particular client. This value is determined by comparing the amount of time the AP spends transmitting data to a client to the amount of time that would be required under ideal conditions, that is, at the maximum Rx rate supported by client, with no data retries.</p> <p>A client health metric of 100% means the actual airtime the AP spends transmitting data is equal to the ideal amount of time required to send data to the client. A client health metric of 50% means the AP is taking twice as long as is ideal, or is sending one extra transmission to that client for every packet. A metric of 25% means the AP is taking four times longer than the ideal transmission time, or sending 3 extra transmissions to that client for every packet.</p> |

## Command History

| Version       | Description                              |
|---------------|------------------------------------------|
| ArubaOS 3.0   | Command Introduced                       |
| ArubaOS 6.3.1 | The Client Health metric was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug client-trace

```
show ap client-trace
 {ap-name <ap-name>}|{ip-addr <ip>}|{ip6-addr <ip6>} mac <client-mac>
```

### Description

Use this command to show counts of different types of management data frames traced from a client MAC address.

### Syntax

| Parameter           | Description                 |
|---------------------|-----------------------------|
| ap-name <ap-name>   | Name of the AP.             |
| ip-addr <ip-addr>   | IPv4 address of the AP.     |
| ip6-addr <ip6-addr> | IPv6 address of the AP.     |
| mac <client-mac>    | MAC address of the client.. |

### Usage Guidelines

This command should only be used under the guidance of Dell technical support.

### Related Commands

| Command                                     | Description                                                                    |
|---------------------------------------------|--------------------------------------------------------------------------------|
| <a href="#">ap debug client-trace start</a> | Use this command to trace management packets from a client MAC address.        |
| <a href="#">ap debug client-trace stop</a>  | Use this command to stop tracing management packets from a client MAC address. |

### Command History

Introduced in ArubaOS 6.3.

### Command Information

| Platforms            | Licensing             | Command Mode                               |

| W-6000M3 controllers | Base operating system | Enable mode on master or local controllers |

## show ap debug counters

```
show ap debug counters {ap-name <ap-name>|bssid <bssid>|group <group>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

### Description

Show AP reboot/bootstrap counters, and crash information for an individual AP or AP group, or all APs referenced on the controller.

### Syntax

| Parameter           | Description                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show debug counters for an AP with a specified name.                                                                                               |
| bssid <bssid>       | Show debug counters for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| group <group>       | Show debug counters for an AP group.                                                                                                               |
| ip-addr <ip-addr>   | Show debug counters for an AP with a specified IP address by entering an IP address in dotted-decimal format.                                      |
| ip6-addr <ip6-addr> | Show debug counters for an AP with a specified IPv6 address by entering an IP address in dotted-decimal format.                                    |

### Example

The output of this command shows how many times each AP has rebooted (a hard boot) or bootstrapped (a soft boot), the number of configuration changes sent and acknowledged by that AP, and whether or not the AP rebooted due to a kernel crash.

In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it will appear in a single, long table.

```
(host) #show ap debug counters group corp1
AP Counters

Name Group IP Address Configs Sent Configs Acked AP Boots Sent
---- -
AL1 corp1 10.6.1.209 1597 1597 0
AL10 corp1 10.6.1.198 165 165 0
AL12 corp1 10.6.1.200 195 195 0
AL15 corp1 10.6.1.197 1580 1580 0
AL16 corp1 10.6.1.199 73 73 0
AL19 corp1 10.6.1.212 8 8 0

AP Boots Acked Bootstraps (Total) Reboots Crash

0 1 (1) 0 N
0 1 (1) 0 N
0 1 (1) 0 N
```

0                      1                      (1)                      0                      N  
Total APs :6

The output of this command includes the following information:

| Column           | Description                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Name             | Name of the AP.                                                                                                                               |
| Group            | Name of the AP's group.                                                                                                                       |
| IP Address       | IP address of the AP.                                                                                                                         |
| Configs sent     | Number of times configuration changes have been sent to the AP.                                                                               |
| Configs Acked    | Number of times that the AP has acknowledged receiving a configuration change.                                                                |
| AP Boots Sent    | Number of times reboot requests have been sent to the AP.                                                                                     |
| AP Boots Acked   | Number of times that the AP has acknowledged receiving a reboot request.                                                                      |
| Bootstraps       | Number of times the AP bootstrapped since AP reboot. Bootstraps are also known as "soft" restarts.                                            |
| Total Bootstraps | Total number of times the AP bootstrapped since AP image upgrade.                                                                             |
| Reboots          | Number of times power to the AP cycled off and then on again since image upgrade. Reboots also known as "hard" restarts.                      |
| Crash            | Indicates whether or not the AP was rebooted due to a kernel crash. Use <a href="#">show ap debug crash-info</a> to view the crash signature. |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug crash-info

```
show ap debug crash-info {ap-name <ap-name>|ip-addr <ip-addr>
```

```
ip6-addr <ip6-addr>}
```

### Description

Show crash log information (if it exists) for an individual AP. The stored information is cleared from the flash after the AP reboots.

### Syntax

| Parameter           | Description                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show crash information for an AP with a specified name.                                                            |
| ip-addr <ip-addr>   | Show crash information for an AP with a specified IP address by entering an IP address in dotted-decimal format.   |
| ip6-addr <ip6-addr> | Show crash information for an AP with a specified IPv6 address by entering an IP address in dotted-decimal format. |

### Example

The output of this command shows a partial sample crash log information for an AP named **MyAP**

```
(host) #show ap debug crash-info ap-name MyAP
```

```

## show ap debug crypto

show ap debug crypto {ap-name <ap-name>|detail|history|ip-addr <ip-addr>}

### Description

This command shows the debug crypto logs for an AP.

### Syntax

| Parameter         | Description                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Shows crypto logs information for an AP with a specified name.                                                                                                   |
| detail            | Specifies the crypto logs details for the following:<br><b>ap-name:</b> Specifies the name of AP.<br><b>ip-addr:</b> Specifies the IP Address of AP.             |
| history           | Specifies the crypto logs history information for the following:<br><b>ap-name:</b> Specifies the name of AP.<br><b>ip-addr:</b> Specifies the IP Address of AP. |
| ip-addr <ip-addr> | Shows crypto logs information for an AP with a specified IP address by entering an IP address in dotted-decimal format.                                          |

### Example

The output of this command shows a partial debug crypto information for an AP named **MyAP**

```
(host) (config) #show ap debug crypto ap-name MyAP
```

```

### Command History

Introduced in ArubaOS 6.3.

## Command Information

| Platforms     | Licensing             | Command Mode          |
|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

## show ap debug datapath

show ap debug datapath {ap-group <ap-group>|ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}

### Description

Show datapath tunnel parameters of an AP or AP group.

### Syntax

| Parameter           | Description                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group> | Show data path information for a specific AP group.                                                                                                       |
| ap-name <ap-name>   | Show data path information for an AP with a specific name.                                                                                                |
| bssid <bssid>       | Show data path information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show data path information for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                       |
| ip6-addr <ip6-addr> | Show data path information for an AP with a specific IPv6 address by entering an IP address in dotted-decimal format.                                     |

### Example

The output of the following command shows datapath tunnel parameters for an AP with the IP address 192.0.2.32.

```
(host) #show ap debug datapath ip-addr 192.0.2.32
```

Datapath Parameters Table

| essid | encr-alg       | client-vlan-id | tunnel-id | gre-type | deny-bcast | num-clients |
|-------|----------------|----------------|-----------|----------|------------|-------------|
| guest | Open           | 63             | 0x10f6    | 0x8300   | disable    | 0           |
| voip  | WPA2 8021X AES | 66             | 0x1103    | 0x8310   | disable    | 7           |
| corp  | WPA2 PSK AES   | 66             | 0x10f1    | 0x8320   | disable    | 0           |
| guest | Open           | 63             | 0x10f7    | 0x8200   | disable    | 1           |
| wpa2  | WPA2 8021X AES | 65             | 0x10be    | 0x8210   | enable     | 15          |

The output of this command includes the following information:

| Column   | Description                                                                             |
|----------|-----------------------------------------------------------------------------------------|
| ESSID    | The Extended Service Set Identifier is a unique name that identifies a wireless network |
| encr-alg | Encryption algorithm used by the network                                                |

| Column         | Description                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| client-vlan-id | ID of the network VLAN                                                                                                               |
| tunnel-id      | Identification number of the AP's tunnel.                                                                                            |
| gre-type       | GRE tunnel type.                                                                                                                     |
| deny-bcast     | If <b>enabled</b> , the AP will respond to broadcast probe requests. If <b>disabled</b> , the AP will not respond to these requests. |
| num-clients    | Number of clients currently using the network.                                                                                       |

The output of the following command shows datapath tunnel parameters for an AP with the IPv6 address 11:12:11:11::2.

```
(host) #show ap debug datapath ip6-addr 11:12:11:11::2
Datapath Parameters Table

```

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug dot11r

```
show ap debug dot11r
 efficiency <client-mac>
 state [ap-name <ap-name> | ip-addr <ip-addr>]
```

### Description

This command displays all the r1 keys that are stored in an AP and the hit/miss rate of r1 keys cached on an AP before a Fast BSS Transition roaming.

### Syntax

| Parameter               | Description                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| efficiency <client-mac> | Show the hit/miss rate of r1 keys cached on an AP before a Fast BSS Transition roaming for the specified client MAC address. |
| state                   | Show all the r1 keys that are stored in an AP based on the filter specified.                                                 |
| ap-name <ap-name>       | Show debugging information for a specific AP.                                                                                |
| ip-addr <ip-addr>       | Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.         |

### Examples

Use this command to view all the r1 keys that are stored in an AP. You can filter the output based on the AP name or IP address.

```
(host) #show ap debug dot11r state ap-name MAcage-105-GL
```

Stored R1 Keys

```

Station MAC Mobility Domain ID Validity Duration R1 Key

00:50:43:21:01:b8 1 3568 (32): 94 ff 18 0a 5f 47 8b 3e 95 2b
93 31 bd 44 58 fe fe 6a ad aa 1d d7 29 94 fb 5b 7c 15 76 66 d2 1f
```

Use this command to view the hit/miss rate of r1 keys cached on an AP before a Fast BSS Transition roaming. This counter helps to verify if enough r1 keys are pushed to the neighboring APs.

```
(host) #show ap debug dot11r efficiency
Fast Roaming R1 Key Efficiency
```

```

Client MAC Hit (%) Miss (%)

00:50:43:21:01:b8 0 (0%) 0 (0%)
```

### Command History

Introduced in ArubaOS 6.3.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show ap debug dot11r state

```
show ap debug dot11r state [ap-name <ap-name> | ip-addr <ip-addr>]
```

### Description

This command displays all the r1 keys that are stored in an AP.

### Syntax

| Parameter         | Description                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show debugging information for a specific AP.                                                                        |
| ip-addr <ip-addr> | Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format. |

### Examples

Use this command to view all the r1 keys that are stored in an AP. You can filter the output based on the AP name or IP address.

```
(host) #show ap debug dot11r state ap-name MAcage-105-GL
```

## show ap debug driver-log

```
show ap debug driver-log {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip-addr>}
```

### Description

Show an AP's driver logs.

### Syntax

| Parameter          | Description                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>  | Show log information for an AP with a specific name.                                                                                                |
| bssid <bssid>      | Show log information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>  | Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                       |
| ip6-addr <ip-addr> | Show log information for an AP with a specific IPv6 address.                                                                                        |

### Usage Guidelines

Use this command to review configuration changes made since the AP was last reset.

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug gre-tun-stats

```
show ap debug gre-tun-stats {ap-name <ap-name>| bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

### Description

Shows GRE tunnel packet statistics of an AP.

### Syntax

| Parameter           | Description                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Shows GRE tunnel packets information for an AP.                                                                                                                     |
| bssid <bssid>       | Shows GRE tunnel packets information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Shows GRE tunnel packets information for an AP with a specified IP address by entering an IP address in dotted-decimal format.                                      |
| ip6-addr <ip6-addr> | Shows GRE tunnel packets information for an AP with a specific IPv6 address.                                                                                        |

### Example

The output of this command shows GRE tunnel packets information for an AP named myAP.

```
(host) #show ap debug gre-tun-stats myAP
GRE HBT Tunnel Stats

AP IP Controller IP Sent Count HBT Tx Seqnum Idle (secs) Rcvd Count HBT Rx
Seqnum Idle (secs)

- -----

0
GRE Tunnel Packet Stats

MAC BSSID Tun Input In IP Frags To WLAN Idle (secs) Rate pps From WLAN Tun Output Out
IP Frags Idle (secs) Rate pps
--- --- --- --- --- --- --- --- --- ---
----- ----- -----
```

### Command History

Introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode          |
|---------------|-----------------------|-----------------------|
| All platforms | Base operating system | Enable or Config mode |

# show ap debug gsm-counters

```
show ap debug gsm-counters
verbose
```

## Description

Displays the GSM counters of an AP or AP group.

## Syntax

| Parameter | Description                                        |
|-----------|----------------------------------------------------|
| verbose   | Displays the event statistics in a tabular format. |

## Example

The output of the following command shows gsm counters of an AP:

```
(host) (config) #show ap debug gsm-counters verbose
STM GSM Counters

Name Value

AP Publish Events 15
AP Delete Events 3
Radio Publish Events 9548
Radio Delete Events 0
BSS Publish Events 6
Responses to BSS Rcvd 6
BSS Delete Events 0
STA Publish Events 0
STA Delete Events 0
WIRED_AP Publish Events 0
Responses to WIRED_AP Rcvd 0
WIRED_AP Delete Events 0
MAC-User Publish Notifications 0
MAC-User Notify Events 0
MAC-User Responses Sent 0
BSS Response time histogram [1...128] seconds in powers of 2 4 2 0 0 0 0 0 0
STA Response time histogram [1...128] seconds in powers of 2 0 0 0 0 0 0 0 0
STA Delete Reason Count

```

## Command History

| All platforms | Base operating system | Enable or Config mode |

## show ap debug ipc forwarding-statistics

```
show ap debug ipc forwarding-statistics {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip-addr>}
```

### Description

Show an AP's ipc forwarding statistics.

### Syntax

| Parameter          | Description                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>  | Show log information for an AP with a specific name.                                                          |
| ip-addr <ip-addr>  | Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format. |
| ip6-addr <ip-addr> | Show log information for an AP with a specific IPv6 address.                                                  |

### Usage Guidelines

Use this command to review configuration changes made since the AP was last reset.

### Command History

Introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug lacp

```
show ap debug lacp {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr<ipv6-addr>}
```

### Description

Displays the number of GRE packets sent and received on the two Ethernet ports.

### Syntax

| Parameter            | Description                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>    | Show LACP information for an AP with a specific name.                                                                                                |
| bssid <bssid>        | Show LACP information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>    | Show LACP information for an AP with a specific IPv4 address.                                                                                        |
| ip6-addr <ipv6-addr> | Show LACP information for an AP with a specific IPv6 address.                                                                                        |

### Usage Guidelines

Use this command to know if LACP is active on an AP from the number of GRE packets sent and received on the two Ethernet ports. If a GRE striping IP address is configured in the **ap-lacp-striping-ap** profile, the output of this command displays the GRE striping IP address.

### Example

The following example displays that the wireless GRE packets are being sent and received on different wired ports of the AP for the 5GHz and 2.4GHz bands. It also shows that the interfaces eth0 and eth1 are part of the link aggregation group (LAG):

```
AP LACP GRE Striping IP: 10.65.30.50
AP LACP Status

Link Status LACP Rate Num Ports Actor Key Partner Key Partner MAC

Up slow 2 17 2 00:0b:86:61:7a:58
Slave Interface Status

Slave I/f Name Permanent MAC Addr Link Status Member of LAG Link Fail Count

eth0 6c:f3:7f:c6:72:82 Up Yes 0
eth1 6c:f3:7f:c6:72:83 Up Yes 1
GRE Radio Traffic Received on Enet Ports

Radio Num Enet 0 Rx Count Enet 1 Rx Count

0 5048 0
1 0 23
Traffic Sent on Enet Ports

Radio Num Enet 0 Tx Count Enet 1 Tx Count

0 65 3466
1 64 0
```

## Command History

| Version       | Modification       |
|---------------|--------------------|
| ArubaOS 6.3.1 | Command introduced |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug lldp

show ap debug lldp

### Description

Show an AP's debug log.

### Syntax

| Parameter         | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show log information for an AP with a specific name.                                                                                                |
| bssid <bssid>     | Show log information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                       |

### Usage Guidelines

An AP's log files show configuration changes since the AP was last reset.

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug log

```
show ap debug log {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

### Description

Show an AP's debug log.

### Syntax

| Parameter           | Description                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show log information for an AP with a specific name.                                                                                                |
| bssid <bssid>       | Show log information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                       |
| ip6-addr <ip6-addr> | Show log information for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.                                   |

### Usage Guidelines

An AP's log files show configuration changes since the AP was last reset.

### Command History

| Release     | Modification                                  |
|-------------|-----------------------------------------------|
| ArubaOS 3.0 | Command introduced                            |
| ArubaOS 6.3 | The <b>ip6-addr</b> parameter was introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug config-msg-history

```
show ap debug config-msg-history [ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]
```

### Description

This command shows recent configuration messages sent and received by an AP.

### Syntax

| Parameter           | Description                      |
|---------------------|----------------------------------|
| ap-name <ap-name>   | Name of the access point.        |
| ip-addr <ip-addr>   | IP address of the access point.  |
| ip6-addr <ip6-addr> | IPv6 address of the access point |

### Examples

The output of this command shows the configuration message history for the AP named "myAP-W-AP105."

```
(host) #show ap debug config-msg-history ap-name myAP-W-AP105
Thu Feb 13 06:32:31 2014(1843 secs ago): RCVD REQ type=CONFIG len=206 peer=10.17.160.4 seq_

| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug dot11r state

```
show ap debug dot11r state [ap-name <ap-name> | ip-addr <ip-addr>]
```

### Description

This command displays all the r1 keys that are stored in an AP.

### Syntax

| Parameter         | Description                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show debugging information for a specific AP.                                                                        |
| ip-addr <ip-addr> | Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format. |

### Examples

Use this command to view all the r1 keys that are stored in an AP. You can filter the output based on the AP name or IP address.

```
(host) #show ap debug dot11r state ap-name MAcage-105-GL
```

Stored R1 Keys

-----

| Station MAC                            | Mobility Domain ID | Validity Duration          | R1 Key                              |
|----------------------------------------|--------------------|----------------------------|-------------------------------------|
| -----                                  | -----              | -----                      | -----                               |
| 00:50:43:21:01:b8                      | 1                  | 3568                       | (32): 94 ff 18 0a 5f 47 8b 3e 95 2b |

### Command History

Introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show ap debug mgmt-frames (deprecated)

### Description

Show traced 802.11 management frames.

### Command History

| Version     | Modification       |
|-------------|--------------------|
| ArubaOS 3.0 | Command Introduced |
| ArubaOS 5.0 | Command deprecated |

## show ap debug port status

```
show ap debug port status {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

### Description

Shows the status of the AP's wired ports.

### Syntax

| Parameter           | Description             |
|---------------------|-------------------------|
| ap-name <ap-name>   | Name of the AP.         |
| bssid <bssid>       | BSSID of the AP.        |
| ip-addr <ip-addr>   | IP address of the AP.   |
| ip6-addr <ip6-addr> | IPv6 address of the AP. |

### Examples

The output of the command displays the wired port status of an AP named **LocalAP1**. In this example, the output is divided into multiple sections to fit better on the pages of this document. In the actual command-line interface, it appears in a single long table.

```
(host) #show ap debug port status ap-name LocalAP1
```

AP "LocalAP1" Port Status

| Port       | MAC               | Type     | Forward Mode | Admin    | Oper | Speed    | Duplex | 802.3az | PoE |
|------------|-------------------|----------|--------------|----------|------|----------|--------|---------|-----|

## show ap debug radar-logs

```
show ap debug radar-logs
 ap-name <ap-name>
 ip-addr <ip-addr>
 ip6-addr <ip6-addr>
```

### Description

Displays the latest four RADAR event logs from the AP. This command is useful for debugging false radar detection related issues.

---

This command is applicable for APs running the Broadcom chip-set.

---

### Syntax

| Parameter           | Description                                                 |
|---------------------|-------------------------------------------------------------|
| ap-name <ap-name>   | Displays RADAR logs for an AP with a specific name.         |
| ip-addr <ip-addr>   | Displays RADAR logs for an AP with a specific IP address.   |
| ip6-addr <ip6-addr> | Displays RADAR logs for an AP with a specific IPv6 address. |

### Example

The output of this command displays RADAR logs from an W-AP225.

```
(host) #show ap debug radar-logs ap-name W-AP225
```
