## show ap debug radio-event-log status

```
show ap debug radio-event-log status {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

### Description

Show information about the radio event information captured in packet log files.

### Syntax

| Parameter           | Description                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show log information for an AP with a specific name.                                                               |
| ip-addr <ip-addr>   | Show log information for an AP with a specific IPv4 address by entering its IPv4 address in dotted-decimal format. |
| ip6-addr <ip6-addr> | Show log information for an AP with a specific IPv6 address by entering its IPv6 address.                          |

### Example

Radio Event Logs

| Radio Index | Radio's Bssid     | Radio's Band | Event Type | Log File Size | Status |
|-------------|-------------------|--------------|------------|---------------|--------|
| 0           | 00:24:6c:bd:65:b0 | 80211a       | N/A        | N/A           | start  |
| 1           | 00:24:6c:bd:65:a0 | 80211g       | N/A        | N/A           | stop   |

The output of this command includes the following information:

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| radio Index   | Index number of the AP radio (0 or 1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Radio's BSSID | BSSID of the AP radio. This is typically the AP radio's MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Radio's Band  | Band used by the AP radio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Event Type    | Type of events recorded. By default, all supported event types are recorded. <ul style="list-style-type: none"><li>• N/A: The default event type setting, which captures all supported types of radio events.</li><li>• ani Adaptive Noise Immunity control events</li><li>• rcfind: Transmission (Tx) control event</li><li>• rcupdate: Transmission (Tx) rate update event</li><li>• rx: Received (Rx) status register event</li><li>• text: Text record event</li><li>• tx: Transmission (Tx) control and Tx status register event</li></ul> |
| Log File Size | Size of the log file. A value of N/A indicates that the packet log feature uses the default log file size of 3145728 bytes (3MB)                                                                                                                                                                                                                                                                                                                                                                                                                |
| Status        | Shows if packet log capture was started or stopped on the AP radio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Related Commands

[ap debug radio-event-log](#)

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|

## show ap debug radio-info

```
show ap debug radio-info
 ap-name <ap-name> radio <radio>
 ip-addr <ip-addr> radio <radio>
 ip6-addr <ip6-addr> radio <radio>
```

### Description

Displays the Wi-Fi radio debug logs from the AP driver.

This command is applicable for W-AP200 Series, W-AP210 Series, W-AP220 Series, and W-AP270 Series access points.

### Syntax

| Parameter           | Description                                                             |
|---------------------|-------------------------------------------------------------------------|
| ap-name <ap-name>   | Displays Wi-Fi radio debug logs for an AP with a specific name.         |
| ip-addr <ip-addr>   | Displays Wi-Fi radio debug logs for an AP with a specific IP address.   |
| ip6-addr <ip6-addr> | Displays Wi-Fi radio debug logs for an AP with a specific IPv6 address. |

### Example

The output of this command displays the log information about Wi-Fi radio 0 for a W-AP225:

```
(host) #show ap debug radio-info ap-name W-AP225 radio 0

Radio Info Script

aruba_dbg_radio_info_0 Start time: Fri Mar 27 14:33:21 IST 2015

## show ap debug radio-registers

```
show ap debug radio-registers {ap-name <name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>} {radio 0|1}
```

### Description

This command allows you to view radio register changes.

### Syntax

| Parameter | Description                                                         |
|-----------|---------------------------------------------------------------------|
| ap-name   | Name of the AP for which you want to view register changes.         |
| ip-addr   | IPv4 address of the AP for which you want to view register changes. |
| ip6-addr  | IPv6 address of the AP for which you want to view register changes. |
| radio 0 1 | Show information for the specified radio on the AP.                 |

### Usage Guidelines

This command displays radio register changes made under the supervision of Dell technical support.

### Command History

Introduced in ArubaOS6.2.

### Command Information

| Platforms           | Licensing             | Command Mode                      |

## show ap debug radio-stats

show ap debug radio-stats {ap-name <ap-name>|ip-addr <ip-addr>} radio {0|1} [advanced]

### Description

Show aggregate radio debug statistics of an AP.

### Syntax

| Parameter           | Description                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show log information for an AP with a specific name.                                                           |
| ip-addr <ip-addr>   | Show log information for an AP with a specific IP address by entering its IP address in dotted-decimal format. |
| ip6-addr <ip6-addr> | IPv6 address of the Access Point.                                                                              |
| radio {0 1}         | Specify the ID number of the radio for which you want to view statistics.                                      |
| advanced            | Include this parameter to display additional radio statistics.                                                 |

### Example

The output of this command displays general statistics for the radio, as well as statistics for transmitted and received frames.

```
(host) #show ap debug radio-stats ap-name AP12 radio 1
RADIO Stats

Parameter Value

General Per-radio Statistics
Total Radio Resets 0
Resets Beacon Fail 0
TX Power Changes 5
Channel Changes 2
Radio Band Changes 0
Current Noise Floor 95
11g Protection 0

Transmit specific Statistics
Frames Rcvd For TX 2452151
Tx Frames Dropped 1736429
Frames Transmitted 4247212
...
```

If you include the **advanced** option at the end of the **show ap debug radio-stats** command, the output of this command will include all the following parameters, as well as additional information for the SNR, frame counts, channel busy times, and data bytes for transmitted and received packets. If you omit the **advanced** option, the output will include less information, and the data will be displayed in a different order. The following table describes the output of this command when the **advanced** option is included.

| Parameter            | Description                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total Radio Resets   | Total number of times the radio reset.                                                                                                                                                                                                   |
| Resets Beacon Fail   | Number of times the radio reset due to beacon failure.                                                                                                                                                                                   |
| BB check positives   | Number of times the radio checked for a base-band hang condition                                                                                                                                                                         |
| Resets BeacQ Stuck   | An AP's radio typically sends a beacon every 100 milliseconds. If beacons are not sent at a regular interval or the radio experiences excessive noise, the beacon queue will reset. This parameter indicates the number of queue resets. |
| Resets Fatal Intr    | Number of time the radio was reset because the AP hardware was unresponsive.                                                                                                                                                             |
| Resets RX Overrun    | The number of radio resets due to Receive FIFO overruns.                                                                                                                                                                                 |
| Resets RF Gain       | Number of radio resets due to gain changes.                                                                                                                                                                                              |
| Resets MTU Change    | Number of times the radio reset due to a change in the Maximum Transmission Unit (MTU) value.                                                                                                                                            |
| Resets TX Timeouts   | Number of radio resets due to transmission timeouts (the radio doesn't transmit a signal within the required time frame.)                                                                                                                |
| POE-Related Resets   | If the radio power profile drops, an AP may not be able to support three transmit chains, and may drop to two chains only. This parameter displays the number of resets due to this type of power change.                                |
| External Reset       | Number of times the AP has been reset because it was unplugged or its reset button was pressed.                                                                                                                                          |
| PCI Fatal Intr Reset | Radio reset due to PCI fatal interrupt received from radio chip.                                                                                                                                                                         |
| Chaimask Reset       | Radio reset when new chain mask is configured.                                                                                                                                                                                           |
| TX stat Reset        | Radio reset caused by inconsistent state of hardware transmit queue.                                                                                                                                                                     |
| TX Power Changes     | Number of times the radio's transmission power changed.                                                                                                                                                                                  |
| Channel Changes      | Number of times the radio's channel changed.                                                                                                                                                                                             |
| Radio Band Changes   | Number of time the radio's band changed.                                                                                                                                                                                                 |
| Current Noise Floor  | The residual background noise detected by an AP.                                                                                                                                                                                         |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | Noise seen by an AP is reported as -dBm. Therefore, a noise floor of -100 dBm is smaller (lower) than a noise floor of -50 dBm. For most environments, the noise floor should be no greater than -80 dBm. Anything larger may indicate an interference problem which is drowning out good signals (data) in background noise.              |
| Dummy NF pkts on home channel | Number of noise floor readings on the home channel.                                                                                                                                                                                                                                                                                        |
| Dummy NF pkts on scan channel | Number of noise floor readings on the scan channel.                                                                                                                                                                                                                                                                                        |
| Avail TX Buffers              | An AP has a set number of buffers which it can use to buffer frames for non-responsive power save clients. The total number of buffer frames depends upon the AP model type.                                                                                                                                                               |
| 11g Protection                | This parameter shows whether 802.11g protection has been enabled or disabled.                                                                                                                                                                                                                                                              |
| Last TX Antenna               | This parameter indicates whether the last frame transmitted was sent on antenna 1 or antenna 0. This parameter can be useful for troubleshooting external antennas.                                                                                                                                                                        |
| Last RX Antenna               | This parameter indicates whether the last frame received was via antenna 1 or antenna 0. This parameter can be useful for troubleshooting external antennas.                                                                                                                                                                               |
| Scan Requests                 | Total number of scan requests received by the AP.                                                                                                                                                                                                                                                                                          |
| Scan Rejects                  | Total number of scan rejected by the AP.                                                                                                                                                                                                                                                                                                   |
| Scan Rejects (Misc 1)         | Number of scan rejects due to pending transmissions.                                                                                                                                                                                                                                                                                       |
| Load aware Scan Rejects       | Load aware ARM preserves network resources during periods of high traffic by temporarily halting scanning if the load for the AP gets too high. The <b>load aware Scan Rejects</b> parameter shows the number of times the AP has rejected a scan because of the load aware scan feature.                                                  |
| PS aware Scan Rejects         | If the ARM power-save aware scan feature is enabled, the AP will not scan a different channel if it has one or more clients and is in power save mode. The <b>ps aware Scan Rejects</b> parameter shows the number of times the AP has rejected a scan because of the power-save aware scan feature.                                       |
| EAP Scan Rejects              | If you enable the EAP-aware scanning feature in the AP's ARM profile, the AP will not attempt to scan a different channel if the Extensible Authentication Protocol over LAN (EAPOL) exchange is in progress with a client. This parameter shows the number of times the AP has rejected a scan because of the EAP aware scanning feature. |

| Parameter                       | Description                                                                                                                                                                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Voice aware Scan Rejects        | If you enable the VoIP Aware Scan feature in the AP's ARM profile, the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This <b>Voice aware scan Rejects</b> parameter shows the number of times the AP has rejected a scan because of the Voip aware scan feature.       |
| Video aware Scan Rejects        | If you enable the Video Aware Scan feature in the AP's ARM profile, the AP will not attempt to scan a different channel if one of its clients has an active video session. This <b>Video aware scan Rejects</b> parameter shows the number of times the AP has rejected a scan because of the Video aware scan feature. |
| UAPSD Scan Rejects              | Number of times the scan was rejected due to UAPSD-related transmissions.                                                                                                                                                                                                                                               |
| Post radar related scan Rejects | Number of times the scan was rejected due to recent radar detection.                                                                                                                                                                                                                                                    |
| CABQ traffic Scan Rejects       | Number of times the scan was rejected due to pending multicast transmissions.                                                                                                                                                                                                                                           |
| Radio Reset Scan Rejects        | Number of times the scan was rejected due to a recent radio reset.                                                                                                                                                                                                                                                      |
| Queue Drain Scan Rejects        | This legacy statistic has been deprecated, and will not increment.                                                                                                                                                                                                                                                      |
| Scan Success                    | Number of successful scans. To view scan details, use the command <a href="#">show ap arm scan-times</a> .                                                                                                                                                                                                              |
| Scan Deferred                   | Number of times the scan was deferred due to pending beacon transmissions on the home channel.                                                                                                                                                                                                                          |
| EIRP                            | The value of this parameter is the transmission power level (in dBm) + the antenna gain value.                                                                                                                                                                                                                          |
| MAX EIRP                        | The max EIRP depends on AP capability and the regulatory domain constraint for the channel of operation. For example, in the US, Channels 36-48 have max EIRP of 23dBm                                                                                                                                                  |
| Dummy<number>                   | For internal use only.                                                                                                                                                                                                                                                                                                  |
| UAPSD Flush STA Wake            | Number of times a client wakes from power-save mode and flushes the UAPSD queue.                                                                                                                                                                                                                                        |
| UAPSD SP Set                    | The number of unique UAPSD Scheduled Period is started in response to UAPSD trigger frames.                                                                                                                                                                                                                             |
| UASPD Dup Trig                  | The number of times duplicate UAPSD trigger frames are received (i.e., retried UAPSD triggers that were received by the AP more than once).                                                                                                                                                                             |

| Parameter                    | Description                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UAPSD Recv frame for TX      | The number of frames received for transmission over the air interface using UAPSD                                                                             |
| UAPSD Ageout Drain           | The number of time UAPSD queue is drained (i.e. frames are dropped) due to ageout.                                                                            |
| UAPSD TX proc comp           | The number of UAPSD frames that were successfully transmitted                                                                                                 |
| UAPSD SP In prog             | The number of times a trigger frame was received while a Scheduled Period (SP) was already in progress based on an earlier trigger frame.                     |
| UAPSD QOS NULL TX            | The number of times the AP had to respond with a QoS Null Data frame in response to a UAPSD trigger because AP did not have Data frame queued for that client |
| UAPSD TX HW Queued           | The number of frames (Data and Null Data) that were transferred to the radio HW for transmission, in response to UAPSD triggers.                              |
| UAPSD SP Reset               | The number of times the UAPSD Scheduled Period (SP) in progress is reset or canceled.                                                                         |
| Tx Time perct @ beacon intvl | Percentage of time spent transmitting Wi-Fi frames since the last beacon.                                                                                     |
| Tx Frames Rcvd               | Number of transmitted frames that were received.                                                                                                              |
| Tx Bcast Frames Rcvd         | Number of transmitted broadcast frames that were received.                                                                                                    |
| Tx Frames Dropped            | Number of transmitted frames that were dropped.                                                                                                               |
| Tx Bcast Frames Dropped      | Number of transmitted broadcast frames that were dropped.                                                                                                     |
| Tx Frames Transmitted        | Number of frames successfully transmitted.                                                                                                                    |
| Tx Bytes Rcvd                | Number of transmitted bytes received.                                                                                                                         |
| Tx Bytes Transmitted         | Number of transmitted bytes                                                                                                                                   |
| Tx Time Frames Rcvd          | Number of times transmitted frames were received.                                                                                                             |
| Tx Time Frames Dropped       | Number of times transmitted frames were dropped.                                                                                                              |
| Tx Time Frames Transmitted   | Number of times frames were transmitted.                                                                                                                      |
| Tx PS Unicast                | Number of power save unicast frames                                                                                                                           |

| Parameter                     | Description                                                                                                       |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Tx DTIM Broadcast             | Number of broadcast frames with DTIM values.                                                                      |
| Tx Success With Retry         | Number of frames that were successfully transmitted after being retried.                                          |
| Tx Multiple retries           | Number of frames that were successfully transmitted after being retried multiple times.                           |
| Tx Mgmt Frames                | Number of management frames transmitted.                                                                          |
| Tx Mgmt Frames (PPS)          | Rate of retransmitted frames, in packets per second.                                                              |
| Tx Beacons Transmitted        | Number of beacons transmitted.                                                                                    |
| Tx Beacons Transmitted (PPS)  | Rate of transmitted beacons, in packets per second.                                                               |
| Tx Probe Responses            | Number of transmitted probe responses.                                                                            |
| Tx Probe Responses (PPS)      | Rate of transmitted probe responses, in packets per second.                                                       |
| Tx Data Transmitted Retried   | Number of retried data frames.                                                                                    |
| Tx Data Transmitted           | Number of transmitted data frames.                                                                                |
| Tx Data Frames                | Number of transmitted data frames.                                                                                |
| Tx Broadcast Data Frames In   | Number of broadcast data frames received by the AP from wired interface to be transmitted in the air.             |
| Tx Data Bytes Transmitted     | Total data bytes received by an AP from its wired interface to be transmitted over the air.                       |
| Tx Data Bytes                 | Total data bytes transmitted by the AP over the air.                                                              |
| Tx Time Data Transmitted      | Total time on spent successfully transmitting frames (including the retried frames).                              |
| Tx Time BC/MC Data            | Total time spent transmitting broadcast/multicast frames.                                                         |
| Tx Time Data dropped          | Total time spent transmitting dropped frames.                                                                     |
| Tx Time Data                  | Total time spent sending frames received for transmission, including the frames that were dropped after retrying. |
| Tx Broadcast Data Frames Sent | Broadcast data frames transmitted by the AP.                                                                      |

| Parameter                           | Description                                                                                                                                                                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tx Broadcast Data Frames Sent (PPS) | Rate of broadcast data frames transmitted by the AP, in packets per second.                                                                                                                                                                                                |
| Tx Multicast Data Frames            | Multicast data frames transmitted by the AP.                                                                                                                                                                                                                               |
| Tx Multicast Data Frames (PPS)      | Rate of multicast data frames transmitted by the AP, in packets per second.                                                                                                                                                                                                |
| Tx DMO Multicast                    | The number of multicast frames transmitted as multicast without converting to unicast.                                                                                                                                                                                     |
| Tx DMO Invalid                      | The number of multicast frames which should have been converted but were not as due to invalid format. (This value is typically normally 0.)                                                                                                                               |
| Tx DMO Converted                    | The number of multicast frames received as multicast which were then converted to unicast one or more times. This counter increments once per multicast frame.                                                                                                             |
| Tx DMO Replicated                   | The number of frames transmitted as unicast frames. For each multicast frame the counter is incremented by the number of replications for that frame. (The number of replications is the number of clients associated to the BSSID, VLAN or group receiving these frames). |
| Tx DMO Dropped                      | The number of frames dropped as conversion was not consistent with state on the AP. (This value is typically normally 0.)                                                                                                                                                  |
| Tx DMO No Client                    | Number of times no client was found for an association-ID indicated by the frame. (This value is typically normally 0.)                                                                                                                                                    |
| Tx DMO No BSSID                     | Number of times the BSSID indicated by the frame was not found. (This value is typically normally 0.)                                                                                                                                                                      |
| Tx Unicast Data Frames              | Number of transmitted unicast data frames                                                                                                                                                                                                                                  |
| Tx RTS Success                      | Number of Ready To Send (RTS) frames successfully transmitted.                                                                                                                                                                                                             |
| Tx RTS Failed                       | Number of Ready To Send (RTS) frames that were not successfully transmitted                                                                                                                                                                                                |
| Tx CTS Frames                       | Number of Clear-to-Send (CTS) frames transmitted.                                                                                                                                                                                                                          |
| Tx CTS Frames (PPS)                 | Rate of CTS frames sent, in packets per second. (This parameter does not include CTS frames sent in response to RTS).                                                                                                                                                      |

| Parameter                   | Description                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Tx Powersave Queue Timeouts | Number of transmit frames discarded from the power save queue because the frames aged out                                          |
| Tx Dropped After Retry      | Number of frames dropped after an attempted retry.                                                                                 |
| Tx Dropped No Buffer        | Number of frames dropped because the AP's buffer was full.                                                                         |
| Tx Missed ACKs              | Number of retries triggered because an acknowledgment was not received.                                                            |
| Tx Failed Beacons           | Number of times a radio failed to transmit a beacon at the scheduled interval (100ms).                                             |
| Tx Multi-Beacon Fail        | Number of times multiple consecutive beacons failed to transmit.                                                                   |
| Tx Long Preamble            | Number of frames sent with a long preamble.                                                                                        |
| Tx Short Preamble           | Number of frames sent with a short preamble.                                                                                       |
| Tx Beacon Interrupts        | Number of broadcast beacons that were interrupted.                                                                                 |
| TX Interrupts               | Number of transmission interrupts.                                                                                                 |
| Tx FIFO Underrun            | The number of transmitted FIFO overruns.                                                                                           |
| Tx Allocated Desc           | Number of allocated transmit descriptors.                                                                                          |
| Tx Freed Desc               | Number of freed transmit descriptors.                                                                                              |
| Tx EAPOL Frames             | Number of EAPOL frames transmitted                                                                                                 |
| TX STBC Frames              | Number of transmitted frames with Space-time block coding (STBC) enabled.                                                          |
| TX LDPC Frames              | Number of transmitted frames with Low Density Parity Check (LDPC) enabled.                                                         |
| Tx AGGR Good                | Number of aggregated frames successfully transmitted.                                                                              |
| Tx AGGR Unaggr              | Number of non-aggregate frames transmitted due to unavailability of additional frames for aggregation at the time of transmission. |
| Tx data <number> Mbps       | Number of frames transmitted at the specified rate (in Mbps).                                                                      |
| Tx <number> Mbps [Long]     | Number of frames with a long preamble transmitted at the specified rate.                                                           |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tx <number> Mbps [Short]  | Number of frames with a short preamble transmitted at the specified rate.                                                                                                                                                                                                                                                                |
| Tx HT <number> Mbps       | Number of high-throughput frames transmitted at the specified rate.                                                                                                                                                                                                                                                                      |
| Tx WMM [category]         | <p>Number of Wi-Fi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <p>Tx WMM [BE]: Best Effort</p> <p>Tx WMM [BK]: Background</p> <p>Tx WMM [VO]: VoIP</p> <p>Tx WMM [VI]: Video</p> |
| Tx WMM [category] dropped | <p>Number of dropped Wi-Fi Multimedia (WMM) packets in the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <p>Tx WMM [BE]: Best Effort</p> <p>Tx WMM [BK]: Background</p> <p>Tx WMM [VO]: VoIP</p> <p>Tx WMM [VI]: Video</p>      |
| Tx UAPSD OverflowDrop     | Number of packets dropped due to Unscheduled Automatic Power Save Delivery (U-APSD) overflow.                                                                                                                                                                                                                                            |
| TX Timeouts               | Number of transmission timeouts                                                                                                                                                                                                                                                                                                          |
| Lost Carrier Events       | Number of carrier sense timeouts.                                                                                                                                                                                                                                                                                                        |
| Tx HT40 Hang Detected     | Parameter deprecated.                                                                                                                                                                                                                                                                                                                    |
| Tx HT40 Hang Stuck        | Parameter deprecated.                                                                                                                                                                                                                                                                                                                    |
| Tx HT40 Hang Possible     | Parameter deprecated.                                                                                                                                                                                                                                                                                                                    |
| Tx HT40 Dfs IMM WAR       | Number of times the HT 40 RX Clear Hang immunity workaround was employed.                                                                                                                                                                                                                                                                |
| Tx HT40 Dfs HT20 WAR      | Number of times the HT 20 RX Clear Hang immunity workaround was employed.                                                                                                                                                                                                                                                                |
| Tx MAC/BB Hang Stuck      | Number of times a workaround was employed for potential beacons stuck due to MAC or base-band stuck conditions.                                                                                                                                                                                                                          |

| Parameter              | Description                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tx Mgmt Bytes          | Total management frame bytes transmitted.                                                                                                                            |
| Tx Beacons Bytes       | Total number of Beacon frame bytes transmitted.                                                                                                                      |
| Tx Data Frames Dropped | Number of transmitted data frames that were dropped.                                                                                                                 |
| Tx AMSDU pkt count     | Total number of AMSDU bytes transmitted.                                                                                                                             |
| Rx Last SNR            | The last recorded signal-to-noise ratio.                                                                                                                             |
| Rx Last SNR CTL0       | The signal-to-noise ratio for the last received data packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.   |
| Rx Last SNR CTL1       | The signal-to-noise ratio for the last received data packet on the secondary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode. |
| Rx Last SNR CTL2       | The signal-to-noise ratio for the last received data packet on the secondary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode. |
| Rx Last SNR EXT0       | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Rx Last SNR EXT1       | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Rx Last SNR EXT2       | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Rx Last ACK SNR EXT0   | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Rx Last ACK SNR EXT1   | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Rx Last ACK SNR EXT2   | Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.    |
| Rx Frames Received     | Number of frames received.                                                                                                                                           |
| Rx Good Frames         | Number of frames received with no errors.                                                                                                                            |

| Parameter                     | Description                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------|
| Rx Bad Frames                 | Number of bad or error frames received.                                               |
| Rx Total Data Frames Recvd    | Total number of data frames received.                                                 |
| Rx Total Mgmt Frames Recvd    | Total number of management frames received.                                           |
| Rx Total Control Frames Recvd | Total number of control frames received.                                              |
| Rx Total Bytes Recvd          | Total number of bytes received.                                                       |
| Rx Total Data Bytes Recvd     | Total number of data bytes received.                                                  |
| Rx Total RTS Frames Recvd     | Total number of Ready-To-Send (RTS) frames received.                                  |
| Zx Total CTS Frames Recvd     | Number of Clear-to-Send (CTS) frames received.                                        |
| Rx Total ACK Frames           | Number of acknowledgment frames received.                                             |
| Rx Total Beacons Received     | Number of beacons received.                                                           |
| Rx Total Probe Requests       | Number of probe requests received.                                                    |
| Rx Total Probe Responses      | Number of probe responses received.                                                   |
| Rx retry frames               | Number of retried frames received.                                                    |
| Channel busy 1s               | The percentage of time the radio channel was busy in the last 1 second.               |
| Channel busy 4s               | The percentage of time the radio channel was busy in the last 4 seconds.              |
| Channel busy 64s              | The percentage of time the radio channel was busy in the last 64 seconds.             |
| Ch Busy perct @ beacon intvl  | Percentage of time the channel was busy over the last 30 beacon intervals.            |
| Rx Time perct @ beacon intvl  | Percentage of time the AP was receiving data over the last 30 beacon intervals.       |
| Rx Discarded Events           | Number of non-802.11 events that were detected and discarded during normal operation. |
| Rx ARM Scan Frames            | Number of scan frames sent for the adaptive radio management (ARM) feature.           |

| Parameter                | Description                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------|
| Rx Data Frames           | Number of data frames received.                                                                  |
| Rx Data Frames (PPS)     | Rate at which data frames were received, in packets per second.                                  |
| Rx Data Bytes            | Number of data bytes received.                                                                   |
| Rx Time Data             | Total time spent on frames successfully received.                                                |
| Rx Duplicate Frames      | Number of duplicate frames received.                                                             |
| Rx Broadcast Data Frames | Number of broadcast frames received.                                                             |
| Rx Multicast Data Frames | Number of multicast frames received.                                                             |
| Rx Unicast Data Frames   | Number of unicast frames received.                                                               |
| Rx Null Data Frames      | Number of null data frames received.                                                             |
| Rx Mgmt Frames           | Number of management frames received.                                                            |
| Rx Mgmt Frames (PPS)     | Rate at which management frames were received, in packets per second.                            |
| Rx Control Frames        | Number of control frames received.                                                               |
| Rx Control Frames (PPS)  | Rate at which control frames were received, in packets per second.                               |
| Rx Frames To Me          | Number of frames received that are addressed to the specified BSSID.                             |
| Rx Bytes To Me           | Number of bytes received that are addressed to the specified BSSID.                              |
| Rx Time To Me            | Total time spent receiving frames sent to a specified BSSID.                                     |
| Rx Broadcast Frames      | Number of broadcast frames received.                                                             |
| Rx Probe Requests        | Number of Probe requests received.                                                               |
| Rx Probe Requests (PPS)  | Rate at which probe requests were received, in packets per second.                               |
| Rx RTS Frames            | Ready To Send (RTS) frames received. These frames are sent when a computer has data to transmit. |

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Rx RTS Frames (PPS)   | Rate at which RTS frames were received, in packets per second.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Rx CTS Frames         | Clear To Send (CTS) frames received. This type of frame are used to verify that a client is ready to receive information.                                                                                                                                                                                                                                                                                                                                                   |
| Rx CTS Frames (PPS)   | Rate at which CTS frames were received, in packets per second.                                                                                                                                                                                                                                                                                                                                                                                                              |
| RX PS Poll Frames     | Power-Save Poll (PS-Poll) frames received. When a client exits a power-saving mode, it transmits a PS-Poll frame to the AP to retrieve any frames buffered while it was in power-saving mode.                                                                                                                                                                                                                                                                               |
| RX CRC Errors         | Cyclic Redundancy Check (CRC) is a data sequence that is sent with a frame to help verify if all the data received correctly. Possible CRC error causes include: <ul style="list-style-type: none"> <li>• Hardware malfunction</li> <li>• Loose or unconnected cables</li> <li>• RF interference, such as overlapping access point coverage on a channel or interfering 2.4-GHz signals from devices like microwave ovens</li> <li>• and wireless handset phones</li> </ul> |
| RX PLCP Errors        | Physical Layer Convergence Protocol (PLCP) errors.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Rx Frames Dropped     | Number of received frames that were dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Rx PHY Events         | The number of Physical Layer Events, that are not 802.11 packets, detected by radio as part of its normal receive operation.                                                                                                                                                                                                                                                                                                                                                |
| Rx RADAR Events       | Number of times an AP detects a radar signature. Dell APs are DFS-compliant detects a radar signature, it will change its channel.                                                                                                                                                                                                                                                                                                                                          |
| RX Interrupts         | The number of receive interrupts received by the CPU from the radio.                                                                                                                                                                                                                                                                                                                                                                                                        |
| RX Overrun            | The number of Receive FIFO overruns.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Rx undecryptable      | Number of non-decryptable frames received.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| RX STBC Frames        | Number of received frames with STBC enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RX LDPC Frames        | Number of received frames with LDPC enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Rx data <number> Mbps | Data packets received at the specified rate (in Mbps).                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Rx <number> Mbps      | Packets received at the specified rate (in Mbps).                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Rx data <number> Mbps       | Packets received at the specified rate (in Mbps).                                                                                                                                                                                                                                                                                    |
| Rx HT <number> Mbps         | Number of high-throughput packets received at the specified rate.                                                                                                                                                                                                                                                                    |
| Rx WMM [BE]                 | <p>Number of Wifi Multimedia (WMM) packets received for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <p>Rx WMM [BE]: Best Effort</p> <p>Rx WMM [BK]: Background</p> <p>Rx WMM [VO]: VoIP</p> <p>Rx WMM [VI]: Video</p> |
| RX bad length               | Number of frames received with incorrect length.                                                                                                                                                                                                                                                                                     |
| Rx Null Src MAC             | Number of received frames with source MAC address as NULL.                                                                                                                                                                                                                                                                           |
| Rx Managment Frames Dropped | Number of received management frames that were dropped.                                                                                                                                                                                                                                                                              |
| Rx Data Frames Dropped      | Number of received data frames that were dropped.                                                                                                                                                                                                                                                                                    |
| SNR from CTL0               | Signal-to-noise ratio (SNR) on chain 0.                                                                                                                                                                                                                                                                                              |
| Throttle drops              | Number of received frames dropped by AP due to throttling when AP is under high load.                                                                                                                                                                                                                                                |
| Stop all but Mgmt           | Number of data frames dropped because radar was detected on a channel. An AP is allowed to send management frames only and must drop all other frames when radar is detected on a channel.                                                                                                                                           |

## Command History

| Command     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

 ap-name <ap-name> [essid <essid>]
 bssid <bssid> [essid <essid>]
 ip-addr <ip-addr> [essid <essid>]
 ip6-addr <ip6-addr> [essid <essid>]
```

### Description

Show the configuration the AP downloaded from the controller.

### Syntax

| Parameter           | Description                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show log information for an AP with a specific name.                                                                                                |
| bssid <bssid>       | Show log information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                       |
| ip6-addr <ip6-addr> | Show log information for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.                                   |

### Example

The output of this command displays configuration information for each interface. The example below shows only part of the output for this command. Additional parameters not displayed are described in the table below.

```
(host) #show ap debug received-config ap-name AP12
```

```
Downloaded Config for WIFI 0
```

```

```

|                                    |              |

The output of this command includes the following information:

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BSSID                          | The BSSID of the AP.                                                                                                                                                                                                                                                                                                                                                     |
| LMS IP                         | The LMS IP is the IP address of the local controller used by the AP for client data processing.                                                                                                                                                                                                                                                                          |
| Master IP                      | For environments with multiple controllers, the master controller is the central configuration and management point for all local controllers.                                                                                                                                                                                                                           |
| Mode                           | Shows the operating modes for the AP.<br><br>ap-mode: Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.<br><br>am-mode: Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc. |
| QBSS Probe Response            | Quality-of-service BSS (QBSS).                                                                                                                                                                                                                                                                                                                                           |
| Native VLAN ID                 | The ID number of the Native VLAN.                                                                                                                                                                                                                                                                                                                                        |
| SAP MTU                        | The Maximum Transmission Unit (MTU) for the GRE tunnel.                                                                                                                                                                                                                                                                                                                  |
| Heartbeat DSCP                 | DSCP value for the heartbeat traffic between the AP and the controller.                                                                                                                                                                                                                                                                                                  |
| High throughput enable (radio) | Shows if high-throughput (802.11n) features are enabled or disabled on the radio.                                                                                                                                                                                                                                                                                        |
| Channel                        | Shows the channel number for the AP's 802.11a/802.11n physical layer.                                                                                                                                                                                                                                                                                                    |
| Beacon Period                  | Shows the time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.                                                                                                                                                                                              |
| Transmit Power                 | Shows the current transmission power level.                                                                                                                                                                                                                                                                                                                              |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                              |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Advertise TPC Capability           | If enabled, the AP will advertise its Transmit Power Control (TPC) capability.                                                                                                                                                                                                                                           |
| Enable CSA                         | Displays whether or not the AP has enabled channel switch announcements (CSAs) for 802.11h.                                                                                                                                                                                                                              |
| CSA Count                          | Number of channel switch announcements that must be sent before the AP will switch to a new channel.                                                                                                                                                                                                                     |
| Management Frame Throttle interval | Average interval that rate limiting management frames are sent from this radio, in seconds. If this column displays a zero ( <b>0</b> ), rate limiting is disabled for this AP.                                                                                                                                          |
| Management Frame Throttle Limit    | Maximum number of management frames that can come from this radio in each throttle interval.                                                                                                                                                                                                                             |
| Active Scan                        | Displays whether or not the active scan feature is enabled.<br><br>This option elicits more information from nearby APs, but also creates additional management traffic on the network. <b>Active Scan</b> is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Dell Support. |
| VoIP Aware Scan                    | Shows if VoIP aware scanning is enabled or disabled. If you use voice handsets in the WLAN, <b>VoIP Aware Scan</b> should be enabled in the ARM profile so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that <b>Scanning</b> is also enabled. |
| Power Save Aware Scan              | Shows if the power save aware scan is enabled or disabled. If enabled, the AP will not scan a different channel if it has one or more clients and is in power save mode.                                                                                                                                                 |
| Load aware Scan Threshold          | The <b>Load Aware Scan Threshold</b> is the traffic throughput level an AP must reach before it stops scanning. Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high.                                                      |
| 40 MHz intolerance                 | The specified setting allows ARM to determine if 40 MHz mode of operation is allowed on the 5 GHz or 2.4 GHz frequency band only, on both frequency bands, or on neither frequency band.                                                                                                                                 |
| Honor 40 MHz intolerance           | Shows if 40 MHz intolerance is enabled or disabled. If enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.                                                                                                                               |
| Legacy station workaround          | Shows if interoperability for misbehaving legacy stations is enabled or disabled.                                                                                                                                                                                                                                        |

| Parameter                           | Description                                                                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Country Code                        | Display the country code for the AP. The country code specifies allowed channels for that country.                                                                                                           |
| ESSID                               | An Extended Service Set Identifier (ESSID), for the AP.                                                                                                                                                      |
| Encryption                          | Encryption type used on this AP.                                                                                                                                                                             |
| WPA2 Pre-Auth                       | 802.11x settings are <b>enabled</b> or <b>disabled</b> .                                                                                                                                                     |
| DTIM Interval                       | Number of beacons that should elapse before an AP sends beacon broadcasts for power save clients.                                                                                                            |
| 802.11a Basic Rates                 | Minimum data rate required for a client to associate with the AP. For an 802.11a radio, this value can be 6, 12 and 24 802.11 data rates. 802.11b/g radios will report a value of 1 and 2 802.11 data rates. |
| 802.11a Transmit Rates              | 802.11 data rate at which the AP will transmit data to its clients. This value can be 6-54 for 802.11a radios, and 1-54 for 802.11b/g radios.                                                                |
| Station Ageout Time                 | Number of seconds a station may be idle before it is deauthorized from an AP.                                                                                                                                |
| Max Transmit Attempts               | maximum number of times the AP will attempt to retransmit data.                                                                                                                                              |
| RTS Threshold                       | The minimum packet size at which the AP will issue a request-to-send (RTS) before sending the packet.                                                                                                        |
| Max Associations                    | The maximum number of clients allowed to associated with the AP                                                                                                                                              |
| Wireless Multimedia (WMM)           | Shows if Wireless Multimedia (WMM) is enabled or disabled for this AP. WMM provides prioritization of specific traffic relative to other traffic in the network.                                             |
| WMM TSPEC Min Inactivity Interval   | Displays the minimum inactivity time-out threshold of WMM traffic for this AP.                                                                                                                               |
| DSCP mapping for WMM voice AC       | Displays the DSCP value used to map WMM voice traffic.                                                                                                                                                       |
| DSCP mapping for WMM video AC       | Displays the DSCP value used to map WMM video traffic.                                                                                                                                                       |
| DSCP mapping for WMM best-effort AC | Displays the DSCP value used to map WMM best-effort traffic                                                                                                                                                  |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DSCP mapping for WMM background AC | Displays the DSCP value used to map WMM background traffic.                                                                                                                                                                                                                                                                       |
| Hide SSID                          | Shows if the feature to hide a SSID name in beacon frames is <b>enabled</b> or <b>disabled</b> .                                                                                                                                                                                                                                  |
| Deny_Broadcast Probes              | When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID. |
| Local Probe Response               | Shows if local probe response is enabled or disabled on the AP. If this option is enabled, the AP is responsible for sending 802.11 probe responses to wireless clients' probe requests. If this option is disabled, then the controller sends the 802.11 probe responses                                                         |
| Disable Probe Retry                | Shows if the AP has enabled or disabled MAC-level retries for probe response frames. By default this parameter is enabled, which mean that MAC level retries for probe response frames is disabled.                                                                                                                               |
| Maximum Transmit Failures          | Display the maximum number of transmission failures allowed before the client gives up.                                                                                                                                                                                                                                           |
| BC/MC Rate Optimization            | Shows if the AP has enabled or disabled scanning of all active stations currently associated to that AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate.       |
| High throughput enable (SSID)      | Shows if the AP has enabled or disabled the use of its high-throughput SSID in 40 MHz mode.                                                                                                                                                                                                                                       |
| 40 MHz channel usage               | Determines if this high-throughput SSID allows high-throughput (802.11n) stations to associate.                                                                                                                                                                                                                                   |
| MPDU Aggregation                   | Shows if the AP has enabled or disabled MAC protocol data unit (MPDU) aggregation.                                                                                                                                                                                                                                                |
| Max transmitted A-MPDU size        | Shows the maximum size, in bytes, of an A-MPDU that can be sent on the AP's high-throughput SSID.                                                                                                                                                                                                                                 |
| Max received A-MPDU size           | Shows the maximum size, in bytes, of an Aggregated-MAC Packet Data Unit (A-MPDU) that can be received on the AP's high-throughput SSID.                                                                                                                                                                                           |

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Min MPDU start spacing              | Displays the minimum time between the start of adjacent MDPU's within an aggregate MDPU, in microseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Supported MCS set                   | Comma-separated list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this high-throughput SSID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Short guard interval in 40 MHz mode | Shows if the AP has enabled or disabled use of short guard interval in 40 MHz mode of operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| VLAN                                | VLAN ID used by the SSID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Forward mode                        | <p>Shows the current forward mode (bridge, split-tunnel, or tunnel) for the virtual AP.</p> <p>This parameter controls whether 802.11 frames are tunneled to the controller using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the controller, and Internet access remains local).</p> <p>Only 802.1X authentication is supported when configuring bridge or split tunnel mode.</p>                                                                                                                                                                                                                                             |
| Band Steering                       | <p>Shows if band-steering has been enabled or disabled for a virtual AP.</p> <p>ARM's band steering feature encourages dual-band capable clients to stay on the 5GHz band on dual-band APs. This frees up resources on the 2.4GHz band for single band clients like VoIP phones.</p> <p>Band steering reduces co-channel interference and increases available bandwidth for dual-band clients, because there are more channels on the 5GHz band than on the 2.4GHz band. Dual-band 802.11n-capable clients may see even greater bandwidth improvements, because the band steering feature will automatically select between 40MHz or 20MHz channels in 802.11n networks. This feature is disabled by default, and must be enabled in a Virtual AP profile.</p> |

## Command History

| Command     | Description                                                      |
|-------------|------------------------------------------------------------------|
| ArubaOS 3.0 | Command Introduced                                               |
| ArubaOS 6.3 | The <b>ip6-addr</b> and <b>essid</b> parameters were introduced. |

## Command Information

## show ap remote debug association-failure

```
show ap remote debug association-failure [{ap-name <ap-name>}|{bssid <bssid>}|{essid <essid>}]
```

### Description

Display association failure information that can be used to troubleshoot problems on an AP.

### Syntax

| Parameter         | Description                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Filter the Association Failure Table by AP name.                                                                         |
| bssid <bssid>     | Filter the Association Failure Table by Basic Service Set Identifier (BSSID). The BSSID is usually the AP's MAC address. |
| essid <essid>     | Filter the Association Failure Table by Extended Service Set Identifier (ESSID) of an AP.                                |

### Usage Guidelines

Use this command to determine whether the client is associated, and identify the last AP to which it was connected.

### Example

The output of the command `show ap remote debug association-failure` displays the Association Failure Table shown below. If the **Idle time** column in the output of this command is a low value, **reason** column will describe why association failed.

```
(host)#show ap remote debug association-failure ap-name AP-65-port3
Association Failure Table

MAC Address AP Name BSSID ESSID State Radio Idle Time Reason

00:16:6f:09:54:3e AL29 00:1a:1e:11:6f:00 guest guest 802.11g 20h:39m:33s Denied; AP
Going Down
00:16:6f:09:54:3e AL33 00:1a:1e:11:6e:60 guest auth 802.11g 20h:39m:33s
Unspecified Failure
00:16:6f:09:54:3e AL40 00:1a:1e:8d:5b:20 guest guest 802.11g 20h:39m:33s Denied;
Ageout
Num Association Failures:3
```

The output of this command includes the following parameters:

| Column      | Description                                                    |
|-------------|----------------------------------------------------------------|
| MAC address | MAC address of the client that failed to associate with an AP. |
| AP Name     | Name of an AP to which the client attempted to associate.      |

| Column    | Description                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------|
| BSSID     | Basic Service Set Identifier of an AP.                                                                     |
| ESSID     | Extended Service Set Identifier of an AP.                                                                  |
| State     | This data column shows if the client is currently authorized or both authorized and associated with an AP. |
| Radio     | The AP radio type.                                                                                         |
| Idle Time | Amount of time that the client has been idle, in the format <i>hours:minutes:seconds</i> .                 |
| Reason    | A brief description of the reason why the client failed to associate.                                      |

## Command History

Introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |

## show ap debug shaping-table

```
show ap debug shaping-table {ap-name <ap-name>|ip-addr <ip-addr>}
```

### Description

Show shaping information for clients associated to an AP.

### Syntax

| Parameter         | Description                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show shaping table information for a specific AP.                                                                |
| ip-addr <ip-addr> | Show shaping table information for a specific AP IP address by entering its IP address in dotted-decimal format. |

### Example

The following command shows the shaping table of an AP named ap22.

```
(host) #show ap debug shaping-table ap-name ap22
```

```
VAP station000
pktin pktout pktdrop pktqd cmn[C:O:H] drop Numcl TotCl BWmgmt

```

The output of this command includes the following information:

| Column      | Description                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------|
| pktin       | Number of packets received by the AP.                                                                           |
| pktout      | Number of packets sent by the AP.                                                                               |
| pktdrop     | Number of packets dropped by the AP.                                                                            |
| pktqd       | Number of packets queued.                                                                                       |
| cmn [C:O:H] | (For internal use only.)                                                                                        |
| drop        | Number of CCK (802.11b) and OFDM (802.11a/g) packets dropped.                                                   |
| Numcl       | Number of CCK (802.11b) and OFDM (802.11a/g) packets dropped.                                                   |
| TotCl       | Total number of clients associated with the AP                                                                  |
| Bwmgmt      | This data column displays a 1 if the bandwidth management feature has been enabled. Otherwise, it displays a 0. |
| d<n>        | (For internal use only.)                                                                                        |
| idx         | Association ID.                                                                                                 |
| tokens      | This value represents the credits the station has to transmit tokens.                                           |
| last-t      | Number of tokens that were allocated to the station last time token allocation algorithm ran.                   |
| in          | Number of packets received.                                                                                     |
| out         | Number of packets sent.                                                                                         |
| drop        | Number of dropped packets.                                                                                      |
| q           | Number of queued packets                                                                                        |
| tx-t        | Total time spent transmitting data.                                                                             |
| rx-t        | Total time spent receiving data.                                                                                |
| al-t        | Total time allocated for transmitting data to this station.                                                     |
| rate        | (For internal use only.)                                                                                        |

## show ap debug spanning-tree

```
show ap debug spanning-tree {ap-group <ap-group>|ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

### Description

Show an AP's spanning tree statistics.

### Syntax

| Parameter           | Description                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show log information for an AP with a specific name.                                                                                                |
| bssid <bssid>       | Show log information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                       |
| ip6-addr <ip6-addr> | Show log information for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.                                   |

### Example

The following command shows the .....

```
(host) #show ap debug spanning-tree
```

### Command History

This command was introduced in ArubaOS 3.0

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.3 | Command introduced |

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug switching

show ap debug switching {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}

### Description

Show an AP's switching statistics.

### Syntax

| Parameter           | Description                       |
|---------------------|-----------------------------------|
| ap-name <ap-name>   | Name of the Access Point.         |
| ip-addr <ip-addr>   | IP address of the Access Point.   |
| ip6-addr <ip6-addr> | IPv6 address of the Access Point. |

### Example

The following command shows the .....

```
(host) #show ap debug switching
```

### Command History

| Release     | Modification                              |
|-------------|-------------------------------------------|
| ArubaOS 3.0 | Command introduced                        |
| ArubaOS 6.3 | The <b>ip6</b> parameters was introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug system-status

```
show ap debug system-status
 ap-name <ap-name>
 bssid <bssid>
 ip-addr <ip-addr>
 ip6-addr <ip6-addr>
```

### Description

Show detailed system status information for an AP.

### Syntax

| Parameter           | Description                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show system status data for an AP with a specific name.                                                                                                         |
| bssid <bssid>       | Show system status data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show system status data for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                                |
| ip6-addr <ip6-addr> | Show system status data for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.                                            |

### Usage Guidelines

Issue this command under the guidance of Dell technical support to troubleshoot network issues. The output of this command displays the following types of information (if it exists) for the selected AP:

|                         |                          |                                  |
|-------------------------|--------------------------|----------------------------------|
| • Bootstrap information | • Per-radio statistics   | • Ethernet duplex/speed settings |
| • Descriptor Usage      | • Encryption statistics  | • Tunnel heartbeat stats         |
| • Interface counters    | • AP uptime              | • Boot version                   |
| • MTU discovery         | • memory usage           | • LMS information                |
| • ARP cache             | • Kernel slab statistics | • Power status                   |
| • Route table           | • Interrupts             | • CPU type                       |
| • Interface Information | • Crash Information      | • CPU usage statistics           |
| • System Status Script  |                          |                                  |

The following parameters are included in the output of this command, and can help troubleshoot problems on an AP or wireless network.

| Parameter                                                                | Description                                                                                                                        |
|--------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| The <b>Failed</b> column in the <b>Descriptor Usage</b> section          | This parameter can tell you if the AP is dropping packets.                                                                         |
| <b>Interface Information</b> table                                       | This parameter can tell you if the Ethernet network is working properly. This table should not show an excessive number of errors. |
| <b>AP Uptime</b> table                                                   | Low values in this table can indicate problems with the wired network, or with the AP itself.                                      |
| <b>Tunnel Heartbeat</b> table                                            | This table can indicate the health of the underlying wired network.                                                                |
| <b>Rebootstrap Information</b> table<br><b>/Reboot Information</b> table | A large number of reboots can mean that the AP has hardware problems.                                                              |

## Command History

| Release         | Modification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ArubaOS 5.0     | Crash information parameter was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ArubaOS 6.3     | <p>The output of this command was enhanced to include the following information type for each ethernet interface:</p> <ul style="list-style-type: none"> <li>• broadcast and multicast TX/RX counts</li> <li>• fragmentation and reassembly counts</li> <li>• packets per second statistics for different frame types</li> </ul> <p>The <b>ip6-addr</b> parameter was introduced.</p>                                                                                                                                         |
| ArubaOS 6.4.2.0 | <p>Changed the format of the <b>System Status Script</b> output to the following:</p> <p><b>function-name(line-num): new-total-drops/total-drops new-priority-drops/total-priority-drops</b></p> <p>Example: <b>wlc_dotxstatus(40576): 5034/3231117 4272/1907873</b></p> <p>This change helps to determine if priority (voice or video) frames are dropped from the AP Wi-Fi driver drop-list.</p> <p><b>NOTE:</b> The <b>System Status Script</b> is displayed for W-AP200 Series and W-AP220 Series access points only.</p> |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug trace-addr

show ap debug trace-addr

### Description

Show MAC addresses in the trace buffer.

### Usage Guidelines

Use this command to troubleshoot wireless clients that are being traced for 802.11 communication

### Examples

The output of the command shows the **Trace List** table. If no wireless clients are being traced, this table will be empty.

```
(host) #show ap debug trace-addr
```

```
Trace List

MAC Address

00:1a:1e:c5:ca:b4
00:1a:1e:c5:d6:46
00:1a:1e:c5:d7:40
00:1a:1e:c5:d7:64
00:1a:1e:c5:d9:56
00:1a:1e:c5:d9:b0
```

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap debug usb

show ap debug usb

ap-name <ap-name>

ip-addr <ip-addr>

ip6-addr <ip6-addr>

### Description

This command displays the USB information provisioned on the RAP.

### Syntax

| Parameter           | Description                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show system status data for an AP with a specific name.                                                              |
| ip-addr <ip-addr>   | Show system status data for an AP with a specific IP address by entering an IP address in dotted-decimal format.     |
| ip6-addr <ip6-addr> | Show system status data for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format. |

### Usage Guidelines

Use this command to view the USB information provisioned on the RAP.

### Examples

The output of the command shows the USB information provisioned on the RAP.

```
(host) #show ap debug usb ap-name RAP2
USB Information

Parameter Value

Manufacturer Pantech,
Product PANTECH
Serial Number
Driver ptuml_cdc_ether
Vendor ID 106c
Product ID 3718
USB Modem State Active
USB Uplink RSSI(in dBm) -73
Supported Network Services CDMA GSM LTE
Firmware Version L0290VWB522F.242
ESN Number 990000472325325
Current Network Service 4G-LTE
```

## Command History

| Release     | Modification                                  |
|-------------|-----------------------------------------------|
| ArubaOS 6.2 | Command introduced                            |
| ArubaOS 6.3 | The <b>ip6-addr</b> parameter was introduced. |

## Command Information

| Platforms                  | Licensing             | Command Mode                               |
|----------------------------|-----------------------|--------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master or local controllers |

## show ap details

```
show ap details [advanced]{ap-name <ap-name>||ip-addr <ip-addr>|ip6-addr <ip6-addr>|wired-mac <wired-mac>}
```

### Description

Show detailed provisioning parameters, hardware, and operating information for a specific AP.

### Syntax

| Parameter             | Description                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| advanced              | Include the following additional data in the output of this command: <ul style="list-style-type: none"><li>• switch message counts</li><li>• AP group information</li><li>• Virtual AP operating information</li></ul> |
| ap-name <ap-name>     | Show data for a specific AP by entering the name of the AP for which you want to display information.                                                                                                                  |
| wired-mac <wired-mac> | Show mac address of an AP.                                                                                                                                                                                             |
| ip-addr <ip-addr>     | Show data for an AP with the specified IP address.                                                                                                                                                                     |
| ip6-addr <ip6-addr>   | Show data for an AP with the specified IPv6 address.                                                                                                                                                                   |

### Examples

The example below shows part of the output for the command **show ap details ap-name <ap-name>**.

```
(host) # show ap details ap-name AP32
```

```
AP "AL39" Basic Information
```

```

```

| Item           | Value          |
|----------------|----------------|
| AP IP Address  | 10.6.1.206     |
| LMS IP Address | 10.6.2.253     |
| Group          | corp1344       |
| Location Name  | N/A            |
| Status         | Up             |
| Up time        | 4d:12h:47m:32s |

```
AP "AL39" Hardware Information
```

```

```

| Item               | Value             |
|--------------------|-------------------|
| AP Type            | 125               |
| Serial #           | AD0054972         |
| Wired MAC Address  | 00:1a:1e:c9:17:38 |
| Radio 0 BSSID      | 00:1a:1e:11:73:90 |
| Radio 1 BSSID      | 00:1a:1e:11:73:80 |
| Enet 1 MAC Address | 00:1a:1e:c9:17:39 |
| Service Tag        | N/A               |

# AP "AL39" Operating Information

| Item                | Value               |
|---------------------|---------------------|
| AP State            | Running             |

| Reboots             | 0                   |
| Bootstraps          | 1                   |
| Bootstrap Threshold | 7Slot/Port 2/24     |

The output of this command includes the following information:

| Column             | Description                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AP IP Address      | IP address of the AP                                                                                                                                                                                    |
| LMS IP Address     | The IP address of the local management switch (LMS)—the Dell controller which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. |
| Group              | Name of the AP's AP group.                                                                                                                                                                              |
| Location Name      | Location of the AP.                                                                                                                                                                                     |
| Status             | Current status of the AP, either <b>Up</b> or <b>Down</b> .                                                                                                                                             |
| Up time            | Number of hours, minutes and seconds since the last controller reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .                                                                        |
| Installation       | AP Installation mode. The AP can be default (the factory set AP installation type, indoor or outdoor).                                                                                                  |
| AP Type            | AP model                                                                                                                                                                                                |
| Serial #           | Serial number for the AP                                                                                                                                                                                |
| Wired MAC address  | MAC address of the wired interface.                                                                                                                                                                     |
| Radio 0 BSSID      | Basic Service Set Identifier (BSSID) of the AP's radio 0. This is usually the radio's MAC address.                                                                                                      |
| Radio 1 BSSID      | Basic Service Set Identifier (BSSID) of the AP's radio 1. This is usually the radio's MAC address.                                                                                                      |
| Enet 1 MAC address | MAC address of the AP's Ethernet port.                                                                                                                                                                  |
| Service Tag        | Service tag of the AP.                                                                                                                                                                                  |
| AP State           | Displays the AP's current operational state.                                                                                                                                                            |

| Column              | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Entry created       | Timestamp showing the time the AP registered with the controller.                                                                                                                                                                                                                                                                                                                                                             |
| Last activity       | Timestamp showing the last time the AP communicated with the controller. An AP typically sends keepalive messages every minute.                                                                                                                                                                                                                                                                                               |
| Reboots             | Number of times power to the AP cycled off and then on again. Reboots also known as "hard" restarts.                                                                                                                                                                                                                                                                                                                          |
| Bootstraps          | Number of times the AP restarted. Bootstraps are also known as "soft" restarts.                                                                                                                                                                                                                                                                                                                                               |
| Bootstrap threshold | Number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots. On the controller, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.                                                                                                                                  |
| Slot/Port           | The controller port used by the AP, in the format <slot>/<port>.<br><br>The <b>&lt;port&gt;</b> parameter refers to the network interfaces that are embedded in the front panel of the W-3000 Series controller. Port numbers start at 0, from the left-most position.                                                                                                                                                        |
| High throughput     | Shows if high-throughput (802.11n) features are <b>enabled</b> or <b>disabled</b> .                                                                                                                                                                                                                                                                                                                                           |
| Mode                | Shows the operating modes for the AP. <ul style="list-style-type: none"> <li>• <b>AP:</b> Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.</li> <li>• <b>AM:</b> Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.</li> </ul> |
| Band                | The RF band in which the AP should operate: <ul style="list-style-type: none"> <li>• 802.11g = 2.4 GHz</li> <li>• 802.11a = 5 GHz</li> </ul>                                                                                                                                                                                                                                                                                  |
| Channel             | Channel number for the AP 802.11a/802.11n physical layer. The available channels depend on the regulatory domain (country).                                                                                                                                                                                                                                                                                                   |
| Secondary Channel   | The secondary channel number for the AP. The secondary channel is a 20 MHz channel used in conjunction with the primary channel to create a 40 MHz channel for high-throughput clients.<br><br>High-throughput capable APs use only the primary channel to communicate with 20 MHz clients. The secondary channel is used for transmissions with 40 MHz capable high-throughput clients.                                      |
| EIRP                | Current effective Isotropic Radiated Power (EIRP).                                                                                                                                                                                                                                                                                                                                                                            |

| Column                   | Description                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AP Name                  | Name of the AP.                                                                                                                                                                             |
| AP Group                 | AP group to which the AP belongs.                                                                                                                                                           |
| Location name            | Fully-qualified location name (FQLN) for the AP.                                                                                                                                            |
| SNMP sysLocation         | User-defined description of the location of the AP, as defined with the command <b>provision-ap syslocation</b> .                                                                           |
| Master                   | Name or IP address for the master controller.                                                                                                                                               |
| Gateway                  | IP address of the default gateway for the AP.                                                                                                                                               |
| Netmask                  | Netmask for the AP's IP address.                                                                                                                                                            |
| IP Addr                  | IP address for the AP.                                                                                                                                                                      |
| Dns IP                   | IP address of the DNS server.                                                                                                                                                               |
| Domain Name              | Domain name used by the AP.                                                                                                                                                                 |
| Server Name              | DNS name of the controller from which the AP boots.                                                                                                                                         |
| Server IP                | IP address of the controller from which the AP boots                                                                                                                                        |
| Antenna gain for 802.11a | Antenna gain for 802.11a (5GHz) antenna.                                                                                                                                                    |
| Antenna gain for 802.11g | Antenna gain for 802.11g (2.4GHz) antenna.                                                                                                                                                  |
| Antenna for 802.11a      | Antenna use for 5 GHz (802.11a) frequency band. <ul style="list-style-type: none"> <li>1: AP uses antenna 1</li> <li>2: AP uses antenna 2</li> <li>both: AP uses both antennas</li> </ul>   |
| Antenna for 802.11g      | Antenna use for 2.4 GHz (802.11g) frequency band. <ul style="list-style-type: none"> <li>1: AP uses antenna 1</li> <li>2: AP uses antenna 2</li> <li>both: AP uses both antennas</li> </ul> |
| IKE PSK                  | The IKE pre-shared key.                                                                                                                                                                     |
| PPPOE User Name          | Point-to-Point Protocol over Ethernet (PPPoE) user name for the AP.                                                                                                                         |

| Column                      | Description                                                                                                                                                                                                                                                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PPPOE Password              | PPPoE password for the AP.                                                                                                                                                                                                                                          |
| PPPOE Service Name          | PPPoE service name for the AP.                                                                                                                                                                                                                                      |
| USB User Name               | The PPP username provided by the cellular service provider.                                                                                                                                                                                                         |
| USB Password                | A PPP password, if provided by the cellular service provider.                                                                                                                                                                                                       |
| USB Device Type             | The USB driver type.                                                                                                                                                                                                                                                |
| USB Device Identifier       | The USB device identifier.                                                                                                                                                                                                                                          |
| USB Dial String             | The dial string for the USB modem.                                                                                                                                                                                                                                  |
| USB Initialization String   | The initialization string for the USB modem.                                                                                                                                                                                                                        |
| USB TTY device path         | The TTY device path for the USB modem.                                                                                                                                                                                                                              |
| Mesh Role                   | If the mesh role is “none,” the AP is operating as a thin AP. An AP operating as a mesh node can have one of two roles: mesh portal or mesh point.                                                                                                                  |
| Installation                | The type of installation ( <b>indoor</b> or <b>outdoor</b> ). The <b>default</b> parameter indicates that the ArubaOS automatically selects an installation mode based upon the AP's model type.                                                                    |
| Latitude                    | Latitude coordinates of the AP, in the format <i>Degrees Minutes Seconds</i> (DMS).                                                                                                                                                                                 |
| Longitude                   | Longitude coordinates of the AP, in the format <i>Degrees Minutes Seconds</i> (DMS).                                                                                                                                                                                |
| Altitude                    | Altitude, in meters, of the AP. This parameter is supported on outdoor APs only.                                                                                                                                                                                    |
| Antenna bearing for 802.11a | Horizontal coverage distance of the 802.11a (5GHz) antenna from true north, from 0-360 degrees.<br><br><b>NOTE:</b> This parameter is supported on outdoor APs only. The horizontal coverage pattern does not consider the elevation or vertical antenna pattern.   |
| Antenna bearing for 802.11g | Horizontal coverage distance of the 802.11g (2.4GHz) antenna from true north, from 0-360 degrees.<br><br><b>NOTE:</b> This parameter is supported on outdoor APs only. The horizontal coverage pattern does not consider the elevation or vertical antenna pattern. |

| Column                         | Description                                                                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antenna tilt angle for 802.11a | The angle of the 802.11a (5GHz) antenna. This parameter can range from between -90 degrees and 0 degrees for downtilt, and between +90 degrees and 0 degrees for uptilt.   |
| Antenna tilt angle for 802.11g | The angle of the 802.11g (2.4GHz) antenna. This parameter can range from between -90 degrees and 0 degrees for downtilt, and between +90 degrees and 0 degrees for uptilt. |
| Mesh SAE                       | Shows if the AP has enabled or disabled Secure Attribute Exchange (SAE) on a mesh network. This setting is disabled by default.                                            |

## Command History

| Release         | Modification                                                                                                                                                                                                                                                                                                    |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced                                                                                                                                                                                                                                                                                              |
| ArubaOS 3.2     | Introduced support for mesh parameters, additional antenna parameters, and AP location parameters.                                                                                                                                                                                                              |
| ArubaOS 3.4     | Introduced support for the following parameters: <ul style="list-style-type: none"> <li>• installation</li> <li>• mesh-sae</li> <li>• set-ikepsk-by-addr</li> <li>• usb-dev</li> <li>• usb-dial</li> <li>• usb-init</li> <li>• usb-passwd</li> <li>• usb-tty</li> <li>• usb-type</li> <li>• usb-user</li> </ul> |
| ArubaOS 5.0     | The <b>mesh-sae</b> parameter no longer displays the <b>sae-default</b> setting if the parameter is disabled. Only the <b>sae-disable</b> option indicates that this parameter is currently in its default disabled state.                                                                                      |
| ArubaOS 6.1     | The parameter <b>ip6-addr</b> was added to show data for an IPv6 AP.                                                                                                                                                                                                                                            |
| ArubaOS 6.3     | The parameter <b>bassid</b> was deprecated.                                                                                                                                                                                                                                                                     |
| ArubaOS 6.4.2.0 | The output of this command displays the service tag of an AP.                                                                                                                                                                                                                                                   |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|

## show ap enet-link-profile

```
show ap enet-link-profile [<profile>]
```

### Description

Show a list of all Ethernet Link profiles.

### Usage Guidelines

Include a profile name to display details for the specified Ethernet Link Profile, or omit the <profile> parameter to display a list of all Ethernet Link profiles.

### Example

This command shows the speed of the Ethernet interface and the current duplex mode for the Ethernet Link profile "default":

```
(host) #show ap enet-link-profile default
```

```
AP Ethernet Link profile "default"
```

```

```

```
Parameter Value
```

```
----- ----
```

```
Speed auto
```

```
Duplex auto
```

The output of this command includes the following parameters:

| Parameter | Description                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Speed     | The speed of the Ethernet interface. This value can be either <b>10 Mbps</b> , <b>100 Mbps</b> , <b>1000Mbps</b> (1 Gbps), or <b>auto</b> (auto-negotiated). |
| Duplex    | The duplex mode of the AP's Ethernet interface. This value can be either <b>full</b> , <b>half</b> , or <b>auto</b> (auto-negotiated).                       |

| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap essid

show ap essid

### Description

Show a Extended Service Set Identifier (ESSID) summary for the controller, including the numbers of APs and clients associated with each ESSID.

### Examples

The output of the command in the example below shows statistics for four configured ESSIDs.

```
(host) #show ap essid
ESSID Summary

ESSID APs Clients VLAN(s) Encryption

vocera 21 0 66 WPA2 PSK AES
voip 23 52 66,64 WPA2 8021X AES
guest 49 6 63 Open
wpa2 26 88 65,64 WPA2 8021X AES
Num ESSID:4
```

The output of this command includes the following information:

| Column     | Description                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| ESSID      | An Extended Service Set Identifier (ESSID) is the identifying name of an 802.11 wireless network.                                                      |
| APs        | Number of APs associated with the ESSID.                                                                                                               |
| VLAN (s)   | VLAN IDs of the VLANs for the ESSID.                                                                                                                   |
| Encryption | The layer-2 authentication and encryption used on this ESSID to protect access and ensure the privacy of the data transmitted to and from the network. |

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |

| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap ht-rates

```
show ap ht-rates bssid <bssid>
```

### Description

Show high-throughput rate information for a basic service set (BSS).

### Syntax

| Parameter     | Description                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid> | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |

### Examples

The output of this command shows high-throughput rates for each supported MCS value. These values are applicable to high-throughput (802.11n-capable) APs only.

```
(host) #show ap ht-rates bssid 00:1a:1e:1e:5a:10
```

```
AP "AL12" Radio 0 BSSID 00:1a:1e:1e:5a:10 High-throughput Rates (Mbps)
```

| MCS | Streams | 20 MHz | 40 MHz | 40 MHz SGI |
|-----|---------|--------|--------|------------|
| 0   | 1       | 6.5    | 13.5   | 15.0       |
| 1   | 1       | 13.0   | 27.0   | 30.0       |
| 2   | 1       | 19.5   | 40.5   | 45.0       |
| 3   | 1       | 26.0   | 54.0   | 60.0       |
| 4   | 1       | 39.0   | 81.0   | 90.0       |
| 5   | 1       | 52.0   | 108.0  | 120.0      |
| 6   | 1       | 58.5   | 121.5  | 135.0      |
| 7   | 1       | 65.0   | 135.0  | 150.0      |
| 8   | 2       | 13.0   | 27.0   | 30.0       |
| 9   | 2       | 26.0   | 54.0   | 60.0       |
| 10  | 2       | 39.0   | 81.0   | 90.0       |
| 11  | 2       | 52.0   | 108.0  | 120.0      |
| 12  | 2       | 78.0   | 162.0  | 180.0      |
| 13  | 2       | 104.0  | 216.0  | 240.0      |
| 14  | 2       | 117.0  | 243.0  | 270.0      |
| 15  | 2       | 130.0  | 270.0  | 300.0      |

The output of this command includes the following information:

| Column  | Description                                                                     |
|---------|---------------------------------------------------------------------------------|
| MCS     | A Modulation Coding Scheme (MCS) values supported on this high-throughput SSID. |
| Streams | Number of spatial streams used by the MCS index value.                          |
| 20 MHz  | 802.11n data rates for the MCS for 20 Mhz transmissions.                        |

| Column     | Description                                                                           |
|------------|---------------------------------------------------------------------------------------|
| 40 MHz     | 802.11n data rates for the MCS for 40 Mhz transmissions.                              |
| 40 MHz SGI | 802.11n data rates for the MCS for 40 Mhz transmissions using a short guard interval. |

## show ap image-preload-status (deprecated)

```
show ap image-preload-status
 page <page>
 start <start>
```

### Description

This command displayed the list of APs that will preload a new version of software from a controller with the AP preload feature activated. Starting with ArubaOS 6.4, command was replaced by the command [show ap image-preload status](#).

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.3 | Command introduced |
| ArubaOS 6.4 | Command deprecated |

## show ap image-preload status

```
show ap image-preload status
 all
 list
 summary
```

### Description

Display the list of APs that will preload a new version of software from a controller with the AP preload feature activated.

### Syntax

| Parameter | Description                                                |
|-----------|------------------------------------------------------------|
| all       | Display the complete status of AP image preload operation. |
| list      | Displays the list of APs and their image preload statuses. |
| summary   | Summarizes the status of AP image preload operation.       |

### Usage Guidelines

Issue this command to display a list of APs in the AP image preload list, and monitor the download status of each AP.

### Example

The example below shows the current status of APs downloading a new image using the AP image preload feature.

```
(host) #show ap image-preload status all
```

```
AP Image Preload Parameters
```

```

```

## show ap image version

show ap image version [ap-name <ap-name>|ip-addr <ip-addr>]

### Description

Display an AP's image version information.

### Syntax

| Parameter         | Description                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | View image version information for an AP with a specific name.                                                             |
| ip-addr <ip-addr> | View image version information for an AP with a specific IP address. Enter the address of the AP in dotted-decimal format. |

### Usage Guidelines

By default, this command displays image version information for all APs associated with the controller. To view image version information for a single AP, specify an AP using the **ap-name** or **ip-addr** parameters

### Example

The output in the example below shows the current running image version as well as the image version stored in the controller's flash memory.

```
(host) #show ap image version ip-addr 192.0.2.45
Access Points Image Version

AP Running Image Version String
-- -----
192.0.2.45 6.4.0.0 Wed Nov 27 10:46:42 PDT 2013

Flash Image Version String Matches Num Matches

6.4.0.0 Wed Nov 27 10:46:42 PDT 2013 Yes 3

Num Mismatches Bad Checksums Image Load Status

0 Done
```

The output of this command includes the following information:

| Column                       | Description                                                                                                                            |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| AP                           | Name or IP address of an AP                                                                                                            |
| Running Image Version String | String identifying the number of the image version currently running on the AP, as well as the date on which that version was created. |
| Flash Image Version String   | String identifying the number of the image version in the AP's flash memory, as well as the date on which that version was created.    |

| Column            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Matches           | If <b>yes</b> , the running image version matches the image version currently in the AP's flash memory. If <b>no</b> , the two image versions do not match.                                                                                                                                                                                                                                                                                                                                                                                    |
| Num Matches       | Number of times the running image version matched the flash image version after a reboot.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Num Mismatches    | Number of times the running image version did not match the flash image version after a reboot. If the images do not match, the AP will upgrade to the flash image.                                                                                                                                                                                                                                                                                                                                                                            |
| Bad Checksums     | Number of bad checksum calculations due to an invalid or corrupted image file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Image Load Status | <p>Current status of the AP following an upgrade.</p> <p><b>Done:</b> This status indicates that the controller reset after the upgrade was performed, or the upgrade was performed after the AP first registered with the controller.</p> <p><b>Completed:</b> The AP was updated after it was registered to the controller, and after the controller's last reset. If AP shows a status of <b>completed</b>, it will also display the time it took it update that AP.</p> <p><b>In progress:</b> The AP is currently updating its image.</p> |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

# show ap-lacp-striping-ip

show ap-lacp-striping-ip

## Description

Define an LLDP MED network policy profile that defines DSCP values and L2 priority levels for a voice or video application.

## Syntax

No parameters

## Usage Guidelines

## Example

@@@.

```
(host) (config) #show ap-lacp-striping-ip
AP LACP LMS map information

Parameter Value

AP LACP Striping IP Enabled
GRE Striping IP 2.2.2.2 LMS 3.3.3.3
GRE Striping IP 4.4.4.4 LMS 5.5.5.5
GRE Striping IP 10.65.30.50 LMS 10.65.30.60
```

## Command History

This command was introduced in ArubaOS 6.4.2.

## Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show ap license-usage

show ap license-usage

### Description

Show AP license usage information.

### Examples

The output of the command below shows that controller has 13 associated campus APs using licenses, with 3 unused campus AP licenses remaining.

```
(host) #show ap license-usage
```

```
AP Licenses

Type Number
---- -
AP Licenses 64
RF Protect Licenses 64
PEF Licenses 64
Overall AP License Limit 64
```

```
AP Usage

Type Count
---- -
CAPs 13
RAPs 2
Remote-node APs 0
Tunneled nodes 0
Total APs 0
```

```
Remaining AP Capacity

Type Number
---- -
CAPs 3
RAPs 62
```

The output of this command includes the following information:

| Parameter           | Description                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------|
| AP Licenses         | Number of AP licenses currently available on the controller.                                |
| RF Protect Licenses | Number of RF Protect licenses currently available on the controller.                        |
| PEF Licenses        | Number of Policy Enforcement Firewall (PEF) licenses currently available on the controller. |
| Overall AP Licenses | Total number of APs supported by licenses on the controller.                                |
| CAPs                | Number of campus APs currently using a license on the controller.                           |

| Parameter       | Description                                                           |
|-----------------|-----------------------------------------------------------------------|
| RAPs            | Number of remote APs currently using a license on the controller.     |
| Remote-Node APs | Number of APs currently using a license on the branch controller.     |
| Tunneled Nodes  | Number of tunneled nodes currently using a license on the controller. |
| CAPs            | Number of unused campus APs licenses remaining on the controller.     |
| RAPs            | Number of unused remote APs licenses remaining on the controller.     |

| All platforms | Base operating system. The output of this command varies, according to the licenses currently installed on the controller. | Enable or Config mode on master controllers |

## show ap lldp

```
show ap lldp [<profile>]
```

### Description

Display a list of LLDP-MED Network Policy profiles, or display the current configuration settings of an individual profile.

### Syntax

| Parameter | Description                                                                  |
|-----------|------------------------------------------------------------------------------|
| <profile> | Specify a LLDP profile name to view configuration settings for that profile. |

### Examples

The following example lists all LLDP profile profiles. The References column lists the number of other profiles with references to that LLDP-MED Network policy profile profile, and the ProfileStatus column indicates whether the profile is predefined.

The output of the command below shows that the controller has two LLDP profiles.

```
(host) #show ap lldp med-network-policy-profile
AP LLDP Profile List

Name References Profile Status

default 0
video 2
Total:2
```

The following command displays configuration details for the LLDP profile named default.

```
(host) #show ap lldp med-network-policy-profile video
AP LLDP Profile "new"

Parameter Value

PDU transmission Enabled
Reception of LLDP PDUs Enabled
Transmit interval (seconds) 30
Transmit hold multiplier 4
Optional TLVs port-description system-description system-name capabilities
management-address
802.1 TLVs port-vlan vlan-name
802.3 TLVs mac link-aggregation mfs power
LLDP-MED TLVs
LLDP-MED network policy profile N/A
```

The output of this command includes the following information:

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PDU transmission                | Shows if LLDP PDU transmission is enabled on the AP.                                                                                                                                                                                                                                                                                                                                |
| Reception of LLDP PDUs          | Shows if LLDP PDU reception is enabled on the AP.                                                                                                                                                                                                                                                                                                                                   |
| Transmit interval (seconds)     | The interval between LLDP TLV transmission seconds. The supported range is 1-3600 seconds and the default value is 30 seconds.                                                                                                                                                                                                                                                      |
| Transmit hold multiplier        | <p>This value is multiplied by the transmit interval to determine the number of seconds to cache learned LLDP information before that information is cleared.</p> <p>If the transmit-hold value is at the default value of 4, and the transmit interval is at its default value of 30 seconds, then learned LLDP information will be cached for 4 x 30 seconds, or 120 seconds.</p> |
| Optional TLVs                   | The AP sends the listed optional TLVs in LLDP PDUs.                                                                                                                                                                                                                                                                                                                                 |
| 802.1 TLVs                      | The AP sends the listed 802.1 TLVs in LLDP PDUs. By default, the AP will send all 802.1 TLVs.                                                                                                                                                                                                                                                                                       |
| 802.3 TLVs                      | The AP sends the listed 802.3 TLVs in LLDP PDUs. By default, the AP will send all 802.3 TLVs.                                                                                                                                                                                                                                                                                       |
| LLDP-MED TLVs                   | Lists the LLDP-MED TLVs the AP will send in LLDP PDUs. By default, the AP will not send any LLDP-MED TLVs                                                                                                                                                                                                                                                                           |
| LLDP-MED network policy profile | Specifies the LLDP MED Network Policy profile to be associated with this LLDP profile.                                                                                                                                                                                                                                                                                              |

## Command History

Command introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing              | Command Mode                                         |
|---------------|------------------------|------------------------------------------------------|
| All platforms | Base operating system. | Enable or Config mode on master or local controllers |

## show ap lldp counters

```
show ap lldp counters
 ap-name <ap-name>
 ip-addr <ip-addr>
 ip6-addr <ip6-addr>
```

### Description

Show LLDP counters for a specific AP, or all APs sending or receiving LLDP Protocol Data Units (PDUs).

### Syntax

| Parameter          | Description                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>  | Show counter statistics for an AP with a specific name.                                                                |
| ip-addr <ip-addr>  | View counter statistics for an AP with a specific IP address. Enter the IP address of the AP in dotted-decimal format. |
| ip6-addr <ip-addr> | View counter statistics for an AP with a specific IPv6 address.                                                        |

### Examples

The output of the command below shows LLDP counter information for two interfaces.

```
(host) #show ap lldp counters
AP LLDP Counters (Updated every 60 seconds)

AP Interface Received Unknown TLVs Malformed Overflow Transmitted
-- -
00:1a:1e:ce:fb:bf bond0 0 0 0 0 68159
00:24:6c:c0:00:86 bond0 0 0 0 0 68153
```

The output of this command includes the following information:

| Parameter                   | Description                                                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------|
| AP                          | Name of the AP sending or receiving LLDP PDUs.                                                                  |
| Interface                   | Name of the AP interface sending or receiving LLDP PDUs.                                                        |
| Received                    | Number of packets received on the specified interface.                                                          |
| Unknown TLVs                | Number of LLDP Protocol Data Units (PDUs) with an unknown type-length-value (TLV).                              |
| Number of Malformed packets | Number of malformed packets received on that interface                                                          |
| Overflow                    | Number of times that an LLDP neighbor could not be added to the neighbor table (there is a limit of 8 per port) |

| Parameter   | Description                                       |
|-------------|---------------------------------------------------|
|             |                                                   |
| Transmitted | Number of packets transmitted from that interface |

## Command History

Command introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing              | Command Mode                                         |
|---------------|------------------------|------------------------------------------------------|
| All platforms | Base operating system. | Enable or Config mode on master or local controllers |

# show ap lldp med-network-policy-profile

show ap lldp med-network-policy-profile [<profile>]

## Description

Display a list of LLDP-MED Network Policy profiles, or display the current configuration settings of an individual profile.

## Syntax

| Parameter | Description                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------|
| <profile> | Specify a LLDP-MED Network Policy profile name to view configuration settings for that profile. |

## Usage Guidelines

The LLDP-MED Network policy profile allows you to configure an extension to LLDP that supports interoperability between VoIP devices and other networking clients. LLDP-MED network policy discovery lets end-points and network devices advertise their VLAN IDs (e.g. voice VLAN), priority levels, and DSCP values. allows you to define a set of provisioning parameters to an AP group.

Issue this command without the **<profile-name>** option to display the entire LLDP-MED Network policy profile list, including profile status and the number of references to each profile. Include a profile name to display the configuration settings for that profile.

## Examples

The following example lists all LLDP-MED Network policy profile profiles. The **References** column lists the number of other profiles with references to that LLDP-MED Network policy profile, and the **ProfileStatus** column indicates whether the profile is predefined.

The output of the command below shows that the controller has three LLDP-MED network profiles.

```
(host) #show ap lldp med-network-policy-profile
AP LLDP-MED Network Policy Profile List
```

```

Name References Profile Status
---- -
default 0
video 2
voice 1
Total:2
```

The following command displays configuration details for the LLDP-MED Network Policy profile named video.

```
(host) #show ap lldp med-network-policy-profile video
AP LLDP-MED Network Policy Profile "default"
```

```

Parameter Value

LLDP-MED application type streaming-video
LLDP-MED application VLAN 16
LLDP-MED application VLAN tagging Tagged
LLDP-MED application Layer-2 priority 0
LLDP-MED application Differentiated Services Code Point 0
```

The output of this command includes the following information:

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LLDP-MED application type | <p>Type of application that this profile manages. This profile supports the following options:</p> <ul style="list-style-type: none"> <li>• <b>guest-voice</b> : The AP services a separate voice network for guest users and visitors.</li> <li>• <b>guest-voice-signaling</b> : The AP is part of a network that requires a different policy for guest voice signaling than for guest voice media. Do not use this application type if both the same network policies apply to both guest voice and guest voice signaling traffic.</li> <li>• <b>softphone-voice</b> : The AP supports voice services using softphone software applications on devices such as PCs or laptops.</li> <li>• <b>streaming-video</b> : T The AP supports broadcast or multicast video or other streaming video services that require specific network policy treatment. This application type is not recommended for video applications that rely on TCP with buffering.</li> <li>• <b>video-conferencing</b> : T The AP supports video conferencing equipment that provides real-time, interactive video/audio services.</li> <li>• <b>video-signaling</b> : T The AP is part of a network that requires a different policy for video signaling than for the video media. Do not use this application type if both the same network policies apply to both video and video signaling traffic.</li> <li>• <b>voice</b> : T he AP services IP telephones and other appliances that support interactive voice services. This is the default application type.</li> <li>• <b>voice-signaling</b> : T The AP is part of a network that requires a different policy for voice signaling than for the voice media. Do not use this</li> </ul> |

| Parameter                                               | Description                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                         | application type if both the same network policies apply to both voice and voice signaling traffic.                                                                                                                                                                                  |
| LLDP-MED application VLAN                               | Indicates the VLAN ID (0-4094) or VLAN name of the VLAN used by the application.                                                                                                                                                                                                     |
| LLDP-MED application VLAN tagging                       | Indicates if the policy applies to a VLAN that is tagged with a VLAN ID or untagged. The default value is untagged.<br><b>NOTE:</b> When an LLDP-MED network policy is defined for use with an untagged VLAN, then the L2 priority field is ignored and only the DSCP value is used. |
| LLDP-MED application Layer-2 priority                   | Displays a configured 802.1p priority level for the specified application type, where 0 is the lowest priority level and 7 is the highest priority.                                                                                                                                  |
| LLDP-MED application Differentiated Services Code Point | Displays a configured Differentiated Services Code Point (DSCP) priority value for the specified application type, where 0 is the lowest priority level and 63 is the highest priority.                                                                                              |

## Command History

Command introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing              | Command Mode                                         |
|---------------|------------------------|------------------------------------------------------|
| All platforms | Base operating system. | Enable or Config mode on master or local controllers |

## show ap lldp neighbors

```
show ap lldp neighbors
 ap-name <ap-name>
 ip-addr <ip-addr>
 ip6-addr <ip6-addr>
```

### Description

Show LLDP neighbors for a specific AP, or all APs sending or receiving LLDP Protocol Data Units (PDUs).

### Syntax

| Parameter           | Description                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show LLDP neighbor statistics for an AP with a specific name.                                                                |
| ip-addr <ip-addr>   | View LLDP neighbor statistics for an AP with a specific IP address. Enter the IP address of the AP in dotted-decimal format. |
| ip6-addr <ip6-addr> | View LLDP neighbor statistics for an AP with a specific IPv6 address.                                                        |

### Usage Guidelines

The LLDP protocol allows switches, routers, and wireless LAN access points to advertise information about themselves such as identity, capabilities, and neighbors to other nodes on the network. Use this command to display information about the AP's LLDP peers.

By default, this command displays LLDP neighbors for the entire list of LLDP interfaces. Include a the name of IP address of an AP to display neighbor information only for that one device.

### Examples

The output of the command below shows the LLDP neighbor list for an AP named **ap12**.

```
(host) show ap lldp neighbors ap-name ap12
AP LLDP Neighbors (Updated every 60 seconds)

AP Interface Neighbor Chassis Name/ID Port Name/ID Mgmt. Address Capabilities
-- -
uc bond0 0 d8:c7:c8:c4:4f:4e bond0 10.3.44.193
Capability codes: (R)Router, (B)Bridge, (A)Access Point, (P)Phone, (O)Other
```

The output of this command includes the following information:

| Parameter | Description                                         |
|-----------|-----------------------------------------------------|
| AP        | Name of the LLDP neighbor                           |
| Interface | Interface on the AP sending or receiving LLDP PDUs. |
| Neighbor  | LLDP neighbor number                                |

| Parameter       | Description                                                                                                                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chassis Name/ID | The name of the LLDP neighbor AP                                                                                                                                                                                                                               |
| Port Name/ID    | Port name or ID if the interface sending LLDP PDUs.                                                                                                                                                                                                            |
| Mgmt. Address   | Management address of the LLDP neighbor                                                                                                                                                                                                                        |
| Capabilities    | <p>This data column can list any of the following data codes to indicate LLDP neighbor capabilities.</p> <ul style="list-style-type: none"> <li>• R: Router</li> <li>• B: Bridge</li> <li>• A: Access Point</li> <li>• P: Phone</li> <li>• O: Other</li> </ul> |

## Command History

Command introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing              | Command Mode                                         |

## show ap load-balancing

show ap load balancing

### Description

Show the load-balancing information for each AP with load balancing enabled.

### Examples

The output of the command in the example below shows details for a single AP enabled with the load-balancing feature.

```
(host) #show ap load-balancing
Load Balance Enabled Access Point Table

bss
cur-cl util(kbps)

00:0b:86:cc:8e:4e Wireless_1 mp22 2/24 10.3.148.12 a-HT 413
```

The output of this command includes the following information:

| Column      | Description                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BSS         | The Basic Service Set (BSS) Identifier for the AP. This is usually the APs MAC address.                                                                                                                                                                                  |
| ESS         | The Extended Service Set (ESS) Identifier is the user-defined name of an 802.11 wireless network.                                                                                                                                                                        |
| s/p         | The controller slot and port used by the AP, in the format <slot>/<port>. The <b>&lt;port&gt;</b> parameter refers to the network interfaces that are embedded in the front panel of the W-3000 Series controller. Port numbers start at 0, from the left-most position. |
| ip          | IP address of the AP                                                                                                                                                                                                                                                     |
| phy         | One of the following 802.11 types <ul style="list-style-type: none"><li>• a</li><li>• a-HT (high-throughput)</li><li>• g</li><li>• g-HT (high-throughput)</li></ul>                                                                                                      |
| chan        | Channel number for the AP 802.11a/802.11n physical layer. The available channels depend on the AP's regulatory domain (country).                                                                                                                                         |
| cur-cl      | Current number of clients on the AP.                                                                                                                                                                                                                                     |
| util (kbps) | Current bandwidth utilization, in kbps.                                                                                                                                                                                                                                  |

## Command History

Introduced in ArubaOS 3.0.

## show ap mesh active

```
show ap mesh active [<mesh-cluster>|{page <page>}|{start <start>}]
```

### Description

Show active mesh cluster APs currently registered on this controller.

### Syntax

| Parameter      | Description                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <mesh-cluster> | Name of a mesh cluster profile.                                                                                                              |
| page <page>    | Limit the output of this command to a specific number of entries by entering the number of entries you want to display.                      |
| start <start>  | Start displaying the index of mesh APs at a chosen index number by entering the index number of the AP at which command output should start. |

### Examples

The output of this command displays a list of all active mesh points and mesh portals.

```
(host) #show ap mesh active

The output of this command includes the following information:

| Column | Description                               |
|--------|-------------------------------------------|
| Name   | Name of an AP.                            |
| Group  | AP group which includes the specified AP. |

| Column               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Address           | IP address of the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| BSSID                | Basic Service Set Identifier (BSSID) for the AP. This is usually the AP's MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Band/Ch/EIRP/MaxEIRP | The RF band in which the AP should operate ( <b>a</b> or <b>g</b> )/ Radio channel used by the AP/Current effective Isotropic Radiated Power (EIRP) /maximum EIRP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| MTU                  | Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Enet 0/1             | Shows the current mode of each wired interface. <ul style="list-style-type: none"> <li>• <b>Bridge:</b> 802.11 frames are bridged into the local Ethernet LAN.</li> <li>• <b>Tunnel:</b> 802.11 frames are tunneled to the controller using generic routing encapsulation (GRE).</li> <li>• <b>Split-tunnel:</b> 802.11 frames are either bridged into the local Ethernet LAN or tunneled to the controller, depending upon their destination.</li> <li>• <b>Off:</b> Interface is not available for serving clients.</li> </ul> <p>If an AP has only one wired interface, the output of this command will display a dash (-) for the unavailable port.</p> |
| Mesh Role            | An AP operating as a mesh node can have one of two roles: mesh portal or mesh point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Parent               | If the AP is operating as a mesh point, this parameter displays the name of its parent mesh portal. Mesh portals will display a dash (-).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| #Children            | If the AP is operating as a mesh portal, this parameter shows the number of mesh point children associated with that mesh portal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| AP type              | The AP model type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Uptime               | Number of hours, minutes and seconds since the last controller reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Command History

Introduced in ArubaOS 3.0.

## show ap mesh-cluster-profile

show ap mesh-cluster-profile [<profile>]

### Description

Show configuration settings for a mesh cluster profile.

### Syntax

| Parameter | Description                    |
|-----------|--------------------------------|
| <profile> | Name of a mesh cluster profile |

### Usage Guidelines

The command **show ap mesh-cluster-profile** displays a list of all mesh cluster profiles configured on the controller, including the number of references to each profile and each profile's status. Include the optional <profile> parameter to show detailed settings for an individual mesh cluster profile.

### Examples

The example below shows the configuration settings for the mesh cluster profile "meshcluster2".

```
(host) #show ap mesh-cluster-profile meshcluster2
```

```
Mesh Cluster profile "meshcluster2"
```

```

Parameter Value

Cluster Name company-mesh
RF Band a
Encryption opensystem
WPA Hexkey N/A
WPA Passphrase N/A
```

The output of this command includes the following information:

| Parameter    | Description                                                                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cluster Name | Name of the mesh cluster using this profile                                                                                                                                                                                               |
| RF band      | The RF band in which the AP should operate: <ul style="list-style-type: none"><li>• <b>g</b> = 2.4 GHz</li><li>• <b>a</b> = 5 GHz</li></ul>                                                                                               |
| Encryption   | Data encryption setting for the mesh cluster profile. <ul style="list-style-type: none"><li>• <b>opensystem</b>—No authentication and encryption.</li><li>• <b>wpa2-psk-aes</b>—WPA2 with AES encryption using a preshared key.</li></ul> |

| Parameter      | Description                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| WPA Hexkey     | The WPA pre-shared key (only for mesh cluster profiles using WPA2 with AES encryption).                            |
| WPA Passphrase | The WPA password that generates the preshared key (only for mesh cluster profiles using WPA2 with AES encryption). |

## Command History

Introduced in ArubaOS 3.2.

## Command Information

| Platforms     | Licensing                                                                                                                     | Command Mode                                |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| All platforms | This show command is available in the base operating system. Commands to configure the mesh feature require the Mesh license. | Enable or Config mode on master controllers |

## show ap mesh debug counters

```
show ap mesh debug counters {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}]
```

### Description

Show counters statistics for a mesh node.

### Syntax

| Parameter         | Description                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show counter statistics for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show counter statistics for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | View counter statistics for an AP with a specific IP address. Enter the IP address of the AP in dotted-decimal format.               |

### Example

The example below shows the Mesh Packet Counters table for an AP named meshpoint1. The **Probe Resp**, **Assoc Req**, and **Assoc Resp** data columns show both the total number of counters and, in parenthesis, the number of requests or responses with high-throughput information elements (HE IEs).

```
(host) #show ap mesh debug counters ap-name meshpoint1
Mesh Packet Counters

Interface Echo Sent Echo Recv Probe Req Probe Resp Assoc Req Assoc Resp Assoc Fail ---

Link up/down Resel. Switch Other

Parent 68865 68755 24 8 (8 HT) 3 (1 HT) 3 (1 HT) 1
1 - - 0
Child 68913 67373 6 8 2
1 2 0 2618886

Received Packet Statistics: Total 2890717, Mgmt 2618946 (dropped non-mesh 0), Data 271771
(dropped unassociated 1)HT: pns=8 ans=1 pnr=0 ars=0 arr=1 anr=0

Recovery Profile Usage Counters

Item Value
---- -
Enter recovery mode 0
Exit recovery mode 0
Total connections to switch 0

Mesh loop-prevention Sequence No.:1256947
Mesh timer ticks:68930
```

The output of this command includes the following information:

| Column       | Description                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface    | Indicates whether the mesh interface connects to a <b>Parent</b> AP or a <b>Child</b> AP. Each row of data in the <i>Mesh Packet Counters</i> table shows counter values for an individual interface. |
| Echo Sent    | Number of echo packets sent.                                                                                                                                                                          |
| Echo Recv    | Number of echo packets received.                                                                                                                                                                      |
| Probe Req    | Number of probe request packets sent from the interface specified in the <b>Mesh-IF</b> parameter.                                                                                                    |
| Probe Resp   | Number of probe response packets sent to the interface specified in the <b>Interface</b> parameter.                                                                                                   |
| Assoc Req    | Number of association request packets from the interface specified in the <b>Interface</b> parameter.                                                                                                 |
| Assoc Resp   | Number of association response packets from the interface specified in the <b>Interface</b> parameter. This number includes valid responses and fail responses.                                       |
| Assoc Fail   | Number of fail responses received from the interface specified in the <b>Interface</b> parameter.                                                                                                     |
| Link up/down | Number of times the link up or link down state has changed.                                                                                                                                           |
| Resel.       | Number of times a mesh point attempted to reselect a different mesh portal.                                                                                                                           |
| Switch       | Number of times a mesh point successfully switched to a different mesh portal.                                                                                                                        |
| Other Mgmt   | Management frames of any type other than association and probe frames, either received on child interface, or sent on parent interface.                                                               |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing                                                                                                                     | Command Mode                                 |

## show ap mesh debug current-cluster

```
show ap mesh debug current-cluster {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}]
```

### Description

Display information for the mesh cluster currently used by a mesh point or mesh portal.

### Syntax

| Parameter         | Description                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show mesh cluster data for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show mesh cluster data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show mesh cluster data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                         |

### Examples

The output of the command below shows mesh cluster profile configuration parameters for the mesh cluster currently used by an AP named "mp2."

```
(host) #show ap mesh debug current-cluster ap-name mp2
```

```
AP "mp2" Current Cluster Profile: default
```

```

Item Value
---- -
Cluster Name smettu-mesh
RF Band a
Encryption opensystem
WPA Hexkey N/A
WPA Passphrase *****
```

The output of this command includes the following information:

| Column       | Description                                                                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cluster Name | Name of the mesh cluster using this profile                                                                                                                                                                                               |
| RF band      | The RF band in which the mesh point or mesh portal operates: <ul style="list-style-type: none"><li>● <b>g</b> = 2.4 GHz</li><li>● <b>a</b> = 5 GHz</li></ul>                                                                              |
| Encryption   | Data encryption setting for the mesh cluster profile. <ul style="list-style-type: none"><li>● <b>opensystem</b>—No authentication and encryption.</li><li>● <b>wpa2-psk-aes</b>—WPA2 with AES encryption using a preshared key.</li></ul> |

| Column         | Description                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| WPA Hexkey     | The WPA pre-shared key (only for mesh cluster profiles using WPA2 with AES encryption).                            |
| WPA Passphrase | The WPA password that generates the preshared key (only for mesh cluster profiles using WPA2 with AES encryption). |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing                                                                                                                     | Command Mode                                |

## show ap mesh debug forwarding-table

```
show ap mesh forwarding-table {ap-name <ap-name>} [{ip-addr <ip-addr>}]
```

### Description

Show the forwarding table for a remote mesh point or remote mesh portal.

### Syntax

| Parameter         | Description                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for a remote mesh node with a specific name.                                                           |
| ip-addr <ip-addr> | Show data for a remote mesh node with a specific IP address by entering its IP address in dotted-decimal format. |

### Usage Guidelines

This is an internal technical support command. Dell technical support may request that you issue this command to help analyze and troubleshoot problems with your mesh network.

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing                                                                                                                     | Command Mode                                |

## show ap mesh debug hostapd-log

```
show ap mesh debug hostapd-log {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

### Description

Show the debug log messages for the **hostapd** process.

### Syntax

| Parameter         | Description                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                                                         |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                                |

### Usage Guidelines

This is an internal technical support command. Dell technical support may request that you issue this command to help analyze and troubleshoot problems with the **hostapd** process or your mesh network.

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing                                                                                                                     | Command Mode                                |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|

## show ap mesh debug meshd-log

```
show ap mesh debug meshd-log {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}] [<page>]
```

### Description

Show the debug log messages for the **meshd** process.

### Syntax

| Parameter         | Description                                                                                                                                                                                        |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                                                                                                          |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                  |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                                                                                 |
| <page>            | Display page number 0, 1 or 2, where page 0 has the newest information and page 2 has the oldest. If this parameter is omitted, this command will display all meshd log information, oldest first. |

### Usage Guidelines

This is an internal technical support command. Dell technical support may request that you issue this command to help analyze and troubleshoot problems with the **meshd** process or your mesh network.

### Command History

| Release     | Modification                              |
|-------------|-------------------------------------------|
| ArubaOS 3.0 | Command introduced.                       |
| ArubaOS 3.4 | The <b>page</b> parameter was introduced. |

## show ap mesh debug provisioned-clusters

```
show ap mesh debug provisioned-clusters {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

### Description

Show cluster profiles provisioned on a mesh portal or mesh point.

### Syntax

| Parameter         | Description                                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for a mesh node with a specific name.                                                                                                           |
| bssid <bssid>     | Show data for a mesh node with a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for a mesh node with a specific IP address by entering an IP address in dotted-decimal format.                                                  |

### Example

The output of the command below shows statistics for the AP's mesh cluster profile and recovery cluster profile.

```
(host) #show ap mesh debug provisioned-clusters ap-name portal2
AP Portal Cluster Profile: mesh-cluster-profile
```

```

```

| Parameter      | Value      |
|----------------|------------|
| Cluster Name   | sw-ad-GB32 |
| RF Band        | a          |
| Encryption     | opensystem |
| WPA Hexkey     | N/A        |
| WPA Passphrase | *****      |

```
AP "Portal" Cluster Profile: Recovery Cluster Profile
```

```

```

| Item           | Value                    |
|----------------|--------------------------|
| Cluster Name   | Recovery-ZF-xAP15z-g15VN |
| RF Band        | a                        |
| Encryption     | pa2-psk-aes              |
| WPA Hexkey     | *****                    |
| WPA Passphrase | N/A                      |

The output of this command displays the following information for the AP's mesh cluster profile and recovery cluster profiles:

| Column         | Description                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cluster Name   | Name of the mesh cluster using this profile                                                                                                                                                                                                  |
| RF band        | The RF band in which the AP should operate: <ul style="list-style-type: none"> <li>• <b>g</b> = 2.4 GHz</li> <li>• <b>a</b> = 5 GHz</li> </ul>                                                                                               |
| Encryption     | Data encryption setting for the mesh cluster profile. <ul style="list-style-type: none"> <li>• <b>opensystem</b>—No authentication and encryption.</li> <li>• <b>wpa2-psk-aes</b>—WPA2 with AES encryption using a preshared key.</li> </ul> |
| WPA Hexkey     | The WPA pre-shared key (only for mesh cluster profiles using WPA2 with AES encryption).                                                                                                                                                      |
| WPA Passphrase | The WPA password that generates the preshared key (only for mesh cluster profiles using WPA2 with AES encryption).                                                                                                                           |

## Command History

Introduced in ArubaOS 3.0.

| All platforms | This show command is available in the base operating system. Commands to configure the mesh feature require the Mesh license. | Enable or Config mode on master controllers |

## show ap mesh-ht-ssid-profile

show ap mesh-ht-ssid-profile [<profile>]

### Description

Show configuration settings for a mesh high-throughput Service Set Identifier (SSID) profile.

### Syntax

| Parameter | Description                                  |
|-----------|----------------------------------------------|
| <profile> | Name of a mesh high-throughput SSID profile. |

### Usage Guidelines

High-throughput APs support additional settings not available in legacy APs. A mesh high-throughput SSID profile can enable or disable high-throughput (802.11n) features and 40 Mhz channel usage, and define values for aggregated MAC protocol data units (MDPUs) and Modulation and Coding Scheme (MCS) ranges.

The command **show ap mesh-ht-ssid-profile** displays a list of all mesh high-throughput SSID profiles configured on the controller, including the number of references to each profile and each profile's status. Include the optional **<profile>** parameter to show detailed settings for an individual mesh high-throughput SSID profile.

### Examples

The example below shows the configuration settings for the mesh high-throughput radio profile "default".

```
(host) #show ap mesh-ht-ssid-profile default
```

```
Mesh High-throughput SSID profile "default"

Parameter Value

40 MHz channel usage Enabled
BA AMSDU Enable Enabled
Temporal Diversity Enable Disabled
High throughput enable (SSID) Enabled
Legacy stations Allowed
Low-density Parity Check Enabled
Maximum number of spatial streams usable for STBC reception 1
Maximum number of spatial streams usable for STBC transmission 1
MPDU Aggregation Enabled
Max received A-MPDU size 65535 bytes
Max transmitted A-MPDU size 65535 bytes
Min MPDU start spacing 8 usec
Short guard interval in 20 MHz mode Enabled
Short guard interval in 40 MHz mode Enabled
Supported MCS set 0-23
```

The output of this command includes the following information:

| Column                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 40 MHz channel usage                                           | This parameter shows if the profile enables or disables the use of 40 MHz channels.                                                                                                                                                                                                                                                                                                                                  |
| BA AMSDU Enable                                                | Shows if the AP has enabled or disabled the ability to receive AMSDU in BA negotiation.                                                                                                                                                                                                                                                                                                                              |
| Temporal Diversity Enable                                      | Shows if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries.                                                                                                                                                    |
| High throughput enable (SSID)                                  | Shows if 802.11n high-throughput features are enabled or disabled for this profile. By default, high-throughput features are enabled.                                                                                                                                                                                                                                                                                |
| Legacy stations                                                | Allow or disallow associations from legacy (non-HT) stations. By default, this parameter is enabled (legacy stations are allowed).                                                                                                                                                                                                                                                                                   |
| Low-density Parity Check                                       | If enabled, the AP will advertise Low-density Parity Check (LDPC) support. LDPC improves data transmission over radio channels with high levels of background noise.                                                                                                                                                                                                                                                 |
| Maximum number of spatial streams usable for STBC reception    | Shows the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the W-AP90 series, W-AP130 Series, W-AP68, W-AP175 and W-AP105 only. The configured value will be adjusted based on AP capabilities.)<br><b>NOTE:</b> If transmit beamforming is enabled, STBC will be disabled for beamformed frames. |
| Maximum number of spatial streams usable for STBC transmission | Shows the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on W-AP90 series, W-AP175, W-AP130 Series and W-AP105 only. The configured value will be adjusted based on AP capabilities.)<br><b>NOTE:</b> If transmit beamforming is enabled, STBC will be disabled for beamformed frames.       |
| MPDU Aggregation                                               | Shows if the profile enables or disables MAC protocol data unit (MPDU) aggregation.                                                                                                                                                                                                                                                                                                                                  |

| Column                                          | Description                                                                                                                                                                                                                           |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max received A-MPDU size                        | Configured maximum size of a received aggregate MPDU, in bytes.                                                                                                                                                                       |
| Max transmitted A-MPDU size                     | Configured maximum size of a transmitted aggregate MPDU, in bytes.                                                                                                                                                                    |
| Min MPDU start spacing                          | Configured minimum time between the start of adjacent MPDUs within an aggregate MPDU, in microseconds.                                                                                                                                |
| Supported MCS set                               | Displays a list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20MHz vs. 40MHz) and the number of spatial streams used by the mesh node. |
| Short guard interval in 20 MHz mode             | Shows if the profile enables or disables use of short (400ns) guard interval in 20 MHz mode.                                                                                                                                          |
| Short guard interval in 20 MHz mode             | Shows if the profile enables or disables use of short (400ns) guard interval in 40 MHz mode.                                                                                                                                          |
| Explicit Transmit Beamforming                   | Shows if Explicit Transmit Beamforming is enabled or disabled for W-AP130 Series APs.<br><b>NOTE:</b> If this parameter is disabled, the other transmit beamforming configuration settings have no effect.                            |
| Transmit Beamforming Compressed Steering        | When enabled, the AP can use explicit compressed feedback from clients to obtain a steering matrix. (For W-AP130 Series APs only.)                                                                                                    |
| Transmit Beamforming non Compressed Steering    | When enabled, the AP can use explicit noncompressed feedback from clients to obtain a steering matrix. (For W-AP130 Series only)                                                                                                      |
| Transmit Beamforming delayed feedback support   | Shows if the AP has enabled or disabled delayed feedback/report support in Transmit Beamforming. (For W-AP130 Series only)                                                                                                            |
| Transmit Beamforming immediate feedback support | Shows if the AP has enabled or disabled immediate feedback/report support in Transmit Beamforming. (For W-AP130 Series only)                                                                                                          |

| Column                                 | Description                                                                                                       |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Transmit Beamforming Sounding Interval | Time interval in seconds between updates of Transmit Beamforming channel estimation.<br>(For W-AP130 Series only) |

## Command History

| Version     | Description                                                                                                                                                                                                                                                                                                                                                                                     |

## show ap mesh neighbors

show ap mesh neighbors {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>} [names]

### Description

Show all mesh neighbors for an AP.

### Syntax

| Parameter         | Description                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show mesh neighbors for an AP with a specific name.                                                                                                                                  |
| bssid <bssid>     | Show mesh neighbors for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                          |
| ip-addr <ip-addr> | Show mesh neighbors for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                                                        |
| names             | If you include this optional parameter, the <b>Portal</b> column in the output of this command will translate the BSSIDs of mesh parent and child APs to AP names (where available). |

### Example

In the example below, the output has been split into two tables to better fit on the page. In the actual command-line interface, the output appears in a single, wide table. The **Flags** column the output of this command indicates the high-throughput (HT) properties of the mesh node. In the example below, the string "HT-40MHzsgi-2ss" indicates that the node uses a 40MHz channel with a short guard interval (sgi) and sends 2 spatial streams (ss).

```
(host) #show ap mesh neighbors ap-name portal
```

Neighbor list

| MAC                          | Portal            | Channel | Age             | Hops        | Cost  | Relation     | Flags | RSSI  |    |

Total count: 5, Children: 2

Relation: P = Parent; C = Child; N = Neighbor; B = Blacklisted-neighbor

Flags: R = Recovery-mode; S = Sub-threshold link; D = Reselection backoff; F = Auth-failure; H = High Throughput; L = Legacy allowed

The output of this command includes the following information:

| Column     | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAC        | MAC address of the mesh node.                                                                                                                                                                                                                                                                                                                                                                  |
| Portal     | By default, this column displays the BSSID of the mesh point. If you include the optional <b>names</b> parameter, this column will display AP names, if available. The AP names will include <b>[p]</b> (parent), or <b>[c]</b> (child) suffixes to indicate the role of the mesh BSSID.                                                                                                       |
| Channel    | Number of a radio channel used by the AP.                                                                                                                                                                                                                                                                                                                                                      |
| Age        | Number of seconds elapsed since the AP heard from the neighbor.                                                                                                                                                                                                                                                                                                                                |
| Hops       | Indicates the number of hops it takes traffic from the mesh node to get to the mesh portal.<br><br>The mesh portal advertises a hop count of 0, while all other mesh nodes advertise a cumulative count based on the parent mesh node                                                                                                                                                          |
| Cost       | A relative measure of the quality of the path from the AP to the controller. A lower number indicates a better quality path, where a higher number indicates a less favorable path (e.g, a path which may be longer or more congested than a path with a lower value.)<br><br>For a mesh point, the path cost is the sum of the (parent path cost) + (the parent node cost) + (the link cost). |
| Relation   | Shows the relationship between the specified AP and the AP on the neighbor list and the amount of time that relationship has existed. <ul style="list-style-type: none"> <li>● <b>P</b> = Parent</li> <li>● <b>C</b> = Child</li> <li>● <b>N</b> = Neighbor</li> <li>● <b>B</b> = Blacklisted-neighbor</li> </ul>                                                                              |
| Flags      | This parameter shows additional information about the mesh neighbor. The key describing each flag appears at the bottom of the neighbor list.                                                                                                                                                                                                                                                  |
| RSSI       | The Receive Signal Strength Indicator (RSSI) value displayed in the output of this command represents signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.                                                                                                                  |
| Rate Tx/Rx | The rate, in Mbps, that a neighbor transmits data to or receives data from the mesh-node specified by the command.                                                                                                                                                                                                                                                                             |

| Column  | Description                                                       |
|---------|-------------------------------------------------------------------|
| A-Req   | Number of association requests from clients                       |
| A-Resp  | Number of association responses from the mesh node                |
| A-Fail  | Number of association failures                                    |
| Cluster | Name of the Mesh cluster that includes the specified AP or BSSID. |

## Command History

## show ap mesh-radio-profile

show ap mesh-radio-profile [<profile>]

### Description

Show configuration settings for a mesh radio profile.

### Syntax

| Parameter | Description                   |
|-----------|-------------------------------|
| <profile> | Name of a mesh radio profile. |

### Usage Guidelines

The radio profile determines the radio frequency/channel used only by mesh nodes to establish mesh links. Mesh nodes operating in different cluster profiles can share the same radio profile. Conversely, mesh portals using the same cluster profile can be assigned different mesh radio profiles to achieve frequency separation.

The command **show ap mesh-radio-profile** displays a list of all mesh radio profiles configured on the controller, including the number of references to each profile and each profile's status. Include the optional <profile> parameter to show detailed settings for an individual mesh radio profile.

### Example

The example below shows the configuration settings for the mesh cluster profile "default".

```
(host) #show ap mesh-radio-profile default
Mesh Radio profile "default"

Parameter Value

802.11a Transmit Rates 6 9 12 18 24 36 48 54
802.11g Transmit Rates 1 2 5 6 9 11 12 18 24 36 48 54
Allowed VLANs on mesh link 1-4094
BC/MC Rate Optimization Enabled
Heartbeat threshold 10
Link Threshold 12
Maximum Children 64
Maximum Hop Count 8
Mesh Private Vlan 0
Mesh High-throughput SSID Profile default
Mesh Survivability Disabled
Metric algorithm distributed-tree-rssi
Rate Optimization for delivering EAPOL frames and mesh echoes Disabled
Reselection mode startup-subthreshold
Retry Limit 8
RTS Threshold 2333 bytes
```

The output of this command includes the following information:

| Parameter                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 802.11a Transmit Rates                                        | Indicates the transmit rates for the 802.11a radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.                                                                                                                                                                                       |
| 802.11g Transmit Rates                                        | Indicates the transmit rates for the 802.11g radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.                                                                                                                                                                                       |
| Allowed VLANs on mesh link                                    | Specify a list of VLAN IDs that can be used by a mesh link on APs associated with this mesh radio profile                                                                                                                                                                                                                                                                                                       |
| BC/MC Rate Optimization                                       | If enabled, the mesh node will use the slowest associated mesh-point rate for broadcast/multicast data (rather than minimum).                                                                                                                                                                                                                                                                                   |
| Heartbeat Threshold                                           | Indicates the maximum number of heartbeat messages that can be lost between neighboring mesh nodes before the mesh node is considered inactive and is dropped as a mesh neighbor.                                                                                                                                                                                                                               |
| Link Threshold                                                | Indicates the threshold for the lowest acceptable Receive Signal Strength Indicator (RSSI) value. Links that drop below this threshold will have an increased link cost. Default: 12.                                                                                                                                                                                                                           |
| Maximum Children                                              | The maximum number of children a mesh portal can accept.                                                                                                                                                                                                                                                                                                                                                        |
| Maximum Hop Count                                             | The maximum number of hops allowed between a mesh point and a mesh portal.                                                                                                                                                                                                                                                                                                                                      |
| Mesh Private Vlan                                             | This parameter is experimental and reserved for future use.                                                                                                                                                                                                                                                                                                                                                     |
| Mesh High-throughput SSID Profile                             | The High-throughput SSID Profile associated with this mesh radio profile.                                                                                                                                                                                                                                                                                                                                       |
| Mesh Survivability                                            | This parameter shows if mesh points and portals can become active even if the controller cannot be reached by bridging LAN traffic. This is a beta feature that is disabled by default; it should not be enabled unless you are instructed to do so by Dell technical support.                                                                                                                                  |
| Metric algorithm                                              | Algorithm used by a mesh node to select its parent.                                                                                                                                                                                                                                                                                                                                                             |
| Rate Optimization for delivering EAPOL frames and mesh echoes | If this option is enabled, mesh APs will use a more conservative rate for more reliable delivery of EAPOL frames.                                                                                                                                                                                                                                                                                               |
| Reselection Mode                                              | <p>Specifies the one of the following methods used to find a better mesh link.</p> <ul style="list-style-type: none"> <li> <b>startup-sub-threshold:</b> When bringing up the mesh network, mesh nodes have 3 minutes to find a better uplink. After that time, each mesh node evaluates alternative links only if the existing uplink falls below the configured threshold level (the link becomes </li> </ul> |

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p>a sub-threshold link). The reselection process is canceled if the average RSSI rises on the existing uplink rises above the configured link threshold.</p> <ul style="list-style-type: none"> <li>• <b>reselect-any-time:</b> Connected mesh nodes evaluate alternative mesh links every 30 seconds. If a mesh node finds a better uplink, the mesh node connects to the new parent to create an improved path to the mesh portal.</li> <li>• <b>reselect-never:</b> Connected mesh nodes do not evaluate other mesh links to create an improved path to the mesh portal.</li> <li>• <b>subthreshold-only:</b> Connected mesh nodes evaluate alternative links only if the existing uplink becomes a sub-threshold link.</li> </ul> |
| Retry Limit   | Maximum number of times a mesh node can re-send a packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| RTS Threshold | The packet size sent by mesh nodes. Mesh nodes transmitting frames larger than this threshold must issue request to send (RTS) and wait for other mesh nodes to respond with clear to send (CTS) to begin transmission. This helps prevent mid-air collisions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Syntax

| Parameter  | Description                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ap-name>  | Name of an AP for which you want to create a report                                                                                                                              |
| <filename> | Filename for the report created by this command. The file can only be saved in the flash directory. If desired, you can use FTP or TFTP to copy the file to another destination. |

### Usage Guidelines

This command displays the output of the multiple mesh and debug CLI commands, then saves that data into a report file on the controller's flash drive, where it can be analyzed for debugging purposes. The information in this report includes the output of the following commands:

- [show ap mesh neighbors](#)
- [show ap mesh debug current-cluster](#)
- [show ap mesh debug provisioned-clusters](#)
- [show ap mesh debug counters](#)
- [show ap mesh debug forwarding-table](#)
- [show ap mesh debug meshd-log](#)
- [show ap mesh debug hostapd-log](#)

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing                                                                                                                     | Command Mode                      |

## show ap mesh topology

show ap mesh topology [long] [page <page>] [start <start>]

### Description

Show the mesh topology tree.

### Syntax

| Parameter     | Description                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| long          | Include the names of a mesh portal's children in the output of this command                                                                   |
| page <page>   | Limit the output of this command to a specific number of entries by entering the number of entries you want to display.                       |
| start <start> | Start displaying the mesh topology tree at a chosen index number by entering the index number of the AP at which command output should start. |

### Example

An **(N)** in the **Mesh Role** column indicates the node is 11N capable. An **(N)** beside the parent name in the **Parent** column indicates that the mesh node's the parent is also 11N capable.

```
(host) #show ap mesh topology
```

```
Mesh Cluster Name: sw-ad-GB32
```

```

Name Mesh Role Parent Path Cost Node Cost Link Cost Hop Count RSSI Rate Tx/Rx Last

Update Uplink Age #Children

ad-ap Point (N) mp3 2 0 0 1 61 300/270 6m:12s
 3h:8m:7s 0

msc-1 Point mp3 2 0 0 1 64 54/54 6m:36s
2h:48m:12s 0
```

```
Total APs :2
```

```
(R): Recovery AP. (N): 11N Enabled. For Portals 'Uplink Age' equals uptime.
```

The output of this command includes the following information:

| Column    | Description                                                                          |
|-----------|--------------------------------------------------------------------------------------|
| Name      | Name of the mesh node.                                                               |
| Mesh Role | An AP operating as a mesh node can have one of two roles: mesh portal or mesh point. |

| Column      | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parent      | If the AP is operating as a mesh point, this parameter displays the name of its parent mesh portal.                                                                                                                                                                                                                                                                                                   |
| Path Cost   | <p>A relative measure of the quality of the path from the AP to the controller. A lower number indicates a better quality path, where a higher number indicates a less favorable path (e.g, a path which may be longer or more congested than a path with a lower value.)</p> <p>For a mesh point, the path cost is the sum of the (parent path cost) + (the parent node cost) + (the link cost).</p> |
| Node Cost   | A relative measure of the quality of the node, where a lower number of is more favorable than a higher number. This cost is related to the number of children on the specified node.                                                                                                                                                                                                                  |
| Link Cost   | A relative measure of the quality of the link. For example, a more congested link will have a higher link cost than a similar, less-congested link.                                                                                                                                                                                                                                                   |
| Hop Count   | Number of hops to the mesh portal.                                                                                                                                                                                                                                                                                                                                                                    |
| RSSI        | The Receive Signal Strength Indicator (RSSI) value displayed in the output of this command represents signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.                                                                                                                         |
| Rate Tx/Rx  | The rate, in Mbps, that a mesh point transmits and receives at on its uplink. Note that the rate information is only as current as indicated in the <b>Last Update</b> column.                                                                                                                                                                                                                        |
| Last Update | Time elapsed since the mesh node last updated its statistics.                                                                                                                                                                                                                                                                                                                                         |
| Uplink Age  | Time elapsed since the mesh node became active in the mesh topology.                                                                                                                                                                                                                                                                                                                                  |
| #Children   | Number of children associated with a parent mesh point.                                                                                                                                                                                                                                                                                                                                               |

```

### Description

Show information for Dell Air Monitors.

### Syntax

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| active-laser-beams | Show active laser beam generators.<br><br>The output of this command shows a list of all APs that are actively performing policy enforcement containment such as rogue containment. This command can tell us which AP is sending out deauthorization frames, although it does not specify which AP is being contained.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ap-list            | Show list of APs being monitored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                     | <p>recognized the client.</p> <ul style="list-style-type: none"> <li>it: Client Idle time, expressed as a number of timer ticks.</li> </ul>                          |
| router              | Show Router MAC Addresses learned. The output of this command includes the router's MAC address, IP address and uptime.                                              |
| wired-mac           | Show Wired MAC Addresses learned.                                                                                                                                    |
| ap-name <ap-name>   | Show data for an AP with a specific name.                                                                                                                            |
| bssid <bssid>       | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                    |
| ip-addr <ip-addr>   | Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                                                  |
| ap-bssid <ap-bssid> | Include the optional <b>ap-bssid &lt;ap-bssid&gt;</b> parameters to show how the AP is monitoring information for another AP with a specific BSSID.                  |
| enet-mac <enet-mac> | Include the optional <b>enet-mac &lt;enet-mac&gt;</b> parameters to show how the AP is monitoring information for an interface with a specific Ethernet MAC address. |

## Examples

The output of the command displays the Monitored AP table, which lists all the APs monitored by a specified AP or BSSID.

```
(host) #show ap monitor ap-list ap-name all2
```

The output of this command includes the following information:

| Parameter | Description                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid     | Basic Service Set Identifier for (bssid) an AP. This is usually the AP's MAC address.                                                                                                                                                     |
| essid     | Extended service set identifier that names a wireless network.                                                                                                                                                                            |
| chan      | Radio channel used by the BSSID.                                                                                                                                                                                                          |
| ap-type   | Shows classification of the AP.                                                                                                                                                                                                           |
| phy-type  | Radio phy type. Possible types include: <ul style="list-style-type: none"> <li>• 802.11a</li> <li>• 802.11a-HT-40</li> <li>• 802.11b/g</li> <li>• 802.11b/g-HT-20</li> </ul>                                                              |
| dos       | Shows if the feature to contain DoS attacks has been enabled or disabled.                                                                                                                                                                 |
| dt/mt     | <b>dt</b> —Detected time: the number of timer ticks since the AP was last detected.<br><b>mt</b> —Monitor time; the number of elapsed timer ticks since the AP first recognized the monitored AP.                                         |
| ut/it     | <b>ut</b> —Unseen time: the number elapsed timer ticks the monitored AP was not seen when scanning a channel of the device.<br><b>it</b> —AP idle time, the number of timer ticks since the AP last saw any frames from the monitored AP. |
| encr      | Shows the encryption type of the BSSID. If there are multiple encryption types, this command shows the lowest encryption type.                                                                                                            |
| ntsas     | Shows the number of stations connected to the AP (as seen by the monitoring AP).                                                                                                                                                          |
| avg-rssi  | Shows the average RSSI (Received Signal Strength) for the device.<br><b>NOTE:</b> RSSI is an indication of the power level being received by the antenna. Therefore, the higher the RSSI number, the stronger the signal.                 |
| curr-rssi | Shows the current RSSI for the device.                                                                                                                                                                                                    |
| wmacs     | Shows the number of unique wireless MAC addresses seen on the Wi-Fi network from the AP's BSSID.                                                                                                                                          |
| ibss      | Shows all the monitored APs (BSSIDs).                                                                                                                                                                                                     |

## Command History

## show ap monitor association

```
show ap monitor association {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}] <ap-bssid>
```

### Description

Show the association table for an Air Monitor (AM).

### Syntax

| Parameter         | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AM with a specific name.                                                                                                           |
| bssid <bssid>     | Show data for an AM with a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AM's MAC address. |
| ip-addr <ip-addr> | Show data for an AM with a specific IP address by entering its IP address in dotted-decimal format.                                                 |
| <ap-bssid>        | BSSID of an AP.                                                                                                                                     |

### Examples

The output of the command lists the MAC addresses associated with the Air Monitor BSSID.

```
(host) #show ap monitor association ap-name ap9 00:1a:1e:11:74:a1
Association Table

mac rsta-type auth phy-type

```

### Description

Show information for an Air Monitor's current status, message counters, or profile settings.

### Syntax

| Parameter         | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| counters          | Show Air Monitor (AM) message counters.                                                                                                             |
| status            | Show the status of an Air Monitor.                                                                                                                  |
| ap-name <ap-name> | Show data for an AM with a specific name.                                                                                                           |
| bssid <bssid>     | Show data for an AM with a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AM with a specific IP address by entering its IP address in dotted-decimal format.                                                 |
| profile-config    | Show an Air Monitor profile configuration.                                                                                                          |
| ap-radio          | Show the Air Monitor radio configuration parameters, as defined in the AM's 802.11a, 802.11b, or high-throughput radio profiles.                    |
| ap-system         | Show an Air Monitor's system configuration settings, as defined in its AP System profile.                                                           |
| arm               | Show an Air Monitor's Adaptive Radio Management (ARM) settings, as defined in its current ARM profile                                               |
| event-thresholds  | Show an Air Monitor Event Thresholds settings, as defined in its current RF Event Thresholds profile                                                |
| ids-dos           | Show an Air Monitor IDS DoS settings, as defined in its current IDS DoS profile.                                                                    |
| ids-general       | Show an Air Monitor IDS General Configuration settings, as defined in its IDS General profile.                                                      |

| Parameter               | Description                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------|
| ids-impersonation       | Show an Air Monitor IDS Impersonation Configuration settings, as defined in its IDS Impersonation profile.             |
| ids-signature-matching  | Show an Air Monitor IDS Signature Matching configuration settings, as defined in its IDS Signature Matching profile    |
| ids-unauthorized-device | Show an Air Monitor IDS Unauthorized Device configuration settings, as defined in its IDS Unauthorized Device profile. |
| interference            | Show an Air Monitor's interference configuration settings, as defined in its current RF Optimization profile.          |
| regulatory-domain       | Show an Air Monitor's Regulatory Domain configuration settings, as defined in its Regulatory Domain profile.           |
| rf-behavior             | Show an Air Monitor RF Behavior Configuration                                                                          |

## Examples

The output of the following command includes the *WLAN Interface*, *Data Structures*, *WLAN InterfaceSwitch Status* and *RTLS Configuration* tables for the specified AP.

```
(host) #show ap monitor debug status ap-name ap12
```

WLAN Interface

The output of this command includes the following information:

| Column     | Description                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid      | The Basic Service Set Identifier (BSSID) for the AP. This is usually the AP's MAC address.                                                                                                                                                                                                |
| scan       | Indicates whether or not if active scanning is enabled on this AP.                                                                                                                                                                                                                        |
| monitor    | Indicates whether the AP radio is currently enabled or disabled.                                                                                                                                                                                                                          |
| probe-type | This parameter displays one of the following options to show the AP is configured. <ul style="list-style-type: none"> <li><b>sap:</b> Default AP setting.</li> <li><b>am:</b> AP is configured as an Air Monitor.</li> <li><b>m-portal:</b> AP is configured as a Mesh portal.</li> </ul> |

| Column               | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <ul style="list-style-type: none"> <li>• <b>m-point:</b> AP is configured as a Mesh point.</li> </ul>                                                                                                                                                                                                                                                                                                        |
| task                 | <p>This parameter displays one of the following options to show the radio's current task:</p> <ul style="list-style-type: none"> <li>• <b>scan:</b> AP is scanning other channels.</li> <li>• <b>tuned:</b> AP is tuned on one channel.</li> <li>• <b>locate:</b> AP has been asked to locate a specific AP or client.</li> <li>• <b>pcap:</b> The AP is enabled with the Packet Capture feature.</li> </ul> |
| channel              | The radio channel currently used by an AP's WLAN interface.                                                                                                                                                                                                                                                                                                                                                  |
| pkts                 | Number of packets seen on the interface.                                                                                                                                                                                                                                                                                                                                                                     |
| mac                  | MAC address for the AP's wired interface.                                                                                                                                                                                                                                                                                                                                                                    |
| ip                   | The AP's IP address.                                                                                                                                                                                                                                                                                                                                                                                         |
| gw-ip                | IP address for the AP's gateway.                                                                                                                                                                                                                                                                                                                                                                             |
| gw-mac               | MAC address for the AP's gateway.                                                                                                                                                                                                                                                                                                                                                                            |
| status               | Shows if the interface is currently enabled or disabled.                                                                                                                                                                                                                                                                                                                                                     |
| pkts                 | Number of packets seen on the AP's wired interface.                                                                                                                                                                                                                                                                                                                                                          |
| macs                 | Number of MAC addresses in the Wired MAC table for that interface.                                                                                                                                                                                                                                                                                                                                           |
| gw-macs              | Number of MAC addresses in the Wired MAC table for that interface.                                                                                                                                                                                                                                                                                                                                           |
| tagged-pkts          | Number VLAN-tagged packets sent to that interface.                                                                                                                                                                                                                                                                                                                                                           |
| vlan                 | The VLAN ID for the packets sent to that interface.                                                                                                                                                                                                                                                                                                                                                          |
| Packets read         | Number of packets read by the AP since it was last reset.                                                                                                                                                                                                                                                                                                                                                    |
| Bytes read           | Number of bytes read by the AP since it was last reset.                                                                                                                                                                                                                                                                                                                                                      |
| Num Intercepts       | Number of interrupts from the AP's driver.                                                                                                                                                                                                                                                                                                                                                                   |
| Num Buffer Overflows | Number of times excessive traffic has filled the AP's buffers.                                                                                                                                                                                                                                                                                                                                               |
| Max PPS              | Maximum throughput rate seen on the interface, in packets per second.                                                                                                                                                                                                                                                                                                                                        |
| Cur PPS              | Current throughput rate seen on the interface, in packets per second.                                                                                                                                                                                                                                                                                                                                        |

| Column                | Description                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max PPI               | Maximum interrupt rate seen on the interface, in interrupts per second.                                                                                                                                           |
| Cur PPI               | Current interrupt rate seen on the interface, in interrupts per second.                                                                                                                                           |
| Uptime                | Number of seconds since the AP was last reset.                                                                                                                                                                    |
| LMS IP                | IP address of the AP's local controller.                                                                                                                                                                          |
| Master IP             | IP address of the AP's master controller.                                                                                                                                                                         |
| AP type               | AP model type.                                                                                                                                                                                                    |
| Country Code          | The AP's country code. Valid radio channels for your wireless network are based on your country code. If you change the AP's country code, the valid channels will be reset to the defaults for the new country.  |
| ap                    | Number of other APs monitored by this AP.                                                                                                                                                                         |
| sta                   | Number of clients and APs seen by this AP.                                                                                                                                                                        |
| pap                   | Number of potential APs; APs which have transmitted a beacon, but have not yet been registered.                                                                                                                   |
| psta                  | Number of potential stations; AP has seen a MAC address from the station but hasn't yet received traffic from it.                                                                                                 |
| ch                    | Number of channel entries in the channel table.                                                                                                                                                                   |
| msg-hash              | Number of different message types seen on the interface.                                                                                                                                                          |
| ap-1                  | (For internal use only)                                                                                                                                                                                           |
| WMS on Master         | Indicates if the AP communicates to the wms process on a master or local controller.<br><b>enabled:</b> Communicates with a master controller.<br><b>disabled:</b> Communicates with a local controller only.     |
| Stats Update Interval | If the AP is collecting statistics, this value is the interval in seconds in which the AP sends statistics to the WMS process on a controller.                                                                    |
| Poll Interval         | Interval, in milliseconds, that the AP sends RSSI updates to the WMS process on a controller.                                                                                                                     |
| Num Switches          | Number of controllers to which this AP has access. If the value is 1, the AP has access to a master <i>or</i> a local controller. If the value is 2, the AP has access to a master <i>and</i> a local controller. |

| Column           | Description                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------|
| Collect Stats    | If enabled, the AP will collect statistics to send the WMS process on its controller.                |
| Bssid            | BSSID of the radio.                                                                                  |
| Type             | Indicates whether the controller type is <b>master</b> or <b>local</b> .                             |
| Status           | If <b>up</b> , the AP can reach the controller. If <b>down</b> , the AP cannot reach the controller. |
| Last-reg         | The time the AP last registered with the WMS process.                                                |
| N-reg            | Number of times the AP has registered with the WMS process.                                          |
| Last-update      | The last timer tick time the AP updated the WMS process.                                             |
| Next-update      | Interval between the last update and the next scheduled update.                                      |
| N-updates        | Number of updates sent to the WMS process.                                                           |
| Last-ack         | Number of timer ticks since the AP received an acknowledgement from the WMS process.                 |
| Type             | Type of RTLS server used by the AP, such as MMS or Aeroscout.                                        |
| Server IP        | IP address of the RTLS server.                                                                       |
| Port             | Port used by the RTLS server.                                                                        |
| Frequency        | Rate, in seconds, at which RTLS messages are sent to the server.                                     |
| Active           | Indicates if the server is active on the AP.                                                         |
| Rpt-Tags         | Displays whether tag reporting is enabled or not.                                                    |
| Tag-Mcast-Addr   | Displays MAC OUI of the tags that are forwarded to the server.                                       |
| Tags-Sent        | Displays the cumulative count of the tag reports sent to server.                                     |
| Rpt-Sta          | Displays whether station reporting is enabled or not.                                                |
| Incl-Unassoc-Sta | Displays whether unassociated stations are included in station reporting or not.                     |
| Sta-Sent         | Displays cumulative count of station reports sent to server.                                         |
| Cmpd-Msgs-Sent   | Displays cumulative count of compound messages containing station reports sent to server.            |

## show ap monitor stats

```
show ap monitor stats advanced {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}] client-
mac <client-mac>
```

```
show ap monitor stats {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}] mac <mac>
```

### Description

Show packet, signal and channel statistics for an AP or a client.

### Syntax

| Parameter               | Description                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| advanced                | Show advanced statistics for an AP or client.                                                                                                     |
| ap-name <ap-name>       | Show statistics for an AP with a specific name.                                                                                                   |
| bssid <bssid>           | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>       | Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                               |
| mac <mac>               | Show data for a specific MAC address by entering the MAC address of a client or AP.                                                               |
| client-mac <client-mac> | Show data for a specific client MAC address by entering the MAC address of a client.                                                              |

### Example

The output of the following command shows monitoring statistics for the AP al12, and a client with the MAC address 00:03:2a:02:6a:d7.

```
(host) #show ap monitor stats ap-name al12 mac 00:03:2a:02:6a:d7
```

Aggregate Stats

```

retry low-speed non-unicast recv-error frag bwidth

0 0 0 0 0 0
```

RSSI

```

avg-signal low-signal high-signal count duration (sec)

51 51 51 4 50
```

Monitored Time:6626

Last Packet Time:585500

Uptime:585502

```

The output of this command includes the following information:

| Column      | Description                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| retry       | Percent of 802.11 retry frames sent because a client failed to send an ACK.                                                                                |
| Low-speed   | Percent of frames sent at a data rate of 18 Mbps or slower.                                                                                                |
| non-unicast | Percent of non-unicast frames                                                                                                                              |
| recev-error | Percent of error frames of all frames seen in the last second.                                                                                             |
| frag        | Rate of fragmented packets, in frames per second                                                                                                           |
| bwth        | Current bandwidth, in bps.                                                                                                                                 |
| avg-signal  | Average signal-to-noise ratio over the interval since the AP's last reset.                                                                                 |
| Low-signal  | Lowest signal-to-noise ratio over the interval since the AP's last reset.                                                                                  |
| high-signal | Highest signal-to-noise ratio over the interval since the AP's last reset.                                                                                 |
| count       | Number of packets seen on the AP over the interval since the AP's last reset.                                                                              |
| Duration    | Time over which the AP has measured RSSI values.                                                                                                           |
| tx          | The total number of deauthorization frames sent to this MAC address for containment in the interval from the AP's last reset until the current timer tick. |
| old-tx      | The total number of deauthorization frames sent to this MAC address for containment until the previous timer tick.                                         |
| rx          | The total number of deauthorization frames spoofing the MAC address in the interval from the AP's last reset until the current timer tick.                 |

| Column            | Description                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| old-rx            | The total number of deauthorization frames sent to this MAC address for containment until the previous timer tick.                                                                                                                                                                             |
| FRR               | Frame retry rate, in frames per second.                                                                                                                                                                                                                                                        |
| FRER              | Frame error retry rate, in frames per second.                                                                                                                                                                                                                                                  |
| rss-index         | This value indicates the number of consecutive timer ticks over which the value of the Receive Signal Strength Indicator (RSSI) of the client has reduced by more than 3 units.<br><b>NOTE:</b> This value is updated only if 'handoff-assist' is enabled in the AP's RF Optimization profile. |
| cur-signal        | The Receive Signal Strength Indicator (RSSI) of the most recent frame received from the specified MAC address.                                                                                                                                                                                 |
| old-cur-signal    | The most recent Receive Signal Strength Indicator (RSSI) of the MAC which is 3 lower or 5 higher than the current RSSI.<br><b>NOTE:</b> This value is updated only if 'handoff-assist' is enabled in the AP's RF Optimization profile                                                          |
| ht-type           | This parameter indicates support for the following HT types:<br><b>no:</b> No support for high-throughput.<br><b>HT-20:</b> Support for 20 Mhz high-throughput only.<br><b>HT-40:</b> Support for 40 Mhz high-throughput.                                                                      |
| primary-channel   | Primary radio channel.                                                                                                                                                                                                                                                                         |
| sec-channel       | Secondary radio channel                                                                                                                                                                                                                                                                        |
| gf-supported      | If <b>1</b> , this AP supports greenfield mode. If <b>0</b> , greenfield is not supported.                                                                                                                                                                                                     |
| 40mhz-intolerance | Indicates whether the specified MAC address is 40 Mhz intolerant.                                                                                                                                                                                                                              |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap packet capture

```
show ap pcap status {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}]
```

### Description

Show the status of outstanding packet capture (pcap) sessions.

### Syntax

| Parameter         | Description                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                                                         |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                               |

### Usage Guidelines

The Packet Capture (pcap) feature copies control path packets from the Dell Control Processor, providing visibility for packets to or from the controller. This provides a useful troubleshooting tool for diagnosing communication problems with elements such as a Radius server. You can retrieve these packets by issuing the command **tar logs**, and then viewing the file filter.pcap on the controller's flash drive.

### Example

The example below shows the Packet Capture Sessions table for an AP named AP16.

```
(host) #show ap pcap status ap-name AP16
```

```
Packet Capture Sessions
```

```

pcap-id filter type intf channel max-pkt-size num-pkts status url
target
----- -

1 raw 00:1a:1e:82:ab:b0 161
 in-progress 10.3.9.225/5555
```

The output of this command includes the following information:

| Column  | Description                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------|
| pcap-id | ID number of the packet capture session.                                                                       |
| filter  | Packet Capture filter specification.                                                                           |
| type    | A <b>raw</b> packet capture type indicates that the controller is streaming raw packets to an external viewer. |

| Column       | Description                                                                           |
|--------------|---------------------------------------------------------------------------------------|
| intf         | BSSID of the interface for the PCAP session.                                          |
| channel      | Channel used by AP to capture packets.                                                |
| max-pkt-size | Maximum size of all captured packets.                                                 |
| num-pkts     | Number of packets captured during the session.                                        |
| status       | Shows the current status of the packet-capture session.                               |
| url          | Packet capture data can be downloaded to this URL                                     |
| target       | IP address of the client station running Wildpacket's AiroPeek monitoring application |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap papi-err

```
show ap papi-err {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

### Description

Show PAPI error messages.

### Syntax

| Parameter           | Description                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show data for an AP with a specific name.                                                                                                         |
| bssid <bssid>       | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                               |
| ip6-addr <ip6-addr> | Show data for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.                                           |

### Examples

The output of the command displays the status.

```
(host) #show ap papi-err
STM SAP PAPI Send Error

Name bssid ip Tunnel Add Tunnel Remove Arp Req Vlan Req Sta Req Mcast Req
---- -

```

### Command History

| Version      | Modification                        |
|--------------|-------------------------------------|
| ArubaOS 3.0. | Command introduced                  |
| ArubaOS 6.3  | The <b>ip6</b> parameter was added. |

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap port status

```
ap-name <ap-name>
bssid <bssid>
ip-addr <ip-addr>
ip6-addr <ip6-addr>
wired-mac <wired-mac>
```

### Description

Shows the status of the AP's wired ports. The status is updated every 60 seconds.

### Syntax

| Parameter             | Description             |
|-----------------------|-------------------------|
| ap-name <ap-name>     | Name of the AP.         |
| bssid <bssid>         | BSSID of the AP.        |
| ip-addr <ip-addr>     | IP address of the AP.   |
| ip6-addr <ip6-addr>   | IPv6 address of the AP. |
| wired-mac <wired-mac> | MAC address of the AP.  |

### Examples

The output of the command displays the wired port status of an AP named **LocalAP1**. In this example, the output is divided into multiple sections to fit better on the pages of this document. In the actual command-line interface, it appears in a single long table.

```
(host) #show ap port status ap-name LocalAP1
```

AP "LocalAP1" Port Status (updated every 60 seconds)

| Port       | MAC               | Type     | Forward Mode | Admin    | Oper | Speed    | Duplex | 802.3az | PoE |
|------------|-------------------|----------|--------------|----------|------|----------|--------|---------|-----|
| ----       | ---               | ----     | -----        | -----    | ---- | -----    | -----  | -----   | --- |
| 0          | 00:1a:1e:10:05:1a | GE       | N/A          | enabled  | up   | 1 Gb/s   | full   | N/A     | N/A |
| 1          | 00:1a:1e:10:05:1b | FE       | tunnel       | enabled  | up   | 100 Mb/s | full   | N/A     | N/A |
| 2          | 00:1a:1e:10:05:1c | FE       | tunnel       | enabled  | down | N/A      | N/A    | N/A     | N/A |
| 3          | 00:1a:1e:10:05:1d | FE       | N/A          | disabled | down | N/A      | N/A    | N/A     | N/A |
|            |                   |          |              |          |      |          |        |         |     |
| STP        | TX-Packets        | TX-Bytes | RX-Packets   | RX-Bytes |      |          |        |         |     |
| ---        | -----             | -----    | -----        | -----    |      |          |        |         |     |
| N/A        | 23697             | 3338307  | 27449        | 8471871  |      |          |        |         |     |
| Forwarding | 12185             | 6593226  | 18436        | 1758272  |      |          |        |         |     |
| Disabled   | 0                 | 0        | 0            | 0        |      |          |        |         |     |

| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap profile-usage

```
show ap profile-usage {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

### Description

Show a complete list of all profiles referenced by an individual AP or an AP BSSID.

### Syntax

| Parameter         | Description                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                                                         |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                               |

### Usage Guidelines

Use this command to monitor the configuration profiles in use by an AP or a specific BSSID. The output of this command shows the name of each profile type that is associated with the AP or BSSID, as well as the source that associates the profile with the AP.

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap provisioning

```
show ap provisioning {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

### Description

Show provisioning parameters currently used by an AP.

### Syntax

| Parameter         | Description                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                              |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address.                                                                        |

### Example

The output of this command shows that the AP named AP8 has mostly default parameters. These appear with the value N/A.

```
(host) #show ap provisioning ap-name AP8
```

```
AP "mp2" Provisioning Parameters
```

```

```

| Item | Value |
|------|-------|
| ---- | ----- |

```
(host) (config) #show ap provisioning ap-name 00:24:6c:c7:d5:c8
```

```
AP "00:24:6c:c7:d5:c8" Provisioning Parameters
```

```

```

| Item                          | Value             |
|-------------------------------|-------------------|
| ----                          | -----             |
| AP Name                       | 00:24:6c:c7:d5:c8 |
| AP Group                      | default           |
| Location name                 | N/A               |
| SNMP sysLocation              | N/A               |
| Master                        | 10.4.62.9         |
| Gateway                       | N/A               |

| USB Device Type    | any |

The output of this command includes the following information:

| Column                   | Description                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------|
| AP Name                  | Name of the AP.                                                                                           |
| AP Group                 | AP group to which the AP belongs.                                                                         |
| Location name            | Fully-qualified location name (FQLN) for the AP.                                                          |
| SNMP sysLocation         | User-defined description of the location of the AP, as defined with the command provision-ap syslocation. |
| Master                   | Name or IP address for the master controller.                                                             |
| Gateway                  | IP address of the default gateway for the AP.                                                             |
| Netmask                  | Netmask for the AP's IP address.                                                                          |
| IP Addr                  | IP address for the AP.                                                                                    |
| IPv6                     | The static IP6 address of the AP. <sup>6</sup>                                                            |
| IPv6 Prefix              | The prefix of static IPv6 address of the AP.                                                              |
| Dns IP                   | IP address of the DNS server.                                                                             |
| DNS IPv6                 | The prefix of static IPv6 address of the AP.                                                              |
| Domain Name              | Domain name used by the AP.                                                                               |
| Server Name              | DNS name of the controller from which the AP boots.                                                       |
| Server IP                | IP address of the controller from which the AP boots                                                      |
| Antenna gain for 802.11a | Antenna gain for 802.11a (5GHz) antenna.                                                                  |
| Antenna gain for 802.11g | Antenna gain for 802.11g (2.4GHz) antenna.                                                                |

| Column                        | Description                                                                                                                                                                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Antenna for 802.11a           | Antenna use for 5 GHz (802.11a) frequency band. <ul style="list-style-type: none"> <li>• <b>1:</b> AP uses antenna 1</li> <li>• <b>2:</b> AP uses antenna 2</li> <li>• <b>both:</b> AP uses both antennas</li> </ul>                                          |
| Antenna for 802.11g           | Antenna use for 2.4 GHz (802.11g) frequency band. <ul style="list-style-type: none"> <li>• <b>1:</b> AP uses antenna 1</li> <li>• <b>2:</b> AP uses antenna 2</li> <li>• <b>both:</b> AP uses both antennas</li> </ul>                                        |
| Single chain mode for Radio 0 | If this parameter is set to 1 for an 802.11n-capable radio, the radio will operate in single-chain mode, and will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This parameter is set to 0 (disabled) by default. |
| Single chain mode for Radio 1 | If this parameter is set to 1 for an 802.11n-capable radio, the radio will operate in single-chain mode, and will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This parameter is set to 0 (disabled) by default. |
| IKE PSK                       | IKE PSK The IKE pre-shared key.                                                                                                                                                                                                                               |
| PAP password                  | Password Authentication Protocol (PAP) password for the AP.                                                                                                                                                                                                   |
| PAP User Name                 | PAP username for the AP.                                                                                                                                                                                                                                      |
| PPPOE User Name               | Point-to-Point Protocol over Ethernet (PPPoE) user name for the AP.                                                                                                                                                                                           |
| PPPOE Password                | PPPoE password for the AP.                                                                                                                                                                                                                                    |
| PPPOE Service Name            | PPPoE service name for the AP.                                                                                                                                                                                                                                |
| PPPOE CHAP secret             | PPPoE CHAP secret key for the AP.                                                                                                                                                                                                                             |
| USB User Name                 | The PPP username provided by the cellular service provider                                                                                                                                                                                                    |
| USB Password                  | A PPP password, if provided by the cellular service provider                                                                                                                                                                                                  |
| USB Type                      | The USB driver type.                                                                                                                                                                                                                                          |
| USB Device Identifier         | The USB device identifier.                                                                                                                                                                                                                                    |
| USB Dial String               | The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.                                                                                                                                            |

| Column                      | Description                                                                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB Initialization String   | The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct.                                                                                                                                             |
| USB TTY device data path    | The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.                                                                                                                                                     |
| USB TTY device control path | The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.                                                                                                                                             |
| Uplink VLAN                 | <p>If you configured an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink.</p> <p>By default, an AP has an uplink vlan of 0, which disables this feature.</p>                        |
| Link Priority Ethernet      | Set the priority of the wired uplink, from 0-255. Each uplink type has an associated priority; wired ports having the highest priority by default.                                                                                                                       |
| Link Priority Cellular      | The priority of the cellular uplink, from 0-255. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link.                                                   |
| Mesh Role                   | If the mesh role is "none," the AP is operating as a thin AP. An AP operating as a mesh node can have one of two roles: mesh portal or mesh point.                                                                                                                       |
| Installation                | Indicates the type of installation ( <b>indoor</b> or <b>outdoor</b> ). The <b>default</b> parameter indicates that the installation mode is determined by the AP model type.                                                                                            |
| Latitude                    | Latitude coordinates of the AP, in the format <i>Degrees Minutes Seconds</i> (DMS).                                                                                                                                                                                      |
| Longitude                   | Longitude coordinates of the AP, in the format <i>Degrees Minutes Seconds</i> (DMS).                                                                                                                                                                                     |
| Altitude                    | Altitude, in meters, of the AP. This parameter is supported on outdoor APs only.                                                                                                                                                                                         |
| Antenna bearing for 802.11a | <p>Horizontal coverage distance of the 802.11a (5GHz) antenna from true north, from 0-360 degrees.</p> <p><b>NOTE:</b> This parameter is supported on outdoor APs only. The horizontal coverage pattern does not consider the elevation or vertical antenna pattern.</p> |
| Antenna bearing for 802.11g | Horizontal coverage distance of the 802.11g (2.4GHz) antenna from true north, from 0-360 degrees.                                                                                                                                                                        |

| Column                         | Description                                                                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | <b>NOTE:</b> This parameter is supported on outdoor APs only. The horizontal coverage pattern does not consider the elevation or vertical antenna pattern.                 |
| Antenna tilt angle for 802.11a | The angle of the 802.11a (5GHz) antenna. This parameter can range from between -90 degrees and 0 degrees for downtilt, and between +90 degrees and 0 degrees for uptilt.   |
| Antenna tilt angle for 802.11g | The angle of the 802.11g (2.4GHz) antenna. This parameter can range from between -90 degrees and 0 degrees for downtilt, and between +90 degrees and 0 degrees for uptilt. |
| Mesh SAE                       | Shows if the AP has enabled or disabled Secure Attribute Exchange (SAE) on a mesh network.                                                                                 |

| All platforms | Base operating system | Enable or Config mode on the controller where the AP is terminating. |

# show ap provisioning-profile

ap provisioning-profile [<profile-name>]

## Description

This command shows information for AP provisioning profiles.

## Syntax

| Parameter      | Description                                         |
|----------------|-----------------------------------------------------|
| <profile-name> | The name of an an existing AP provisioning profile. |

## Usage Guidelines

The AP provisioning profile allows you to define a set of provisioning parameters to an AP group. These settings can be saved or assigned to an AP group via the command **ap-group <group> provisioning-profile <profile>**.

Issue this command without the **<profile-name>** option to display the entire AP provisioning profile list, including profile status and the number of references to each profile. Include a profile name to display the authorization group defined for that profile.

## Examples

The following example lists all AP provisioning profiles. The **References** column lists the number of other profiles with references to that provisioning profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined AP provisioning profiles will not have an entry in the **Profile Status** column.

```
(host) #show ap provisioning-profile
```

```
Provisioning profile List
```

```

Name References Profile Status
---- -
default 12
outdoor 3
```

To display the configuration settings for an individual profile, include the <profile> parameter. The example below shows the profile details for the AP provisioning profile **Default**.

```
(host) #show ap provisioning-profile default
```

```
Provisioning profile "default"
```

```

Parameter Value

Remote-AP No
Master IP/FQDN N/A
PPPOE User Name N/A
PPPOE Password N/A
PPPOE Service Name N/A
USB User Name N/A
USB Password N/A
USB Device Type none
USB Device Identifier N/A
USB Dial String N/A
```

|                                                                 |          |
|-----------------------------------------------------------------|----------|
| USB Initialization String                                       | N/A      |
| USB TTY device data path                                        | N/A      |
| USB TTY device control path                                     | N/A      |
| USB modeswitch parameters                                       | N/A      |
| Link Priority Ethernet                                          | 0        |
| Link Priority Cellular                                          | 0        |
| Cellular modem network preference                               | auto     |
| Username of AP so that AP can authenticate to 802.1x using PEAP | N/A      |
| Password of AP so that AP can authenticate to 802.1x using PEAP | N/A      |
| Uplink VLAN                                                     | 0        |
| USB power mode                                                  | auto     |
| AP POE Power optimization                                       | disabled |

## Description

This command defines a provisioning profile for an AP or group of APs.

## Syntax

| Parameter                   | Description                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Remote-AP                   | Indicates that the profile is associated with a remote AP using certificates.                                                |
| Master IP/FQDN              | The FQDN or IP address for the master controller.                                                                            |
| PPPOE User Name             | PPPoE username for the AP.                                                                                                   |
| PPPOE Password              | Point-to-Point Protocol over Ethernet (PPPoE) password for the AP.                                                           |
| PPPOE Service Name          | PPPoE service name for the AP.                                                                                               |
| USB User Name               | The PPP username provided by the cellular service provider                                                                   |
| USB Password                | A PPP password, if provided by the cellular service provider                                                                 |
| USB Device Type             | The USB driver type.                                                                                                         |
| USB Device Identifier       | The USB device identifier.                                                                                                   |
| USB Dial String             | The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.           |
| USB Initialization String   | The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct. |
| USB TTY device data path    | The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.         |
| USB TTY device control path | The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct. |

| Parameter                                                       | Description                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB modeswitch parameters                                       | All the parameters that is required to be passed to the USB mode switch utility.                                                                                                                                                                  |
| Link Priority Ethernet                                          | Set the priority of the wired uplink, from 0-255. Each uplink type has an associated priority; wired ports having the highest priority by default.                                                                                                |
| Link Priority Cellular                                          | The priority of the cellular uplink, from 0-255. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link.                            |
| Cellular modem network preference                               | Multi-mode cellular modem network preference type.                                                                                                                                                                                                |
| Username of AP so that AP can authenticate to 802.1x using PEAP | If your AP uses PEAP authentication, this field displays the AP username.                                                                                                                                                                         |
| Password of AP so that AP can authenticate to 802.1x using PEAP | If your AP uses PEAP authentication, this field displays the AP password.                                                                                                                                                                         |
| Uplink VLAN                                                     | <p>If you configured an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink.</p> <p>By default, an AP has an uplink vlan of 0, which disables this feature.</p> |
| USB power mode                                                  | The USB power mode to control the power to the USB port.                                                                                                                                                                                          |
| AP POE Power optimization                                       | Displays the AP POE power optimization status.                                                                                                                                                                                                    |

## Usage Guidelines

The AP provisioning profile allows you to define a set of provisioning parameters to an AP group. These settings can be saved or assigned to an AP group via the command **ap-group <group> provisioning-profile <profile>**.

## show ap radio-database

```
show ap radio-database [band a|g] [group <group>] [mode access-point|air-
monitor|disabled|ht|ht-40mhz|legacy|sap-monitor] [sort-by ap-group|ap-ip|ap-name|ap-
type|switch-ip] [sort-direction ascending|descending] [start <start>] [switch <switch-ip-
addr>]
```

### Description

Show radio information for Access Points visible to this controller.

### Syntax

| Parameter     | Description                                                         |
|---------------|---------------------------------------------------------------------|
| band          | Show only APs with a radio operating in the specified band.         |
| a             | Show only APs with a radio operating in the 802.11a band (5 GHz).   |
| g             | Show only APs with a radio operating in the 802.11g band (2.4 GHz). |
| group <group> | Show only APs associated with the specified AP group.               |
| mode          | Show only APs with a radio operating in the specified mode.         |
| access-point  | Show only APs operating as access points.                           |
| air-monitor   | Show only APs operating as air monitors.                            |
| disabled      | Show only disabled APs.                                             |
| ht            | Show only high-throughput APs.                                      |
| ht-40mhz      | Show only 40 Mhz high-throughput APs.                               |
| legacy        | Show only legacy (not high-throughput) APs.                         |
| sap-monitor   | Show only APs operating as SAP monitors.                            |
| sort-by       | Sort the output of this command by a specific data column.          |
| ap-group      | Sort the output of this command by AP group name.                   |
| ap-ip         | Sort the output of this command by AP IP address.                   |
| ap-name       | Sort the output of this command by AP name.                         |
| ap-type       | Sort the output of this command by AP model type.                   |

| Parameter               | Description                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| switch-ip               | Sort the output of this command by controller ip address.                                                                                         |
| sort-direction          | Select a sort direction for the output of this command.                                                                                           |
| ascending               | Sort the output in ascending order.                                                                                                               |
| descending              | Sort the output in descending order.                                                                                                              |
| start                   | Start displaying the output of this command at a chosen index number by entering the index number of the AP at which command output should start. |
| switch <switch-ip-addr> | Display information for APs associated with a specific controller by entering the IP address of that controller.                                  |

## Example

The output of the command shows that the AP is aware of five other access points, three of which are active.

```
(host) #show ap radio-database
```

```
AP Radio Database
```

```

The output of this command includes the following information:

| Column     | Description                             |
|------------|-----------------------------------------|
| Name       | Name of the AP.                         |
| Group      | AP group to which the AP is associated. |
| AP Type    | AP model type.                          |
| IP address | IP address of the AP.                   |

| Column                 | Description                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status                 | Current AP status. If the AP is currently up, this data column also shows the amount of time for which the AP has been active.                                                               |
| Flags                  | This column displays a letter that corresponds to some type of additional information for the AP. The key to the list of possible flags appears at the bottom of the output of this command. |
| Switch IP              | IP address of the AP's controller.                                                                                                                                                           |
| 11g Mode/Chan/EIRP/Cli | 802.11g radio type and mode/802.11g radio channel used by the AP/current Effective Isotropic Radiated Power (EIRP)/Number of Clients associated with the radio                               |
| 11a Mode/Chan/EIRP/Cli | 802.11a radio type and mode/802.11a radio channel used by the AP/current Effective Isotropic Radiated Power (EIRP)/Number of Clients associated with the radio.                              |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap radio-summary

```
show ap radio-summary
 ap-group <ap-group>
 ap-name <ap-name>
 dot11a
 dot11g
 ip-addr <ip-addr>
 ip6-addr <ip6-addr>
```

### Description

Show AP radios registered to this controller.

### Syntax

| Parameter           | Description                                             |
|---------------------|---------------------------------------------------------|
| ap-group            | Allows you to filter radio information by AP group.     |
| ap-name <ap-name>   | Allows you to filter radio information by AP name.      |
| dot11a              | Allows you to filter 802.11a radio information.         |
| dot11g              | Allows you to filter 802.11g radio information.         |
| ip-addr <ip-addr>   | Allows you to filter radio information by IP address.   |
| ip6-addr <ip6-addr> | Allows you to filter radio information by IPv6 address. |

### Example

The output of the command in the example below displays statistics for the AP's radio, as well as statistics for transmitted and received frames.

In the actual command-line interface, it will appear in a single, long table.

```
(host) #show ap radio-summary
```

APs Radios information

TD: Time used by data frames (%); TM: time used by mgmt frames(%); time used by ctrl frames (%)  
Total Radios:6

The output of this command includes the following information:

| Parameter     | Description                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name          | Name of the AP.                                                                                                                                               |
| Group         | Group to which AP radio is assigned.                                                                                                                          |
| AP Type       | AP model.                                                                                                                                                     |
| IP Address    | Radio IP address.                                                                                                                                             |
| Band          | Band on which radio is operating on (2.4 or 5 GHz).                                                                                                           |
| Mode          | Mode on which radio is operating; AP: AP Mode; AM: Air Monitor Mode, Spectrum: Spectrum Monitor Mode.<br>Optionally, you can also specify the channel number. |
| EIRP/Max EIRP | Current EIRP output and maximum EIRP allowed for this radio (dBm).                                                                                            |
| NF/U/I        | Noise Floor (dBm)/Utilization (%)/Interference (%).                                                                                                           |
| TD            | Time used by data frames (%).                                                                                                                                 |
| TM            | Time used by mgmt frames(%).                                                                                                                                  |
| TC            | Time used by ctrl frames (%).                                                                                                                                 |

## Command History

| Release     | Modification                                  |
|-------------|-----------------------------------------------|
| ArubaOS 6.2 | Command was introduced                        |
| ArubaOS 6.3 | The <b>ap-group</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

# show ap regulatory

show ap regulatory

## Description

Shows the currently active Regulatory Cert.

## Syntax

None.

## Usage Guidelines

Issue this command to view the currently active Regulatory Cert

## Examples

The example below shows the version of Regulatory Cert currently active on the controller.

```
(host) #show ap regulatory
Regulatory Version :1.0_43859
```

## Command History

Introduced in ArubaOS 6.4.1.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

# show ap regulatory-domain-profile

show ap regulatory-domain-profile [<profile-name>]

## Description

Show the list of regulatory domain profiles, or the settings in an individual regulatory domain profile

## Syntax

| Parameter      | Description                                        |
|----------------|----------------------------------------------------|
| <profile-name> | Show data for a specific regulatory domain profile |

## Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire regulatory domain profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has three regulatory domain profiles. The **References** column lists the number of other profiles with references to the regulatory domain profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show ap regulatory-domain-profile
Regulatory Domain profile List

Name References Profile Status

corp-channel-profile 8
default 10
channel-test 1.
```

This example displays the configuration settings for the profile **corp-channel-profile**. The output of this command shows the profile's country code and the valid channel and channel pairs for that profile.

```
host) #show ap regulatory-domain-profile corp-channel-profile
Regulatory Domain profile "corp-channel-profile"

Parameter Value

Country Code US
Valid 802.11g channel 1
Valid 802.11g channel 6
Valid 802.11a channel 36
Valid 802.11a channel 40
Valid 802.11a channel 44
Valid 802.11a channel 48
Valid 802.11a channel 149
Valid 802.11a channel 153
Valid 802.11g 40MHz channel pair N/A
Valid 802.11a 40MHz channel pair 36-40
Valid 802.11a 40MHz channel pair 44-48
Valid 802.11a 40MHz channel pair 149-153
Valid 802.11a 80MHz channel group 36-48
```

```
Valid 802.11a 80MHz channel group 52-64
Valid 802.11a 80MHz channel group 100-112
Valid 802.11a 80MHz channel group 116-128
Valid 802.11a 80MHz channel group 132-144
Valid 802.11a 80MHz channel group 149-161
```

The output of this command includes the following information:

| Column                            | Description                                                                                                                                                                     |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Country Code                      | Code that represents the country in which the APs will operate. The country code determines the 802.11 wireless transmission spectrum.                                          |
| Valid 802.11g channel             | Selected 802.11b/g channel available for use by an AP using the specified regulatory domain profile. These channels are limited to those valid for the profile's country code.  |
| Valid 802.11a channel             | Selected 802.11a channel available for use by an AP using the specified regulatory domain profile. These channels are limited to those valid for the country code.              |
| Valid 802.11g 40MHz channel pair  | Selected 802.11b/g 40 MHz channel pair available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code. |
| Valid 802.11a 40MHz channel pair  | Selected 802.11a 40 MHz channel pair available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.   |
| Valid 802.11a 80MHz channel group | Selected 802.11a 80 MHz channel group available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.  |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap remote counters

```
show ap remote counters {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

### Description

Show the numbers of message counters for Remote APs

### Syntax

| Parameter         | Description                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show data for an AP with a specific name.                                                                                                     |
| bssid <bssid>     | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. You must specify an AP's BSSID, which is usually the AP's MAC address |
| ip-addr <ip-addr> | Show data for an AP with a specific IP address.                                                                                               |

### Examples

Use this command to determine the number of message counters recorded for each counter type seen by the remote AP. The output of the command in the example below shows counters for Remote AP State and VoIP CAC State Announcements.

```
(host) #show ap remote counters ap-name al22
```

```
Counters

Name Value
---- -
Remote AP State 62851
VoIP CAC State Announcement 13605
```

The output of this command includes the following information:

| Column | Description                                              |
|--------|----------------------------------------------------------|
| Name   | Name of the counter type.                                |
| Value  | Number of counters recorded since the AP was last reset. |

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap remote debug association

```
show ap remote debug association [ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>]
```

### Description

Show the association table of the AP to identify the clients associated to each AP.

### Syntax

| Parameter         | Description                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show client associations for a specific AP name.                                                                             |
| bssid <bssid>     | Show client associations for an specific AP Basic Service Set Identifier (BSSID). The BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show client associations for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                |

### Usage Guidelines

Use this command to verify if a remote user is connected to an AP, and to validate the AP to which is connected.

### Example

The output of this command displays information about the remote clients associated with an AP with the IP address 192.0.2.32.

```
(host) #show ap remote debug association ip-addr 192.0.2.32
```

Flags: W: WMM client, A: Active, R: RRM client

PHY Details: HT: High throughput; 20: 20MHz; 40: 40MHz  
<n>ss: <n> spatial streams

Association Table

```

Name bssid mac auth assoc aid l-int essid

111 0x108e a 23s 1 A
```

Num Clients:1

The output of this command includes the following information:

| Column | Description    |
|--------|----------------|
| Name   | Name of an AP. |

| Column      | Description                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid       | The AP Basic Service Set Identifier (BSSID).                                                                                                                          |
| mac         | MAC address of the client.                                                                                                                                            |
| auth        | This column displays a <b>y</b> if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an <b>n</b> .                              |
| assoc       | This column displays a <b>y</b> if the AP has been configured for 802.11 association frame types. Otherwise, it displays an <b>n</b> .                                |
| aid         | 802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.                                                                  |
| l-int       | Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second. |
| essid       | Name that uniquely identifies the AP's Extended Service Set Identifier (ESSID).                                                                                       |
| vlan-id     | Identification number of the AP's VLAN.                                                                                                                               |
| tunnel-id   | Identification number of the AP's tunnel.                                                                                                                             |
| phy         | The RF band in which the AP operates:<br><b>a</b> = 5 GHz<br><b>b, g</b> = 2.4 GHz                                                                                    |
| assoc. time | Amount of time the client has associated with the AP, in the format hours:minutes:seconds.                                                                            |
| num assoc   | Number of clients associated with the AP.                                                                                                                             |
| flags       | This column displays any flags for this AP. The list of flag abbreviations is included in the output of the <b>show ap association</b> command.                       |

## Command History

Introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap remote debug association

show ap remote debug association [ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>

### Description

Show the association table for an AP.

### Syntax

| Parameter         | Description                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show AP associations for a specific AP. You can also include the <b>essid</b> , <b>phy</b> or <b>voip-only</b> keywords to further filter the output of this command.                                                    |
| bssid <bssid>     | Show the AP associations for an specific AP Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                              |
| ip-addr <ip-addr> | Show AP associations for a specific AP by entering an IP address in dotted-decimal format. You can also include the <b>essid</b> , <b>phy</b> or <b>voip-only</b> keywords to further filter the output of this command. |

### Usage Guidelines

Use this command to check if user is connected to an AP. This command validates whether the client is associated and indicates the last AP to which it was connected. If the flags column shows an 'A', the client is currently associated with that AP. Alternately, if the client is not currently associated, the AP with the smallest value of association time is the last AP used by the client.

### Example

Use the **show ap association bssid** command to verify that a user has associated with an AP, or to determine last AP to which the client was connected. The output of this command in the example below shows the association table for the client with the MAC address 00:13:fd:5c:7c:59. If the flags column in the output of this command shows an 'A', the client associated last to that AP. Alternately, the AP with the smallest value of association time is the last AP to which the client had associated.

In the example below, the output of this command has been broken into two separate tables to better fit this page. In the actual output of the command, this information is shown in a single, wide table.

```
host) #show ap association bssid 00:13:fd:5c:7c:59
```

```
Flags: W: WMM client, A: Active, R: RRM client
PHY Details: HT: High throughput; 20: 20MHz; 40: 40MHz
 ss: spatial streams
```

Association Table

```

Name bssid mac auth assoc aid l-int essid

```

The output of this command includes the following information:

| Column      | Description                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name        | Name of an AP                                                                                                                                                         |
| bssid       | The AP Basic Service Set Identifier (BSSID)                                                                                                                           |
| mac         | MAC address of the AP                                                                                                                                                 |
| auth        | This column displays a <b>y</b> if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an <b>n</b> .                              |
| assoc       | This column displays a <b>y</b> if the AP has been configured for 802.11 association frame types. Otherwise, it displays an <b>n</b> .                                |
| aid         | 802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.                                                                  |
| l-int       | Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second. |
| essid       | Name that uniquely identifies the AP's Extended Service Set Identifier (ESSID).                                                                                       |
| vlan-id     | Identification number of the AP's VLAN.                                                                                                                               |
| tunnel-id   | Identification number of the AP's tunnel.                                                                                                                             |
| assoc. time | Amount of time the client has associated with the AP, in the format <i>hours:minutes:seconds</i> .                                                                    |
| num assoc   | Number of clients associated with the AP.                                                                                                                             |
| flags       | This column displays any flags for this AP. The list of flag abbreviations is included in the output of the <b>show ap association</b> command.                       |

## Command History

Introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers. |

## show ap remote debug bss-config

show ap remote debug bss-config [ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>]Description

Show the configuration for each BSSID of an AP. This information can be used to troubleshoot problems on an AP.

### Syntax

| Parameter         | Description                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Filter the AP Config Table by AP name.                                                       |
| ip-addr <ip-addr> | Filter the AP Config Table by IP address by entering an IP address in dotted-decimal format. |

### Examples

The output of this command shows the AP configuration table for a specific BSSID.

```
host) #show ap remote debug bss-config ap-name ap93-3
Dell AP Config Table

| type     | This column shows if the BSSID is for an access point ( <b>ap</b> ) or an air monitor ( <b>am</b> ).                                                                                                                                                                      |
| fw-mode  | <p>The configured forward mode for the AP's virtual AP profile.</p> <ul style="list-style-type: none"> <li>• <b>bridge</b>: Bridge locally</li> <li>• <b>split-tunnel</b>: Tunnel to controller or NAT locally</li> <li>• <b>tunnel</b>: Tunnel to controller</li> </ul>  |
| max-cl   | The maximum number of clients allowed for this BSSID.                                                                                                                                                                                                                     |
| preamble | Shows if short preambles are enabled for 802.11b/g radios. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using a short preamble. |
| MTU      | Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.                                                                                                                           |
| status   | Shows if this BSSID is enabled or disabled.                                                                                                                                                                                                                               |
| wmm      | Shows if the BSSID has enabled or disabled WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF) WMM provides prioritization of specific traffic relative to other traffic in the network.                                                   |

## Command History

Introduced in ArubaOS 5.0.

## show ap remote debug client-mgmt-counters

```
show ap remote debug client-mgmt-counters
```

### Description

Show the numbers of each type of message from an AP's clients. This information can be used to troubleshoot problems on an AP.

### Examples

The output of this command shows client management counters for the specified AP

```
host)#show ap remote debug client-mgmt-counters ap-name ap120-3
```

```
Counters
```

```

| ARM Neighbor Assigned        | (For internal use only)                                                                                                                                                                                                           |
| STM SAP Down                 | (For internal use only)                                                                                                                                                                                                           |
| AP Message                   | (For internal use only)                                                                                                                                                                                                           |
| STA On Call Message          | Number of counters indicating that a station has an active phone call                                                                                                                                                             |
| STA Message                  | (For internal use only)                                                                                                                                                                                                           |
| STA SIP authenticate Message | Number of messages indicating that a telephone has completed SIP registration and authentication.                                                                                                                                 |
| STA Deauthenticate           | Number of times a station sent a message to an AP to deauthenticate a client.                                                                                                                                                     |
| Stat Update V3               | (For internal use only)                                                                                                                                                                                                           |
| VoIP CAC State Announcement  | Number of times a controller announces a call admission control (CAC) state change to the AP. Changes in CAC state could include the ability of call admission controls to accept more or fewer calls than previously configured. |
| Remote AP State              | (For internal use only)                                                                                                                                                                                                           |
| AP Message Response          | (For internal use only)                                                                                                                                                                                                           |
| assoc-req                    | Number of 802.11 association request management frames from the controller.                                                                                                                                                       |
| assoc-resp                   | Number of 802.11 association responses to the controller.                                                                                                                                                                         |
| reassoc-req                  | Number of 802.11 reassociation requests to the controller.                                                                                                                                                                        |
| reassoc-resp                 | Number of 802.11 reassociation responses from the controller.                                                                                                                                                                     |

| Parameter | Description                                                    |
|-----------|----------------------------------------------------------------|
| disassoc  | Number of 802.11 disassociation messages to the controller.    |
| deauth    | Number of 802.11 deauthorization messages from the controller. |
| sapcp     | (For internal use only)                                        |

## Command History

## show ap remote debug flash-config

```
show ap remote debug flash-config {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>} acls|vap <vap>|vaps
```

### Description

Show the remote AP configuration stored in flash memory.

### Syntax

| Parameter           | Description                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | Show debugging data for an AP with a specific name.                                                                                               |
| bssid <bssid>       | Show data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address. |
| ip-addr <ip-addr>   | Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                               |
| ip6-addr <ip6-addr> | Show data for an AP with a specific IP6 address by entering its IP6 address in dotted-decimal format.                                             |
| acls                | Display ACLs of offline Virtual APs (VAPs).                                                                                                       |
| vap <vap>           | Display the configuration of a specific offline VAP by entering the name of an VAP.                                                               |
| vaps                | Display the current number of offline VAPs.                                                                                                       |

### Example

The output of this command can be used to debug problems with a remote AP. The command below shows statistics for an AP with the IP address 192.0.2.64.

```
(host) #show ap remote debug flash-config ip-addr 192.0.2.64 acls
```

```
Offline ACLs
```

```

```

The output of this command includes the following information:

| Column            | Description                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------|
| Native VLAN       | VLAN ID of the native VLAN.                                                                                    |
| DHCP VLAN         | VLAN ID of Remote AP DHCP server used when the controller is unreachable.                                      |
| DHCP ADDR         | IP Address used as DHCP Server Identifier.                                                                     |
| DHCP POOL NETMASK | Netmask of the DHCP server pool.                                                                               |
| DHCP POOL START   | IP Address used as the start of a range of addresses for a DHCP pool.                                          |
| DHCP POOL END     | IP Address used as the end of a range of addresses for a DHCP pool.                                            |
| DHCP DNS SERVER   | IP Address for the DHCP DNS server.                                                                            |
| DHCP ROUTER       | IP Address for the DHCP default router.                                                                        |
| DHCP DNS DOMAIN   | Domain name for the DHCP DNS server.                                                                           |
| DHCP LEASE        | Length of DHCP DNS leases in days. If this parameter displays a zero (0) the DHCP lease is has no defined end. |
| Session ACL       | Name of the ACL applied to the user session.                                                                   |
| Session ACL name  | Name of the ACL applied to the user session.                                                                   |
| Session ACL count | Number of rules in the applied to the user session.                                                            |
| Session Aces      | A list of the individual rules in the session ACL.                                                             |
| ACL 1             | This parameter shows the position of an individual ACL.                                                        |
| ACL1 Name         | Name of the ACL in the first position.                                                                         |
| ACL1 Count        | Number of rules in the specified ACL.                                                                          |
| ACL1 Aces         | A list of the individual rules in the specified ACL.                                                           |

## Command History

| Release     | Modification                                  |
|-------------|-----------------------------------------------|
| ArubaOS 3.0 | Command was introduced                        |
| ArubaOS 6.3 | The <b>ip6-addr</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap remote debug mgmt-frames

```
show ap remote debug mgmt-frames {ap-name <ap-name>} [{bssid <bssid>}|{ip-addr <ip-addr>}]
[client-mac <client-mac>] [count <count>]
```

### Description

Show traced 802.11 management frames for a remote AP.

### Syntax

| Parameter         | Description                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | Show debugging information for a specific AP.                                                                                                            |
| bssid <bssid>     | Show debugging information for a specific Basic Service Set Identifier (BSSID). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address |
| ip-addr           | Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.                                     |
| client-mac        | Show the AP associations for a specific MAC address by entering the MAC address of the client.                                                           |
| count <count>     | Limit the amount of information displayed by specifying number of frames to appear in the output of this command.                                        |

### Examples

Use this command to debug 802.1 authentication on a remote AP. The example below shows that a client successfully associated with the remote AP, then was later deauthenticated.

```
(host) #show ap remote debug mgmt-frames ap-name AP32
```

```
Traced 802.11 Management Frames
```

```

Timestamp stype SA DA BSS
 signal Misc

Oct 30 11:20:19 deauth 00:23:6c:2f:9a:85 00:1a:1e:11:56:40

```

The output of this command includes the following information:

| Column    | Description                            |
|-----------|----------------------------------------|
| Timestamp | The time the management frame was sent |

| Column | Description                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stype  | One of the following 802.11 frame types:<br>auth: Authorization frame<br>deauth: Deauthorization frame<br>assoc-resp: Association response<br>assoc-req: Association request |
| SA     | Source MAC address.                                                                                                                                                          |
| DA     | Destination MAC address.                                                                                                                                                     |
| BSS    | Basic Service Set Identifier (BSSID) of the AP                                                                                                                               |
| signal | Signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.      |
| Misc   | Additional information describing the client's action. In the case of deauthentication, a reason associated with the event will be displayed in this column.                 |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap snmp

```
show ap snmp
 wlsxSwitchStationMgmtTable
 wlsxSwitchStationStatsTable
 wlsxWlanAPBssidTable
 wlsxWlanAPTable
 wlsxWlanRadioTable
```

### Description

This command displays the AP-related SNMP tables.

### Syntax

| Parameter                   | Description                    |
|-----------------------------|--------------------------------|
| wlsxSwitchStationMgmtTable  | Display user tree.             |
| wlsxSwitchStationStatsTable | Display user statistics tree.  |
| wlsxWlanAPBssidTable        | Display BSSID SNMP tree.       |
| wlsxWlanAPTable             | Display SNMP tree              |
| wlsxWlanRadioTable          | Display radio table SNMP tree. |

### Example

Access the controller's command-line interface and use the following command to display BSSID SNMP tree:

```
(host) #show ap snmp wlsxWlanAPBssidTable
```

```
SNMP - AP BSSID Table
```

```

AP MAC Radio BSSID Phy Type Status Channel

00:24:6c:c3:d6:82 1 00:24:6c:bd:68:30 1 1 149
00:24:6c:c3:d6:82 2 00:24:6c:bd:68:20 2 1 11
```

```
Num BSSIDs:2
```

### Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                  |
|---------------|-----------------------|-------------------------------|
| All platforms | Base operating system | Enable or configuration mode. |

## show ap spectrum ap-list

```
show ap spectrum ap-list {ap-name <ap-name>} [{ip-addr <ip-addr>}
 ap-bssid <bssid>
 channel <channel>
 essid <essid>
 limit <number>
 or
 page <number>
 freq-band 2.4ghz|5ghz
 sort <sort>
 start <index>
```

### Description

This command shows spectrum data seen by an access point that has been converted to a spectrum monitor.

### Syntax

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor for which you want to view spectrum information.                                                                                                                                                                                                                                                                                                          |
| ip-addr <ip-addr>     | IP address of the spectrum monitor for which you want to view spectrum information.                                                                                                                                                                                                                                                                                                    |
| channel <channel>     | View spectrum information for a specific radio channel.                                                                                                                                                                                                                                                                                                                                |
| essid <essid>         | View spectrum information for a specific ESSID.                                                                                                                                                                                                                                                                                                                                        |
| limit <number>        | Limit the displayed output to the specified number of entries                                                                                                                                                                                                                                                                                                                          |
| or                    | Use this parameter to display information that meets either of two criteria, such as a specified ESSID or channel.                                                                                                                                                                                                                                                                     |
| page <number>         | Enter a number from 10-100 (inclusive) to specify the number of entries that should appear in each page of the output for this command. For example, if the output of this command has 100 entries and you select a page value of 20, the output will appear in 5 pages each with 20 entries. If you selected a page value of 10, the output would appear in 10 pages with 10 entries. |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 Ghz.                                                                                                                                                                                                                                                                                                                   |
| sort <sort>           | Sort the output by the specified data column                                                                                                                                                                                                                                                                                                                                           |
| start <index>         | Start displaying the output at specific spectrum index value.                                                                                                                                                                                                                                                                                                                          |

### Usage Guidelines

The Spectrum Analysis feature provides visibility into RF coverage, allowing you to troubleshoot RF interference and identify 802.11 devices on the network. Issue this command to display and sort APs seen by a specific

spectrum monitor.

## Examples

The output of this example shows spectrum data seen by spectrum monitor ap123. The output in the example below has been divided into two tables to better fit this document. In the ArubaOS CLI, the output appears as a single, long table.

```
(host)# show ap spectrum ap-list ap-name ap123
```

Spectrum AP Table

| bssid             | essid         | spectrum-id | chan | phy-type | signal (dBm) |
|-------------------|---------------|-------------|------|----------|--------------|
| 00:0b:86:cd:22:d0 | ECSD Wireless | 2           | 161  | 80211a   | 62           |
| 00:0b:86:cb:cf:30 | ECSD Wireless | 3           | 157  | 80211a   | 68           |
| 00:0b:86:f6:f6:a0 | osuwireless   | 3           | 1    | 80211b/g | 48           |
| 00:0b:86:f6:f6:a1 | osuvoice      | 4           | 1    | 80211b/g | 47           |
| 00:0b:86:f6:f6:a2 | osuguest      | 5           | 1    | 80211b/g | 45           |

| avg-rssi (dB) | curr-rssi (dB) | ibss | add-time            | last-seen           |
|---------------|----------------|------|---------------------|---------------------|
| 29            | 31             | no   | 2010-05-16 17:41:36 | 2010-05-18 13:39:38 |
| 24            | 25             | no   | 2010-05-16 17:41:36 | 2010-05-18 14:19:03 |

| 38            | 38             | no   | 2010-05-16 17:41:36 | 2010-05-18 15:04:23 |
| 37            | 40             | no   | 2010-05-16 17:41:36 | 2010-05-18 15:07:32 |

The output of this command includes the following information:

| Column       | Description                                                                                                                              |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| bssid        | Basic Service Set Identifier for an AP. This is usually the AP's MAC address.                                                            |
| essid        | Extended service set identifier that names a wireless network.                                                                           |
| spectrum-id  | Identifier assigned to the device by the spectrum monitor                                                                                |
| chan         | Radio channel used by the BSSID                                                                                                          |
| freq-band    | Radio phy type. Possible types include: <ul style="list-style-type: none"><li>• 2.4 GHz</li><li>• 5 GHz</li></ul>                        |
| signal (dBm) | Strength of the signal received by the device, in dBm.                                                                                   |
| avg-rssi     | The average signal-to-noise ratio seen by the AP.                                                                                        |
| curr-rssi    | Most recent signal-to-noise ratio seen by the AP.                                                                                        |
| ibss         | Shows if ad-hoc BSS is enabled or disabled. It will be enabled if the bssid has detected an ad-hoc BSS (an ibss bit in an 802.11 frame). |

| Column    | Description                                                  |
|-----------|--------------------------------------------------------------|
| add-time  | Time when the AP was first detected by the spectrum monitor. |
| last-seen | Time when the AP was last seen by the spectrum monitor.      |

## show ap spectrum channel-metrics

```
show ap spectrum channel-metrics {ap-name <ap-name>} [{ip-addr <ip-addr>} freq-band 2.4ghz|5ghz
```

### Description

This command shows channel quality, availability and utilization metrics as seen by a spectrum monitor.

### Syntax

| Parameter             | Description                                                                   |
|-----------------------|-------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor for which you want to view spectrum information. |
| ip-addr <ip-addr>     | IP address of the spectrum monitor.                                           |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 GHz.          |

### Usage Guideline

This chart displays channel utilization data, showing the percentage of each channel that is currently being used by Wi-Fi devices, and the percentage of each channel being used by non-Wi-Fi devices and 802.11 adjacent channel interference (ACI).

ACI refers to the interference on a channel created by a transmitter operating in an adjacent channel. A transmitter on a nonadjacent or partially overlapping channel may also cause interference, depending on the transmit power of the interfering transmitter and/or the distance between the devices. In general, ACI may be caused by a Wi-Fi transmitter or a non-Wi-Fi interferer. However, whenever the term ACI appears in Spectrum Analysis graphs, it refers to the ACI caused by Wi-Fi transmitters. The channel utilization option in the Channel Metrics Chart shows the percentage of the channel utilization due to both ACI and non-Wi-Fi interfering devices. Unlike the ACI shown in the [show ap spectrum interference-power](#) output, the ACI shown in this graph indicates the percentage of channel time that is occupied by ACI or unavailable for Wi-Fi communication due to ACI.

The Channel Metrics table can also show channel availability, the percentage of each channel that is available for use, or display the current relative quality of selected channels in the 2.4 GHz or 5 GHz radio bands. In the spectrum analysis feature, channel quality is a relative measure that indicates the ability of the channel to support reliable Wi-Fi communication. Channel quality, which is represented as a percentage in this chart, is a weighted metric derived from key parameters that can affect the communication quality of a wireless channel, including noise, non-Wi-Fi (interferer) utilization and duty-cycles, and certain types of retries. Note that channel quality is not directly related to Wi-Fi channel utilization, as a higher quality channel may or may not be highly utilized.

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

### Examples

The output of this example shows part of the channel metrics table for channels seen by the spectrum monitor ap123.

```
(host)# show ap spectrum channel-metrics ap-name ap123 freq-band 2.4GHz
```

Channel Metrics Table

| Channel | Quality(%) | Availability(%) | Utilization(%) | WiFi Util(%) | Interference Util(%) |
|---------|------------|-----------------|----------------|--------------|----------------------|
| 1       | 97         | 57              | 43             | 40           | 3                    |
| 2       | 80         | 58              | 42             | 22           | 20                   |
| 3       | 63         | 58              | 42             | 5            | 37                   |
| 4       | 71         | 57              | 43             | 16           | 27                   |
| 5       | 88         | 54              | 46             | 36           | 10                   |
| 6       | 98         | 51              | 49             | 47           | 2                    |
| 7       | 88         | 54              | 46             | 35           | 11                   |

## show ap spectrum channel-summary

```
show ap spectrum channel-summary {ap-name <ap-name>} [{ip-addr <ip-addr>} freq-band 2.4ghz|5ghz]
```

### Description

This command displays a summary of the 802.11 a or 802.11 g channels seen by a spectrum monitor.

### Syntax

| Parameter             | Description                                                                         |
|-----------------------|-------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor for which you want to view spectrum information.       |
| ip-addr <ip-addr>     | IP address of the spectrum monitor for which you want to view spectrum information. |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either <b>2.4 GHz</b> or <b>5 GHz</b> . |

### Usage Guidelines

This table can display data aggregate data for each channel seen by the spectrum monitor radio, including the maximum AP power, interference and the signal-to-noise-and-interference Ratio (SNIR).

SNIR is the ratio of signal strength to the combined levels of interference and noise on that channel. This value is calculated by determining the maximum noise-floor and interference-signal levels, and then calculating how strong the desired signal is above this maximum.

---

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

---

### Examples

The output of the example below shows information for 802.11 a radio channels seen by the spectrum monitor **ap999**.

```
(host)# show ap spectrum channel-summary ap-name ap999 freq-band 5ghz
```

Channel Summary Table

| Channel | KnownAPs | UnknownAPs | Util(%) | MaxAPSignal (dBm) | MaxInterference (dBm) | SNIR (dB) |
|---------|----------|------------|---------|-------------------|-----------------------|-----------|
| 149     | 69       | 0          | 5       | -39               | -69                   | 30        |
| 153     | 20       | 0          | 100     | -42               | -60                   | 18        |
| 157     | 56       | 0          | 6       | -53               | -59                   | 6         |
| 161     | 54       | 0          | 4       | -43               | -71                   | 28        |
| 165     | 32       | 0          | 3       | -27               | -70                   | 43        |
| 149+    | 69       | 0          | 100     | -39               | -60                   | 21        |
| 157+    | 20       | 0          | 6       | -43               | -59                   | 16        |

The output of this command includes the following information:

| Column                 | Description                                                                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Channel                | An 802.11a or 802.11g radio channel.                                                                                                                                                                                                                                     |
| Known APs              | Number of valid APs identified on the radio channel.                                                                                                                                                                                                                     |
| UnKnown APs            | Number of invalid or rogue APs identified on the radio channel.                                                                                                                                                                                                          |
| Channel Util (%)       | Percentage of the channel currently in use.                                                                                                                                                                                                                              |
| Max AP Signal (dBm)    | Signal strength of the AP that has the maximum signal strength on a channel.                                                                                                                                                                                             |
| Max Interference (dBm) | Signal strength of the non-Wi-Fi device that has the highest signal strength.                                                                                                                                                                                            |
| SNIR (db)              | The ratio of signal strength to the combined levels of interference and noise on that channel. This value is calculated by determining the maximum noise-floor and interference-signal levels, and then calculating how strong the desired signal is above this maximum. |

### Description

This command shows details for clients seen by a specified spectrum monitor.

### Syntax

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor for which you want to view spectrum information.                                                                                                                                                                                                                                                                                                          |
| ip-addr <ip-addr>     | IP address of the spectrum monitor for which you want to view spectrum information.                                                                                                                                                                                                                                                                                                    |
| ip6-addr <ip6-addr>   | IPv6 address of the spectrum monitor for which you want to view spectrum information.                                                                                                                                                                                                                                                                                                  |
| ap-bssid <bssid>      | View information for a client with a specific BSSID.                                                                                                                                                                                                                                                                                                                                   |
| channel <channel>     | view information for clients on a specific radio channel.                                                                                                                                                                                                                                                                                                                              |
| ssid <ssid>           | View information for clients using a specific ESSID.                                                                                                                                                                                                                                                                                                                                   |
| mac <mac-addr>        | View information for a client with a specific MAC address.                                                                                                                                                                                                                                                                                                                             |
| or                    | Use this parameter to display information that meets either or two criteria, such as a specified ESSID or channel.                                                                                                                                                                                                                                                                     |
| page <number>         | Enter a number from 10-100 (inclusive) to specify the number of entries that should appear in each page of the output for this command. For example, if the output of this command has 100 entries and you select a page value of 20, the output will appear in 5 pages each with 20 entries. If you selected a page value of 10, the output would appear in 10 pages with 10 entries. |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either <b>2.4 GHz</b> or <b>5 GHz</b> .                                                                                                                                                                                                                                                                                                    |

### Usage Guidelines

Use this command to view channel and signal information for wireless clients seen by the spectrum monitor.

## Examples

The example shows that the spectrum monitor **ap999** sees eight different clients on channel 149. The output in the example below has been divided into two tables to better fit this document. In the ArubaOS CLI, the output appears as a single, long table.

```
(host)# show ap spectrum client-list ap-name ap999 channel 149
```

### Spectrum Client Table

| mac               | bssid             | essid            | spectrum-id | channel | phy-type     |
|-------------------|-------------------|------------------|-------------|---------|--------------|
| 00:14:a4:d1:34:63 | 00:24:6c:80:48:79 | ethersphere-wpa2 | 14          | 149     | 80211a       |
| 00:19:7d:3a:96:d9 | 00:24:6c:80:7b:c9 | ethersphere-wpa2 | 198         | 149     | 80211a       |

## show ap spectrum debug

```
show ap spectrum debug {channel-info|channel-quality|classify|classify-fft|device-
details|device-info|devices-seen} {ap-name <ap-name>} [{ip-addr <ip-addr>} freq-band
{2.4ghz|5ghz}]
```

### Description

This command saves spectrum analysis channel information to a file on the spectrum monitor.

### Syntax

| Parameter             | Description                                                                         |
|-----------------------|-------------------------------------------------------------------------------------|
| channel-info          | Save channel information for later analysis.                                        |
| channel-quality       | Save channel quality information for later analysis                                 |
| classify              | Save information on classification for later analysis.                              |
| classify-fft          | Save information on classification and FFT data for later analysis.                 |
| device-details        | Save device details for later analysis.                                             |
| device-info           | Save device information for later analysis.                                         |
| devices-seen          | Save information on devices seen by the spectrum monitor.                           |
| ap-name <ap-name>     | Name of the spectrum monitor for which you want to view spectrum information.       |
| ip-addr <ip-addr>     | IP address of the spectrum monitor for which you want to view spectrum information. |
| freq-band 2.4ghz 5ghz | Save information for a specific radio type, either <b>2.4 GHz</b> or <b>5 GHz</b> . |

### Usage Guidelines

Use this command under the supervision of your Dell technical support representative to troubleshoot spectrum analysis issues or errors. If a dump-server is defined in the AP's AP system profile, the file created by this command will be sent from the AP to the dump-server using TFTP.

## show ap spectrum debug fft

```
show ap spectrum debug fft {ap-name <ap-name>}[ip-addr <ip-addr>] freq-band {2.4ghz|5ghz}
 avg
 duty-cycle
 fft-to-controller
 max
 normalized
 raw
 raw-normalized
```

### Description

Save FFT (Fast Fourier Transform) power data to a file on the spectrum monitor.

### Syntax

| Parameter             | Description                                                                         |
|-----------------------|-------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor for which you want to view spectrum information.       |
| ip-addr <ip-addr>     | IP address of the spectrum monitor.                                                 |
| freq-band 2.4ghz 5ghz | Save information for a specific radio type, either <b>2.4 GHz</b> or <b>5 GHz</b> . |
| avg                   | Save FFT average information.                                                       |
| duty-cycle            | Save FFT duty-cycle data.                                                           |
| fft-to-controller     | Save the FFT max, average and duty-cycle data.                                      |
| max                   | Save the maximum FFT power measured for all samples taken over the last second.     |
| normalized            | Save normalized FFT information.                                                    |
| raw                   | Save the raw FFT information received from driver.                                  |
| raw-normalized        | Save FFT information received from driver and its normalized FFT.                   |

### Usage Guidelines

Use this command under the guidance of your Dell technical support representative to troubleshoot FFT power issues seen on W-AP104, W-AP105, W-AP175, W-AP130 Series, W-AP220 Series or W-AP90 series APs.

# show ap spectrum debug monitors

show ap spectrum debug monitors

## Description

Show a detailed description of all spectrum monitors on the controller.

## Syntax

No parameters

## Examples

The output of this command shows a list of available spectrum monitor or hybrid AP devices, a list of spectrum devices currently subscribed to a spectrum client, message counters for subscribed spectrum devices and the subscription history.

```
(host)# show ap spectrum debug monitors

| ap-name <ap-name>     | Name of the spectrum device for which you want to view status information.       |
| ip-addr <ip-addr>     | IP address of the spectrum device for which you want to view status information. |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 GHz.             |

### Usage Guidelines

Use this command under the guidance of a Dell technical support representative to troubleshoot spectrum analysis errors.

### Related Commands

| Command                                                  | Description                                                                                                                           | Mode                                       |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| <a href="#">ap spectrum local-override</a>               | Convert an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.                                         | Config mode on master or local controllers |
| <a href="#">rf dot11a-radio-profilemodespectrum-mode</a> | Set a 802.11a radio so the device operates as an spectrum monitor, and can send spectrum analysis data to a desktop or laptop client. | Config mode on master or local controllers |
| <a href="#">rf dot11g-radio-profilemodespectrum-mode</a> | Set a 802.11g radio so the device operates as an spectrum monitor, and can send spectrum analysis data to a desktop or laptop client. | Config mode on master or local controllers |

### Command History

Introduced in ArubaOS 6.0.

| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show ap spectrum device-duty-cycle

```
show ap spectrum device-duty-cycle {ap-name <ap-name>} [{ip-addr <ip-addr>} freq-band
2.4ghz|5ghz]
```

### Description

Shows the current duty cycle for devices on all channels being monitored by the spectrum monitor or hybrid AP radio.

### Syntax

| Parameter             | Description                                                                        |
|-----------------------|------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum device for which you want to view spectrum information.       |
| ip-addr <ip-addr>     | IP address of the spectrum device for which you want to view spectrum information. |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 GHz.               |

### Usage Guidelines

The FFT Duty Cycle table in the output of this command shows the duty cycle for each radio channel. The duty cycle is the percentage of time each device type operates or transmits on that channel. For additional details about non-Wi-Fi device types shown in this table, see [Non-Wi-Fi Interferers on page 1295](#).

This chart is not available for W-AP68 access points. A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

### Examples

The output of this command shows that video devices sent a signal on channels 153 and 157 during 99% of the last sample interval.

Device Duty Cycle Table (in %)

| Device Type         | 149 | 153 | 157 | 161 | 165 | 149+ | 157+ |
|---------------------|-----|-----|-----|-----|-----|------|------|
| Generic Interferer  | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| WIFI                | 5   | 0   | 5   | 12  | 8   | 0    | 12   |
| Microwave           | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Bluetooth           | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Generic Fixed Freq  | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Cordless Phone FF   | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Video               | 0   | 99  | 99  | 0   | 0   | 0    | 0    |
| Audio               | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Generic Freq Hopper | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Cordless Network FH | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Xbox                | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Microwave Inverter  | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
| Cordless Base FH    | 5   | 5   | 5   | 5   | 5   | 0    | 0    |
| Total:              | 7   |     |     |     |     |      |      |

| video              | View information for video devices seen by the spectrum device.                                                                                          |
| xbox               | View information for Xbox devices seen by the spectrum device.<br><b>NOTE:</b> This option is available only for 2.4 GHz spectrum devices.               |

## Usage Guidelines

Use this command to view channel, signal and duty-cycle information and add/delete times for the last 256 devices seen by a spectrum monitor or hybrid AP.

## Non-Wi-Fi Interferers

The following table describes each type of non-Wi-Fi interferer detected by a spectrum monitor or hybrid AP. Note also that a hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

| Non-Wi-Fi Interferer Type         | Description                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bluetooth                         | Any device that uses the Bluetooth protocol to communicate in the 2.4 GHz band is classified as a <i>Bluetooth</i> device. Bluetooth uses a frequency hopping protocol.                                                                                                                                                                      |
| Fixed Frequency (Audio)           | Some audio devices such as wireless speakers and microphones also use fixed frequency to continuously transmit audio. These devices are classified as <i>Fixed Frequency (Audio)</i> .                                                                                                                                                       |
| Fixed Frequency (Cordless Phones) | Some cordless phones use a fixed frequency to transmit data (much like the fixed frequency video devices). These devices are classified as <i>Fixed Frequency (Cordless Phones)</i> .                                                                                                                                                        |
| Fixed Frequency (Video)           | Video transmitters that continuously transmit video on a single frequency are classified as <i>Fixed Frequency (Video)</i> . These devices typically have close to a 100% duty cycle. These types of devices may be used for video surveillance, TV or other video distribution, and similar applications.                                   |
| Fixed Frequency (Other)           | All other fixed frequency devices that do not fall into one of the above categories are classified as <i>Fixed Frequency (Other)</i> . Note that the RF signatures of the fixed frequency audio, video and cordless phone devices are very similar and that some of these devices may be occasionally classified as Fixed Frequency (Other). |
| Frequency Hopper (Cordless Base)  | Frequency hopping cordless phone base units transmit periodic beacon-like frames at all times. When the handsets are not transmitting (i.e., no active phone calls), the cordless base is classified as <i>Frequency Hopper (Cordless Base)</i> .                                                                                            |

| Non-Wi-Fi Interferer Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frequency Hopper (Cordless Network) | When there is an active phone call and one or more handsets are part of the phone conversation, the device is classified as <i>Frequency Hopper (Cordless Network)</i> . Cordless phones may operate in 2.4 GHz or 5 GHz bands. Some phones use both 2.4 GHz and 5 GHz bands (for example, 5 GHz for Base-to-handset and 2.4 GHz for Handset-to-base). These phones may be classified as unique Frequency Hopper devices on both bands.                                                                                                                                                     |
| Frequency Hopper (Xbox)             | The Microsoft Xbox device uses a frequency hopping protocol in the 2.4 GHz band. These devices are classified as <i>Frequency Hopper (Xbox)</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Frequency Hopper (Other)            | When the classifier detects a frequency hopper that does not fall into one of the above categories, it is classified as Frequency Hopper (Other). Some examples include IEEE 802.11 FHSS devices, game consoles and cordless/hands-free devices that do not use one of the known cordless phone protocols.                                                                                                                                                                                                                                                                                  |
| Microwave                           | Common residential microwave ovens with a single magnetron are classified as a <i>Microwave</i> . These types of microwave ovens may be used in cafeterias, break rooms, dormitories and similar environments. Some industrial, healthcare or manufacturing environments may also have other equipment that behave like a microwave and may also be classified as a Microwave device.                                                                                                                                                                                                       |
| Microwave (Inverter)                | Some newer-model microwave ovens have the inverter technology to control the power output and these microwave ovens may have a duty cycle close to 100%. These microwave ovens are classified as <i>Microwave (Inverter)</i> . Dual-magnetron industrial microwave ovens with higher duty cycle may also be classified as Microwave (Inverter). As in the Microwave category described above, there may be other equipment that behave like inverter microwaves in some industrial, healthcare or manufacturing environments. Those devices may also be classified as Microwave (Inverter). |
| Generic Interferer                  | Any non-frequency hopping device that does not fall into one of the other categories described in this table is classified as a <i>Generic Interferer</i> . For example a Microwave-like device that does not operate in the known operating frequencies used by the Microwave ovens may be classified as a Generic Interferer. Similarly wide-band interfering devices may be classified as Generic Interferers.                                                                                                                                                                           |

## Example

The output of this example shows details for fixed-frequency video devices seen by a spectrum monitor or hybrid AP radio.

```
host)# show ap spectrum device-history ap-name ap123 freq-band 5ghz type video
```

Non-Wifi Device History Table

| Type       | ID       | Cfreq(Khz) | Bandwidth(KHz) | Channels-affected | Signal-strength | Duty-cycle |
|------------|----------|------------|----------------|-------------------|-----------------|------------|
| -----      | --       | -----      | -----          | -----             | -----           | -----      |

The output of this command includes the following information:

| Column            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type              | <p>Device type. This parameter can be any of the following:</p> <ul style="list-style-type: none"> <li>• audio FF (fixed frequency)</li> <li>• bluetooth</li> <li>• cordless base FH (frequency hopper)</li> <li>• cordless phone FF (fixed frequency)</li> <li>• cordless network FH (frequency hopper)</li> <li>• generic FF (fixed frequency)</li> <li>• generic FH (frequency hopper)</li> <li>• generic interferer</li> <li>• microwave</li> <li>• microwave inverter</li> <li>• video</li> <li>• xbox</li> </ul> <p><b>NOTE:</b> For additional details about non-Wi-Fi device types shown in this table, see <a href="#">Non-Wi-Fi Interferers on page 1295</a></p> |
| ID                | ID number assigned to the device by the spectrum monitor or hybrid AP radio. Spectrum monitors and hybrid APs assign a unique spectrum ID per device type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Cfreq             | Center frequency of the signal sent from the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Bandwidth         | Channel bandwidth used by the device, in Kilohertz.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Channels-affected | Radio channels affected by the wireless device, in Kilohertz.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Signal-strength   | Strength of the signal sent from the device, in dBm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Duty-cycle        | Device duty cycle. This value represents the percent of time the device broadcasts on the specified channel or frequency.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Add-time          | Time at which the device was first detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Delete-time       | Time at which the device was aged out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

```

### Description

Show a device summary table and channel information for non-Wi-Fi devices currently seen by a spectrum monitor or hybrid AP radio.

### Syntax

| Parameter             | Description                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor or hybrid AP for which you want to view spectrum information.               |
| ip-addr <ip-addr>     | IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.         |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 GHz.                                     |
| type                  | Show data for a specific device type only.                                                               |
| audio-ff              | Show only audio fixed frequency devices.                                                                 |
| bluetooth             | Show only bluetooth devices.<br><b>NOTE:</b> This option is available only for 2.4 GHz spectrum devices. |
| cordless-base-fh      | View information for frequency-hopping cordless phone bases seen by the spectrum device.                 |
| cordless-phone-ff     | View information for frequency-hopping cordless phones seen by the spectrum device.                      |
| cordless-network-fh   | View information for frequency-hopping cordless network devices seen by the spectrum device.             |
| generic-ff            | View information for generic fixed-frequency devices seen by the spectrum device.                        |
| generic-fh            | View information for generic frequency-hopping devices seen by the spectrum device.                      |
| generic-interferer    | Show only generic interfering devices.                                                                   |
| microwave             | Show only microwave devices.<br><b>NOTE:</b> This option is available only for 2.4 GHz spectrum devices. |

| Parameter          | Description                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| microwave-inverter | Show only microwave inverter devices.<br><b>NOTE:</b> This option is available only for 2.4 GHz spectrum devices.    |
| video              | Show only video fixed frequency devices.                                                                             |
| xbox               | Show only xbox frequency hopper devices.<br><b>NOTE:</b> This option is available only for 2.4 GHz spectrum devices. |

## Usage Guidelines

Issue this command to view detailed information about currently active non-Wi-Fi devices on the network. Use the optional **type** parameter to display data for one specific device type only. For additional details about non-Wi-Fi device types shown in this table, see [Non-Wi-Fi Interferers on page 1295](#).

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

## Examples

The output of this example shows that the spectrum monitor **ap123** is able to see data for a single non-Wi-Fi device on its 802.11a radio. Note that the output below is divided into two sections to better fit on the page of this document. In the ArubaOS CLI, this information is displayed in a single long table.

```
(host) #show ap spectrum device-list ap-name ap123 freq-band 5ghz

| ID                | ID number assigned to the device by the spectrum monitor or hybrid AP radio. Spectrum monitors and hybrid APs assign a unique spectrum ID per device type.                                                                                                                       |
| Cfreq             | Center frequency of the signal sent from the device.                                                                                                                                                                                                                             |
| Bandwidth         | Channel bandwidth used by the device.                                                                                                                                                                                                                                            |
| Channels-affected | Radio channels affected by the wireless device.                                                                                                                                                                                                                                  |
| Signal-strength   | Strength of the signal sent from the device, in dBm.                                                                                                                                                                                                                             |
| Duty-cycle        | Device duty cycle. This value represents the percent of time the device broadcasts a signal.                                                                                                                                                                                     |
| Add-time          | Time at which the device was first detected.                                                                                                                                                                                                                                     |
| Update-time       | Time at which the device's status was updated.                                                                                                                                                                                                                                   |

| video              | Show only video fixed frequency devices.                                                                                   |
| xbox               | Show only xbox frequency hopper devices.<br><b>NOTE:</b> This option is available only for 2.4 GHz spectrum device radios. |

## Usage Guidelines

Use this table to show a time log of when non-Wi-Fi devices were added to and deleted from the Wi-Fi Device log table. For additional details about non-Wi-Fi device types shown in this table, see [Non-Wi-Fi Interferers on page 1295](#).

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

## Examples

The output of this example shows that the spectrum monitor **ap123** logged data for four frequency-hopping cordless base devices seen by its 802.11g radio. Note that the output below is divided into two sections to better fit on the page of this document. In the ArubaOS CLI, this information is displayed in a single long table.

```
(host) #show ap spectrum device-log ap-name ap123 freq-band 5ghz cordless-base-fh
```

Non-Wifi Device Log Table

| Device Type      | ID | Added/Deleted | Signal Strength | Duty Cycle | Center Freq |
|------------------|----|---------------|-----------------|------------|-------------|

The output of this command includes the following information:

| Column            | Description                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Device Type       | Type of non-Wi-Fi device detected by the spectrum monitor or hybrid AP                                                        |
| ID                | The spectrum ID number assigned to that device. Spectrum monitors and hybrid APs assign a unique spectrum ID per device type. |
| Added/Deleted     | The non-Wi-Fi Device Log table can show signal data for a device when that device was added or removed from the log table.    |
| Signal Strength   | Strength of the signal sent by the device.                                                                                    |
| Duty Cycle        | Device duty cycle. This value represents the percent of time a signal is broadcast on a specific channel or frequency.        |
| Center Freq       | Center frequency of the signal sent by the device.                                                                            |
| Start Freq        | Lowest signal frequency sent by the device.                                                                                   |
| End Freq          | Highest signal frequency sent by the device.                                                                                  |
| Channels affected | Radio channels affected by the device signal.                                                                                 |
| Bandwidth         | Amount of signal bandwidth used by the device, in kilohertz.                                                                  |

## show ap spectrum device-summary

```
show ap spectrum device-summary {ap-name <ap-name>}|{ip-addr <ip-addr>} freq-band 2.4ghz|5ghz
```

### Description

This command shows the numbers of wi-fi and non-Wi-Fi device types on each channel monitored by a spectrum monitor or hybrid AP

### Syntax

| Parameter             | Description                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor or hybrid AP for which you want to view spectrum information.       |
| ip-addr <ip-addr>     | IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information. |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 GHz.                             |

### Usage Guidelines

Use this command to show the types of devices that the spectrum device can detect on each channel it monitors. For additional details about non-Wi-Fi device types shown in this table, see [Non-Wi-Fi Interferers on page 1295](#).

### Examples

The output of this example shows that the spectrum monitor **ap123** is able to detect 61 wi-fi devices on channel 149g.

```
(host) #show ap spectrum device-summary ap-name ap123 freq-band 5ghz
```

```

## show ap spectrum interference-power

```
show ap spectrum interference-power {ap-name <ap-name>} [{ip-addr <ip-addr>} freq-band
2.4ghz|5ghz [<chan-width>]
```

### Description

This command shows the interference power detected by a 802.11a or 802.11g radio on a spectrum monitor or hybrid AP.

### Syntax

| Parameter             | Description                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>     | Name of the spectrum monitor or hybrid AP for which you want to view spectrum information.                                                                                                                         |
| ip-addr <ip-addr>     | IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.                                                                                                                   |
| freq-band 2.4ghz 5ghz | View information for a specific radio type, either 2.4 GHz or 5 GHz.                                                                                                                                               |
| <chan-width>          | Specify <b>20MHz</b> or <b>40MHz</b> to select the channel width for which you want to view information. If you do not specify a channel width, the output of this command will display the default 20MHz setting. |

### Usage Guidelines

This table displays information about AP power levels, channel noise and adjacent channel interference seen on each channel by a spectrum monitor or hybrid AP radio.

The output of this command displays the noise floor of each selected channel in dBm. The noise floor of a channel depends on the noise figure of the RF components used in the radio, temperature, presence of certain types of interferers or noise, and the width of the channel. For example, in a clean environment, the noise floor of a 20 MHz channel will be around -95 dBm and that of a 40 MHz channel will be around -92 dBm. Certain types of fixed frequency continuous transmitters such as video bridges, fixed frequency phones, and wireless cameras typically elevate the noise floor as seen by the Wi-Fi radio. Other interferers such as the frequency hopping phones, Bluetooth and Xbox devices may not affect the noise floor of the radio. A Wi-Fi radio can only reliably decode Wi-Fi signals that are a certain dB above the noise floor and therefore estimating and understanding the actual noise floor of the radio is critical to understanding the reliability of the RF environment.

The ACI column displayed in the Interference Power Chart displays adjacent-channel interference (ACI) power levels based on the signal strength(s) of the Wi-Fi APs on adjacent channels. A higher ACI value in Interference Power Chart does not necessarily mean higher interference since the AP that is contributing to the maximum ACI may or may not be very actively transmitting data to other clients at all times. The ACI power levels are derived from the signal strength of the beacons.

### Examples

The output of this example shows interference power levels for each channel seen by the spectrum monitor **ap123**.

```
(host)# show ap spectrum interference-power ap-name ap123 freq-band 5ghz
```

#### Interference Power Table

| Channel                | Noise Floor (dBm) | Max AP Signal (dBm) | Max AP SSID       | Max AP BSSID      | ACI (dBm) |
|------------------------|-------------------|---------------------|-------------------|-------------------|-----------|
| Max Interference (dBm) |                   |                     |                   |                   |           |
| 149                    | -91               | -40                 | ethersphere-wpa2  | 00:24:6c:80:7b:c9 | -77       |

| 149+                   | -60               | -40                 | ethersphere-wpa2  | 00:24:6c:80:7b:c9 | -0        |
| -58                    |                   |                     |                   |                   |           |
| 157+                   | -89               | -39                 | 00:24:6C:C0:15:EB | 00:24:6c:81:57:c8 | -0        |
| -60                    |                   |                     |                   |                   |           |

The output of this command includes the following information:

| Column                       | Description                                                                   |
|------------------------------|-------------------------------------------------------------------------------|
| Channel                      | An 802.11a or 802.11g radio channel.                                          |
| Noise Floor (dBm)            | Current noise floor recorded on the channel.                                  |
| Max AP Signal (dBm)          | Power level of the AP on the channel with the highest signal power.           |
| Max AP SSID                  | SSID of the AP on the channel with the highest signal power.                  |
| Max AP BSSID                 | BSSID of the AP on the channel with the highest signal power.                 |
| ACI (dBm)                    | Adjacent channel interference level detected by the spectrum device.          |
| Max Interference Power (dBm) | Signal strength of the non-Wi-Fi device that has the highest signal strength. |

## Command History

Introduced in ArubaOS 6.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show ap spectrum-load-balancing

show ap spectrum-load-balancing [group <group>]

### Description

Show spectrum load balancing information for an AP with this feature enabled.

### Syntax

| Parameter     | Description                                                                                 |
|---------------|---------------------------------------------------------------------------------------------|
| group <group> | Filter this information to show only data for the specified spectrum load balancing domain. |

### Examples

The output of the command below shows the APs currently using the spectrum load-balancing domain **default-1**.

```
(host) #show ap spectrum-load-balancing group default-1
```

Spectrum Load Balancing Group

| Name    | IP Address      | Domain    | Assignment | Clients |
|---------|-----------------|-----------|------------|---------|
| -----   | -----           | -----     | -----      | -----   |
| ap121-1 | 192.168.151.253 | default-1 | 149/21     | 3       |
| ap124-1 | 192.168.151.254 | default-1 | 48/15      | 3       |
| ap125-1 | 192.168.151.251 | default-1 | 44/15      | 2       |

The output of this command includes the following information:

| Column     | Description                                                   |
|------------|---------------------------------------------------------------|
| Name       | Name of an AP                                                 |
| IP address | AP IP address                                                 |
| Domain     | Name of the spectrum load balancing domain assigned to the AP |
| Assignment | Current channel and power assignment for the AP.              |
| Clients    | Number of clients currently using the AP.                     |

### Command History

Introduced in ArubaOS 3.3.2.14.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap spectrum local-override

show ap spectrum local-override

### Description

This command shows a list of AP radios currently converted to spectrum monitors via the spectrum local-override list

### Syntax

No parameters

### Examples

The output of this example shows that three APs each have two radios defined as spectrum monitors.

```
(host) #show ap spectrum local-override
Spectrum Local Override Profile

Parameter Value

Override Entry AP apl25 band 2ghz
Override Entry AP apl25 band 5ghz
Override Entry AP apl05 band 2ghz
Override Entry AP apl05 band 5ghz
Override Entry AP apcorp1 band 2ghz
Override Entry AP APcorp1 band 5ghz
```

The Value column in the output of this command includes the following information:

| Parameter      | Description                                                                      |
|----------------|----------------------------------------------------------------------------------|
| Override Entry | Indicates that an AP radio has been added to the local override list             |
| Value          | Radio that has been added to the override list, and the band used by that radio. |

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show ap spectrum monitors

show ap spectrum monitors

### Description

This command shows a list of APs terminating on the controller that are currently configured as spectrum monitors or hybrid APs

### Syntax

No parameters

### Examples

The output of this example shows that the 802.11a radio on a spectrum monitor named **ap123** is sending spectrum analysis data to a client with the IP address 10.240.16.177.

```
(host)#show ap spectrum monitors
```

List of Sensors

```

AP name Group AP Type Phy Band Channel Mode
 Subscribe Time

00:24:6c:c0:0c:89 default 105 G 2GHz 1 Access Point

00:24:6c:c0:0c:89 default 105 A 5GHz 44+ Access Point 10.240.16.177
2011-01-21 07:17:57 AM
00:24:6c:c7:d6:1c default 93 A 5GHz - Spectrum Monitor 10.240.16.177
2011-01-21
07:18:22 AM
```

The output of this command includes the following information:

| Column    | Description                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------|
| AP name   | Name of an AP configured as a spectrum monitor or hybrid AP                                               |
| Group     | Name of the spectrum device's AP group                                                                    |
| Ap Type   | the AP model number                                                                                       |
| Phy       | The radio's PHY type. Possible values are <b>A</b> for 802.11a and <b>G</b> for 802.11b/g,                |
| Band      | Spectrum band that the spectrum monitor or hybrid AP radio s currently monitoring.                        |
| Mode      | This column shows whether the device is an access point configured as a hybrid AP, or a spectrum monitor. |
| Client IP | IP address of the client to which the spectrum monitor or hybrid AP is sending data.                      |

| Column         | Description                                                                  |
|----------------|------------------------------------------------------------------------------|
| Subscribe time | Time at which the spectrum monitor or hybrid AP was connected to the client. |

## show ap spectrum technical-support

```
show ap spectrum technical-support ap-name <ap-name> <filename>
```

### Description

Save spectrum data for later analysis by technical support.

### Syntax

| Parameter  | Description                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ap-name>  | Save technical support information for a specific spectrum monitor.                                                                                                                           |
| <filename> | Name of the file to which this data should be saved. This file does not have to already exist on the controller, the <b>show ap spectrum technical-support</b> command will create this file. |

### Usage Guidelines

Use this command under the supervision of your Dell technical support representative to troubleshoot spectrum analysis issues or errors.

### Command History

Introduced in ArubaOS 6.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap standby

```
show ap active [ap-name <ap-name>|{arm-edge dot11a|dot11g|voip-only}|dot11a|dot11g|ssid
<ssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>|{type access-point|air-monitor|(sensor
dot11a|dot11g|voip-only)}|voip-only
```

### Description

Show all APs in standby mode currently registered to a controller.

### Syntax

| Parameter           | Description                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------|
| ap-name <ap-name>   | View data for an AP with a specified name.                                                          |
| bssid <bssid>       | View data for a specific BSSID.                                                                     |
| ip-addr <ip-addr>   | View data for an AP with a specified IP address by entering an IP address in dotted-decimal format. |
| ip6-addr <ip6-addr> | View data for an AP with a specified IPv6 address.                                                  |

### Usage Guidelines

This command displays details for all APs connected to a controller in standby mode.

### Example

```
host)# show ap active
Active AP Table
```

```

Name Group IP Address 11g Clients 11g Ch/EIRP/MaxEIRP 11a Clients 11a
Ch/EIRP/MaxEIRP AP Type Flags Uptime Outer IP

AP1X default 10.3.15.107 0 AP:HT:1/15/21.5 0 AP:HT:44/15/21
125 1E2 5m:48s N/A
```

Flags: 1 = 802.1x authenticated AP; 2 = Using IKE version 2;  
A = Enet1 in active/standby mode; B = Battery Boost On; C = Cellular;  
D = Disconn. Extra Calls On; E = Wired AP enabled; F = AP failed 802.1x authenticati  
H = Hotspot Enabled; K = 802.11K Enabled; L = Client Balancing Enabled; M = Mesh;  
N = 802.11b protection disabled; P = PPPOE; R = Remote AP;  
S = AP connected as standby; X = Maintenance Mode;  
a = Reduce ARP packets in the air; d = Drop Mcast/Bcast On; u = Custom-Cert RAP;  
r = 802.11r Enabled

The output of this command includes the following information:

| Column | Description   |
|--------|---------------|
| Name   | Name of an AP |

| Column              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Column   | Description                                                                                                                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Uptime   | Number of hours, minutes and seconds since the last controller reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .                                                                                                                                                                                  |
| Outer IP | The outer IP address of a remote AP (RAP) is used to establish an IPsec VPN tunnel to the terminating master controller. The RAP acquires an outer IP address from the locally connected network, usually via DHCP. (A RAP is typically behind a NAT device whose public IP is seen as the outer IP for the RAP). |

## Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.3 | Command introduced |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|

## show ap system-profile

show ap system-profile <profile>

### Description

Show an AP's system profile settings.

### Syntax

| Parameter | Description               |
|-----------|---------------------------|
| <profile> | Name of a system profile. |

### Examples

The output of the command below shows the current configuration settings for the default system profile.

```
(host) #show ap system-profile default
```

```
AP system profile "default"
```

```

```

| Parameter                              | Value          |

| BLE Auth Token                         | N/A      |

The output of this command includes the following information:

| Column                       | Description                                                                                                                                                                                                                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RF Band                      | For dual-band radios, this parameter displays the RF band in which the AP should operate: <ul style="list-style-type: none"> <li><b>g</b> = 2.4 GHz</li> <li><b>a</b> = 5 GHz</li> </ul>                                                                                                          |
| RF Band for AM mode scanning | Scanning band for multiple RF radios. <ul style="list-style-type: none"> <li><b>g</b> = 2.4 GHz</li> <li><b>a</b> = 5 GHz</li> <li><b>all</b> = Radio scans both bands. This is the default setting.</li> </ul>                                                                                   |
| Native VLAN ID               | Native VLAN for bridge mode virtual APs (frames on the native VLAN are not tagged with 802.1q tags).                                                                                                                                                                                              |
| Tunnel Heartbeat Interval    | Interval between heartbeat messages between a remote or campus AP and its associated controller. An increase in the heartbeat interval increases the time it will take for an AP to detect the loss in connectivity to the controller, but can reduce internet bandwidth consumed by a remote AP. |
| Session ACL                  | This parameter shows the access control list (ACL) applied on the uplink of a remote AP.                                                                                                                                                                                                          |
| Corporate DNS Domain         | DNS name used by the corporate network.                                                                                                                                                                                                                                                           |
| SNMP sysContact              | SNMP system contact information.                                                                                                                                                                                                                                                                  |

| Column                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SAP MTU                       | Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.                                                                                                                                                                                                                                                                                                                                           |
| LMS IP                        | <p>The IP address of the local management switch (LMS)—the Dell controller which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network.</p> <p><b>NOTE:</b> If the LMS-IP is blank, the access point will remain on the controller that it finds using methods like DNS or DHCP. If an IP address is configured for the LMS IP parameter, the AP will be immediately redirected to the controller at that address.</p> |
| Backup LMS IP                 | For multi-controller networks, this parameter displays the IP address of a backup to the IP address specified with the lms-ip parameter.                                                                                                                                                                                                                                                                                                                                                  |
| LMS IPv6                      | In multi-controller ipv6 networks, this parameter specifies the IPv6 address of the local management switch (LMS)—the Dell controller—which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. This can be the IP address of the local or master controller.                                                                                                                                                       |
| Backup LMS IPv6               | In multi-controller ipv6 networks, this parameter specifies the IPv6 address of a backup to the IPv6 address specified with the <b>LMS IPv6</b> setting.                                                                                                                                                                                                                                                                                                                                  |
| LMS Preemption                | When this parameter is enabled, the local management switch automatically reverts to the primary LMS IP address when it becomes available.                                                                                                                                                                                                                                                                                                                                                |
| LMS Hold-down Period          | Time, in seconds, that the primary LMS must be available before an AP returns to that LMS after failover.rap-dhcp-server-vlan VLAN ID of the remote AP DHCP server used if the controller is unavailable. This VLAN enables the DHCP server on the AP (also known as the remote AP DHCP server VLAN). If you enter the native VLAN ID, the DHCP server is unavailable.                                                                                                                    |
| Remote-AP DHCP Server VLAN    | VLAN ID of the remote AP DHCP server used if the controller is unavailable. This VLAN enables the DHCP server on the AP (also known as the remote AP DHCP server VLAN).                                                                                                                                                                                                                                                                                                                   |
| Remote-AP DHCP Server ID      | IP address used as the DHCP server identifier.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Remote-AP DNS Server          | IP address of the DNS server.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Remote-AP DHCP Default Router | IP address for the default DHCP router.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Column                                                                                 | Description                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remote-AP DHCP Pool Start                                                              | This parameter defines the starting IP address in the DHCP pool for remote APs.                                                                                                                                                                                                                                            |
| Remote-AP DHCP PoolEnd                                                                 | This parameter defines the last IP address in the DHCP pool for remote APs.                                                                                                                                                                                                                                                |
| Remote-AP DHCP PoolNetmask                                                             | Configures a DHCP pool for remote APs. This is the netmask used for the DHCP pool.                                                                                                                                                                                                                                         |
| Remote-AP uplink total bandwidth                                                       | This is the total reserved uplink bandwidth (in Kilobits per second).                                                                                                                                                                                                                                                      |
| Remote-AP bw reservation 1<br>Remote-AP bw reservation 2<br>Remote-AP bw reservation 3 | Session ACLs with uplink bandwidth reservation in kilobits per second. You can specify up to three session ACLs to reserve uplink bandwidth. The sum of the three uplink bandwidths should not exceed the rap-bw-total value.                                                                                              |
| Remote-AP Local Network Access                                                         | Shows if Remote-AP Local Network Access is enabled or disabled. By enabling this option, the clients that are connected to a RAP can communicate.<br><br>Note: By default, the Remote-AP Local Network Access will be disabled.                                                                                            |
| Bootstrap threshold                                                                    | Number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots. On the controller, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.                               |
| Double Encrypt                                                                         | This parameter applies only to remote APs. Double encryption is used for traffic to and from a wireless client that is connected to a tunneled SSID. When enabled, all traffic is re-encrypted in the IPsec tunnel. When disabled, the wireless frame is only encapsulated inside the IPsec tunnel.                        |
| Dump Server                                                                            | (For debugging purposes.) Displays the server to receive the core dump generated if an AP process crashes.                                                                                                                                                                                                                 |
| Heartbeat DSCP                                                                         | DSCP value of AP heartbeats (0-63).                                                                                                                                                                                                                                                                                        |
| Maintenance Mode                                                                       | Shows if Maintenance mode is enabled or disabled. If enabled, APs stop flooding unnecessary traps and syslog messages to network management systems or network operations centers when deploying, maintaining, or upgrading the network. The controller still generates debug syslog messages if debug logging is enabled. |

| Column                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximum Request Retries   | Maximum number of times to retry AP-generated requests, including keepalive messages. After the maximum number of retries, the AP either tries the IP address specified by the bkup-lms-ip (if configured) or reboots.                                                                                                                                                                                                     |
| Request Retry Interval    | Interval, in seconds, between the first and second retries of AP-generated requests. If the configured interval is less than 30 seconds, the interval for subsequent retries is increased up to 30 seconds.                                                                                                                                                                                                                |
| Number of IPSEC retries   | The number of times the AP will attempt to recreate an IPsec tunnel with the master controller before the AP will reboot. A value of 0 disables the reboot.                                                                                                                                                                                                                                                                |
| AeroScout RTLS Server     | IP address of an AeroScout real-time asset location (RTLS) server.                                                                                                                                                                                                                                                                                                                                                         |
| RTLS Server configuration | <p>This parameter contains the following information, separated by colons.</p> <ul style="list-style-type: none"> <li>• The IP address of the RTLS server to which the AP sends RFID tag information.</li> <li>• Number of the RTLS server port to which the AP sends RFID tag information</li> <li>• Shared secret key for the server</li> <li>• Frequency at which packets are sent to the server, in seconds</li> </ul> |
| Telnet                    | Reports whether telnet access the AP is enabled or disabled.                                                                                                                                                                                                                                                                                                                                                               |
| RF Band for Backup        | If the system profile is enabled AP console access using a backup ESSID, this parameter                                                                                                                                                                                                                                                                                                                                    |
| Operation for Backup      | This parameter allows AP console access using a backup ESSID, allowing users to access an AP console after the AP has disconnected from the controller. When the AP advertises a backup ESSID in either static or dynamic mode, a user is able to access and debug the AP remotely through a virtual AP. This feature is disabled by default.                                                                              |
| BLE Endpoint URL          |                                                                                                                                                                                                                                                                                                                                                                                                                            |
| BLE Auth Token            |                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Command History

| Release         | Modification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ArubaOS 3.2     | Support for additional RTLS servers and remote AP enhancements was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ArubaOS 3.3.2   | <ul style="list-style-type: none"> <li>• <b>Maintenance-mode</b> parameter was introduced.</li> <li>• Multiple remote AP DHCP server enhancements were introduced.</li> <li>• Support for RFprotect server and backup server configuration was introduced.</li> <li>• The <b>mms-rtls-server</b> parameter was deprecated in ArubaOS 3.3.2.</li> </ul>                                                                                                                                                       |
| ArubaOS 5.0     | The <b>master IP</b> , <b>RFProtect server IP</b> and <b>RFProtect Backup Server IP</b> parameters were deprecated.                                                                                                                                                                                                                                                                                                                                                                                          |
| ArubaOS 6.0     | Added support for the option to set the RF scanning band (am-scan-rf-band). The <b>keepalive interval</b> parameter was deprecated.                                                                                                                                                                                                                                                                                                                                                                          |
| ArubaOS 6.2.1.3 | The <b>root-ap</b> parameter was deprecated. This parameter identified the root AP in a hierarchy of Remote APs.                                                                                                                                                                                                                                                                                                                                                                                             |
| ArubaOS 6.3     | The output of this command includes the <b>Tunnel Heartbeat Interval</b> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                          |

## show ap tech-support

```
show ap tech-support ap-name <name> [<filename>]
```

### Description

Display all information for an AP, or save that information to a file on the controller. This information can be used by Dell technical support to diagnose a problem with an AP.

### Syntax

| Parameter  | Description                                                                                |
|------------|--------------------------------------------------------------------------------------------|
| <name>     | Name of the AP for which you want to view tech support data.                               |
| <filename> | Save the output of this command into a file on the controller with the specified filename. |

### Usage Guidelines

This is an internal technical support command. Dell technical support may request that you issue this command to help analyze and troubleshoot problems with an AP or your wireless network.

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap vht-rates

```
show ap vht-rates bssid <bssid>
```

### Description

Show very-high-throughput (VHT) rates for an AP that supports 802.11ac.

### Syntax

| Parameter     | Description                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid> | Show VHT rates for a specific Basic Service Set Identifier (BSSID) on an 802.11ac-capable AP. The Basic Service Set Identifier (BSSID) is usually the AP's radio's MAC address. |

### Examples

The output of the command below shows very-high-throughput rates for 20Mhz, 40 Mhz and 80 Mhz data streams with and without a short guard interval (SGI).

```
(host) # show ap vht-rates bssid 6c:f3:7f:e6:52:f1
AP "Corp-ac" Radio 0 BSSID 6c:f3:7f:e7:51:f0 Very-high-throughput Rates (Mbps)
```

| MCS | Streams | 20 MHz | 20 MHz SGI | 40 MHz | 40 MHz SGI | 80 MHz | 80 MHz SGI |
|-----|---------|--------|------------|--------|------------|--------|------------|
| 0   | 1       | 6.5    | 7.2        | 13.5   | 15.0       | 29.3   | 32.5       |
| 1   | 1       | 13.0   | 14.4       | 27.0   | 30.0       | 58.5   | 65.0       |
| 2   | 1       | 19.5   | 21.7       | 40.5   | 45.0       | 87.8   | 97.5       |

## show ap virtual-beacon-report

```
show ap virtual-beacon-report
 all
 ap-name <name>
 client-mac <macaddr>
 ip-addr <ipaddr>
 ip6-addr <ipv6addr>
```

### Description

If the client match feature is enabled, the output of this command displays the virtual beacon report for an AP or a client with a specific IP or MAC address.

### Syntax

| Parameter            | Description                                                                 |
|----------------------|-----------------------------------------------------------------------------|
| all                  | Virtual beacon report for all clients on the controller.                    |
| ap-name <name>       | Name of the AP for which you want to view a virtual beacon report.          |
| client-mac <macaddr> | MAC address of a client for which you want to view a virtual beacon report. |
| ip-addr <ipaddr>     | IPv4 address of an AP for which you want to view a virtual beacon report.   |
| ip6-addr <ipv6addr>  | IPv6 address of an AP for which you want to view a virtual beacon report.   |

### Usage Guidelines

Use this command to display the client RSSI from the APs in its RF neighborhood, the channel used by each AP radio, and the number of clients associated to each radio.

### Example

The example below displays the virtual beacon report for a client with MAC address 24:77:03:d1:24:b8.

```
(host) #show ap virtual-beacon-report client-mac 24:77:03:d1:24:b8
```

```
Client MAC :24:77:03:d1:24:b8
Current association :1260-205 (9c:1c:12:fe:0f:d0)
Steer attempts/Success :2/1
Consecutive (Fails/BTM Rej/BTM Timeouts) :0/0/0
Bandsteer window (Steers/Start time/Expiry time) :0/0/0
Client Device Type :Win 7
Current state :Steerable
Client Supported Channels :{36,4}{52,4}{100,11}{149,4}{165,1}
Current Time :Oct 29 15:56:06 2014
```

STA Beacon Report

```

| Steer Attempts/Success                           | Number of steer attempts, and the number of successful steers                                                                     |
| Consecutive (Fails/BTM Rej/BTM Timeouts)         | Consecutive number of failed steer attempts, rejected BSS Transition Management Requests, and BSS Transition Management timeouts. |
| Bandsteer Window (Steers/State Time/Expiry Time) | Number of band steers, the start time of the band steer, and the expiry time of band the steer                                    |
| Client Device Type                               | Type of device used by the client (e.g. Windows)                                                                                  |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Current State             | Indicates whether the client is currently steerable                                                                                                                                                                                                                                                                                                                                                                      |
| Client Supported Channels | Lists the channels that support client use                                                                                                                                                                                                                                                                                                                                                                               |
| Current Time              | Timestamp showing the current date and time                                                                                                                                                                                                                                                                                                                                                                              |
| AP                        | Name of the AP from which the client can detect a signal                                                                                                                                                                                                                                                                                                                                                                 |
| IP address                | IP address of the AP from which the client can detect a signal                                                                                                                                                                                                                                                                                                                                                           |
| Radio                     | MAC address of the AP radio from which the client can detect a signal                                                                                                                                                                                                                                                                                                                                                    |
| ESSID                     | Identifying name of the wireless network for each AP                                                                                                                                                                                                                                                                                                                                                                     |
| Signal (dBm)              | Signal strength, in dBm, from the AP radio                                                                                                                                                                                                                                                                                                                                                                               |
| Last Update               | Time that the virtual beacon report last updated information for the AP radio                                                                                                                                                                                                                                                                                                                                            |
| Add Time                  | Date and time the client is successfully steered and added to the AP                                                                                                                                                                                                                                                                                                                                                     |
| Channel/EIRP/Clients      | Channel used by the AP radio, the amount of power transmitted from the AP antennae, and the number of clients associated to it                                                                                                                                                                                                                                                                                           |
| Flag                      | <p>The output of this column shows the following values:</p> <ul style="list-style-type: none"> <li>• *: Flag indicating that the client is currently associated to this AP</li> <li>• S: Flag indicating a stale entry, with the last client update from this radio produced 120+ seconds ago</li> <li>• U: Flag indicating that the client does not support the channel the radio is currently operating on</li> </ul> |

The following example displays a virtual beacon report for all clients in the network.

```
(host) #show ap virtual-beacon-report all
```

```
Client MAC :60:d9:c7:a2:42:cb
Current association :1260-205 (9c:1c:12:fe:0f:d2)
Steer attempts/Success :0/0
Consecutive (Fails/BTM Rej/BTM Timeouts) :0/0/0
Bandsteer window (Steers/Start time/Expiry time) :0/0/0
Client Device Type :Unknown
Current state :Steerable
Active media sessions: No
Client Supported Channels :{36,4}{52,4}{100,11}{149,4}{165,1}
Current Time :Oct 29 12:38:35 2014
```

## show ap vlan-usage

```
show ap vlan-usage [{ap-name <ap-name>}|{bssid <bssid>}|{essid <essid>}|{ip-addr <ip-addr>}|
{virtual-ap <virtual-ap>}]
```

### Description

Show the numbers of clients on each VLAN.

### Syntax

| Parameter               | Description                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>       | Show VLAN data for an AP with a specific name.                                                                                                                                                                                                                    |
| bssid <bssid>           | Show VLAN data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                                                                            |
| essid <essid>           | Show VLAN data for a specific Extended Service Set Identifier (ESSID). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |
| ip-addr <ip-addr>       | Show VLAN data for an AP with a specific IP address by entering an IP address in dotted-decimal format.                                                                                                                                                           |
| ip6-addr <ip6-addr>     | Show VLAN data for an AP with a specific IPv6 address by entering an IP address in dotted-decimal format.                                                                                                                                                         |
| virtual-ap <virtual-ap> | Show VLAN pool allocation by VAP name.                                                                                                                                                                                                                            |

### Examples

The output of this command displays the **VLAN Usage** table.

```
(host) #show ap vlan-usage
VLAN Usage Table

VLAN ID Clients
----- -
64 1
65 32
66 44
```

The output of this command includes the following information:

| Column  | Description                                           |
|---------|-------------------------------------------------------|
| VLAN ID | ID number of the wireless VLAN.                       |
| Clients | Number of clients currently using the specified VLAN. |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap wired-ap-profile

show ap wired-ap-profile [<profile>]

### Description

Show a list of all wired AP profiles, or display the configuration parameters in a specific wired AP profile.

### Syntax

| Parameter | Description                 |
|-----------|-----------------------------|
| <profile> | Name of a wired AP profile. |

### Usage Guidelines

The command show ap wired-ap-profile displays a list of all wired AP profiles, including the number of references to each profile and the profile status. If you include the optional <profile> parameter, the command will display detailed information for that one profile.

### Example

The output of this command shows the configuration parameters for the wired AP profile “default”.

```
(host) #show ap wired-ap-profile default
```

```
Wired AP profile "default"
```

```

```

| Parameter                | Value       |
|--------------------------|-------------|
| Wired AP enable          | Disabled    |
| Forward mode             | tunnel      |
| Switchport mode          | access      |
| Access mode VLAN         | 1           |
| Trunk mode native VLAN   | 1           |
| Trunk mode allowed VLANs | 1-4094      |
| Trusted                  | Not Trusted |
| Broadcast                | Broadcast   |

The output of this command includes the following information:

| Column          | Description                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wired AP enable | Indicates whether the wired AP profile is <b>enabled</b> or <b>disabled</b> .                                                                                                                                                                 |
| Forward mode    | The configured forward mode for the profile. <ul style="list-style-type: none"><li>• <b>bridge</b>: Bridge locally</li><li>• <b>split-tunnel</b>: Tunnel to controller or NAT locally</li><li>• <b>tunnel</b>: Tunnel to controller</li></ul> |
| Switchport mode | The profile's switching mode. <ul style="list-style-type: none"><li>• <b>access</b>: Set access mode characteristics of the interface.</li></ul>                                                                                              |

| Column                   | Description                                                                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <ul style="list-style-type: none"> <li>• <b>mode:</b> Set trunking mode of the interface.</li> <li>• <b>trunk:</b> Set trunk mode characteristics of the interface.</li> </ul> |
| Access mode VLAN         | VLAN ID of the access mode VLAN.                                                                                                                                               |
| Trunk mode native VLAN   | VLAN ID of the native VLAN.                                                                                                                                                    |
| Trunk mode allowed VLANs | Range of allowed VLAN IDs for the native VLAN.                                                                                                                                 |
| Trusted                  | Shows if the wired port on an AP using this profile is a trusted port. Possible values are <b>Trusted</b> or <b>Not Trusted</b> .                                              |
| Broadcast                | If set to <b>broadcast</b> , the wired AP port will forward broadcast traffic. If the parameter displays <b>Do Not Broadcast</b> , broadcast traffic will not be forwarded.    |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap wired-port-profile

```
show ap wired-port-profile
```

### Description

Shows all AP wired port profiles and their status.

### Syntax

No parameters.

### Example

The example below shows that the controller has three wired port profiles. The **References** column lists the number of other profiles with references to the wired port profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) (config) #show ap wired-port-profile
```

```
AP wired port profile List
```

```

Name References Profile Status
---- -
default 3
NoAuthWiredPort 4 Predefined (editable)
shutdown 3 Predefined
Total:3
```

The following command displays information for an individual wired port profile:

```
(host)#show ap wired-port-profile default
```

```
AP wired port profile "default"
```

```

Parameter Value

Wired AP profile default
Ethernet interface link profile default
AP LLDP profile default
Shut down? No
Remote-AP Backup Enabled
AAA Profile N/A
Time to wait for authentication to succeed 20 sec
```

The output of this command includes the following information:

| Parameter        | Description                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wired AP profile | Name of a wired AP profile to be used by devices connecting the AP's wired port. The wired AP profile defines the forwarding mode and switchport values used by the port. |

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ethernet interface link profile            | An Ethernet Link profile to be used by devices connecting to the AP's wired port profile. This profile defines the duplex value and speed to be used by the port.                                                                                                                                                                               |
| AP LLDP Profile                            | Name of an LLDP Profile associated with this wired port.                                                                                                                                                                                                                                                                                        |
| Shut Down?                                 | Shows if the wired AP port is enabled (no) or disabled (yes).                                                                                                                                                                                                                                                                                   |
| Remote AP Backup                           | Use the rap-backup parameter to use the wired port on a Remote AP for local connectivity and troubleshooting when the AP cannot reach the controller. If the AP is not connected to the controller, no firewall policies will be applied when this option is enabled. (The AAA profile will be applied when the AP is connected to controller). |
| AAA Profile                                | Name of a AAA profile to be used by devices connecting to the AP's wired port.                                                                                                                                                                                                                                                                  |
| Time to wait for authentication to succeed | Authentication timeout value, in seconds, for devices connecting the AP's wired port. The supported range is 1-65535 seconds, and the default value is 20 seconds.                                                                                                                                                                              |

## Command History

This command was introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap wired stats

```
show ap wired stats {ip-addr <ip-addr>} | {ap-name <ap-name>}|{client-ip <client-ip>} |
{client-mac <client-mac>}
```

### Description

Shows statistics for campus and remote AP wired clients.

### Syntax

| Parameter               | Description                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------|
| ap-name <ap-name>       | Show wired AP statistics for a specified AP name.                                               |
| ip-addr <ip-addr>       | Show wired AP statistics for a specified AP by entering an IP address in dotted-decimal format. |
| client-ip <client-ip>   | Show wired AP statistics for a specified client IP address.                                     |
| client-mac <client-mac> | Show wired AP statistics for a specified client MAC address                                     |

### Example

```
(host) #show ap wired stats ap-name rap5wn client-mac 00:14:d1:19:3c:0b
```

AP Wired User Statistics

```

Counter Value

Slot 0
Port 1
VLAN 1
TX Packets 78
TX Bytes 7894
RX Packets 37
RX Bytes 5352
TX Broadcast Packets 36
TX Broadcast Bytes 4410
TX Multicast Packets 22
TX Multicast Bytes 1990
```

The output of this command includes the following information:

| Column | Description            |
|--------|------------------------|
| Slot   | Slot number            |
| Port   | Port number            |
| VLAN   | Associated VLAN number |

| Column               | Description                      |
|----------------------|----------------------------------|
| TX Packets           | Number of packets sent           |
| TX Bytes             | Number of bytes sent             |
| RX Packets           | Number of packets received       |
| RX Bytes             | Number of bytes received         |
| TX Broadcast Packets | Number of broadcast packets sent |
| TX Broadcast Bytes   | Number of broadcast bytes sent   |
| TX Multicast Packets | Number of multicast packets sent |
| TX Multicast Bytes   | Number of multicast bytes sent   |

## Command History

| Version         | Description                                                                 |
|-----------------|-----------------------------------------------------------------------------|
| ArubaOS 5.0     | Command Introduced.                                                         |
| ArubaOS 6.4.3.0 | This command now displays results for both Campus and Remote access points. |

## Command Information

| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap wmm-flow

```
show ap wmm-flow [{ap-name <ap-name>}|{bssid <bssid>}|{essid <essid>}|{ip-addr <ip-addr>}]
dot11a|dot11g
```

### Description

Show the Wireless Multimedia (WMM) flow table.

### Syntax

| Parameter         | Description                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name> | View an AP with a specified name.                                                                                                                                                                                                                            |
| bssid <bssid>     | View data for an AP with a specific BSSID (Basic Service Set Identifier). The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.                                                                                                          |
| essid <essid>     | View data for a specific ESSID (Extended Service Set Identifier). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks. |
| ip-addr <ip-addr> | View an AP with a specified IP address by entering an IP address in dotted-decimal format.                                                                                                                                                                   |
| dot11a            | Show the WMM flow table for a 802.11a radio.                                                                                                                                                                                                                 |
| dot11g            | Show the WMM flow table for a 802.11g radio.                                                                                                                                                                                                                 |

### Usage Guidelines

WMM, or Wireless Multimedia Extensions, are a subset of the 802.11e standard. WMM provides for four different types of traffic classification: voice, video, best effort, and background, with voice having the highest priority and background the lowest. Issue the **show ap wmm-flow** command to view WMM flow data for all APs. Include any of the optional parameters described in the table above to filter the table by a specific AP, radio channel (a or g), or both an ap and radio type.

### Example

The example below shows WMM flow data for all APs.

```
(host) #show ap wmm-flow
```

WMM Flow Table

```

AP Name ESSID Client Description

AP125-srk NOE 00:90:7a:06:1f:5b tsid 6:prio 6:inactivity 2157352960

The TSID should match the priority level for each flow.</p> <p><b>Priority:</b> One of the following IEEE 802.1p priority values:</p> <ul style="list-style-type: none"> <li>• 0,3 = Best Effort</li> <li>• 1,2 = Background</li> <li>• 4-5 = Video</li> <li>• 6-7 = Voice</li> </ul> <p><b>Inactivity:</b> Tspec inactivity threshold, in microseconds.</p> <p><b>&lt;country code&gt;:</b> AP country code, e.g. US.</p> <p><b>bdir:</b> flow is bidirectional.</p> <p><b>apsd:</b> flow has enabled auto power save delivery.</p> <p><b>&lt;ack&gt;:</b> Displays the ack policy negotiated for the flow. Possible values are:</p> <ul style="list-style-type: none"> <li>• normalack</li> <li>• noack</li> <li>• blockack</li> <li>• resack (reserved ack)</li> </ul> <p><b>Tclas:</b> traffic classification element. Tclas information includes one of the following classification types, the 802.1p priority and IP version (ver-4 or ver-6)</p> <ul style="list-style-type: none"> <li>• <b>type0</b> - Classification based on Ethernet parameters</li> <li>• <b>type1</b> - Classification based on TCP/UDP or IP parameters (IPv4 or IPv6)</li> <li>• <b>type2</b> - Classification based on based on IEEE802.1Q</li> </ul> <p><b>DIP:</b> Destination IP address for the flow.</p> <p><b>DP:</b> Destination IP Port specified in the TCLAS for flow negotiation.</p> <p><b>DCSP:</b> The Differentiated Services Code Point (DSCP) priority value that matches the flows 802.1p priority.</p> |

## Command History

Introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show app lync call-cdrs

```
show app lync prioritized-calls [all]
```

### Description

This command displays the Call Detail Record (CDR) for prioritized Lync calls in the controller.

### Syntax

| Parameter | Description                                  |
|-----------|----------------------------------------------|
| all       | Displays CDR information for all Lync calls. |

### Example

In this example, the output is divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it appears in a single, long table.

```
(host) #show app lync call-cdrs
```

Lync Session CDRs (Prioritized)

| CDR Id | Client IP  | Client Name | ALG  | Dir | Called to | Status |
|--------|------------|-------------|------|-----|-----------|--------|
| 4      | 192.0.2.10 | 6000        | lync | IC  | 6001      | SUCC   |
| 3      | 192.0.2.20 | 6002        | lync | OG  | 6012      | SUCC   |

| Dur(sec) | Orig time       | MOS Value | Reason     | Codec | Band  |
|----------|-----------------|-----------|------------|-------|-------|
| 19       | May 15 15:20:34 | 3.910000  | Terminated | G722  | GREEN |
| 85       | May 15 15:16:30 | 3.910000  | Terminated | G722  | GREEN |

| Setup Time(sec) | Re-Assoc | Initial-BSSID     | Initial-ESSID |
|-----------------|----------|-------------------|---------------|
| 0               | 0        | 00:24:6c:27:5f:f0 | test1         |
| 0               | 0        | 00:24:6c:27:5f:f0 | test1         |

| Initial-AP Name | Call Type | Src port | Dest port | DSCP | WMM AC |
|-----------------|-----------|----------|-----------|------|--------|
| AP175           | Voice     | 17120    | 31826     | 46   | 7      |
| AP175           | Voice     | 31826    | 17120     | 46   | 7      |

Num CDRS:2

The output of this command includes the following parameters:

| Column      | Description                                        |
|-------------|----------------------------------------------------|
| CDR Id      | Displays the call detail record ID of a Lync call. |
| Client IP   | Displays the IP address of the Lync client.        |
| Client Name | Displays the user name of the Lync client.         |

| Column          | Description                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALG             | Displays the Application Layer Gateway protocol for Lync clients.                                                                                                                                                   |
| Dir             | Displays the following call direction: <ul style="list-style-type: none"> <li>• <b>OG</b> — outgoing</li> <li>• <b>IC</b> — incoming</li> </ul>                                                                     |
| Called To       | Displays the user name of the Lync client being called.                                                                                                                                                             |
| Status          | Displays the following call status: <ul style="list-style-type: none"> <li>• <b>CONNECTED</b> — active call</li> <li>• <b>SUCC</b> — successful terminated call</li> <li>• <b>ABORTED</b> — aborted call</li> </ul> |
| Dur (sec)       | Displays the time duration of the Lync call.                                                                                                                                                                        |
| Orig time       | Displays the time stamp when the Lync call originated.                                                                                                                                                              |
| MOS Value       | Displays the Mean Opinion Score of the voice call.                                                                                                                                                                  |
| Reason          | Displays the reason code for call termination.                                                                                                                                                                      |
| Codec           | Displays the voice compression protocol used for the Lync call.                                                                                                                                                     |
| Band            | Indicates the quality of the Lync call based on the following color band: <ul style="list-style-type: none"> <li>• <b>GREEN</b></li> <li>• <b>YELLOW</b></li> <li>• <b>RED</b></li> </ul>                           |
| Setup Time(sec) | Displays the time taken to establish the call.                                                                                                                                                                      |
| Re-Assoc        | Displays the number of times the client re-associated while on an active call.                                                                                                                                      |
| Initial-BSSID   | Displays the BSSID of the AP the client was connected while the call was made.                                                                                                                                      |
| Initial-ESSID   | Displays the ESSID the client was connected while the call was made.                                                                                                                                                |
| Initial-AP Name | Displays the name of the AP the client was connected while the call was made.                                                                                                                                       |
| Call Type       | Displays the type of Lync call: <ul style="list-style-type: none"> <li>• <b>Desktop-sharing</b></li> <li>• <b>Desktop-sharing conference</b></li> <li>• <b>File-transfer</b></li> <li>• <b>Video</b></li> </ul>     |

| Column    | Description                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>• <b>Voice</b></li> <li>• <b>Video conference</b></li> <li>• <b>Voice conference</b></li> </ul> |
| Src Port  | Displays the source port of the Real-Time Protocol (RTP) session or file transfer session.                                             |
| Dest Port | Displays the destination port of the RTP session or file transfer session.                                                             |
| DSCP      | Displays the DSCP value for the session.                                                                                               |
| WMM AC    | Displays the value of the Wi-Fi Multimedia Access Category. The controller sends the packet with this value.                           |

## Command History

## show app lync call-quality

```
show app lync call-quality [all]
```

### Description

This command displays the call quality information for Lync voice and video calls.

### Syntax

| Parameter | Description                                                           |
|-----------|-----------------------------------------------------------------------|
| all       | Displays call quality information for all voice and video Lync calls. |

### Example

In this example, the output is divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it appears in a single, long table.

```
(host) #show app lync call-quality
```

```
Lync Client(s) Prioritized Call Quality Reports (Only Voice & Video)
```

| Client (IP) | Client (MAC)      | Client (Name) | ALG  | Orig Time       |

| 4.130000  | GREEN | d8:c7:c8:89:51:f2 | test  | local1  | Voice     |

```
Num Records:2
```

The output of this command includes the following parameters:

| Column        | Description                                                       |
|---------------|-------------------------------------------------------------------|
| Client (IP)   | Displays the IP address of the Lync client.                       |
| Client (MAC)  | Displays the MAC address of the Lync client.                      |
| Client (Name) | Displays the user name of the Lync client.                        |
| ALG           | Displays the Application Layer Gateway protocol for Lync clients. |
| Orig Time     | Displays the time stamp when the Lync call originated.            |
| Direction     | Displays the call direction.                                      |

| Column    | Description                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>● <b>OG</b> — Outgoing</li> <li>● <b>IC</b> — Incoming</li> </ul>                                                                                                                                                                                                      |
| Called To | Displays the user name of the Lync client being called.                                                                                                                                                                                                                                                       |
| Duration  | Displays the time duration of the Lync call.                                                                                                                                                                                                                                                                  |
| Codec     | Displays the voice compression protocol used for the Lync call.                                                                                                                                                                                                                                               |
| Delay     | Displays the average delay in milli seconds.                                                                                                                                                                                                                                                                  |
| Jitter    | Displays the jitter in milli seconds.                                                                                                                                                                                                                                                                         |
| Pkt Loss  | Displays the loss of packet in percentage.                                                                                                                                                                                                                                                                    |
| MOS Value | Displays the Mean Opinion Score of the voice call.                                                                                                                                                                                                                                                            |
| Band      | Indicates the quality of the Lync call based on the following color band. <ul style="list-style-type: none"> <li>● <b>GREEN</b></li> <li>● <b>YELLOW</b></li> <li>● <b>RED</b></li> </ul>                                                                                                                     |
| BSSID     | Displays the BSSID of the AP to which the Lync client is connected.                                                                                                                                                                                                                                           |
| ESSID     | Displays the SSID of the wireless network.                                                                                                                                                                                                                                                                    |
| AP Name   | Displays the name of the access point to which the Lync client is connected.                                                                                                                                                                                                                                  |
| Call Type | Displays the type of Lync call: <ul style="list-style-type: none"> <li>● <b>Desktop-sharing</b></li> <li>● <b>Desktop-sharing conference</b></li> <li>● <b>File-transfer</b></li> <li>● <b>Video</b></li> <li>● <b>Voice</b></li> <li>● <b>Video conference</b></li> <li>● <b>Voice conference</b></li> </ul> |

## Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

## Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show app lync client-status

```
show app client-status
 active-only
 bssid <bssid_string>
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 sta <mac>
 <cr>
```

### Description

Displays details of clients that are actively using Lync. An entry is created for clients that have actively participated in voice, video, desktop-sharing or file-sharing sessions.

### Syntax

| Parameter            | Description                                               |
|----------------------|-----------------------------------------------------------|
| active-only          | Filter records based on active Lync clients               |
| bssid <bssid_string> | Filter records based on BSSID of a Lync client.           |
| essid <essid_string> | Filter records based on ESSID of Lync client.             |
| extn <extn_string>   | Filter records based on the extension of a Lync client.   |
| ip <ipaddr>          | Filter records based on the IP address of a Lync client.  |
| sta <mac>            | Filter records based on the MAC address of a Lync client. |

### Example

The output of the command in the example below displays all current Lync client statistics in the controller. The output is divided into multiple sections to better fit on the pages of this document, however, in the actual command-line interface, data appears in a single, long table.

```
(host) #show app lync client-status
```

```
Lync Client(s) Status
```

```

Client(IP) Client(MAC) Client Name Registration State

```

The output of this command includes the following parameters:

| Column             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client (IP)        | Displays the IP address of the Lync client.                                                                                                                                                                                                                                                                                                                                                                                                               |
| Client (MAC)       | Displays the MAC address of the Lync client.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Client Name        | Displays the user name of the Lync client.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Registration State | Displays the following registration state of the Lync client with Lync server: <ul style="list-style-type: none"><li>• <b>UNKNOWN:</b> The Lync client is connected to the controller. The client is yet to initiate any Lync voice, video, desktop sharing, or file transfer session.</li><li>• <b>REGISTERED:</b> The Lync client is in registered state once it makes or receives a voice, video, desktop sharing, or file transfer session.</li></ul> |
| Call Status        | Displays if the Lync client is in any of the following call status: <ul style="list-style-type: none"><li>• <b>Idle</b></li><li>• <b>In-Call</b></li></ul>                                                                                                                                                                                                                                                                                                |
| BSSID              | Displays the BSSID of the AP to which the Lync client is connected.                                                                                                                                                                                                                                                                                                                                                                                       |
| ESSID              | Displays the SSID of the wireless network to which the Lync client is connected.                                                                                                                                                                                                                                                                                                                                                                          |
| AP Name            | Displays the name of the access point to which the Lync client is connected.                                                                                                                                                                                                                                                                                                                                                                              |
| Flags              | Displays any flag for a Lync client. The list of flag abbreviations is also included as part of this command.                                                                                                                                                                                                                                                                                                                                             |

## show app lync tracebuf

show app lync tracebuf

### Description

This command displays the Lync message trace buffer for the first 256 events. Events such as establishing voice, video, desktop sharing, and file transfer are recorded.

### Syntax

No parameters.

### Example

The output is divided into multiple sections to better fit on the pages of this document, however, in the actual command-line interface, data appears in a single, long table.

```
(host) #show app lync tracebuf
```

Lync Voice Client(s) Message Trace

| Client Name | Client (MAC)      | Client (IP) | Called To |
|-------------|-------------------|-------------|-----------|
| 6000        | 9c:b7:0d:89:a5:f5 | 192.0.2.10  | 6001      |
| 6002        | 9c:b7:0d:89:ae:83 | 192.0.2.20  | 6012      |

| 46   | 7      | local1  | 33228    | 35546     | After call update |

Num of Rows:2

The output of this command includes the following parameters:

| Column       | Description                                             |
|--------------|---------------------------------------------------------|
| Client Name  | Displays the user name of the Lync client.              |
| Client (MAC) | Displays the MAC address of the Lync client.            |
| Client (IP)  | Displays the IP address of the Lync client.             |
| Called To    | Displays the user name of the Lync client being called. |
| Event Time   | Displays the time stamp when the Lync call originated.  |

| Column      | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BSSID       | Displays the BSSID of the access point to which the Lync client is connected.                                                                                                                                                                                                                                                                            |
| CAC-Status  | <p>Displays if call admission control limit is reached. The values are:</p> <ul style="list-style-type: none"> <li>● <b>PASS</b></li> <li>● <b>FAIL</b></li> <li>● <b>NA</b></li> </ul> <p><b>NOTE:</b> When the call status for the Lync client is <b>Call quality update</b>, the value of the <b>CAC-Status</b> for the Lync client is <b>NA</b>.</p> |
| Media Type  | <p>Displays the type of Lync call:</p> <ul style="list-style-type: none"> <li>● <b>Desktop-sharing</b></li> <li>● <b>File-transfer</b></li> <li>● <b>Video</b></li> <li>● <b>Voice</b></li> </ul>                                                                                                                                                        |
| DSCP        | Displays the DSCP value for the session.                                                                                                                                                                                                                                                                                                                 |
| WMM AC      | Displays the value of the Wi-Fi Multimedia Access Category. The controller sends the packet with this value.                                                                                                                                                                                                                                             |
| AP-Name     | Displays the name the access point receiving calls.                                                                                                                                                                                                                                                                                                      |
| Src Port    | Displays the source port of the Real-Time Protocol (RTP) session or file transfer session.                                                                                                                                                                                                                                                               |
| Dest Port   | Displays the destination port of the RTP session or file transfer session.                                                                                                                                                                                                                                                                               |
| Call Status | <p>Displays if the Lync client is in any one of the following call status:</p> <ul style="list-style-type: none"> <li>● <b>Start of call</b></li> <li>● <b>End of call</b></li> <li>● <b>Before call update</b></li> <li>● <b>Call quality update</b></li> <li>● <b>After call update</b></li> </ul>                                                     |

## Command History

| Version     | Description         |
|-------------|---------------------|

## show app lync traffic-control

show app lync traffic-control [<profile-name>]

### Description

This command displays the types of Lync traffic prioritized through the Lync Application Layer Gateway (ALG) QoS.

### Syntax

| Parameter    | Description                        |
|--------------|------------------------------------|
| profile-name | Lync traffic control profile name. |

### Example

The following command displays the Lync traffic control profile configuration in the controller:

```
(host) #show app lync traffic-control default
```

```
Lync Traffic-Control
```

```

```

| Parameter                  | Value   |
|----------------------------|---------|
| -----                      | -----   |
| Prioritize Voice           | Enabled |
| Prioritize Video           | Enabled |
| Prioritize Desktop-sharing | Enabled |
| Prioritize File-transfer   | Enabled |

### Command History

| Version     | Description                                       |
|-------------|---------------------------------------------------|
| ArubaOS 6.3 | Command introduced.                               |
| ArubaOS 6.4 | The <b>profile-name</b> parameter was introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show ap-group

show ap-group [<ap-group>]

### Description

Show settings for an AP group.

### Syntax

| Parameter  | Description              |
|------------|--------------------------|
| <ap-group> | The name of an AP group. |

### Usage Guidelines

Issue this command without the optional **<ap-group>** parameter to display the entire AP group list, including profile status for each profile. Include an AP group name to display detailed configuration information for that AP group profile.

### Example

This first example shows that the controller has nine configured AP groups. The **Name** column lists the names of all configured AP groups. the **Profile Status** column indicates whether the AP group is predefined. (User-defined profiles will not have an entry in the **Profile Status** column.)

```
(host) #show ap-group
AP group List

Name Profile Status
---- -
corp-office
branch-office-am
corp
corp1
Corp1-AM
Corp1-AM-Ch11
Corp1-AM-Ch6
corp1-AP85
corp1-lab

Total: 9
```

Include an AP group name to display a complete list of configuration settings for that profile. The example below shows settings for the AP group **corp1**.

```
(host) #show ap-group corp1
AP group "corp1"

Parameter Value

Virtual AP corp1-guest
Virtual AP corp1-wpa2
802.11a radio profile default
802.11g radio profile profile1-g
Wired AP profile default
```

```

Ethernet interface 0 link profile default
Ethernet interface 1 link profile default
AP system profile corp1344
VoIP Call Admission Control profile default
802.11a Traffic Management profile N/A
802.11g Traffic Management profile N/A
Regulatory Domain profile corp1344-channel-profile
SNMP profile default
RF Optimization profile handoff-aggressive
RF Event Thresholds profile default
IDS profile ids-low-setting
Mesh Radio profile default
Mesh Cluster profile N/A

```

The output of this command includes the following parameters:

| Parameter                           | Description                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------|
| Virtual AP                          | Virtual AP profile that which configures a specified WLAN.                       |
| 802.11a radio profile               | Profile that defines 802.11a radio settings for the AP group.                    |
| 802.11g radio profile               | Profile that defines 802.11g radio settings for the AP group.                    |
| Wired AP profile                    | Profile that defines wired port settings for APs assigned to the AP group.       |
| Ethernet interface 0 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| Ethernet interface 1 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| AP system profile                   | Name of the AP system profile for the AP group.                                  |
| VoIP Call Admission Control profile | Name of the AP system profile for the AP group.                                  |
| 802.11a Traffic Management profile  | Name of the 802.11a WLAN traffic management profile for the AP group.            |
| 802.11g Traffic Management profile  | Name of the 802.11g WLAN traffic management profile for the AP group.            |
| Regulatory Domain profile           | Name of the regulatory domain profile for the AP group.                          |
| SNMP profile                        | Name of the SNMP profile for the AP group.                                       |
| RF Optimization profile             | Name of the RF optimization profile for the AP group.                            |
| RF Event Thresholds profile         | Name of the RF event thresholds profile for the AP group.                        |
| IDS profile                         | IDS profile for the AP group.                                                    |

| Parameter            | Description                                    |
|----------------------|------------------------------------------------|
| Mesh Radio profile   | Mesh radio profile assigned to the AP group.   |
| Mesh Cluster profile | Mesh cluster profile assigned to the AP group. |

## Related Commands

Configure AP group settings using the command [ap-group](#).

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers |

## show ap-name

show ap-name [<ap-name>]

### Description

Show a list of AP names. Include the **<ap-name>** parameter to display detailed configuration information for that AP.

### Syntax

| Parameter | Description        |
|-----------|--------------------|
| <ap-name> | The name of an AP. |

### Example

This first example shows that the controller has eight registered APs. The **Name** column lists the names of each registered AP. Note that APs are all user-defined, so they will not have an entry in the **Profile Status** column.

```
(host) #show ap-name
AP name List

Name Profile Status
---- -
mp3
sw-ad-W-AP124-11
sw-ad-W-AP125-13sw-ad-W-AP125-15sw-ad-W-AP125-17sw-ad-W-AP125-18sw-ad-W-AP125-19sw-ad-W-AP125-3
Total: 8
```

Include an AP name to display a complete list of configuration settings for that AP. If the AP has default settings, the value may appear as N/A. The AP in the example below has all default profile settings.

```
(host) #show ap-group corp1
AP name "mp3"

Parameter Value

Virtual AP N/A
Excluded Virtual AP N/A
802.11a radio profile N/A
802.11g radio profile N/A
Wired AP profile N/A
Ethernet interface 0 link profile N/A
Ethernet interface 1 link profile N/A
AP system profile N/A
VoIP Call Admission Control profile N/A
802.11a Traffic Management profile N/A
802.11g Traffic Management profile N/A
Regulatory Domain profile N/A
RF Optimization profile N/A
RF Event Thresholds profile N/A
IDS profile N/A
Mesh Radio profile N/A
Mesh Cluster profile N/A
Excluded Mesh Cluster profile N/A
```

The output of this command includes the following parameters:

| Parameter                           | Description                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------|
| Virtual AP                          | Virtual AP profile that which configures a specified WLAN.                       |
| Excluded Virtual AP                 | Excludes the specified mesh cluster profile from this AP.                        |
| 802.11a radio profile               | Profile that defines 802.11a radio settings for the AP.                          |
| 802.11g radio profile               | Profile that defines 802.11g radio settings for the AP.                          |
| Wired AP profile                    | Profile that defines wired port settings for APs assigned to the AP.             |
| Ethernet interface 0 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| Ethernet interface 1 link profile   | Profile that defines the duplex and speed of the Ethernet 0 interface on the AP. |
| AP system profile                   | Name of the AP system profile for the AP.                                        |
| VoIP Call Admission Control profile | Name of the AP system profile for the AP.                                        |
| 802.11a Traffic Management profile  | Name of the 802.11a WLAN traffic management profile for the AP group.            |
| 802.11g Traffic Management profile  | Name of the 802.11g WLAN traffic management profile for the AP.                  |
| Regulatory Domain profile           | Name of the regulatory domain profile for the AP.                                |
| RF Optimization profile             | Name of the RF optimization profile for the AP.                                  |
| RF Event Thresholds profile         | Name of the RF event thresholds profile for the AP.                              |
| IDS profile                         | IDS profile for the AP.                                                          |
| Mesh Radio profile                  | Mesh radio profile assigned to the AP.                                           |
| Mesh Cluster profile                | Mesh cluster profile assigned to the AP.                                         |
| Excluded Mesh Cluster profile       | Excludes the specified mesh cluster profile from this AP.                        |

## show arp

show arp

### Description

Show Address Resolution Protocol (ARP) entries for the controller.

### Syntax

No parameters

### Example

This example shows configured static ARP entries for the controller.

```
(host) #show arp
Protocol Address Hardware Address Interface
Internet 10.3.129.98 00:1A:1E:C0:80:28 vlan1
Internet 10.3.129.253 00:0B:86:42:35:80 vlan1
Internet 10.3.129.250 00:1A:92:45:DB:00 vlan1
Internet 10.3.129.99 00:1A:1E:C0:1C:60 vlan65
Internet 10.3.129.96 00:1A:1E:C0:80:1E vlan65
Internet 10.3.129.254 00:0B:86:02:EE:00 vlan1
```

The output of this command includes the following parameters:

| Parameter        | Description                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol         | Protocol using ARP. Although the controller will most often use ARP to translate IP addresses to Ethernet MAC addresses, ARP may also be used for other protocols, such as Token Ring, FDDI, or IEEE 802.11, and for IP over ATM. |
| Address          | IP address of the device.                                                                                                                                                                                                         |
| Hardware Address | MAC address of the device.                                                                                                                                                                                                        |
| Interface        | Interface used to send ARP requests and replies.                                                                                                                                                                                  |

### Related Commands

Add a static Address Resolution Protocol (ARP) entry using the command [show arp](#).

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master and local controllers |

## show audit-trail

show audit-trail {<number> | login <number>}

### Description

Show the controller's audit trail log.

### Syntax

| Parameter      | Description                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------|
| <number>       | Start displaying the log output from the specified number of lines from the end of the log.              |
| login <number> | Start displaying the log output from the specified number of lines from the end of the login/logout log. |

### Example

By default, the audit trail feature is enabled for all commands in configuration mode. The example below shows the most recent ten audit log entries for the controller.

```
(host) # show audit-trail 10
Feb 5 06:13:17 cli[1239]: USER: admin has logged in from 10.240.16.118.
Feb 5 06:20:13 cli[1239]: USER: admin connected from 10.240.16.118 has logged out.
Feb 5 06:24:37 cli[1239]: USER: admin has logged in from 10.240.16.118.

## show auth-survivability

show auth-survivability

### Description

This command displays the **auth-survivability** parameters that are configured in the local controller.

### Example

```
host # show auth-survivability
Auth-Survivability: Enabled (Running)
Survival-Server Server-Cert: dot1x2k-server
Survival-Server Cache lifetime: 48 hours
```

### Command History

| Version         | Description         |
|-----------------|---------------------|
| ArubaOS 6.4.3.0 | Command introduced. |

### Platform Support

## show auth-tracebuf

show auth-tracebuf [count <1-250>] [failures] [mac <address>]

### Description

Show the trace buffer for authentication events.

### Syntax

| Parameter     | Description                                                                                |
|---------------|--------------------------------------------------------------------------------------------|
| count <1-250> | limit the output of the command to the specified number of packets.                        |
| failures      | Filter the output of this command to display only authentication failures                  |
| mac <address> | Filter the output of this command to display only information for a specified MAC address. |

### Usage Guidelines

Use the output of this command to troubleshoot 802.1X authentication errors. Include the **<address>** parameter to filter data by the MAC address of the client which is experiencing errors. This command can tell you, for example, when 802.1X authentication completed and when keys were plumbed correctly.

### Example

The example below shows the most recent ten trace buffer entries for the controller. Each row includes the following information:

```
(host) # show auth-tracebuf count 10
Auth Trace Buffer

Feb 5 08:08:29 wpa2-key2 -> 00:09:ef:05:1e:b2 00:1a:1e:97:e5:42 - 119 mic

```

Each row in the output of this table may include some or all of the following information:

- A timestamp that indicates when the entry was created.
- The type of exchange that was made.
- The direction the packet was sent.
- The source MAC address.
- The destination MAC address.
- BSSID/Server Name.
- The packet number.
- The packet length.
- Additional information (if available), e.g. username, encryption and WPA type, or reason for failure.

## show banner

show banner

### Description

Show the current login banner

### Syntax

No parameters

### Usage Guidelines

Issue this command to review the banner message that appears when you first log in to the controller's command-line or browser interfaces.

### Example

```
(host) # show banner This testlab controller is scheduled for maintenance starting Saturday night at 11 p.m.
```

### Related Commands

Configure a banner message using the command [banner motd](#).

### Command History

This command was available in ArubaOS 3.0.

### Command Information

## show branch

```
show branch
 config {mac-address <mac-address>}|{name <hostname>}
 dhcp-instance {mac-address <mac-address>}|{name <hostname>}
 running-config
```

### Description

Shows configuration and DHCP address settings on a branch controller.

### Syntax

| Parameter                                                     | Description                                                                                                                                                                                 |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| config <mac-address>                                          | Shows configuration information for the branch controller                                                                                                                                   |
| dhcp-instance<br>mac-address <mac-address><br>hostname <name> | Shows the branch controller address pool information including pool name, DHCP pool start IP address, DHCP pool mask, DHCP pool broadcast IP address, and the DHCP pool gateway IP address. |
| running-config                                                | Shows the running configuration for a branch controller.                                                                                                                                    |

### Usage Guidelines

Issue this command to display the configuration, DHCP pool information and running configuration information for a branch controller.

### Examples

This example shows a the branch config group settings applied to a branch controller.

```
(host) #show branch config mac-address 00:0b:86:f0:26:e0

model 7010

# show branch-config-group

show branch-config-group [<group-name>]

## Description

The output of this command shows configuration settings for a branch config group.

## Syntax

| Parameter    | Description                                 |
|--------------|---------------------------------------------|
| <group-name> | (Optional) Name of the branch config group. |

## Usage Guidelines

When this command includes the optional branch config group name, the output of the command shows the configuration status of that specific branch config group. If no branch config group name is specified, the output of this command displays a high-level status of all branch config groups configured on that master controller.

## Example

The following example shows the configuration status of all branch config groups on the controller.

```
(host) (config) #show branch-config-group
Branch Config Groups

Name Status Reboot-Required
---- -
branch1 Validated No
branch2 Validated No
New-Group Not Validated No
```

The output of this command displays the branch config group name, validated/not validated status, and reboot status for each branch config group.

- **Status:** A status of **Validated** indicates that the branch config group has a complete configuration that can be applied to branch controllers. (For example, a branch config group might have a status of **Not Validated** if the branch config group does not have a IP address defined for the controller or a controller VLAN interface.)
- **Reboot-Required:** This column indicates that the branch config group includes a configuration change that requires a reboot on the branch controllers using that config group.

The following example shows the configuration status of branch config group named "branch1"

```
(host) #show branch-config-group branch1
model 7005
vlan 4094
interface vlan 4094
uplink wired vlan 4094
controller-ip vlan 1
vlan 1
interface vlan 1
description "test"
operstate up
ip address internal
```

```

!
uplink wired vlan 1 priority 102
uplink enable
interface gigabitethernet "0/0/0"
bandwidth-contract app "vox" "test" downstream
!
remote-node-dhcp-pool Pool1
pool-type vlan 1
domain-name example.com
dns-server 10.1.1.91
range startip 5.5.5.16 endip 6.6.6.6 hosts 16
!
!

```

## Command History

| Release         | Modification        |

| ArubaOS 6.4.3.0 | Command introduced. |

## Command Information

| Platforms                                                                    | Licensing             | Command Mode                       |
|------------------------------------------------------------------------------|-----------------------|------------------------------------|
| Available on W-7010, W-7005, W-7024, W-7030 , and W-7200 Series controllers. | Base operating system | Enable mode on master controllers. |

## show branch-dhcp-pool

```
show branch-dhcp-pool config-group <group-name> [pool-name <pool>]
```

### Description

The output of this command shows a summary of DHCP pool information for branch controllers.

### Syntax

| Parameter                 | Description                                                                                                                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| config-group <group-name> | Name of the branch config group                                                                                                                                                                                                                             |
| pool-name <pool>          | (Optional) include the name of the DHCP pool in this command to view information only for the selected DHCP pool. If these parameters are omitted, the output of this command shows information for all DHCP pools associated with the branch config group. |

### Usage Guidelines

Each branch config group contains a branch controller DHCP address pool, which defines a range of IP addresses allocated for branch controllers at a remote site, and the VLAN to be associated with those addresses. A remote-node dhcp pool is configured in the branch controller mode.

Use the **show branch-dhcp-pool** command to view a summary of branch controller address pool information.

### Example

This example shows a summary of branch controller DHCP address pool information.

DHCP Address Pools

```

Start IP Address Mask Interface IP Address Is Active

192.168.20.2 255.255.255.252 192.168.20.1 Active
192.168.20.6 255.255.255.252 192.168.20.5 Active
```

```
Branch controller MAC Address Hostname

00:0b:86:99:d6:97 Cube-7010
00:0b:86:99:89:97 7010-234
```

```
(host) #show branch-dhcp-pool config-group it pool-name controller_ip
Pool Name : controller_ip
Vlan : 20
Start IP : 192.168.20.0
End IP : 192.168.20.16
Domain Name :
Number of Hosts : 4
```

The output of this command includes the following parameters:

| Parameter        | Description                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------|
| Pool Name        | Name of the new DHCP pool.                                                                    |
| Type             | Type of pool. This can be tunnel or vlan.                                                     |
| Start IP Address | IP addresses at the start of the branch controller's address range, in dotted-decimal format. |
| End IP Address   | IP address at the end of the branch controller's address range, in dotted-decimal format.     |
| Domain Name      | The DHCP domain name.                                                                         |
| Num Hosts        | Maximum number of hosts allocated by a branch controller using this pool.                     |

## Command History

| Release         | Modification            |
|-----------------|-------------------------|
| ArubaOS 6.0     | Command introduced.     |
| ArubaOS 6.2     | Command was deprecated. |
| ArubaOS 6.4.3.0 | Command reinstated.     |

## Command Information

| Platforms                                                   | Licensing             | Command Mode                                 |
|-------------------------------------------------------------|-----------------------|----------------------------------------------|
| Available on W-7010, W-7005, W-7024, and W-7030 controllers | Base operating system | Enable mode on master and branch controllers |

## show cellular profile

show cellular profile [<name>] | [factory]

### Description

Display the cellular profiles and profile settings.

### Syntax

| Parameter | Description                                            |
|-----------|--------------------------------------------------------|
| <name>    | Enter the name of an existing cellular profile         |
| factory   | Display a list of factory supported cellular profiles. |

### Usage Guidelines

Issue this command without the **<name>** parameter to display configuration parameters for the entire list of available cellular profiles. Include a profile name to display configuration information for that one profile.

### Example

The output of this command displays the Cellular Profile table. The example below shows eight preconfigured cellular profiles.

```
(host) #show cellular profile
```

Cellular Profile Table

| Name                       | Vend | Prod | Serial | Dialer  | Tty     | Driver | Priority |       |
|----------------------------|------|------|--------|---------|---------|--------|----------|-------|
| Modeswitch                 |      |      |        |         |         |        |          |       |
| ----                       | ---- | ---- | -----  | -----   | ---     | -----  | -----    | ----- |
| --                         |      |      |        |         |         |        |          |       |
| Novatel_U720               | 1410 | 2110 |        | evdo_us | ttyUSB0 | option | default  |       |
| Novatel_U727               | 1410 | 4100 |        | evdo_us | ttyUSB0 | option | default  |       |
| Kyocera_KPC680             | 0c88 | 180a |        | evdo_us | ttyUSB0 | option | default  |       |
| Sierra_Compass_597         | 1199 | 0023 |        | evdo_us | ttyUSB0 | sierra | default  |       |
| Pantech_UM175              | 106c | 3714 |        | evdo_us | ttyUSB1 | option | default  |       |
| Sierra_USBConn_881         | 1199 | 6856 |        | gsm_us  | ttyUSB0 | option | default  |       |
| USBConn_Mercury_C885       | 1199 | 6880 |        | gsm_us  | ttyUSB3 | option | default  |       |
| Globetrotter_Icon322       | 0af0 | d033 |        | gsm_us  | ttyHS3  | hso    | default  |       |
| Default cellular priority: |      | 100  |        |         |         |        |          |       |

The output of this command includes the following parameters:

| Parameters | Description                 |
|------------|-----------------------------|
| Name       | Name of a cellular profile. |
| Vend       | Vendor ID in hexadecimal    |

| Parameters | Description                                                                                                                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Prod       | USB product ID in hexadecimal                                                                                                                                                                                                                                  |
| Serial     | USB device serial number.                                                                                                                                                                                                                                      |
| Dialer     | Name of a dialer group profile.                                                                                                                                                                                                                                |
| TTY        | Modem TTY port.                                                                                                                                                                                                                                                |
| Driver     | One of the following cellular modem drivers: <ul style="list-style-type: none"> <li>acm: Linux ACM driver.</li> <li>hso: Option High Speed driver.</li> <li>option: Option USB data card driver (default).</li> <li>sierra: Sierra Wireless driver.</li> </ul> |
| Priority   | Displays the cellular profile priority; profiles with the default priority of 100 will display the word default in the Priority column<br>Range: 1 to 255.<br>Default: 100                                                                                     |
| Modeswitch | One of two USB device modeswitch settings: <ul style="list-style-type: none"> <li>eject: Eject the CDROM device.</li> <li>rezero: Send SCSI CDROM rezero command.</li> </ul>                                                                                   |

## Command History

Introduced in ArubaOS 3.4.

## Command Information

| Platforms  | Licensing             | Command Mode                                         |
|------------|-----------------------|------------------------------------------------------|
| 600 Series | Base operating system | Config or Enable mode on master or local controllers |

## show clock

`show clock [summer-time|timezone|append]`

### Description

Display the system clock.

### Syntax

| Parameter   | Description                                                                        |
|-------------|------------------------------------------------------------------------------------|
| summer-time | Show summer (daylight savings) time settings.                                      |
| timezone    | Show the configured timezone for the controller.                                   |
| append      | If the timestamp feature is enabled, including a timestamp in show command output. |

### Usage Guidelines

Include the optional summer-time parameter to display configured daylight savings time settings. The timezone parameter shows the current timezone, with its time offset from Greenwich Mean Time.

### Example

The output below shows the current time on the controller clock.

```
(host) # show clock Thu Feb 5 16:52:28 PST 2009
```

### Related Commands

Configure clock settings using the commands [clock append](#), [clock summer-time recurring](#), and [clock timezone](#).

### Command History

This command was available in ArubaOS 1.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show cluster-config

show cluster-config

### Description

Show the multi-master cluster configuration for the control plane security feature.

### Usage Guidelines

When you issue this command from the cluster *root*, the output of this command shows the cluster role of the controller, and the IP address of each member controller in the cluster.

When you issue this command from a cluster *member*, the output of this command shows the cluster role of the controller, and the IP address of the cluster root.

### Example

In the example below, the **Cluster Role** section in the output of this command shows that the controller on which the command was issued is the cluster root. The **Cluster IPSEC Controllers** section of the output shows the IP address of each cluster member.

```
(host) (config) #show cluster-config

Cluster Role

Root

Cluster IPSEC Controllers

Switch IP address of Cluster-Members Key

172.21.18.18 *****
172.21.18.19 *****
```

|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| <a href="#">control-plane-security</a> | Configure the control plane security profile.                                                                                                                                          | Config mode                               |
| <a href="#">cluster-member-ip</a>      | This command sets the controller as a control plane security cluster root, and specifies the IPsec key for a cluster member.                                                           | Config mode on cluster root controllers   |
| <a href="#">cluster-root-ip</a>        | This command sets the controller as a control plane security cluster member, and defines the IPsec key for communication between the cluster member and the controller's cluster root. | Config mode on cluster member controllers |

### Command History

This command was introduced in ArubaOS 5.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                              |
|---------------|-----------------------|-----------------------------------------------------------|
| All platforms | Base operating system | Enable mode on cluster member or cluster root controllers |

## show cluster-switches

show cluster-switches

### Description

Issue this command on a master controller using control plane security in a multi-master environment to show other the other controllers to which it is connected.

### Usage Guidelines

When you issue this command from the cluster root, the output of this command displays the IP address of the VLAN used by the cluster member to connect to the cluster root.

If you issue this command from a cluster member ,the output of this command displays the IP address of the VLAN used by the cluster root to connect to the cluster member.

### Example

In the example below, the **show cluster-switches** command was issued on a cluster member. The **Switch-IP** section of the output shows the IP address of a VLAN on cluster root, indicating that the cluster member can currently communicate with the cluster root. If the member controller cannot communicate with the cluster root, this table will be blank.

```
(host) (config) #show cluster-switches
```

```
SWITCH-IP CLUSTER-ROLE

172.21.18.18 ROOT
```

In this example, the **show cluster-switches** command was issued on a cluster root. The **Switch-IP** section of the output shows the IP address of a VLAN on each cluster member that can currently communicate with the cluster root.

```
(host) (config) #show cluster-switches
```

```
SWITCH-IP CLUSTER-ROLE

172.21.18.18 MEMBER
172.21.18.19 MEMBER
```

| All platforms | Base operating system | Enable mode on cluster member or cluster root controllers |

# show command-mapping

show command-mapping [reverse]

## Description

Show the mapping new commands to deprecated commands.

## Syntax

| Parameter | Description                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| reverse   | Sort the command map by deprecated command syntax. This command is useful to find the current command syntax for a deprecated command. |

## Usage Guidelines

The syntax of many commands changed after the release of ArubaOS 3.0. Use this command to display a list of current commands and their deprecated command equivalents. Include the **reverse** parameter sort the output of this table by the deprecated command syntax.

## Example

The example below shows part of the output for this command. Note that a single new command may have replaced several older commands.

```
(host) # show command-mappingCommand Map

New Command Old Command

show ap active show wlan ap
show ap arm neighbors show ap arm-neighbors
show ap arm rf-summary show am rf-summary
show ap arm scan-times show am scan-times
show ap arm state show wlan arm
show ap association show stm association
show wlan client show wlan remote-client
show wlan remote-client show stm dos-sta
show ap blacklist-clients show stm connectivity
show ap bss-table show stm state
show ap client status show rfsm coverage-holes
show ap coverage-holes show ap global-list
show ap database show sapm ap search
show wlan association-failure show ap registered
show ap debug association-failure show wlan association-failure
....
```

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show configuration

```
show configuration
diff
```

### Description

Show the saved configuration on the controller.

### Syntax

| Parameter | Description                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| diff      | Displays a list of successfully executed configuration commands since the last <b>write memory</b> . The configuration differences are cleared whenever a <b>write memory</b> is performed. |

### Usage Guidelines

Issue this command to view the entire configuration saved on the controller, including all profiles, ACLs, and interface settings.

### Example

The example below shows part of the output for this command.

```
(host) #show configuration diff
interface port-channel 6
interface port-channel 6 trusted
ids unauthorized-device-profile "default"
```

### Command History

| Release     | Modification                              |
|-------------|-------------------------------------------|
| ArubaOS 1.0 | Command introduced.                       |
| ArubaOS 6.3 | The <b>diff</b> parameter was introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show controller-ip

show controller-ip

### Description

Show controller's country and domain upgrade trail.

### Syntax

No parameters.

### Example

The output of this command shows the controller's IP address and VLAN interface ID.

```
(host) # show controller-ip

Switch IP Address: 10.168.254.221
Switch IP is configured to be Vlan Interface: 1
```

### Command History

This command was available in ArubaOS 3.4

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show controller-ipv6

show controller-ipv6

### Description

Show controller's IPv6 address and VLAN interface ID.

### Syntax

No parameters.

### Example

```
(host) # show controller-ipv6
```

```
Switch IPv6 Address: 2005:d81f:f9f0:1001::14
Switch IPv6 address is from Vlan Interface: 1
```

The output of this command shows the controller's IPv6 address and VLAN interface ID.

### Command History

This command is introduced in ArubaOS 6.1

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show control-plane-security

show control-plane-security

### Description

Show the current configuration of the control plane security profile.

### Syntax

No parameters.

### Usage Guidelines

The control plane security profile enables and disables the control plane security feature and identifies campus APs to receive security certificates. Issue this command to view current control plane security settings.

### Example

The following command shows the control plane security and auto certificate provisioning features are enabled in the control plane security profile, and that the controller will send certificates to a range of IP addresses:

```
(host)(config) #show control-plane-security
Control Plane Security Profile

Parameter Value

Control Plane Security Enabled
Auto Cert Provisioning Enabled
Auto Cert Allow All Disabled
Auto Cert Allowed Addresses 10.1.1.16 - 10.1.42.55
```

### Related Commands

| Command                                | Description                                                                                       | Mode        |
|----------------------------------------|---------------------------------------------------------------------------------------------------|-------------|
| <a href="#">control-plane-security</a> | Configure the control plane security profile by identifying APs to receive security certificates. | Config mode |

### Command History

This command was introduced in ArubaOS 5.0.

### Command Information

| Platforms     | Licensing              | Command Mode                               |
|---------------|------------------------|--------------------------------------------|
| All platforms | Base operating system. | Enable mode on master or local controllers |

## show country

show country [trail]

### Description

Show controller's country and domain upgrade trail.

### Syntax

| Parameter | Description                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------|
| trail     | Display the record showing how the switch was reconfigured for its current country domain when the controller hardware was upgraded. |

### Usage Guidelines

A controller's country code sets the regulatory domain for the radio frequencies that the APs use. This value is typically set during the controller's initial setup procedure. Use this command to determine the country code specified during setup.

### Example

The output of this command shows the controller's country, model and hardware types.

```
(host) # show country
```

```
Country:US
Model:DellW-650-US
Hardware:Restricted US
```

### Command History

This command was available in ArubaOS 1.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show cp-bwcontracts

show cp-bwcontract

### Description

Displays a list of Control Processor (CP) bandwidth contracts for whitelist ACLs.

### Syntax

No parameters.

### Example

The *CP bw contracts* table lists the contract names, the ID number assigned to each contract, and its defined traffic rate in packets per second.

```
(host) #show cp-bwcontracts
```

```
CP bw contracts

Contract Id Rate (packets/second)

cpbwc-ipv4 15785 2000
cpbwc-ipv6 15798 2000
cp-rate 15809 20
```

### Related Commands

| Command                               | Description                                                                                                          |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">cp-bandwidth-contract</a> | This command configures a bandwidth contract traffic rate which can then be associated with a whitelist session ACL. |
| <a href="#">firewall cp</a>           | This command creates a new whitelist ACL and can associate a bandwidth contract with that ACL.                       |

### Command History

| Version         | Modification                                                                                          |
|-----------------|-------------------------------------------------------------------------------------------------------|
| ArubaOS 3.4     | Command introduced.                                                                                   |
| ArubaOS 6.4.3.0 | The <b>CP bw contracts</b> table now lists the traffic rate in packets/second instead of bits/second. |

### Command Information

| Platforms     | Licensing                                | Command Mode                      |
|---------------|------------------------------------------|-----------------------------------|
| All platforms | This command requires the PEFNG license. | Config mode on master controllers |

## show cpuload

show cpuload [current]

### Description

Display the controller CPU load for application and system processes.

### Syntax

| Parameter | Description                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------|
| current   | Include this optional parameter at the request of Dell technical support to display additional CPU troubleshooting statistics. |

### Example

This example shows that the majority of the controller's CPU resources are not being used by either application (user) or system processes.

```
(host) #show cpuload
user 6.9%, system 7.7%, idle 85.4%
```

The output of this command includes the following parameters:

| Parameter | Description                                                           |
|-----------|-----------------------------------------------------------------------|
| user      | Percentage of controller CPU resources used by application processes. |
| system    | Percentage of controller CPU resources used by system processes.      |
| idle      | Percentage of unused controller CPU resources.                        |

### Command History

This command was available in ArubaOS 1.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show crypto-local ipsec-map

show crypto-local ipsec [tag <ipsec-map-name>]

### Description

Displays the current IPsec map configuration on the controller.

### Syntax

| Parameter            | Description                   |
|----------------------|-------------------------------|
| tag <ipsec-map-name> | Display a specific IPsec map. |

### Usage Guidelines

The command **show crypto-local ipsec** displays the current IPsec configuration on the controller.

### Examples

The command **show crypto-local ipsec-map** shows the default map configuration along with any specific IPsec map configurations.

```
(host) #show crypto-local ipsec-map
Crypto Map Template"sample" 5
IKE Version: 1
IKEv1 Policy: All
Security association lifetime seconds : [300 -86400]
Security association lifetime kilobytes: N/A
PFS (Y/N): N
Transform sets={ default-transform }
Peer gateway: 0.0.0.0
Interface: VLAN 0
Source network: 0.0.0.0/0.0.0.0
Destination network: 0.0.0.0/0.0.0.0
Pre-Connect (Y/N): N
Tunnel Trusted (Y/N): N
Forced NAT-T (Y/N): N
```

### Related Commands

|----------------------------------------|-------------------------------------------------------------------|-------------|
| <a href="#">crypto-local ipsec-map</a> | Use this command to configure IPsec mapping for site-to-site VPN. | Config mode |

## Command History

| Version     | Modification                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------|
| ArubaOS 3.4 | Command introduced.                                                                               |
|             |                                                                                                   |
| ArubaOS 6.1 | The output of this command displays the configured IKE version.                                   |
| ArubaOS 6.3 | The output of this command displays the <b>Security association lifetime kilobytes</b> parameter. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show crypto dp

```
show crypto dp [peer <source-ip>]
```

### Descriptions

Displays crypto data packets.

### Syntax

| Parameter        | Description                                                              |
|------------------|--------------------------------------------------------------------------|
| dp               | Shows crypto latest datapath packets. The output is sent to crypto logs. |
| peer <source-ip> | Clears crypto ISAKMP state for this IP.                                  |

### Usage Guidelines

Use this command to send crypto data packet information to the controller log files, or to clear a crypto ISAKMP state associated with a specific IP address.

### Examples

The command `show crypto dp` sends debug information to CRYPTO logs.

```
(host) # show crypto
```

Datapath debug output sent to CRYPTO logs.

### Related Commands

| Command                       | Description                                                                                                                                     | Mode                    |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <a href="#">crypto isakmp</a> | Use this command to configure Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP) | Enable and Config modes |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show crypto dynamic-map

show crypto dynamic-map [tag <dynamic-map-name>]

### Descriptions

Displays IPsec dynamic map configurations.

### Syntax

| Parameter              | Description                       |
|------------------------|-----------------------------------|
| dynamic-map            | IPsec dynamic maps configuration. |
| tag <dynamic-map-name> | A specific dynamic map.           |

### Usage Guidelines

Dynamic maps enable IPsec SA negotiations from dynamically addressed IPsec peers. Once you have defined a dynamic map, you can associate that map with the default global map using the command [crypto map global-map](#).

### Examples

The command show crypto dynamic-map shows IPsec dynamic map configuration.

```
(host) #show crypto dynamic-map
```

```
Crypto Map Template"default-dynamicmap" 10000
 IKE Version: 1
 lifetime: [300 - 86400] seconds, no volume limit
 PFS (Y/N): N
 Transform sets={ default-transform }
```

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show crypto ipsec

```
show crypto ipsec {mtu|sa[peer <peer-ip>]|transform-set [tag <transform-set-name>]}
```

### Descriptions

Displays the current IPsec configuration on the controller.

### Syntax

| Parameter                | Description                             |
|--------------------------|-----------------------------------------|
| mtu                      | IPsec maximum mtu.                      |
| sa                       | Security associations.                  |
| peer <peer-ip>           | IPsec security associations for a peer. |
| transform-set            | IPsec transform sets.                   |
| tag <transform-set-name> | A specific transform set.               |

### Usage Guidelines

The command **show crypto ipsec** displays the Maximum Transmission Unit (MTU) size allowed for network transmissions using IPsec security. It also displays the transform sets that define a specific encryption and authentication type.

### Examples

The command **show crypto transform-set** shows the settings for both preconfigured and manually configured transform sets.

```
(host) #show crypto ipsec transform-set

Transform set default-transform: { esp-3des esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-ml-transform: { esp-3des esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-boc-bm-transform: { esp-3des esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-cluster-transform: { esp-aes256 esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-1st-ikev2-transform: { esp-aes256 esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-3rd-ikev2-transform: { esp-aes128 esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-gcm256: { esp-aes256-gcm esp-null-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-gcm128: { esp-aes128-gcm esp-null-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-rap-transform: { esp-aes256 esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set default-remote-node-bm-transform: { esp-3des esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
```

```

Transform set default-aes: { esp-aes256 esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set newset: { esp-3des esp-sha-hmac }
 will negotiate = { Transport, Tunnel }
Transform set name: { esp-aes256-gcm esp-sha-hmac }
 will negotiate = { Transport, Tunnel }

```

| eap-passthrough      | Display configured IKEv2 EAP Methods.                                                                                                                                                                                                                                                            |
| groupname            | Show the IKE Aggressive group name.                                                                                                                                                                                                                                                              |
| ipsecSPI             | Show IPSEC spi hash table entries.                                                                                                                                                                                                                                                               |
| key                  | Show the IKE pre-shared keys.                                                                                                                                                                                                                                                                    |
| log ap <mac-address> | Show debugging log.                                                                                                                                                                                                                                                                              |
| packet-dump          | Show the packet dump configuration.                                                                                                                                                                                                                                                              |
| policy               | Show the following information for predefined and manually configured IKE policies: <ul style="list-style-type: none"><li>• IKE version</li><li>• encryption and hash algorithms</li><li>• authentication method</li><li>• PRF methods,</li><li>• DH group</li><li>• lifetime settings</li></ul> |
| sa                   | Show the security associations.                                                                                                                                                                                                                                                                  |
| peer <peer-ip>       | Shows crypto ISAKMP security associations for this IP.                                                                                                                                                                                                                                           |

| Parameter                  | Description                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------|
| stats                      | Show detailed IKE statistics. This information can be very useful for troubleshooting problems with ISAKMP. |
| transports                 | Show IKE Transports.                                                                                        |
| udpencap-behind-nat-device | Show the Configuration if NAT-T is enabled if controller is behind a NAT device .                           |

## Usage Guidelines

Use the show crypto isakmp command to view ISAKMP settings, statistics and policies.

## Examples

The command **show crypto isakmp stats** shows the IKE statistics.

```
(host) #show crypto isakmp stats
```

```
Default protection suite 10001
 Version 1
 encryption algorithm: 3DES - Triple Data Encryption Standard (168 bit keys)
 hash algorithm: Secure Hash Algorithm 160
 authentication method: Pre-Shared Key
 Diffie-Hellman Group: #2 (1024 bit)
 lifetime: [300 - 86400] seconds, no volume limit
Default RAP Certificate protection suite 10002
 Version 1
 encryption algorithm: AES - Advanced Encryption Standard (256 bit keys)
 hash algorithm: Secure Hash Algorithm 160
 authentication method: Rivest-Shamir-Adelman Signature
 Diffie-Hellman Group: #2 (1024 bit)
 lifetime: [300 - 86400] seconds, no volume limit
Default RAP PSK protection suite 10003
 Version 1
 encryption algorithm: AES - Advanced Encryption Standard (256 bit keys)
 hash algorithm: Secure Hash Algorithm 160
 authentication method: Pre-Shared Key
 Diffie-Hellman Group: #2 (1024 bit)
 lifetime: [300 - 86400] seconds, no volume limit
```

## show crypto-local isakmp

```
show crypto-local isakmp
 ca-certificate
 certificate-group
 disable-aggressive-mode
 dpd
 key
 server-certificate
 xauth
```

### Descriptions

This command displays Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP).

### Syntax

| Parameter               | Description                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ca-certificate          | Shows all the Certificate Authority (CA) certificate associated with VPN clients.                                                                                                              |
| certificate-group       | Shows the existing certificate groups by server certificate name and CA certificate.                                                                                                           |
| disable-aggressive-mode | Shows if aggressive-mode is enabled or disabled.                                                                                                                                               |
| dpd                     | Shows the IKE Dead Peer Detection (DPD) configuration on the local controller.                                                                                                                 |
| key                     | Shows the IKE preshared key on the local controller for site-to-site VPN. This includes keys configured by Fully Qualified Domain Name (FQDN) and local and global keys configured by address. |
| server-certificate      | Shows all the IKE server certificates used to authenticate the controller for VPN clients.                                                                                                     |
| xauth                   | Shows the IKE XAuth configuration for VPN clients.                                                                                                                                             |

### Usage Guidelines

Use the **show crypto-local isakmp** command to view IKE parameters.

### Examples

This example shows sample output for the **show crypto-local ca-certificate**, **show crypto-local dpd**, **show crypto-local key**, **show crypto-local server-certificate** and **show crypto-local xauth** commands:

```
(host) #show crypto-local isakmp ca-certificate
ISAKMP CA Certificates

CA certificate name Client-VPN # of Site-Site-Maps

```

Dell-Factory-CA        Y                    0

```
(host) #show crypto-local isakmp certificate-group
```

ISAKMP Certificate Groups

-----  
Server certificate name    CA certificate name  
-----

```
(host) #show crypto-local isakmp dpd
```

DPD is Enabled: Idle-timeout = 22 seconds, Retry-timeout = 2 seconds, Retry-attempts = 3

```
(host) #show crypto-local isakmp key
```

ISAKMP Local Pre-Shared keys configured for ANY FQDN

-----  
Key

ISAKMP Local Pre-Shared keys configured by FQDN

-----  
FQDN of the host        Key  
-----

servers.mycorp.com    \*\*\*\*\*

ISAKMP Local Pre-Shared keys configured by Address

-----  
IP address of the host    Subnet Mask Length    Key  
-----

10.4.62.10                32                        \*\*\*\*\*

ISAKMP Global Pre-Shared keys configured by Address

-----  
IP address of the host    Subnet Mask Length    Key  
-----

0.0.0.0                    0                        \*\*\*\*\*

```
(host) (config) #show crypto-local isakmp server-certificate
```

ISAKMP Server Certificates

-----  
Server certificate name                    Client-VPN    # of Site-Site-Maps  
-----

Dell-Factory-Server-Cert-Chain    RAP-only        0

```
(host) #show crypto-local isakmp xauth
```

IKE XAuth Enabled.

### Descriptions

Issue this command to show local certificate, OCSP signer or responder certificate and CRL data and statistics.

### Syntax

| Parameter              | Description                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| CRL                    | Shows the name, original filename, reference count and expiration status of all CRLs on this controller.                           |
| <CRL name> ALL         | Shows the version, signature algorithm, issuer, last update, next update, and CRL extensions and all other attributes of this CRL. |
| <CRL name> crlnumber   | Shows the number of this CRL.                                                                                                      |
| <CRL name> fingerprint | Shows the fingerprint of this CRL.                                                                                                 |
| <CRL name> hash        | Shows the hash number of this CRL.                                                                                                 |
| <CRL name> issuer      | Shows the issuer of this CRL.                                                                                                      |
| <CRL name> lastupdate  | Shows the last update (date and time) at which the returned status is known to be correct.                                         |

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <CRL name> nextupdate | Shows the next date and time (date and time) where the responder retrieves updated status information for this certificate. If this information is not present, then the responder always holds up to date status information.                                                                                                                                                                                                |
| IntermediateCA        | Shows the name, original filename, reference count and expiration status of this certificate.<br><b>NOTE:</b> IntermediateCA has the identical sub-parameters as those listed under the TrustedCA parameter in this table.                                                                                                                                                                                                    |
| OCSPResponderCert     | Shows the name, original filename, reference count and expiration status of all ocspprespondercert certificates on this controller.<br><b>NOTE:</b> OCSPResponderCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.                                                                                                                                                           |
| OCSPSignerCert        | Shows the OCSP Signer certificate.<br><b>NOTE:</b> OCSPSignerCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.                                                                                                                                                                                                                                                               |
| PublicCert            | Shows Public key information of a certificate. This certificate allows an application to identify an exact certificate.<br><b>NOTE:</b> PublicCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.                                                                                                                                                                              |
| ServerCert            | Shows Server certificate information. This certificate must contain both a public and a private key (the public and private keys must match). You can import a server certificate in either PKCS12 or x509 PEM format; the certificate is stored in x509 PEM DES encrypted format on the controller.<br><b>NOTE:</b> ServerCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table. |
| TrustedCA             | Shows trusted CA certificate information. This certificate can be either a root CA or intermediate CA. Dell encourages (but does not require) an intermediate CA's signing CA to be the controller itself.                                                                                                                                                                                                                    |
| <name> ALL            | Shows the version, signature algorithm, issuer, last update, next update, and CRL extensions and all other attributes of this certificate.                                                                                                                                                                                                                                                                                    |
| <name> alias          | Shows this certificate's alias, if it exists.                                                                                                                                                                                                                                                                                                                                                                                 |
| <name> dates          | Shows the dates for which this certificate is valid.                                                                                                                                                                                                                                                                                                                                                                          |
| <name> fingerprint    | Shows the certificate's fingerprint.                                                                                                                                                                                                                                                                                                                                                                                          |
| <name> hash           | Shows the hash number of this certificate.                                                                                                                                                                                                                                                                                                                                                                                    |
| <name> issuer         | Shows the certificate issuer.                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                      | Description                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------|
| <name> modulus                 | Shows the modulus which is part of the public key of the certificate.                       |
| <name> purpose                 | Shows the certificate's purposes such as if this is an SSL server, SSL server CA and so on. |
| <name> serial                  | Shows the certificate's serial number.                                                      |
| <name> subject                 | Shows the certificate's subject identification number.                                      |
| crl-stats                      | Shows the CRL request statistics.                                                           |
| ocsp-client-stats              | Shows the OCSP client statistics.                                                           |
| rcp                            | Shows the revocation check point.                                                           |
| service-ocsp-responder [stats] | Shows if OCSP responder service is enabled and shows statistics.                            |

## Usage Guidelines

Use the **show crypto-local pki** command to view all CRL and certificate status, OCSP client and OCSP responder status and statistics.

## Example

This example displays a list of all OCSP responder certificates on this controller.

```
(host) (config) #show crypto-local pki OCSPResponderCert
```

Certificates

-----

| Name                      | Original Filename        | Reference Count | Expired |
|---------------------------|--------------------------|-----------------|---------|
| -----                     | -----                    | -----           | -----   |
| ocspJan28                 | ocspresp-jan28.cer       | 0               | No      |
| ocspresp-standalone-feb21 | ocspresp-feb21.cer       | 0               | No      |
| ocsprespFeb02             | ocspresp-feb2.cer        | 1               | No      |
| OCSPresponder1            | ocspresponder-new1.cer   | 0               | No      |
| ocspresponder2            | subsubCA-ocsp-res-2.cer  | 0               | No      |
| OCSPresponderlatest       | ocspresponder-latest.cer | 0               | No      |

The output of this command includes the following parameters:

| Parameter         | Description                                                                               |
|-------------------|-------------------------------------------------------------------------------------------|
| Name              | Name of the OCSP responder certificate.                                                   |
| Original Filename | Name of the original certificate when it was added to the controller.                     |
| Reference Count   | Number of RCPs that reference this OCSP responder certificate, signer certificate or CRL. |

| Parameter | Description                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------|
| Expired   | Shows whether the controller has enabled or disabled client remediation with Sygate-on-demand-agent. |

This example shows the dates for which this OCSP responder certificate is valid.

```
(host) (config) #show crypto-local pki OCSPResponderCert ocsJan28 dates
notBefore=Jan 21 02:37:47 2011 GMT
notAfter=Jan 20 02:37:47 2013 GMT
```

This example displays the certificate's hash number.

```
(host) (config) #show crypto-local pki OCSPResponderCert ocsJan28 hash 91dcb1b3
```

This example shows the purpose and information about this certificate.

```
(host) (config) #show crypto-local pki OCSPResponderCert ocsJan28 purpose
Certificate purposes:For validation
SSL client : No
SSL client CA : No
SSL server : No
SSL server CA : No
Netscape SSL server : No
Netscape SSL server CA : No
S/MIME signing : No
S/MIME signing CA : No
S/MIME encryption : No
S/MIME encryption CA : No
CRL signing : No
CRL signing CA : No
Any Purpose : Yes
Any Purpose CA : Yes
OCSP helper : Yes
OCSP helper CA : No
```

This example displays the certificate's subject.

```
(host) (config) #show crypto-local pki OCSPResponderCert ocsJan28 subject
subject= /CN=WIN-T1BQQFMVDED.security1.qa.mycorp.com
```

## show crypto map

show crypto ipsec map

### Descriptions

This command displays the IPsec map configurations.

### Syntax

| Parameter | Description |
|-----------|-------------|
| map       |             |

### Usage Guidelines

Use the show crypto map command to view configuration for global, dynamic and default map configurations.

### Examples

The command **show crypto map** shows statistics for the global, dynamic and default maps.

```
(host) (config) #show crypto map
Crypto Map "GLOBAL-IKEV2-MAP" 10000 ipsec-isakmp
Crypto Map Template"default-rap-ipsecmap" 10001
IKE Version: 2
IKEv2 Policy: DEFAULT
Security association lifetime seconds : [300 -86400]
Security association lifetime kilobytes: N/A
PFS (Y/N): N
Transform sets={ default-gcm256, default-gcm128, default-rap-transform }
Crypto Map "GLOBAL-MAP" 10000 ipsec-isakmp
Crypto Map Template"default-dynamicmap" 10000
IKE Version: 1
IKEv1 Policy: All
Security association lifetime seconds : [300 -86400]
Security association lifetime kilobytes: N/A
PFS (Y/N): N
Transform sets={ default-transform, default-aes }
```

## show crypto pki

show crypto pki csr

### Descriptions

This command displays the certificate signing request (CSR) for the captive portal feature.

### Syntax

| Parameter | Description |
|-----------|-------------|
| csr       |             |

### Usage Guidelines

Use the **show crypto pki** command to view the CSR output.

### Examples

The command **show crypto pki** shows output from the **crypto pki csr** command.

```
(host) #show crypto pki csr
```

## show database

show database synchronization

### Description

Shows database synchronization status.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to show the status database synchronization status.

### Example

This example shows a database synchronization status.

```
(host) #show database synchronize
```

Last synchronization time: Not synchronized since last reboot

Periodic synchronization is enabled and runs every 25 minutes

|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| acl id <id-name>     | Displays datapath statistics associated with a specified ACL. The ACL index is found in the <b>show rights</b> command.                                                                                                                                                                                             |
| amsdu tx             | Shows datapath AMSDU TX queue statistics                                                                                                                                                                                                                                                                            |
| ap-name <ap-name>    | Name of the AP.                                                                                                                                                                                                                                                                                                     |
| ip-addr <ip-address> | IP address of the AP                                                                                                                                                                                                                                                                                                |
| application counters | Shows application counters and errors generated by applications running on a particular AP. These include stateful firewall application layer statistics.                                                                                                                                                           |
| ap-name <ap-name>    | Name of the AP.                                                                                                                                                                                                                                                                                                     |
| ip-addr <ip-address> | IP address of the AP.                                                                                                                                                                                                                                                                                               |
| bridge               | Shows bridge table entry statistics including MAC address, VLAN, assigned VLAN, Destination and flag information for an AP.                                                                                                                                                                                         |
| ap-name <ap-name>    | Name of the AP. Shows MAC address, VLAN, assigned VLANs, destination and flags information.                                                                                                                                                                                                                         |
| counters             | Shows datapath bridge table statistics such as current entries, high water mark, maximum entries, total entries, allocation failures and max link length.                                                                                                                                                           |
| ip-addr <ip-address> | IP address of the AP. Shows MAC address, VLAN, assigned VLANs, destination and flags information.                                                                                                                                                                                                                   |
| table <macaddr>      | Displays the current high, maximum, and total number of bridge table entries for the Dell controller.                                                                                                                                                                                                               |
| verbose              | Displays datapath bridge details in a tabular format.                                                                                                                                                                                                                                                               |
| bwm                  | Displays the following bandwidth management table entry statistics: <ul style="list-style-type: none"> <li>Type: Indicates whether the contract is a control plane denial-of-service contract (0), a contract configured through the bandwidth management WebUI or CLI Interfaces (1), or a contract for</li> </ul> |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| ap-name<br><ap-name> | View a bandwidth contract for a specific AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ip-addr<br><ip-addr> | View a bandwidth contract for an AP with the specified IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| table                | Display a table of all configured bandwidth contracts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| type                 | Display only bandwidth contracts of a specific type (0,1 or 2).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| compression          | Displays datapath compression statistics. By default, the combined statistics of all CPUs are shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| cp-bwm               | Displays the data path CP bandwidth management table information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| crypto counters      | Displays crypto parameter statistics including crypto, IPsec, PPTP, WEP, TKIP, AESCCM encryption and decryptions, WEP CRC, crypto hardware, XSEC, DOT1X, and L2TP information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| debug                | Displays datapath debug details. These are low-level datapath details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| dma counters         | DMA statistics are displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| eap counters         | EAP termination statistics are displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ethlinfo             | Displays IPv4 fragment table statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| memory               | Displays SOS memory statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| opcode               | Displays datapath debugging information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter               | Description                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | <b>NOTE:</b> Use this command only under the supervision of Dell technical support.                                                                                             |
| performance all         | Displays datapath debug performance statistics including the SUM/CPU, addr, and description.                                                                                    |
| <id>                    | Displays datapath performance counters by specified CPU ID display.                                                                                                             |
| counters                | Displays datapath performance counters.                                                                                                                                         |
| event-guide             | Displays : <ul style="list-style-type: none"> <li>• COP0 Events</li> <li>• L3 Cache Events</li> <li>• NAE-RX Events</li> <li>• NAE-TX Events (by register index 0-4)</li> </ul> |
| verbose                 | Displays debug performance statistics including: SUM/CPU, addr, description, value, and difference from last show.                                                              |
| dhcp                    | Datapath DHCP -related information.                                                                                                                                             |
| dpi application <appid> | Displays the Deep Packet Inspection application default ports.                                                                                                                  |
| error                   | Datapath error statistic errors.                                                                                                                                                |
| counters                | Show datapath errors including SUM, CPU, Addr and description information.                                                                                                      |
| esi table               | Displays the contents of the datapath ESI server table entries including server, IP, MAC, destination, VLAN, type, session and flag information.                                |
| exthdr                  | Displays the datapath default IPv6 Extended Header Map.                                                                                                                         |
| firewall-aggr-sess      | Displays the datapath firewall aggregated sessions table.                                                                                                                       |
| counters                | Displays the datapath aggregate session statistics.                                                                                                                             |
| fqdn                    | Displays datapath fully qualified domain name (FQDN) entries.                                                                                                                   |
| frame counters          | Displays frame statistics that are received and transmitted from the data path of the controller.<br><br>Several output fields include the following descriptions:              |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <ul style="list-style-type: none"> <li>• <b>Descr failures</b>-This is the number of times a packet descriptor was not available and the packet dropped.</li> <li>• <b>Dot1QDiscards</b>-The number of packets received on a trunk port where the VLAN presented did not match any configured on the controller and the packet dropped.</li> <li>• <b>Dot1d Discards</b>-Spanning tree is disabled and each BPDU frame is counted and dropped.</li> <li>• <b>Denied Frames</b>-Frames that are denied by the ACL's data path of the controller.</li> </ul> |
| ap-name <ap-name>    | Name of the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| destination          | Datapath tunnel and port membership.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| group                | Datapath Layer 3 groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| station              | Datapath station membership.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ip-reassembly        | Displays the contents of the IP Reassembly statistics tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Parameter              | Description                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name <ap-name>      | Name of the AP.                                                                                                                                                     |
| counters               | IP reassembly counters.                                                                                                                                             |
| ip-addr <ip-address>   | IP address of the AP                                                                                                                                                |
| ipv4                   | Displays the IPv4 contents of the IP Reassembly statistics table.                                                                                                   |
| ipv6                   | Displays the IPv6 contents of the IP Reassembly statistics table.                                                                                                   |
| ipv6-mcast             | Displays the datapath IP multicast table statistics.                                                                                                                |
| destination            | Displays the IPv6 tunnel and port membership.                                                                                                                       |
| group                  | Displays the IPv6 multicast group.                                                                                                                                  |
| station                | Displays the IPv6 station membership.                                                                                                                               |
| lag table              | Displays contents of the datapath link aggregation group (LAG) or port channel table.                                                                               |
| message-queue counters | Displays statistics of messages received by a CPU from other datapath CPUs (only CPUs that receive messages and non-zero statistics are shown).                     |
| maintenance counters   | Displays datapath maintenance statistics.                                                                                                                           |
| mobility               | Displays datapath IP mobility information.                                                                                                                          |
| discovery-table        | Displays the discovery count table that is used to keep track of per client home agent discovery.                                                                   |
| home-agent-table       | Displays the datapath HA table information.                                                                                                                         |
| mcast-table            | Displays the mobility multicast-group table that is used to flood the multicast RA traffic to the roamed clients.                                                   |
| stats                  | Displays the statistics of the datapath mobility.                                                                                                                   |
| nat                    | Displays the contents of the datapath NAT entries table. It displays NAT pools as configured in the datapath. Statistics include pool, SITP start, SIP end and DIP. |
| network ingress        | Displays ingress queue counters.                                                                                                                                    |
| ap-name <ap-name>      | Name of AP.                                                                                                                                                         |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| counters                   | Nat counters.                                                                                                                                                                                                                                                                                                                                                                                                      |
| ip-addr <ip-address>       | IP address of the AP.                                                                                                                                                                                                                                                                                                                                                                                              |
| nexthop-list               | <p>Displays the following types of information about the datapath for packets routed to next-hop devices.</p> <ul style="list-style-type: none"> <li>• SOS Dest : Unique datapath identifier for each next-hop list</li> <li>• Active IP:</li> <li>• NhIdx: Unique identifier for each next-hop list</li> <li>• NhVer: Internally generated number used to synchronize the next-hop and session tables.</li> </ul> |
| papi                       | Displays datapath papi counters including: SUM/CPU, addr, description, and value.                                                                                                                                                                                                                                                                                                                                  |
| port                       | <p>Displays the datapath port table information. This includes the port number, PVID, Ingress ACL, Egress ACL, Session ACL, and the following flags:</p> <ul style="list-style-type: none"> <li>• B: Blocked by the Spanning Tree protocol</li> <li>• L: LSG</li> <li>• M: Tunneled node</li> <li>• Q: Trunk</li> <li>• T: Trusted</li> <li>• X: xSec</li> <li>• Z: QinQ</li> </ul>                                |
| link-event                 | Displays port link up and link down event counters.                                                                                                                                                                                                                                                                                                                                                                |
| monitor                    | Displays the monitor port configuration.                                                                                                                                                                                                                                                                                                                                                                           |
| stats <slot/port>          | Displays the physical port statistics.                                                                                                                                                                                                                                                                                                                                                                             |
| status <slot/port>         | Displays the physical port status.                                                                                                                                                                                                                                                                                                                                                                                 |
| trusted                    | Displays the trusted ports.                                                                                                                                                                                                                                                                                                                                                                                        |
| tunneled-node              | Displays the tunneled node ports.                                                                                                                                                                                                                                                                                                                                                                                  |
| untrusted-vlan <slot/port> | Show if there are untrusted vlan entries for the indicated slot and port.                                                                                                                                                                                                                                                                                                                                          |
| xsec                       | Displays the xsec ports.                                                                                                                                                                                                                                                                                                                                                                                           |
| rap-bw-resv<br>ap-name     | Displays the remote AP uplink BW reservation statistics of the RAP only.                                                                                                                                                                                                                                                                                                                                           |

| Parameter                           | Description                                                                                                                                              |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| ip-addr                             |                                                                                                                                                          |
| rap-pkt-trace<br>ap-name<br>ip-addr | Displays the remote AP packet-trace statistics of the RAP only.                                                                                          |
| rap-stats<br>ap-name<br>ip-addr     | Displays the remote AP statistics of the RAP only.                                                                                                       |
| route                               | Displays datapath route table statistics.                                                                                                                |
| ap-name <ap-name>                   | Name of the AP.                                                                                                                                          |
| counters                            | Displays route table statistics such as current entries, high water mark, maximum entries, total entries, allocation failures and max link length.       |
| ip-addr <ip-address>                | IP address of the AP.                                                                                                                                    |
| ipv4                                | Displays datapath IPv4 routing table.                                                                                                                    |
| ipv6                                | Displays datapath IPv6 routing table.                                                                                                                    |
| table                               | Displays route table entries such as IP, mask, gateway, cost, VLAN and flags.                                                                            |
| verbose                             | Displays all detailed route table entries including IP, mask, gateway, cost, VLAN, flags, Internal VerNum Index.                                         |
| route-cache                         | Displays datapath route cache table statistics.                                                                                                          |
| ap-name <ap-name>                   | Name of the AP.                                                                                                                                          |
| counters                            | Displays route cache table statistics such as current entries, high water mark, maximum entries, total entries, allocation failures and max link length. |
| ip-addr <ip-address>                | Address of IP.                                                                                                                                           |
| ipv4                                | Displays datapath IPv4 route cache.                                                                                                                      |
| ipv6                                | Displays datapath IPv6 route cache.                                                                                                                      |
| table                               | Displays route cache table entries such as IP, mask, gateway, cost, VLAN and flags.                                                                      |
| verbose                             | Displays all detailed route cache table entries including IP, mask, gateway, cost, VLAN, flags, Internal VerNum Index.                                   |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| counters      | Display the current and high water mark amount of 802.11 associated wireless devices on a controller. Values output from this command represent the water-marks since the last boot of the controller. This is the same value obtainable from the Num Associations output from the <b>show stm connectivity</b> command.                                                                                                                                                                                                                                                             |
| mac <macaddr> | Hardware address, in hexadecimal format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| tcp           | Displays contents of the tcp tunnel table. This command displays all tcp tunnels that are terminated by the controller.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| app <app>     | Name of the application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| counters      | Displays the tcp tunnel statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| tunnel        | Displays the tcp tunnel table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| table         | <p>This command displays the Datapath Station Table Statistics detail. Display all associated wireless devices on the controller with their corresponding AP BSSID and VLAN ID.</p> <p>Displays the wireless device is associated with the correct encryption type (if the device is associated to an AP BSSID that has encryption enabled and verifies whether the controller is having a problem in decrypting the wireless device's frames.</p>                                                                                                                                   |
| tunnel        | <p>Displays contents of the datapath tunnel table. This command displays all the tunnels that are terminated by the controller, including Dell AP's GRE tunnels. For example, a GRE tunnel is created and terminated on the Dell controller for every SSID/BSSID configured on the Dell AP. You can filter and view the tunnel using the following options:</p> <ul style="list-style-type: none"> <li>• counters</li> <li>• encaps</li> <li>• heartbeat</li> <li>• ipv4</li> <li>• ipv6</li> <li>• station-list</li> <li>• table</li> <li>• tunnel-id</li> <li>• verbose</li> </ul> |
| counters      | Tunnel counters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter            | Description                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| heartbeat            | Displays the datapath heartbeat tunnel details.                                                                                                                                                            |
| ipv4                 | Displays the TCP tunnel table filtered on IPv4 entries.                                                                                                                                                    |
| ipv6                 | Displays the TCP tunnel table filtered on IPv6 entries.                                                                                                                                                    |
| station-list         | Displays the list of stations on the tunnel.                                                                                                                                                               |
| table                | Tunnel table statistics.                                                                                                                                                                                   |
| tunnel-group         | Displays the tunnel group, active status and members.                                                                                                                                                      |
| user                 | Displays datapath user statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users and maximum link length.                   |
| ap-name <ap-name>    | Name of AP.                                                                                                                                                                                                |
| counters             | User counters.                                                                                                                                                                                             |
| ip-addr <ip-address> | IP address of the AP.                                                                                                                                                                                      |
| ipv4                 | Displays datapath IPv4 user entries and statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users, and maximum link length. |
| ipv6                 | Displays datapath IPv6 user entries and statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users, and maximum link length. |
| table                | User table statistics.                                                                                                                                                                                     |
| utilization          | Displays the current CPU utilization of all datapath CPUs.                                                                                                                                                 |
| vlan                 | Displays VLAN table information such as VLAN memberships inside the datapath including Layer 2 tunnels which tunnel L2 traffic.                                                                            |
| ap-name <ap-name>    | Name of the AP.                                                                                                                                                                                            |
| ip-addr <ip-address> | IP address of AP.                                                                                                                                                                                          |
| table                | Displays VLAN number, flag, port and datapath VLAN multicast entries.                                                                                                                                      |
| vlan-mcast           | Displays the datapath VLAN multicast table.                                                                                                                                                                |
| ap-name <ap-name>    | Name of the AP.                                                                                                                                                                                            |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ip-addr <ip-address>     | IP address of AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| table                    | Displays datapath VLAN Multicast table entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| web-cc [counters]        | <p>Displays web content classification table information. The output of this command includes the following data columns:</p> <ul style="list-style-type: none"> <li>• <b>WebCC rep:</b> Reputation score (integer). To see the reputation type associated with that particular score, issue the command <b>show web-cc reputation</b>.</li> <li>• <b>WebCCID:</b> Web content category ID. To see the name of the category associated with that category ID, issue the command <b>show web-cc category</b>.</li> <li>• <b>WebCCU:</b> URL for that session entry.</li> </ul> <p>Include the optional <b>counters</b> parameter to display the maximum number of entries allowed in the web content category table.</p> |
| wifi-reassembly counters | Displays WiFi reassembly counters including CPU, current entries, high water-mark, maximum entries, total entries, and allocation failures.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| wmm counters             | Displays VOIP statistics, including the number of uplink and downlink resets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Usage Guidelines

Use the **show datapath** command to display various datapath statistics for debugging purposes.

## Example

The following example displays the discovery count table that keeps track of per client home agent discovery:

```
(host) #show datapath mobility discovery-table
Datapath Mobility Discovery Count Table
```

| Index | Valid | Version | Retry# | No-Response | Ack | Mac               | Vlan |
|-------|-------|---------|--------|-------------|-----|-------------------|------|
| 1     | 1     | 2       | 1      | a           | 0   | 10:78:D2:FA:7D:38 | 74   |

The following example displays the datapath HA table information:

```
(host) #show datapath mobility home-agent-table
Datapath Mobility Home Agent Table
```

```
Switch IP

10.16.19.14
10.16.19.140
```

The following example displays the mobility multicast-group table that floods the multicast RA traffic to the roaming clients:

```
(host) # show datapath mobility mcast-table
Datapath Mobility Multicast Table
```

| GRE Tunnel | HomeVlan | McastGroup | Members |
|------------|----------|------------|---------|
| 0x10009    | 501      | 0 1        |         |

The following example displays the statistics of the datapath mobility:

```
(host) #show datapath mobility stats
Datapath Mobility Stats
Mcast group entry alloc errors : 0
Frames flooded over MMG (@HA) : 0
Frames subjected to MMG (@FA) : 0
Frames sent to roamed clients : 0
HA Discovery failure to notify NACK : 0
HA Discovery invalid DCT : 0
HA Discovery DCT allocation failed : 0
HA Discovery Probes sent : 0
HA Discovery NULL bridge entry in DCT : 0
HA Discovery failed to start : 0
HA Discovery successfully started : 0
HAT insert failure : 0
HAT insert success : 0
HAT delete failure : 0
HAT delete success : 0
```

The following example displays the mobility multicast VLAN table information:

```
(host) #show ip mobile multicast-vlan-table
Mobility Multicast Vlan Table

Client MAC Home vlan Current vlan

40:2C:F4:36:16:07 501 501
```

The following example displays a list of tunnels.

```
(host) (config) #show datapath tunnel
+---+-----+-----+-----+
|SUM/| | | |

The following parameters appear in the output of the **show datapath crypto counters** command, and are useful for debugging purposes.

| Parameter              | Description                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Crypto BadNPlus        | Indicates a queue overrun in the output of the encryption circuit.                                                                                                                                                                                             |
| Crypto SendNPlusFailed | Indicates a queue overrun in the input of the encryption circuit.                                                                                                                                                                                              |
| IPSec Frag Failures    | This counter increments when the AP detects a failure to fragment a frame before or after IPsec encryption.                                                                                                                                                    |
| IPSec Invalid Length   | The inbound IPsec frame length is verified before and after decryption. If the frame length is found to be incorrect, this counter is incremented.                                                                                                             |
| IKE Rate               | When the controller firewall receives a UDP packet, it determines if the packet is destined for an IKE (500) or IPSEC_NATT (4500) port. This counter increments when the AP receives an initial IKE packet that has an 8-byte responder cookie defined all 0s. |

Example of the **show datapath compression** command output

```

+---+-----+-----+-----+-----+
|SUM/| | | | |
|CPU | Addr | Description | | Value |
+---+-----+-----+-----+-----+
	[00]	Compression Engine Present		True
	[01]	Comp Response received		150
	[02]	Comp Response failed		0
	[03]	Decomp Requests		80
	[04]	Decomp Response received		80
	[05]	Decomp Requests queued		75
G	[06]	Compression Engine Total		4
+---+-----+-----+-----+-----+

```

The following output displays the

## Command History

| Version         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ArubaOS 5.0     | The <b>tcp</b> parameter was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ArubaOS 6.1     | <p>The <b>crypto counters</b> parameter now displays a number of TKIP/AESCCM/AESGCM decriptions per priority level along with any counter errors per priority.</p> <p>The <b>ipv6</b> filter option is added to the following parameters in the command:</p> <ul style="list-style-type: none"> <li>● <b>session</b></li> <li>● <b>tunnel</b></li> <li>● <b>user</b></li> <li>● <b>route-cache</b></li> <li>● <b>route</b></li> <li>● <b>ip-reassembly</b></li> </ul> |
| ArubaOS 6.1.3.2 | The <b>debug opcode</b> parameter was introduced. Issue this command only under the supervision of Dell technical support.                                                                                                                                                                                                                                                                                                                                            |

| ArubaOS 6.4.3.0 | <p>The following changes were introduced:</p> <ul style="list-style-type: none"> <li>The <b>compression</b> parameter displays datapath compression statistics. By default, the combined statistics for all CPUs are shown.</li> <li>The output of the <b>show datapath session</b> command now supports the <b>r</b> flag, which indicates that the session was routed through a nexthop device defined by a nexthop-list. For more information, see <a href="#">ip nexthop-list</a>.</li> <li>The output of the <b>show datapath cp-bwm</b> command now displays the rate in pps.</li> </ul> |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show destination

show destination <string>

### Description

Display the aliases for default and user-defined network destinations.

### Syntax

| Parameter | Description                                                         |
|-----------|---------------------------------------------------------------------|
| string    | Optional parameter to view details of a specific destination alias. |

### Example

This example displays the network destinations configured in the controller.

```
(host) #show destination
controller

Position Type IP addr Mask/Range

1 host 10.16.15.1

user

Position Type IP addr Mask/Range

1 network 255.255.255.255 0.0.0.0

mswitch

Position Type IP addr Mask/Range

1 host 10.16.15.1

any

Position Type IP addr Mask/Range

1 network 0.0.0.0 0.0.0.0
```

The output of this command includes the following parameters:

| Parameter | Description                                  |
|-----------|----------------------------------------------|
| Position  | Displays the priority position of the alias. |
| Type      | The rule type of the destination alias.      |

| Parameter  | Description                                                                                     |
|------------|-------------------------------------------------------------------------------------------------|
| IP addr    | The IP address configured in the alias. This can be a network address, host address or a range. |
| Mask/Range | Network mark or the IP address range.                                                           |

## Command History

This command was available in ArubaOS 1.0.

Replaced with `netdestination` in 3.0.

## Command Information

| Platforms     | Licensing                                                         | Command Mode                                          |
|---------------|-------------------------------------------------------------------|-------------------------------------------------------|
| All platforms | You must have a PEFNG license to configure or view a destination. | Enable or Config mode on master and local controllers |

## show dialer group

```
show dialer group
```

### Description

Display dialer group information.

### Syntax

No parameters.

### Usage Guidelines

Displays the Dialer Group Table with the current dialing parameters.

### Example

```
(host) #show dialer group
Dialer Group Table

Name Init String Dial String
---- -
evdo_us ATQ0V1E0 ATDT#777
gsm_us AT+CGDCONT=1,"IP","ISP.CINGULAR" ATD*99#
```

### Command History

Introduced in ArubaOS 3.4.

### Command Information

| Platforms                | Licensing             | Command Mode                                |
|--------------------------|-----------------------|---------------------------------------------|
| W-600 Series controllers | Base operating system | Config mode on master and local controllers |

## show dir

```
show dir usb: disk <disk-name><filesystem-path>
```

### Description

Display the list of directories in the specified disk and the filesystem path.

### Syntax

| Parameter         | Description                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <disk-name>       | Name of the USB device. If you do not know the name of the USB disk, issue the command <b>show usb-storage</b> to view a list of device names. |
| <filesystem-path> | The USB file system path.                                                                                                                      |

### Example

The command below displays the USB directory list for a device named **SEGATE-HJ1235\_p1**.

```
(host) # (show dir usb: SEGATE-HJ1235_p1/docs
```

```
USB directory list
```

```

Permission Size Time Stamp Directory Name

drwxr-xr-x 0 May 13 09:39 samba
```

The output of this command includes the following parameters:

| Parameter      | Description                                            |
|----------------|--------------------------------------------------------|
| Permission     | Read, write and execute permissions for the directory. |
| Size           | Size of the directory.                                 |
| Time Stamp     | Date and time that the directory was last modified.    |
| Directory Name | Name of the directory on the USB device.               |

### Command History

This command was introduced in ArubaOS 3.4.

### Command Information

| Platforms                | Licensing             | Command Mode                                |
|--------------------------|-----------------------|---------------------------------------------|
| W-600 Series controllers | Base operating system | Config mode on master and local controllers |

## show dot1x ap-table

show dot1x ap-table

### Description

Shows the 802.1X AP table.

### Syntax

No parameters.

### Example

Issue this command to display details from the AP table.

```
AP Table

MAC IP Essid Type AP name Vlan Enc Stations
Forwarding-Mode Profile Acl

00:1a:1e:87:ff:c0 10.3.9.242 AP 00:1a:1e:c0:7f:fc 0 - 0
FORWARD_TUNNEL_80211 default/ 1
00:1a:1e:87:ff:d0 10.3.9.242 sw-pn-nokia AP 00:1a:1e:c0:7f:fc 0 WPA2-AES 0
FORWARD_TUNNEL_80211 default/default 1
00:1a:1e:82:ab:a0 10.3.9.220 AP monitor-124 0 - 0
FORWARD_TUNNEL_80211 default/ 1
00:1a:1e:82:ab:b0 10.3.9.220 AP monitor-124 0 - 0
FORWARD_TUNNEL_80211 default/ 1
00:1a:1e:87:ff:d1 10.3.9.242 sw-pn-t2 AP 00:1a:1e:c0:7f:fc 0 WPA2-PSK-AES 0
FORWARD_TUNNEL_80211 default/default 1
Num APs: 5
```

The output of this command includes the following parameters:

| Parameter | Description                                         |
|-----------|-----------------------------------------------------|
| MAC       | The MAC address of the AP                           |
| IP        | The IP address of the AP                            |
| Essid     | The AP's ESSID                                      |
| Type      | Device type                                         |
| AP name   | Name of the AP                                      |
| Vlan      | Number of VLANs associated with the specified AP    |
| Enc       | AP's encryption method                              |
| Stations  | Number of stations associated with the specified AP |

| Parameter       | Description                              |
|-----------------|------------------------------------------|
| Forwarding Mode | Forwarding mode used by the specified AP |
| Profile         | AP profile                               |
| Acl             | Number of ACLs this AP belongs to        |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x ap-table aes

```
show dot1x ap-table aes
```

### Description

Shows the AES keys of all APs.

### Syntax

No parameters.

### Example

Issue this command to display AES keys of all APs.

AP Table Showing AES Keys

```

AP-MAC GTK/Size/Slot

00:1a:1e:87:ff:d0 * * * * * */128-Bit/1
00:1a:1e:87:ff:d1 * * * * * */128-Bit/1
```

The output of this command includes the following parameters:

| Parameter     | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| AP-MAC        | AP MAC address                                                                |
| GTK/Size/Slot | GTK: The group temporal key<br>Size: Size of the AES key<br>Slot: Slot number |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

## show dot1x ap-table dynamic-wep

show dot1x ap-table dynamic-wep

### Description

Shows the dynamic WEP keys of all APs.

### Syntax

No parameters.

### Example

Issue this command to display dynamic keys of all APs.

```
Dynamic-WEP Key Information

AP-MAC Key1/Size/Slot Key2/Size/Slot

Num APs: 0
```

The output of this command includes the following parameters:

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| AP-MAC          | AP MAC address                                                      |
| Key1/Size/Slot  | Key1: The WEP key<br>Size: Size of the WEP key<br>Slot: Slot number |
| Key12/Size/Slot | Key2: The WEP key<br>Size: Size of the WEP key<br>Slot: Slot number |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x ap-table static-wep

show dot1x ap-table static-wep

### Description

Shows the static WEP keys of all APs.

### Syntax

No parameters.

### Example

Issue this command to display the static WEP keys of all APs.

```
Static-WEP Key Information

AP-MAC Key1/Size Key2/Size Key3/Size Key3/Size

Num APs: 0
```

The output of this command includes the following parameters:

| Parameter | Description            |
|-----------|------------------------|
| AP-MAC    | AP's MAC address       |
| Key1/Size | WEP key 1 and its size |
| Key2/Size | WEP key 2 and its size |
| Key3/Size | WEP key 3 and its size |
| Key3/Size | WEP key 3 and its size |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x ap-table tkip

```
show dot1x ap-table tkip
```

### Description

Displays a table of TKIP keys on the controller.

### Syntax

No parameters.

### Example

Issue this command to display all TKIP keys.

```
AP Table Showing TKIP Keys
```

```

AP-MAC GTK/Size/Slot

00:1a:1e:6f:e5:10 * * * * * */256-Bit/1
Num APs: 1
```

The output of this command includes the following parameters:

| Parameter     | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| AP-MAC        | AP MAC Address                                                                |
| GTK/Size/Slot | GTK: The group temporal key<br>Size: Size of the AES key<br>Slot: Slot number |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x counters

show dot1x counters

### Description

Displays a table of dot1x counters.

### Example

Issue this command to display all 802.1X counter information.

802.1x Counters

```
AP

## show dot1x supplicant-info

```
show dot1x supplicant-info <supplicant-mac> <ap-mac>
```

### Description

Shows the details about a specific supplicant.

### Example

Issue this command to display the details about a supplicant.

| ID of the last radius response    | 0                      |

The output of this command includes the following parameters:

| Parameter                     | Description                                               |
|-------------------------------|-----------------------------------------------------------|
| Name                          | Supplicant name.                                          |
| MAC Address                   | Supplicant MAC address.                                   |
| AP MAC Address                | AP MAC address.                                           |
| Status                        | Supplicant's status.                                      |
| Unicast Cipher                | Supplicant's unicast cipher.                              |
| Multicast Cipher              | Supplicant's multicast cipher.                            |
| EAP-Type                      | Supplicant's EAP-Type.                                    |
| EAPOL Starts                  | Number of EAPOL starts.                                   |
| EAP ID Requests               | Number of EAP ID requests.                                |
| EAP ID Responses              | Number of EAP ID responses.                               |
| EAPOL Logoffs from station    | Number of EAPOL logoffs from the station.                 |
| EAP pkts to the station       | Number of EAP packets sent to the station.                |
| EAP pkts from station         | Number of EAP packets sent from the station.              |
| Unknown EAP pkts from station | Number of unknown EAP packets sent from the station.      |
| EAP Successes sent            | Number of EAP successes sent.                             |
| EAP Failures sent             | Number of EAP failures sent.                              |
| Station failed to respond     | Number of times the station failed to respond.            |
| Station NAKs                  | Number of station negative-acknowledgement characters.    |
| Radius pkts to the server     | Number of radius packets set to the server.               |
| Radius pkts from the server   | Number of radius packets sent from the server.            |
| Server failed to respond      | Number of times the server failed to respond.             |
| Server rejects                | Number of times ac connection was rejected by the server. |
| WPA/WPA2-Key Message1         | Number of WPA message-1s sent.                            |

| Parameter                          | Description                             |
|------------------------------------|-----------------------------------------|
| WPA/WPA2-Key Message2              | Number of WPA message-2s sent.          |
| WPA/WPA2-Key Message3              | Number of WPA message-3s sent.          |
| WPA/WPA2-Key Message4              | Number of WPA message-4s sent.          |
| WPA-GKey Message1                  | Number of WPA group message-1s sent.    |
| WPA-GKey Message2                  | Number of WPA group message-2s sent.    |
| ID of the last EAP request         | The ID of the last EAP request.         |
| Length of the last EAP request     | The length of the last EAP request.     |
| ID of the last EAP response        | The ID of the last EAP response.        |
| Length of the last EAP response    | The length of the last EAP response.    |
| ID of the last radius request      | The ID of the last radius request.      |
| Length of the last radius request  | The length of the last radius request.  |
| ID of the last radius response     | The ID of the last radius response.     |
| Length of the last radius response | The length of the last radius response. |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x supplicant-info list-all

```
show dot1x supplicant-info list all
```

### Description

Shows all 802.1X supplicants.

### Syntax

No parameters.

### Example

Issue this command to display all 802.1X supplicants as well as additional relevant information.

```
802.1x User Information

 MAC Name Auth AP-MAC Enc-Key/Type Auth-Mode
 EAP-Type Remote

00:15:00:26:f8:f5 user1 Yes 00:0b:86:8b:68:68 * * * * * /WPA2-AES Explicit Mode
EAP-PEAP No

Station Entries: 1
```

The output of this command includes the following parameters:

| Parameter    | Description                                                                          |
|--------------|--------------------------------------------------------------------------------------|
| MAC          | Supplicant MAC address                                                               |
| Name         | Supplicant name                                                                      |
| Auth         | Shows if the supplicant authenticated successfully                                   |
| AP-MAC       | AP MAC address                                                                       |
| Enc-Key/Type | Enc-Key: Supplicant's encryption key<br>Type: Encryption type used by the supplicant |
| Auth-Mode    | Authentication mode                                                                  |
| EAP-Type     | EAP type                                                                             |
| Remote       | Is the supplicant remote                                                             |

### Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |

## show dot1x supplicant-info pmkid

```
show dot1x supplicant-info pmkid <supplicant-mac>
```

### Description

Shows the PMKIDs of the various stations on the controller.

### Syntax

No parameters.

### Example

Issue this command to display the PMKIDs of the various stations on the controller.

PMKID Table

```

Mac Name AP PMKID
--- -
00:03:7f:bf:12:ac zoobar22 00:0b:86:a0:57:60
c2:7d:12:1a:1c:5b:40:f8:89:46:22:a5:ec:9b:fb:a6
00:03:7f:bf:12:ac zoobar22 00:0b:86:c0:04:88
bb:2d:e1:57:e1:b8:9b:a2:71:f5:98:ad:61:db:47:e7
```

The output of this command includes the following parameters:

| Parameter | Description            |
|-----------|------------------------|
| MAC       | Supplicant MAC address |
| Name      | Supplicant name        |
| AP        | AP MAC address         |
| PMKID     | Station PMKID          |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |

| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x supplicant-info statistics

show dot1x supplicant-info statistics

### Description

Shows the 802.1X statistics of the users.

### Syntax

No parameters.

### Example

Issue this command to display the 802.1X statistics of the users.

```
802.1x Statistics

Mac Name AP Auth-Succs Auth-Fails Auth-Tmout Re-Auths
Supp-Naks UKeyRotations MKeyRotations
--- -

00:15:00:26:f8:f5 user1 00:0b:86:8b:68:68 1 0 0 0 0
0 0
Total: 2 0 0 0 0
0 0

Station Entries: 1
```

The output of this command includes the following parameters:

| Parameter     | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| MAC           | Supplicant MAC address.                                               |
| Name          | Supplicant name.                                                      |
| AP            | AP MAC address.                                                       |
| Auth-Succs    | Number of successful authentications.                                 |
| Auth-Fails    | Number of authentication failures.                                    |
| Auth-Tmout    | Number of authentication timeouts.                                    |
| Re-Auths      | Number of reauthentications.                                          |
| Supp-Naks     | Number of negative-acknowledgement characters sent by the supplicant. |
| UKeyRotations | Number of unicast key rotations.                                      |
| MKeyRotations | Number of multicast key rotations.                                    |

## Command History

This command was introduced in ArubaOS 3.0.

| All platforms | Base operating system | Enable or config mode on master controllers |

## show dot1x watermark

```
show dot1x watermark
 history
 table {active|pending}
```

### Description

Use this command under the guidance of Dell support to view information about the table that contains 802.1X sessions being processed.

### Syntax

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                  | Range | Default |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| history                | Displays all historical sessions in the 802.1X session queue.                                                                                                                                                                                                                                                                                | —     | —       |
| table {active pending} | Table types: <ul style="list-style-type: none"><li>• <b>active:</b> Displays all current active sessions in the 802.1X queue and the corresponding user-age.</li><li>• <b>pending:</b> Displays all pending sessions in the 802.1X queue, the duration for which the user is pending in the queue, and the corresponding user-age.</li></ul> | —     | —       |

### Command History

| Version         | Modification                               |
|-----------------|--------------------------------------------|
| ArubaOS 6.3.1.0 | Command introduced.                        |
| ArubaOS 6.4.2.4 | The <b>table</b> parameter was introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                               |

| All platforms | Base operating system | Enable mode on master or local controllers |

## show dpi

```
show dpi
application
 name
 all
 category <name>
 custom-app <name>
global-bandwidth-contract
 all
 category <name>
 custom-app <name>
```

### Description

Shows applications and application categories that are configured for deep-packet inspection. It also shows DPI global bandwidth contracts by application or application category.

### Syntax

| Parameter                 | Description                                             |
|---------------------------|---------------------------------------------------------|
| name                      | Name of the application                                 |
| all                       | Shows all applications                                  |
| category <name>           | Shows all applications within a category.               |
| custom-app <name>         | Shows all custom applications.                          |
| global-bandwidth-contract | Shows the DPI global bandwidth contracts.               |
| all                       | Shows all bandwidth contracts.                          |
| app <name>                | Shows bandwidth contracts by application name.          |
| appcategory <name>        | Shows bandwidth contracts by application category name. |

### Example

The output of the following command shows custom applications by name, ID, application category, and default ports that are configured for DPI.

```
(host) (config) #show dpi application all
Applications
```

```

Name App ID App Category Default Ports Applied

01net 948 web tcp 80 0
050plus 1123 audio-video tcp 80 443 0
0zz0 584 web tcp 80 0
10050net 1339 web tcp 80 0
10086cn 949 web tcp 80 443 0
104com 1336 web tcp 80 0
1111tw 1338 web tcp 80 0
1141a 950 web tcp 80 0
115com 951 web tcp 80 443 0
118114cn 952 web tcp 80 0
11st 1191 web tcp 80 0
```

## Related Commands

| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show esi groups

```
show esi groups [{group-name <groupname>|{ping-name <ping-name>}}]
```

### Description

Show ESI group information.

### Syntax

| Parameter                 | Description                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| group-name<br><groupname> | View the facility used when logging messages into the remote syslog server.                                                                                                           |
| ping-name <ping-name>     | Enter the name of a set of ping values to how the names of ESI groups using that set of ping attributes. Define a set of ESI ping values using the command <a href="#">esi ping</a> . |
| server                    | Show the IP address of a remote logging server.                                                                                                                                       |

### Usage Guidelines

The ESI parser is a mechanism for interpreting syslog messages from third party appliances such as anti-virus gateways. Use this command to view configured ESI server groups.

### Example

This example below displays the name of each configured ESI group, including its ping definitions and ESI server.

```
(host) #show esi groups
```

```
ESI Group Table
```

```

Name Tunnel ID Ping Flags Servers
---- -
anything 0x1042 pingset_1 C 0
cupertino 0x1043 - C 0
```

```
Flags:
```

```

| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

## show esi parser

show esi parser domains|rules|stats

### Description

Show ESI parser information.

### Syntax

| Parameter | Description                         |
|-----------|-------------------------------------|
| domains   | Show ESI parser domain information. |
| rules     | Show ESI parser rule information.   |
| stats     | Show ESI parser rule stats.         |

### Usage Guidelines

The ESI parser is a generic syslog parser on the controller that accepts syslog messages from external third-party appliances such as anti-virus gateways, content filters, and intrusion detection systems. It processes syslog messages according to user-defined rules and takes configurable actions on the corresponding system users.

ESI servers are configured into domains to which ESI syslog parser rules are applied.

Use the **show esi parser domains** command to show ESI parser domain information.

### Example

The ESI Parser Domain table in the example below shows that the controller has two ESI domains and two ESI servers.

```
(host) #show esi parser domains

ESI Parser Domain Table

Domain ESI Servers Peer Controllers

corp_domain 172.21.5.50 10.3.132.14
remote_domain 192.84.66.30

Total number of servers configured: 2
```

## show esi ping

show esi ping [ping-name <ping-name>]

### Description

Show settings for ESI ping health check attributes.

### Syntax

| Parameter             | Description                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------|
| ping-name <ping-name> | Include the optional <b>ping-name &lt;ping-name&gt;</b> parameters to display settings for one specified set of ping settings. |

### Example

This example below shows that the controller has three defined sets of ping attributes.

```
(host) #show esi groups
```

ESI Ping Table

| Name      | Frequency (sec) | Timeout (sec) | Retry Count | ID | Num Groups |   |   |   |     |
|-----------|-----------------|---------------|-------------|----|------------|---|---|---|-----|
| ping_att1 |                 | 5             | 2           |    | 2          |   | 0 | 1 |     |
| ESIping   |                 | 5             |             | 2  |            | 2 |   |   | 1 0 |
| ESIping2  |                 | 50000         |             | 2  |            | 2 |   |   | 2 2 |

The output of this command includes the following information:

| Column      | Description                                                                        |
|-------------|------------------------------------------------------------------------------------|
| Name        | Name of a group of ping settings.                                                  |
| frequency   | Specifies the ping frequency in seconds.                                           |
| timeout     | Specifies the ping timeout in seconds.                                             |
| retry-count | Specifies the ping retry count                                                     |
| ID          | ID number assigned to the ping attributes when that set of attributes was defined. |
| Num Groups  | Number of ESI groups to which this set of ping attributes is assigned.             |

## show esi servers

```
show esi servers [{group-name <groupname>|{server-name <server-name>}}]
```

### Description

Show configuration information for ESI servers.

### Syntax

| Parameter                    | Description                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------|
| group-name<br><groupname>    | Include this optional parameter to display information for all ESI servers assigned to a specific ESI group. |
| server-name<br><server-name> | Specify an ESI server name to view configuration information for just that server.                           |

### Usage Guidelines

By default, this command displays configuration settings for all ESI servers. You can include the name of an ESI group to view servers assigned to just that group, or specify a server name to view information for that server only.

### Example

This example below displays configuration details for the ESI server name **forti\_1**.

```
(host) #show esi servers server-name forti_1
```

```
ESI Server Table
```

```

```

| Name    | Trusted IP   | Untrusted IP | Trusted s/p | Untrusted s/p | Group   | Mode  | NAT Port | ID |
|---------|--------------|--------------|-------------|---------------|---------|-------|----------|----|
| ----    | -----        | -----        | -----       | -----         | -----   | ----  | -----    | -- |
| forti_1 | 10.168.173.2 | 10.168.171.3 | -/-         | -/-           | default | route | 0        | 4  |

```
Flags
```

```

```

```
U
```

```
Flags:

```

The output of this command includes the following information:

| Column        | Description                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Name          | Name of the ESI server.                                                                                                                |
| Trusted IP    | Displays the server IP address on the trusted network. As an option, you can also enable a health check on the specified address       |
| Untrusted IP  | Displays the server IP address on the untrusted network. As an option, you can also enable a health check on the specified address     |
| Trusted s/p   | Shows the slot and port connected to the trusted side of the ESI server; slot/port format.                                             |
| Untrusted s/p | Shows the slot and port connected to the untrusted side of the ESI server.                                                             |
| Group         | Name of the ESI group to which this server is assigned. If the server has not yet been assigned to a group, this column will be blank. |
| Mode          | Specifies the ESI server mode of operation: bridge, nat, or route                                                                      |
| Nat Port      | Displays the NAT destination TCP/UDP port.                                                                                             |
| ID            | ID number assigned to the server when it was first defined.                                                                            |
| Flags         | This data column displays any flags associated with this server. The flag key appears below the ESI Server Table.                      |

## show faults

show fault [history]

### Description

Display a list of faults, which are any problematic conditions of the ArubaOS software or hardware.

### Syntax

| Parameter | Description                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------|
| history   | Include this parameter to display a history of faults cleared by the controller or the operator. |

### Usage Guidelines

A controller can maintain a list of up to 100 faults. Once 100 faults have been logged, any faults arising after that are dropped. The controller maintains a history of the last 100 faults that have cleared. Every time a new fault clears clear, the oldest fault in the fault history is purged from the list.

### Example

This example below shows all active faults the controller, including the time the fault occurred, the fault ID number, and a description of the problem.

```
(host) #show faults
```

```
Active Faults
```

```

```

| Time                | Number | Description                                                                      |
|---------------------|--------|----------------------------------------------------------------------------------|
| ----                | -----  | -----                                                                            |

## show file syncing profile

show file syncing profile

### Description

This command displays the configuration the file syncing profile.

### Syntax

None.

### Usage Guidelines

Execute this command to view the file syncing profile.

### Example

The following example shows the output of **show file syncing profile**.

```
(host) #show file syncing profile
File syncing profile

Parameter Value

File syncing Enabled
sync time 30
```

### Command History

This command was introduced in ArubaOS 6.4.1.

### Command Information

| Platform                   | License                                | Command Mode                       |
|----------------------------|----------------------------------------|------------------------------------|
| Available on all platforms | Available in the base operating system | Enable mode on master controllers. |

## show fips

show fips

---

This command applies only to the FIPS version of ArubaOS.

---

### Description

Displays FIPS mode of operation status as enabled or disabled.

### Syntax

No parameters.

### Example

The output of this command shows that the FIPS mode of operation is currently enabled.

```
(host) # show fips
```

```
FIPS Settings:
```

```

```

```
Mode Enabled
```

### Command History

This command was introduced in ArubaOS-FIPS 2.4.

### Command Information

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

# show firewall

show firewall

## Description

Display a list of global firewall policies.

## Syntax

No parameters

## Example

This example below shows all firewall policies currently configured on the controller.

```
(host) (config) #show firewall
Global firewall policies
```

| Policy                                     | Action   | Rate     | Port |
|--------------------------------------------|----------|----------|------|
| -----                                      | -----    | ----     | ---- |
| Enforce TCP handshake before allowing data | Disabled |          |      |
| Prohibit RST replay attack                 | Disabled |          |      |
| Deny all IP fragments                      | Disabled |          |      |
| Prohibit IP Spoofing                       | Enabled  |          |      |
| Monitor ping attack                        | Disabled |          |      |
| Monitor TCP SYN attack                     | Disabled |          |      |
| Monitor IP sessions attack                 | Disabled |          |      |
| Deny inter user bridging                   | Disabled |          |      |
| Log all received ICMP errors               | Disabled |          |      |
| Per-packet logging                         | Disabled |          |      |
| Blacklist Grar ARP attack client           | Disabled |          |      |
| Stateful SIP Processing                    | Enabled  |          |      |

| STUN Based Traversal                        | Enabled                                        |
| Web Content Classification                  | Enabled                                        |
| Web Content Cache Miss Drop                 | Disabled                                       |
| Stateful ICMP Processing                    | Disabled                                       |
| Optimize Duplicate Address Detection frames | Enabled                                        |

The output of this command includes the following information:

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enforce TCP handshake before allowing data | If enabled, this feature prevents data from passing between two clients until the three-way TCP handshake has been performed. This option should be disabled when you have mobile clients on the network as enabling this option will cause mobility to fail. You can enable this option if there are no mobile clients on the network. |
| Prohibit RST replay attack                 | If enabled, this setting closes a TCP connection in both directions if a TCP RST is received from either direction.                                                                                                                                                                                                                     |
| Deny all IP Fragments                      | If enabled, all IP fragments are dropped.                                                                                                                                                                                                                                                                                               |
| Prohibit IP Spoofing                       | When this option is enabled, source and destination IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.                                                                                                                                                                                 |
| Monitor ping attack                        | If enabled, the controller monitors the number of ICMP pings per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack.                                                                                                                                                    |
| Monitor TCP SYN attack                     | If enabled, the controller monitors the number of TCP SYN messages per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack.                                                                                                                                              |
| Monitor IP sessions attack                 | If enabled, the controller monitors the number of TCP sessions requests per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack sessions.                                                                                                                                |

| Parameter                        | Description                                                                                                                                                                                                                              |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deny inter user bridging         | If enabled this setting prevents the forwarding of Layer-2 traffic between wired or wireless users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic. |
| Log all received ICMP errors     | Shows if the controller will log received ICMP errors.                                                                                                                                                                                   |
| Per-packet logging               | If active, and logging is enabled for the corresponding session rule, this feature logs every packet.                                                                                                                                    |
| Blacklist Grat ARP attack client | If enabled, blacklist clients exceeding the Gratuitous ARP attack rate.                                                                                                                                                                  |
| Stateful SIP Processing          | Shows if the controller has enabled or disabled monitoring of exchanges between a voice over IP or voice over WLAN device and a SIP server. This option should be enabled only when there is no VoIP or VoWLAN traffic on the network    |
| Allow tri-session with DNAT      | Shows if the controller allows three-way session when performing destination NAT.                                                                                                                                                        |
| Disable FTP server               | If active, this feature disables the FTP server on the controller.                                                                                                                                                                       |
| Blacklist ARP attack client      | If enabled, blacklist clients exceeding the ARP attack rate.                                                                                                                                                                             |
| Monitor ARP attack               | Shows the status of the ARP attack monitor.                                                                                                                                                                                              |
| Monitor Gratuitous ARP attack    | Shows the status of the Gratuitous ARP attack monitor.                                                                                                                                                                                   |
| GRE call id processing           | If active the controller creates a unique state for each PPTP tunnel.                                                                                                                                                                    |
| Session Idle Timeout             | Shows if a session idle timeout interval has been defined.                                                                                                                                                                               |
| WMM content enforcement          | If traffic to or from the user is inconsistent with the associated QoS policy for voice, this feature reclassifies traffic to best effort and data path counters are incremented.                                                        |
| Session VOIP Timeout             | If enabled, a idle session timeout is defined for sessions that are marked as voice sessions.                                                                                                                                            |

| Parameter                                  | Description                                                                                                                                                                                                 |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stateful H.323 Processing                  | Shows if the controller has enabled or disabled stateful H.323 processing.                                                                                                                                  |
| Stateful SCCP Processing                   | Shows if the controller has enabled or disabled stateful SCCP processing.                                                                                                                                   |
| Only allow local subnets in user table     | If enabled, the controller only adds IP addresses which belong to a local subnet to the user table.                                                                                                         |
| Monitor/police CP attacks                  | If enabled, the controller monitors a misbehaving user's inbound traffic rate. If this rate is exceeded, the controller can register a denial of service attack.                                            |
| Rate limit CP untrusted ucast traffic      | Shows the inbound traffic rate                                                                                                                                                                              |
| Rate limit CP untrusted mcast traffic      | Displays the untrusted multicast traffic rate limit.                                                                                                                                                        |
| Rate limit CP trusted ucast traffic        | Displays the trusted unicast traffic rate limit.                                                                                                                                                            |
| Rate limit CP trusted mcast traffic        | Displays the trusted multicast traffic rate limit.                                                                                                                                                          |
| Rate limit CP route traffic                | Displays the traffic rate limit for traffic that needs generated ARP requests.                                                                                                                              |
| Rate limit CP session mirror traffic       | Displays the traffic rate limit for session mirrored traffic forwarded to the controller.                                                                                                                   |
| Rate limit CP auth process traffic         | Displays the traffic rate limit for traffic forwarded to the authentication process.                                                                                                                        |
| Deny inter user traffic                    | If enabled, this setting disables traffic between all untrusted users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic. |
| Prohibit ARP Spoofing                      | When this option is enabled, possible arp spoofing attacks are logged and an SNMP trap is sent.                                                                                                             |
| Stateful VOCERA Processing                 | VOCERA processing is disabled by default.                                                                                                                                                                   |
| Stateful UA Processing                     | UA processing is disabled by default.                                                                                                                                                                       |
| Enforce bw contracts for broadcast traffic | If enabled, bw contracts are applied to local subnet broadcast traffic.                                                                                                                                     |

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multicast automatic shaping  | If enabled, enables multicast optimization and provides excellent streaming quality regardless of the amount of VLANs or IP IGMP groups that are used.                                                                                                                                                                                                                                   |
| Stall Detection              | If enabled, triggers datapath crash on stall detection. Applies to the to W-7200 Series controllers only.                                                                                                                                                                                                                                                                                |
| Enforce TCP Sequence numbers | If enabled, prevents data from passing between two clients until the three-way TCP handshake has been performed.                                                                                                                                                                                                                                                                         |
| AMSDU Rx                     | Aggregated Medium Access Control Service Data Units (AMSDU) packets are dropped if this option is enabled.                                                                                                                                                                                                                                                                               |
| Jumbo Frames                 | If enabled, supports up to 9216 bytes of payload on the controller.                                                                                                                                                                                                                                                                                                                      |
| Session-tunnel FIB           | Enables session tunnel based forwarding.                                                                                                                                                                                                                                                                                                                                                 |
| Prevent DHCP Exhaustion      | If enabled, this option checks for DHCP client hardware address against the packet source MAC address. This command checks the frame's source-MAC against the DHCPv4 client hardware address and drops the packet if it does not match. This feature prevents a client from submitting multiple DHCP requests with different hardware addresses, thereby preventing DHCP pool depletion. |
| Stateful SIPS Processing     | If disabled, disables monitoring of exchanges between a voice over IP or voice over WLAN device and a SIP server. This option should be enabled only when there is no VoIP or VoWLAN traffic on the network.                                                                                                                                                                             |
| Deny Source Routing          | If enabled, forwarding of IP frames with source routing with the source routing options set is disallowed.                                                                                                                                                                                                                                                                               |
| Immediate Freeback           | If enabled, immediately frees buffers on W-7200 controllers. Do not enable this option unless instructed to do so by a technical support representative.                                                                                                                                                                                                                                 |
| DPI Classification           | If enabled, performs deep packet inspection.                                                                                                                                                                                                                                                                                                                                             |
| STUN Based Traversal         | If enabled, allows STUN- based firewall traversal.                                                                                                                                                                                                                                                                                                                                       |
| Web Content Classification   | If enabled, allows web content classification for all HTTP traffic.                                                                                                                                                                                                                                                                                                                      |

| Parameter                                   | Description                                                                                                                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                             | Default: disabled                                                                                                                                                                                     |
| Web Content Cache Miss Drop                 | <p>If enabled, allows the controller to drop any packets that do not match any web content category or reputation levels in the controller's internal web content cache.</p> <p>Default: disabled</p> |
| Stateful ICMP Processing                    | <p>Process stateful inspection of ICMP packets.</p> <p>Default: disabled</p>                                                                                                                          |
| Optimize Duplicate Address Detection frames | <p>Reduce flooding of IPv4 Gratuitous ARPs/IPv6 Duplicate Address Detection (DAD) frames onto wireless clients.</p> <p>Default: enabled</p>                                                           |

## Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers |

## show firewall-cp

show firewall-cp [internal]

### Description

Displays the captive-portal (CP) firewall policies on the controller.

### Syntax

No Parameters

### Example

The output of this command shows the CP firewall policies.

```
(host) #show firewall-cp

CP firewall policies

IP Version Source IP Source Mask Protocol Start Port End Port Permit/Deny hits
contract

ipv4 any 2.2.2.2 6 21 21 Permit 0 test
ipv4 10.10.10.10 2.2.2.2 6 8 9 Permit 0
ipv4 2:2:2:2::2 1 1 1 2 Permit 0
```

### Command History

| Release     | Modification                               |
|-------------|--------------------------------------------|
| ArubaOS 3.4 | Command introduced.                        |
| ArubaOS6.2  | The <b>IP Version</b> parameter was added. |

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show firewall-visibility

```
show firewall-visibility {debug|status}
```

### Description

Displays the policy enforcement firewall visibility process state and status information.

### Syntax

| Parameter | Description                                                           |
|-----------|-----------------------------------------------------------------------|
| debug     | Displays process state information for debugging firewall visibility. |
| status    | Displays the status of firewall visibility as enabled or disabled.    |

### Example

The output of this command shows the status of firewall visibility.

```
(host) #show firewall-visibility status
```

```
enabled
```

### Command History

This command is introduced in ArubaOS 6.2.

### Command Information

| Platforms                                                     | Licensing                               | Command Mode                                        |
|---------------------------------------------------------------|-----------------------------------------|-----------------------------------------------------|
| W-3200, W-3400, W-3600, W-6000M3, and 7200 Series controllers | This command requires the PEFNG license | Config or Enable mode on master or local controller |

## show flush-r1-on-new-r0

ap•flush-r1-on-new-r0 {enable|disable}

### Description

Use this command to view the status of flushing r1 keys on new r0.

### Syntax

No parameters.

### Example

The following example displays the status of flushing r1 keys on new r0:

```
(host) (config) #show flush-r1-on-new-r0
Fast Roaming flush-r1-on-new-r0:enable
```

### Command History

```

The output of this command includes the following information:

| Column        | Description                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP            | The IP address of the local management switch (LMS).                                                                                                            |
| Master Cookie | The cookie information on the master controller that is used to communicate with the LMS.                                                                       |
| Master Seq    | The sequence number used by the master controller to sync up with the LMS. This tracks the number of times the master controller has communicated with the LMS. |
| LMS Cookies   | The cookie information on the LMS that is used to communicate with the master controller.                                                                       |
| LMS Seq       | The sequence number used by the LMS to sync up with the master controller. This                                                                                 |

| Column            | Description                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | tracks the number of times the LMS has communicated with the master controller.                                                                                              |
| Activity          | The time at which the last activity happened on the LMS.                                                                                                                     |
| Status            | Indicates if the status of the LMS is up or down.                                                                                                                            |
| Msg in Prog       | Indicates if an active communication is happening between the LMS and the master controller. It can be Yes or No. If it is yes, then the Msg Len and Attempt fields are set. |
| Msg Len           | The length of the message that the master controller is syncing with the LMS.                                                                                                |
| Attempts          | Number of times the master controller has attempted to sync with the LMS.                                                                                                    |
| Last Reset Reason | Indicates the reason for last reset.                                                                                                                                         |

## Command History

This command is introduced in Dell Networking W-Series ArubaOS 6.4.x.

## Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master controllers. |

# show gateway health-check

show gateway health-check

## Description

Display the current status of the gateway health-check feature.

## Syntax

No parameters.

## Usage Guidelines

The gateway health check feature can only be enabled by Dell Technical Support.

## Example

This example below shows that the gateway health-check feature has not been enabled on the controller.

```
(host) #show gateway health-check
Gateway health check not enabled
```

## show global-user-table count

```
show global-user-table count
 [current-switch] <IP address>
 [authentication-method] {dot1x | mac | stateful-dot1x | vpn | web}
 [role] <role name>
 [bssid] <bssid MAC>
 [essid] <essid>
 [ap-name] <AP name>
 [phy-type] {a | b | g}
 [age] <starting time dd:hh:mm> <ending time dd:hh:mm>
```

### Description

This command displays a count of global user based on the specified criteria.

### Syntax

| Parameter             | Description                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|
| current-switch        | Match IP address of the switch where the user is currently associated                                           |
| authentication-method | Count users matching the specified authentication method                                                        |
| role                  | Count users matching the specified role                                                                         |
| bssid                 | Count users matching the specified BSSID                                                                        |
| essid                 | Count users matching the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks. |
| ap-name               | Count users matching the specified AP name                                                                      |
| phy-type              | Count users matching the specified Phy type                                                                     |
| age                   | Count users matching the specified age                                                                          |

### Example

Issue this command to display a global user count. The output shown below is a result of the command **show global-user-table count current-switch <ip-address>**.

Complete results.

The number of global users : 2

The output includes the following parameters:

| Parameter                   | Description                                                  |
|-----------------------------|--------------------------------------------------------------|
| The number of global users: | Total number of global users meeting the specified criteria. |

## Command History

| rows      | Number of rows to show                                                        |
| sort      | Sort the list based on a specified criteria, in ascending or descending order |
| start     | Show user table starting from a specific row                                  |

## Example

Issue this command to display a global user count. The output of this command is split into two tables in this document, however it appears in one table in the CLI.

```
(host) (config) show user role employee
Global Users
```

```

 IP MAC Name Role Age (d:h:m) Auth VPN link AP

## show guest-access-email

show guest-access-email

### Description

This command shows a guest access email profile configuration. The guest access email process sends email to either the guest or the sponsor whenever a guest user account is created or when the Guest Provisioning user manually sends email from the Guest Provisioning page.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to show the current guest access email profile parameters. The Parameter and Value columns show the configured SMTP server and SMTP ports. that process guest email.

```
(host) #show guest-access-email
```

```
Guest-access Email Profile
```

```

Parameter Value

SMTP Server 10.1.1.4
SMTP Port 25
```

## show ha ap

```
show ha ap
 information {ip-addr <ip-addr>|ip6-addr <ip6-addr>}
 table
```

### Description

This command displays information about APs using the High Availability feature.

### Syntax

| Parameter                                               | Description                                                                                                           |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| information<br>ip-addr <ip-addr><br>ip6-addr <ip6-addr> | Issue this command under the supervision of Dell support to troubleshoot the High Availability feature.               |
| table                                                   | Display the High Availability AP table to view information about APs configured to use the High Availability feature. |

### Usage Guidelines

The High Availability features work across Layer-3 networks, so there is no need for a direct Layer-2 connection between in a high-availability group. When the AP first connects to its active, the active provides the IP address of a standby, and the AP attempts to establish a tunnel to the standby. If an AP fails to connect to the first standby, the active will select a new standby for that AP, and the AP will attempt to connect to that standby.

An AP will failover to its backup if it fails to contact its active through regular heartbeats and keepalive messages, or if the user manually triggers a failover using the WebUI or CLI.

### Examples

The following command displays the HA table for the HA group **default**.

```
(host) #show ha ap table
HA AP Table

AP IP-Address MAC-Address AP-flags HA-flags
-- -
ard 10.3.31.245 6c:f3:7f:c6:72:c0 LU

kalap105-2 10.3.31.253 00:24:6c:c0:22:6b LU S
Total Num APs::3
Active APs::2
Standby APs::1
AP Flags: R=RAP; S=Standby; s=Bridge Split VAP L=Licensed; M=Mesh, U=Up
HA Flags: S=Standby, C=Standby connected, L=LMS, F=Sent Failover Request to AP,
H=AP flagged for Inter Controller Heartbeat
```

### Command History

Introduced in ArubaOS 6.4

## Command Information

| Platform                   | License                                 | Command Mode                                 |
|----------------------------|-----------------------------------------|----------------------------------------------|
| Available on all platforms | Available in the base operating system. | Enable mode on master and local controllers. |

## show ha group

```
show ha
 group-membership
 group-profile [<profile>]
```

### Description

This command displays High Availability profile settings and shows the high availability group to which the controller is currently assigned.

### Syntax

| Parameter                  | Description                                                                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| group-membership <profile> | Name of the high availability group to which the controller should be a member.                                                                          |
| group-profile [<profile>]  | Display a list of all high availability groups, or include the optional <profile> parameter to display configuration settings for the specified profile. |

### Usage Guidelines

The High Availability feature supports redundancy models with an active controller pair, or an active/standby deployment model with one backup controller supporting one or more active controllers. Each of these clusters of active and backup controllers comprises a high-availability group. Note that all active and backup controllers within a single high-availability group must be deployed in a single master-local topology. The High Availability feature works across Layer-3 networks, so there is no need for a direct Layer-2 connection between controllers in a high-availability group.

### Examples

The following command shows that the controller from which the command was issued is a member of the high availability group ha-group2.

```
(host) #show ha-group-member
Member of HA group :ha-group2
```

The example below shows that the controller has two configured high availability group profiles. The **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
HA group information List

Name Profile Status
---- -
default
new
Total:2
```

### Command History

Introduced in ArubaOS 6.3

|----------------------------|-----------------------------------------|----------------------------------------------|
| Available on all platforms | Available in the base operating system. | Enable mode on master and local controllers. |

## show ha heartbeat counters

show ha heartbeat counters

### Description

This command displays statistics for the High Availability extended controller capacity feature.

### Syntax

No parameters.

### Usage Guidelines

The high availability inter-controller heartbeat feature allows for faster AP failover from an active controller to a standby controller, especially in situations where the active controller reboots or loses connectivity to the network.

The inter-controller heartbeat feature works independently from the AP mechanism that sends heartbeats from the AP to the controller. If enabled, the inter-controller heartbeat feature supersedes the AP's heartbeat to its controller. As a result, if a standby controller detects missed inter-controller heartbeats from the active controller, it triggers its standby APs to failover to the standby controller, *even if those APs have not detected any missed heartbeats between the APs and their active controller*. Use this feature with caution in deployments where the active and standby controllers are separated over high-latency WAN links.

When this feature is enabled, the standby controller starts sending regular heartbeats to an AP's active controller as soon as the AP has an UP status on the standby controller. By default, the standby controller sends heartbeat messages every 100ms. If the active controller becomes unreachable for the number of heartbeats defined by the heartbeat threshold (by default, 5 missed heartbeats), the standby controller immediately detects this error, and informs the APs using the standby controller to fail over from the active controller to the standby controller.

This feature is disabled by default. It can be used in conjunction with the high availability state synchronization feature only in topologies that use a single active and standby controller, or a pair dual-mode active controllers that act as standby controllers for each other. High availability inter-controller heartbeats can be enabled and configured in the high-availability group profile using the WebUI or Command-Line interfaces.

### Examples

The following command displays high-availability heartbeat statistics for the high availability group **default**.

```
(host) (HA group information "default") #show ha heartbeat counters
```

```
Heartbeat stats
```

```

Controller IP Active Reference Count Total Heartbeat Sent Total Heartbeat Received

172.14.0.2 1 101 101
```

```
Last Missed Heartbeat (Count) Time
```

```

0
```

The output of this command includes the following parameters:

| Parameter     | Description                                                      |
|---------------|------------------------------------------------------------------|
| Controller IP | IP address of the controller from which this command was issued. |

| Parameter                          | Description                                                                                                                  |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Active Reference Count             | Number of APs that are using that standby controller as their active controller.                                             |
| Total HeartBeat Sent               | Total number of heartbeats sent by the controller.                                                                           |
| Total Heartbeat REceived           | Total number of heartbeats received by the controller.                                                                       |
| Last Missed Heartbeat (count) time | Timestamp showing when the last heartbeat sent was not received, as well as the number of heartbeats that failed to be sent. |

# show ha oversubscription statistics

show ha oversubscription statistics

## Description

This command displays statistics for the High Availability extended controller capacity feature

## Syntax

No parameters.

## Usage Guidelines

Starting with ArubaOS 6.4.0.0, a W-7200 Series controller acting as a standby controller can oversubscribe to standby APs by up to four times that controller's rated AP capacity, and a standby W-6000M3 controller module or W-3600 controller can oversubscribe by up to two times its rated AP capacity, as long as the tunnels consumed the standby APs do not exceed the maximum tunnel capacity for that standby controller.

## Feature Requirements

All controllers using this feature must be deployed in a master-local topology where centralized licensing is enabled on the active and standby controllers. If centralized licensing is disabled, the standby AP oversubscription feature are disabled also. Standby controller oversubscription and the high availability state synchronization features are mutually incompatible cannot be enabled simultaneously. If your deployment uses the state synchronization feature, you must disable it before you enable standby controller oversubscription.

W-3200, W-3400 and W-600 Series controllers do not support this feature.

## Standby Controller Capacity

The following table describes the AP oversubscription capacity maximum supported tunnels and for controllers that support this feature.

| Controller Model | Standby AP Capacity  | Maximum Tunnels Supported |
|------------------|----------------------|---------------------------|
| W-6000M3         | 2x rated AP capacity | 16384 tunnels             |
| W-3600           | 2x rated AP capacity | 16384 tunnels             |
| W-7210           | 4x rated AP capacity | 16384 tunnels             |
| W-7220           | 4x rated AP capacity | 32768 tunnels             |
| W-7240           | 4x rated AP capacity | 65536 tunnels             |

To determine the number of standby tunnels consumed by APs on each active controller, multiply the number of APs on the active controllers by the number of BSSIDs per AP. As an example, consider a deployment with four active W-7210 controllers that each have 512 APs with 8 BSSIDs. The APs on each active controller consume (512 \* 8) tunnels, for a combined total of 16,384 tunnels. A single W-7210 controller using the standby controller oversubscription feature can act as the standby controller for all four active controllers in

this example, because this topology is within the the 4x rated AP capacity limit and maximum tunnel limit for the a W-7210 controller model.

If the network administrator later changed all the APs in this deployment to support 10 BSSIDs, each active controller would use (512 \* 10) tunnels, for a combined total of 20,480 tunnels on the four active controllers. The tunnels required by the APs on the active controllers would then exceed the maximum tunnel limit for the standby controller, so the standby controller can no longer support all APs on the active controllers.

## AP Failover

If a standby controller reaches its AP oversubscription capacity or exceeds its maximum BSSID limit, the standby controller drops any subsequent standby AP connections. A dropped AP attempts to reconnect to the standby controller, but after it exceeds the maximum number of request retries, the AP informs the active controller that it is unable to connect to the standby controller. The active controller then prompts the AP to create a standby tunnel to another standby controller, if one is configured.

If an active controller fails, the APs on the active controller fail over to the standby controller. Once the standby controller has reached its capacity for active APs, it terminates tunnels to any standby APs that controller can no longer serve. When these APs detect that there is no longer a heartbeat between the AP and the standby controller, they notify their active controller that they can no longer connect to the standby. The active controller then prompts the APs to establish standby tunnels to another standby controller, if one is configured.

## Examples

The following command displays oversubscription statistics for APs and tunnels

```
(host) #show ha oversubscription statistics
Platform oversubscription factor : 4
APs Limits

APs Number
---- -
Platform Limit 512
Current Active 2
Current Standby 694
Active remaining 0
Standby remaining 1
Maximum allowed Standby 697

BSS Limits

Tunnels Limits

Maximum BSS tunnels 16384
Average BSS/AP 23
BSS tunnels in use 16360
BSS tunnels available 24
```

The output of this command includes the following parameters:

| Parameter       | Description                                                                    |
|-----------------|--------------------------------------------------------------------------------|
| Platform limit  | Maximum number of APs supported by the controller platform.                    |
| Current Active  | Number of active APs currently associated to the controller.                   |
| Current Standby | Number of APs that are currently using the controller as a standby controller. |

| Parameter               | Description                                                                            |
|-------------------------|----------------------------------------------------------------------------------------|
| Active Remaining        | Number of APs that can connect to this controller in Active mode.                      |
| Standby Remaining       | Number of APs that can connect to this controller in Standby mode.                     |
| Maximum allowed Standby | Maximum number of Standby APs supported by the controller.                             |
| Maximum BSS tunnels     | The maximum number of BSS tunnels supported by the controller.                         |
| Average BSS/AP          | The average number of BSS tunnels per AP using the controller as a standby controller. |
| BSS tunnels in use      | Number of BSS tunnels currently in use by the controller.                              |
| BSS tunnels available   | Number of BSS tunnels not currently in use by the controller.                          |

## show iap detailed-table

```
show iap detailed-table
 branch-key <brkey>
 long
```

### Description

Displays the details of all the branches terminating at the controller.

### Syntax

| Parameter          | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| branch-key <brkey> | Key for the branch, which is unique to each branch.                 |
| long               | Displays the branches connected to the controller in detailed view. |

### Example

This example shows the details of the branches connected to the controller:

```
(host) #show iap detailed-table long
```

| Name             | VC MAC Address    | Status | Inner IP | Key                                                |
|------------------|-------------------|--------|----------|----------------------------------------------------|
| Instant-C0:8C:08 | d8:c7:c8:c4:73:53 | UP     | 1.1.1.1  | 2d15576901190269568c3d9837fc1b414e1b06523282805aaa |
| Instant-C0:8C:08 | d8:c7:c8:c4:73:53 | UP     | 1.1.1.1  | 2d15576901190269568c3d9837fc1b414e1b06523282805aaa |
| Instant-C0:8C:08 | d8:c7:c8:c4:73:53 | UP     | 1.1.1.1  | 2d15576901190269568c3d9837fc1b414e1b06523282805aaa |

| Flags | Branch (Subnet / Vlan) | BID | IP Address Range    | Client Count |
|-------|------------------------|-----|---------------------|--------------|
| PD2   | 52                     | 0   | 52.1.1.2-52.1.1.100 | 5            |
| PD3   | 53.1.1.8/29            | 0   | 53.1.1.1-53.1.1.100 | 5            |
| PC2   | 51                     | 0   |                     |              |

Flags: P = Primary Tunnel; B = Backup Tunnel; C = Centralized; U = Unassigned;  
D = Distributed; L = Local; 3 = Routed(L3); 2 = Bridged(L2);

The output of this command includes the following parameters:

| Parameter      | Description                                         |
|----------------|-----------------------------------------------------|
| Name           | Name of the branch                                  |
| VC MAC Address | MAC address of the Virtual Controller of the branch |
| Status         | Current status of the branch (UP/DOWN)              |
| Inner IP       | Internal VPN IP of the branch                       |

| Parameter            | Description                                                                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Key                  | Key for the branch, which is unique to each branch                                                                                                                                                                                                                                                                 |
| Flags                | This column displays any flags for the branch subnet <ul style="list-style-type: none"> <li>• P = Primary Tunnel</li> <li>• B = Backup Tunnel</li> <li>• C = Centralized</li> <li>• D = Distributed</li> <li>• L = Local</li> <li>• U = Unassigned</li> <li>• 3 = Routed(L3)</li> <li>• 2 = Bridged(L2)</li> </ul> |
| Branch (Subnet/Vlan) | Subnet mask or VLAN assigned to the branch                                                                                                                                                                                                                                                                         |
| BID                  | Branch ID                                                                                                                                                                                                                                                                                                          |
| IP Address Range     | Allocated branch subnet IP address range                                                                                                                                                                                                                                                                           |
| Client Count         | Number of client terminating on this controller                                                                                                                                                                                                                                                                    |

## Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.4 | Command introduced |

## Command Information

| All platforms | Base operating system, except for noted parameters | Enable or Configuration mode on master and local controller |

## show iap table

```
show iap table
 branch-key <brkey>
 long
```

### Description

Displays the branch details connected to the controller.

### Syntax

| Parameter          | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| branch-key <brkey> | Key for the branch, which is unique to each branch.                 |
| long               | Displays the branches connected to the controller in detailed view. |

### Example

This example shows the details of the branches connected to the controller:

```
(host) #show iap table long
```

IAP Branch Table

| Name           | VC MAC Address    | Status | Inner IP      | Assigned Subnet  | Assigned Vlan |
|----------------|-------------------|--------|---------------|------------------|---------------|

## show iap trusted-branch-db

show iap trusted-branch-db

### Description

Displays the details of IAP trusted branch database information.

### Syntax

None

### Example

This example shows the details of IAP trusted branch database information:

```
(host) #show iap trusted-branch-db

Trusted Branch Validation: Enabled
IAP Trusted Branch Table

Branch MAC

01:01:0e:3e:4c:33
```

Another example:

```
(host) #show iap trusted-branch-db

Trusted Branch Validation: Disabled
IAP Trusted Branch Table

Branch MAC

(allow all as trusted branch)
```

The output of this command includes the following parameters:

| Parameter  | Description                           |
|------------|---------------------------------------|
| Branch MAC | MAC address of the trusted IAP branch |

### Related Commands

| All platforms | Base operating system, except for noted parameters | Enable or Configuration mode on master and local controller |

## show ids ap-classification-rule

id-classification-rule <rule-name>

### Description

Display the IDS AP classification rule profile.

### Syntax

| Parameter   | Description                                    |
|-------------|------------------------------------------------|
| <rule-name> | Enter the AP classification rule profile name. |

### Usage Guidelines

Issue this command without the <rule-name> option to view the AP Classification Rule Profile list. Add the rule name option to display values for the rule.

### Example

Below is the show command *without* the rule name option:

```
(host) (config) #show ids ap-classification-rule
IDS AP Classification Rule Profile List

Name References Profile Status

exclude-ssid-rule 1
rule1 1
rule2 1
Total:3
```

In the example above, the **Reference** column indicates the number of references to the rule named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined. Optionally, you can enter a rule name to view the parameters for that rule. For example:

```
(host) (config) # show ids ap-classification-rule rule1
IDS AP Classification Rule Profile "rule1"

Parameter Value

SSID Dell-ap
Match SSIDs true
Min SNR value 0
Max SNR value 255
Discovered APs count 2
Check for Min Discovered APs true
Classify To AP Type suspected-rogue
Confidence level increase 5
```

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.0 | Command introduced |

## Command Information

| Platforms                  | Licensing                      | Command Mode                      |
|----------------------------|--------------------------------|-----------------------------------|
| Available on all platforms | Requires the RFprotect license | Config mode on master controllers |

## show ids ap-rule-matching

### Description

Display the IDS active AP rules profile.

### Example

```
(host) (config) #show ids ap-rule-matching
```

```
IDS Active AP Rules Profile
```

```

```

```
Parameter Value
```

```

```

```
AP Rule name snr0
```

```
AP Rule name rule1
```

```
AP Rule name rule2
```

```
AP Rule name exclude-ssid-rule
```

In the above example, the rule names in the *Value* column have been activated by the **ids ap-rule-matching** command.

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.0 | Command introduced |

### Command Information

| Platforms                  | Licensing                      | Command Mode                      |
|----------------------------|--------------------------------|-----------------------------------|
| Available on all platforms | Requires the RFprotect license | Config mode on master controllers |

## show ids dos-profile

show ids dos-profile <profile-name>

### Description

Show an IDS Denial Of Service (DoS) Profile

### Syntax

| Parameter      | Description                 |
|----------------|-----------------------------|
| <profile-name> | Name of an IDS DoS profile. |

### Usage Guidelines

Issue this command without the <profile-name> parameter to display an IDS DoS profile.

### Examples

The example below shows that the controller has four configured DoS profiles.

```
((host) (config) #show ids dos-profile
```

```
IDS Denial Of Service Profile List
```

```

Name References Profile Status

default 4
test 0
test1 1
Wizard-test 1
Wizard-test2 1
```

```
Total:5
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The example below displays a partial output for the profile "test1".

```
((host) (config) #show ids dos-profile test1
Parameter Value

Detect Disconnect Station Attack true
Disconnect STA Assoc Response Theshold 5
Disconnect STA Deauth and Disassoc Theshold 8
Disconnect STA Detection Quiet Time 900 sec
Spoofed Deauth Blacklist Disabled
Detect AP Flood Attack false
AP Flood Threshold 50
AP Flood Increase Time 3 sec
AP Flood Detection Quiet Time 900 sec
Detect Client Flood Attack false
Client Flood Threshold 150
Client Flood Increase Time 3 sec
Client Flood Detection Quiet Time 900 sec
Detect EAP Rate Anomaly false
```

```

EAP Rate Threshold 60
EAP Rate Time Interval 3 sec
EAP Rate Quiet Time 900 sec
Detect CTS Rate Anomaly false
CTS Rate Threshold 5000
CTS Rate Time Interval 5 sec
CTS Rate Quiet Time 900 sec
Detect RTS Rate Anomaly false
RTS Rate Threshold 5000
RTS Rate Time Interval 5 sec
RTS Rate Quiet Time 900 sec
Detect Rate Anomalies false
Rate Thresholds for Assoc Frames default
Rate Thresholds for Disassoc Frames default
Rate Thresholds for Deauth Frames default
...

```

For a detailed explanation of the output shown above, see the [ids dos-profile](#) command.

| Available on all platforms | Requires the RFprotect license | Config mode on master controllers |

## show ids general-profile

show ids general-profile <profile-name>

### Description

Display an IDS General profile.

### Syntax

| Parameter      | Description                     |
|----------------|---------------------------------|
| <profile-name> | Name of an IDS General profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the IDS General profile list. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has four configured General profiles.

```
(host) (config) # show ids general-profile
IDS General Profile List

Name References Profile Status

default 2
helen 0
wired-lb 1
Wizard-test2 1
Total:4
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The example below displays the settings for the profile **Michael**.

```
(host) (config) #show ids general-profile Michael

IDS General Profile "Michael"

Parameter Value

Adhoc AP Max Unseen Timeout 180 sec
Adhoc (IBSS) AP Inactivity Timeout 5 sec
AP Inactivity Timeout 20 sec
AP Max Unseen Timeout 600 sec
Frame Types for RSSI calculation ba pr dlow dnull mgmt ctrl
IDS Event Generation on AP none
Max Monitored Stations 1024
Max Unassociated Stations 256
Min Potential AP Beacon Rate 25 %
Min Potential AP Monitor Time 2 sec
Mobility Manager RTLS false
Monitored Device Stats Update Interval 0 sec
Packet SNR Threshold 0
```

```

Send Adhoc Info to Controller true
Signature Quiet Time 900 sec
STA Inactivity Timeout 60 sec
STA Max Unseen Timeout 600 sec
Stats Update Interval 60 sec
Wired Containment true
Wired Containment of AP's Adj MACs true
Wired Containment of Suspected L3 Rogue false
Wireless Containment deauth-only
Debug Wireless Containment false
WMS Client Monitoring all

```

The output of this command includes the following parameters:

| Parameter                              | Description                                                                                                                                                                                          |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Adhoc AP Max Unseen Timeout            | Ageout time in seconds since adhoc (IBSS) AP was last seen.                                                                                                                                          |
| Adhoc (IBSS) AP Inactivity Timeout     | Adhoc (IBSS) AP inactivity timeout in number of scans.                                                                                                                                               |
| AP Inactivity Timeout                  | Time, in seconds, after which an AP is aged out.                                                                                                                                                     |
| AP Max Unseen Timeout                  | Ageout time, in seconds, since AP was last seen.                                                                                                                                                     |
| Frame Types for RSSI calculation       | Frame types used in AM RSSI calculation.                                                                                                                                                             |
| IDS Event Generation on AP             | Enable or disable IDS event generation from the AP. Event generation from the AP can be enabled for syslogs, traps, or both. This does not affect generation of IDS correlated events on the switch. |
| Max Monitored Stations                 | Maximum number of monitored stations.                                                                                                                                                                |
| Max Unassociated Stations              | Maximum number of unassociated stations.                                                                                                                                                             |
| Min Potential AP Beacon Rate           | Minimum beacon rate acceptable from a potential AP, in percentage of the advertised beacon interval.                                                                                                 |
| Min Potential AP Monitor Time          | Minimum time, in seconds, a potential AP has to be up before it is classified as a real AP.                                                                                                          |
| Mobility Manager RTLS                  | Shows if RTLS communication with the configured mobility-manager is enabled or disabled.                                                                                                             |
| Monitored Device Stats Update Interval | Time interval, in seconds, for AP to update the switch with stats for monitored devices. Minimum is 60.                                                                                              |
| Packet SNR Threshold                   | The packet Signal to Noise Ratio (SNR) threshold. All packets with SNR below this threshold is dropped from IDS and ARM processing.<br><br>No packets are dropped if the threshold is set to 0.      |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Send Adhoc Info to Controller           | Enable or disable sending adhoc information to the controller from the AP.                                                                                                                                                                                                                                        |
| Signature Quiet Time                    | After a signature match is detected, the time to wait, in seconds, to resume checking.                                                                                                                                                                                                                            |
| STA Inactivity Timeout                  | Time, in seconds, after which a station is aged out.                                                                                                                                                                                                                                                              |
| STA Max Unseen Timeout                  | Time, in seconds, after which an AP is aged out.                                                                                                                                                                                                                                                                  |
| Stats Update Interval                   | Interval, in seconds, for the AP to update the controller with statistics. This setting takes effect only if the Dell Mobility Manager is configured. Otherwise, statistics update to the controller is disabled.                                                                                                 |
| Wired Containment                       | Shows if the profile has enabled or disabled containment from the wired side.                                                                                                                                                                                                                                     |
| Wired Containment of AP's Adj MACs      | Shows if the profile has enabled or disabled wired containment of MACs offset by one from APs BSSID.                                                                                                                                                                                                              |
| Wired Containment of Suspected L3 Rogue | Shows if the profile has enabled or disabled the feature to identify and contain an AP with a preset wired MAC address that is completely different from the AP's BSSID. where the MAC address that the AP provides to wireless clients as a 'gateway MAC' is offset by one character from its wired MAC address. |
| Wireless Containment                    | Shows if the profile has enabled or disabled containment from the wireless side.                                                                                                                                                                                                                                  |
| Debug Wireless Containment              | Shows if the profile has enabled or disable debugging of containment from the wireless side.                                                                                                                                                                                                                      |
| Wired Containment of AP's Adj MACs      | Enable/disable wired containment of MACs offset by one from APs BSSID.                                                                                                                                                                                                                                            |

| Available on all platforms | Requires the RFprotect license | Config mode on master controllers |

## show ids impersonation-profile

show ids impersonation-profile <profile-name>

### Description

Display an IDS Impersonation Profile.

### Syntax

| Parameter      | Description                           |
|----------------|---------------------------------------|
| <profile-name> | Name of an IDS Impersonation profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the IDS Impersonation profile list. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below displays that the controller has five configured Impersonation profiles.

```
(host) (config) #show ids impersonation-profile
```

```
IDS Impersonation Profile List

Name References Profile Status

default 4
test 0
test1 1
Wizard-test 1
Wizard-test2 1
```

Total:5

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The example below displays the configuration settings for the profile **test1**.

```
(host) (config) #show ids impersonation-profile test1
```

```
IDS Impersonation Profile "test1"

Parameter Value

Detect AP Impersonation false
Protect from AP Impersonation false
Beacon Diff Threshold 50 %
Beacon Increase Wait Time 3 sec
Detect AP Spoofing true
Detect Beacon Wrong Channel false
Beacon Wrong Channel Detection Quiet Time 900 sec
Detect Hotspotter Attack true
Hotspotter Quiet Time 900 sec
```

The output of this command includes the following parameters:

| Parameter                                 | Description                                                                                                                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detect AP Impersonation                   | Shows if the profile has enabled or disabled detection of AP impersonation.                                                                                                                  |
| Protect from AP Impersonation             | Shows if AP impersonation is enabled or disabled for the profile. When AP impersonation is detected, both the legitimate and impersonating AP are disabled using a denial of service attack. |
| Beacon Diff Threshold                     | Percentage increase in beacon rates that triggers an AP impersonation event.                                                                                                                 |
| Beacon Increase Wait Time                 | Time, in seconds, after the beacon difference threshold is crossed before an AP impersonation event is generated.                                                                            |
| Detect AP Spoofing                        | AP Spoofing detection is enabled                                                                                                                                                             |
| Detect Beacon Wrong Channel               | Disable detection of beacons advertising the incorrect channel                                                                                                                               |
| Beacon Wrong Channel Detection Quiet Time | Wait 90 seconds after detecting a beacon with the wrong channel after which the check can be resumed.                                                                                        |
| Detect Hotspotter Attack                  | Enable detection of the Hotspotter attack to lure away valid clients.                                                                                                                        |
| Hotspotter Quiet Time                     | Wait 90 seconds after detecting an attempt to Use the Hotspotter tool against clients.                                                                                                       |

## show ids management-profile

### Description

Displays the management event correlation for IDS event traps and sylogs (logs).

### Example

The following example displays the current management status.

```
(host) (config) #show ids management-profile
```

```
IDS Management Profile
```

```

```

| Parameter                    | Value          |
|------------------------------|----------------|
| -----                        | -----          |
| IDS Event Correlation        | logs-and-traps |
| Event Correlation Quiet Time | 900 sec        |

The display output of the above command includes:

| Parameter                    | Description                                                          |
|------------------------------|----------------------------------------------------------------------|
| IDS Event Correlation        | Management profile is set for logs-and-traps.                        |
| Event Correlation Quiet Time | The time to wait, 900 seconds, before the event can be raised again. |

### Command History

| Version     | Description        |
|-------------|--------------------|
| ArubaOS 6.0 | Command Introduced |

### Command Information

| Platforms                  | Licensing                      | Command Mode                      |
|----------------------------|--------------------------------|-----------------------------------|
| Available on all platforms | Requires the RFprotect license | Config mode on master controllers |

## show ids profile

show ids profile <profile-name>

### Description

Display all ids profiles or display a specific profile name.

### Syntax

| Parameter      | Description             |
|----------------|-------------------------|
| <profile-name> | Name of an IDS profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the list of IDS profiles. Include a profile name to display detailed information for that profile.

### Examples

The example below shows that the controller has seven configured IDS Profiles.

```
(host) (config) #show ids profile
```

```
IDS Profile List
```

```

Name References Profile Status
---- -
default 5
test 0
test-tarpit 1
test-wired-lb 0
test1 0
Wizard-test 0
Wizard-test2 0
```

```
Total:7
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

This example displays the configuration settings for the profile **test1**.

```
(host) (config) #show ids profile test1
```

```
IDS Profile "test1"
```

```

Parameter Value

IDS General profile test1
IDS Signature Matching profile test1
IDS DOS profile test1
IDS Impersonation profile test1
IDS Unauthorized Device profile test1
```

The output of this command includes the following parameters:

| Parameter                       | Description                                                                   |
|---------------------------------|-------------------------------------------------------------------------------|
| IDS General profile             | Name of a IDS General profile to be applied to an AP or AP group.             |
| IDS Signature Matching profile  | Name of a IDS Signature Matching profile to be applied to an AP or AP group.  |
| IDS DOS profile                 | Name of a IDS Denial of Service profile to be applied to an AP or AP group.   |
| IDS Impersonation profile       | Name of a IDS Impersonation profile to be applied to an AP or AP group.       |
| IDS Unauthorized Device profile | Name of a IDS Unauthorized Device profile to be applied to an AP or AP group. |

## Related Commands

## show ids rate-thresholds-profile

show ids rate-thresholds-profile <profile-name>

### Description

Show an IDS Rate Thresholds profile.

### Syntax

| Parameter      | Description                            |
|----------------|----------------------------------------|
| <profile-name> | Name of an IDS Rate Threshold profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the IDS Rate Threshold profile list. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has three configured IDS Rate Threshold profiles.

```
(host) (config) #show ids rate-thresholds-profile
```

```
IDS Rate Thresholds Profile List

Name References Profile Status
---- -
default 20
probe-request-response-thresholds 10 Predefined
test 0
```

Total:3

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

This example displays the configuration settings for the profile **test**.

```
(host) (config) #show ids rate-thresholds-profile test
```

```
IDS Rate Thresholds Profile "test"

Parameter Value

Channel Increase Time 15 sec
Channel Quiet Time 900 sec
Channel Threshold 300
Node Time Interval 15 sec
Node Quiet Time 900 sec
Node Threshold 200
```

The output of this command includes the following parameters:

| Parameter             | Description                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Channel Increase Time | Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm.                                                                        |
| Channel Quiet Time    | The time that must elapse after a channel rate alarm before another identical alarm may be triggered. This option prevents excessive messages in the log file. |
| Channel Threshold     | Number of a specific type of frame that must be exceeded within a specific interval in an entire channel to trigger an alarm.                                  |
| Node Time Interval    | Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm.                                                                        |
| Node Quiet Time       | The time that must elapse after a node rate alarm before another identical alarm may be triggered. This option prevents excessive messages in the log file.    |
| Node Threshold        | Number of a specific type of frame that must be exceeded within a specific interval for a particular client MAC address to trigger an alarm.                   |

## Related Commands

## show ids signature-matching-profile

show ids signature-matching-profile <profile-name>

### Description

Show an IDS Signature Matching profile.

### Syntax

| Parameter      | Description                                |
|----------------|--------------------------------------------|
| <profile-name> | Name of an IDS Signature Matching profile. |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the entire IDS Signature Matching profile list. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has four configured Signature Matching profiles.

```
(host) (config) #show ids signature-matching-profile
```

```
IDS Signature Matching Profile List

Name References Profile Status

default 4
test1 1
Wizard-test 1
Wizard-test2 1
```

Total:4

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

This example displays the configuration settings for the profile **test1**.

```
(host) (config) #show ids signature-matching-profile test1
```

```
IDS Signature Matching Profile "test1"

Parameter Value

IDS Signature Deauth-Broadcast
IDS Signature Disassoc-Broadcast
```

The output of this command includes the following parameters:

| Parameter     | Value                       |
|---------------|-----------------------------|
| IDS Signature | Broadcast is not authorized |
| IDS Signature | Disassociate broadcast      |

## Related Commands

Configure the Signature Matching profile using the command [ids signature-matching-profile](#).

## Command History

|-------------|-----------------------|
| ArubaOS 3.0 | Command Introduced    |
| ArubaOS 6.0 | Refreshed show output |

## Command Information

| Platforms                  | Licensing                      | Command Mode                      |
|----------------------------|--------------------------------|-----------------------------------|
| Available on all platforms | Requires the RFprotect license | Config mode on master controllers |

## show ids signature-profile

show ids signature-profile <profile-name>

### Description

Show an IDS signature profile.

### Syntax

| Parameter      | Description                       |
|----------------|-----------------------------------|
| <profile-name> | Name of an IDS Signature profile. |

### Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire IDS Signature profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has eight configured Signature profiles.

```
(host) # show ids signature-profile

IDS Signature Profile List

Name References Profile Status

AirJack 1 Predefined
ASLEAP 1 Predefined
Deauth-Broadcast 1 Predefined
default 1
Netstumbler Generic 1 Predefined
Netstumbler Version 3.3.0x 1 Predefined
Null-Probe-Response 1 Predefined
sample 0

Total:8
```

This example displays the configuration settings for the profile **AirJack**.

```
(host) # show ids signature-profile
IDS Signature Profile "AirJack" (predefined)

Parameter Value

Frame Type beacon SSID = AirJack
```

The output of this command includes the following parameters:

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame Type      | <p>Type of 802.11 frame. For each type of frame, further parameters may be included to filter and detect only the required frames.</p> <ul style="list-style-type: none"> <li>• <b>assoc</b>: Association frame type.</li> <li>• <b>auth</b>: Authentication frame type.</li> <li>• <b>beacon</b>: Beacon frame type.</li> <li>• <b>control</b>: All control frames.</li> <li>• <b>data</b>: All data frames.</li> <li>• <b>deauth</b>: Deauthentication frame type.</li> <li>• <b>disassoc</b>: Disassociation frame type.</li> <li>• <b>mgmt</b>: Management frame type.</li> <li>• <b>probe-request</b>: Probe request frame type.</li> <li>• <b>probe-response</b>: Probe response frame type.</li> <li>• <b>ssid</b>: For beacon, probe-request, and probe-response frame types, the SSID as either a string or hex pattern.</li> <li>• <b>ssid-length</b>: For beacon, probe-request, and probe-response frame types, the length, in bytes, of the SSID.</li> </ul> |
| payload         | Pattern at a fixed offset in the payload of an 802.11 frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| sequence number | Sequence number of the frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| src- mac        | Source MAC address in the 802.11 frame header.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| dst- mac        | Source MAC address in the 802.11 frame header.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| bssid           | BSSID field in the 802.11 frame header.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## show ids unauthorized-device-profile

show ids unauthorized-device-profile <profile-name>

### Description

Show an IDS Unauthorized Device Profile.

### Syntax

| Parameter      | Description                                |
|----------------|--------------------------------------------|
| <profile-name> | Name of an IDS Unauthorized Device profile |

### Usage Guidelines

Issue this command without the **<profile-name>** parameter to display the IDS Unauthorized Device profile list. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has five configured Unauthorized Device profiles.

```
(host) (config) #show ids unauthorized-device-profile
```

```
IDS Unauthorized Device Profile List

Name References Profile Status
---- -
default 4
test 0
test1 1
Wizard-test 1
Wizard-test2 1
```

Total:5

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

This example displays the configuration settings for the profile **test1**.

```
(host) (config) #show ids unauthorized-device-profile test1
```

```
IDS Unauthorized Device Profile "test1"
IDS Unauthorized Device Profile "default"

Parameter Value

Protect 802.11n High Throughput Devices false
Protect 40MHz 802.11n High Throughput Devices false
Detect Active 802.11n Greenfield Mode false
Detect Adhoc Networks false
Protect from Adhoc Networks false
Protect from Adhoc Networks - Enhanced false
Detect Adhoc Network Using Valid SSID true
Adhoc Network Using Valid SSID Quiet Time 900 sec
Allow Well Known MAC N/A
```

| Protect From Wireless Hosted Networks              | false   |

The output of this command includes the following parameters:

| Parameter                                     | Description                                                                                                               |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| Protect 802.11n High Throughput Devices       | Shows if the profile enables or disables protection of high-throughput (802.11n) devices.                                 |
| Protect 40MHz 802.11n High Throughput Devices | Shows if the profile enables or disables protection of high-throughput (802.11n) devices operating in 40 MHz mode.        |
| Detect Active 802.11n Greenfield Mode         | Shows if the profile enables or disables detection of high-throughput devices advertising greenfield preamble capability. |
| Detect AdHoc Networks                         | Shows if the profile has enabled or disabled detection of adhoc networks.                                                 |
| Protect from Adhoc Networks                   | Shows if the profile has enabled or disabled protection from WPA/WPA2 adhoc networks.                                     |

| Parameter                                    | Description                                                                                                                                                                                          |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protect from Adhoc Networks-Enhanced         | Shows if the profile has enabled or disabled protection from WEP/Open adhoc networks.                                                                                                                |
| Detect Valid SSID Misuse                     | Shows if the detect valid SSID misuse is enabled (true) or disabled (false).                                                                                                                         |
| Adhoc Network Using Valid SSID Quiet Time    | Shows time to wait, in seconds, after detecting an adhoc network using a valid SSID, after which the check can be resumed.                                                                           |
| Allow Well Known MAC                         | Shows if the profile allows devices with known MAC addresses to classify rogue APs.                                                                                                                  |
| Detect Devices with an Invalid MAC OUI       | Shows if the profile has enabled or disabled checking of the first three bytes of a MAC address, known as the organizationally unique identifier (OUI), assigned by the IEEE to known manufacturers. |
| MAC OUI detection Quiet Time                 | Time, in seconds, that must elapse after an invalid MAC OUI alarm has been triggered before another identical alarm may be triggered.                                                                |
| Detect Misconfigured AP                      | Shows if the profile has enabled or disabled detection of misconfigured APs.                                                                                                                         |
| Protect Misconfigured AP                     | Shows if the profile has enabled or disabled protection of misconfigured APs.                                                                                                                        |
| Detect Bad WEP                               | Shows if the profile has enabled or disabled detection of WEP initialization vectors that are known to be weak and/or repeating.                                                                     |
| Privacy                                      | Shows if the profile has enabled or disabled encryption as a valid AP configuration.                                                                                                                 |
| Require WPA                                  | Shows if the controller will flag any valid AP not using WPA as a misconfigured AP.                                                                                                                  |
| Valid 802.11g channel for policy enforcement | A list of valid 802.11g channels that third-party APs are allowed to use.                                                                                                                            |
| Valid 802.11a channel for policy enforcement | A list of valid 802.11a channels that third-party APs are allowed to use.                                                                                                                            |
| Valid and Protected SSIDs                    | A list of valid and protected SSIDs.                                                                                                                                                                 |

| Parameter                                          | Description                                                                                                                                      |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Valid MAC OUIs                                     | A list of valid MAC Organizationally Unique Identifiers (OUIs).                                                                                  |
| Rogue AP Classification                            | Shows if the profile has enabled or disabled rogue AP classification.                                                                            |
| Overlay Rogue AP Classification                    | Shows if the controller allows APs that are plugged into the wired side of the network to be classified as “suspected rogue” instead of “rogue”. |
| OUI-based Rogue AP Classification                  | Shows if OUI-based rogue AP classification is enabled or disabled.                                                                               |
| Propagated Wired MAC based Rogue AP Classification | Shows if rogue AP classification through propagated wired MACs is enabled or disabled.                                                           |
| Rogue Containment                                  | Shows if the controller will automatically shut down rogue APs.                                                                                  |
| Suspected Rogue Containment                        | Shows if the controller will automatically treat suspected rogue APs as interfering APs.                                                         |
| Suspected Rogue Containment Confidence Level       | Confidence level of suspected Rogue AP to trigger containment, expressed as a percentage.                                                        |
| Detect Station Association To Rogue AP             | Shows if the profile has been configured to detect station association to a rogue AP.                                                            |
| Detect Unencrypted Valid Clients                   | Shows if the profile has enabled or disabled detection of unencrypted valid clients.                                                             |
| Unencrypted Valid Client Detection Quiet Time      | Shows the time to wait, in seconds, after detecting an unencrypted valid client after which the check can be resumed.                            |
| Detect Valid Client Misassociation                 | Shows if the profile has enabled or disabled detection of a misassociation between a valid client and an unsafe AP.                              |
| Detect Valid SSID Misuse                           | Shows if the profile has enabled or disabled detection of Interfering or Neighbor APs using valid/protected SSIDs.                               |
| Protect SSID                                       | Shows if the profile has enabled or disabled use of SSID by valid APs only.                                                                      |
| Protect Valid Stations                             | Shows if the controller will allow valid stations to connect to a non-valid AP.                                                                  |
| Valid Wired MACs                                   | List of valid and protected SSIDs.                                                                                                               |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detect Windows Bridge                 | Shows if the profile has enabled or disabled detection of Windows station bridging.                                                                                                                                                                                                                                                                       |
| Protect Windows Bridge                | Shows if the profile has enabled or disabled protection of Windows station bridging.                                                                                                                                                                                                                                                                      |
| Detect Wireless Bridge                | Shows if the profile has enabled or disabled detection of wireless bridging.                                                                                                                                                                                                                                                                              |
| Wireless Bridge detection Quiet Time  | Time, in seconds, that must elapse after a wireless bridge alarm has been triggered before another identical alarm may be triggered.                                                                                                                                                                                                                      |
| Protect From Wireless Hosted Networks | Shows if the profile has enabled or disabled detection of a wireless hosted network.                                                                                                                                                                                                                                                                      |
| Wireless Hosted Network Quiet Time    | The wireless hosted network detection feature sends a log message and trap when a wireless hosted network is detected. The quiet time displayed in this field displays the amount of time, in seconds, that must elapse after a wireless hosted network log message or trap has been triggered before an identical log message or trap can be sent again. |
| Protect From Wireless Hosted Networks | Shows if the profile has enabled or disabled containment on a wireless hosted network by launching a denial of service attack to disrupt associations between a Windows 7 software-enabled Access Point (softAP) and a client, and disrupt associations between the client that is hosting the softAP and any access point to which the host connects.    |

## show ids wms-general-profile

show ids wms-general-profile

### Description

Display general statistics for the wms configuration.

### Syntax

No parameters.

### Example

This example shows per-channel statistics for all monitored APs.

```
(host) #show ids wms-general-profile
```

```
IDS WMS General Profile
```

```

```

| Parameter                                   | Value       |
|---------------------------------------------|-------------|
| -----                                       | -----       |
| AP poll interval                            | 60000 msec  |
| AP poll retries                             | 3           |
| AP ageout interval                          | 0 minutes   |
| Adhoc AP ageout interval                    | 31 minutes  |
| Station ageout interval                     | 100 minutes |
| Statistics update                           | true        |
| Persistent Neighbor APs                     | true        |
| Persistent Valid STAs                       | false       |
| AP learning                                 | false       |
| Propagate Wired Macs                        | true        |
| Collect Stats for Monitored APs and Clients | false       |
| Learn System Wired Macs                     | false       |

| Column                   | Description                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AP poll interval         | Interval, in milliseconds, for communication between the controller and AMs. The controller contacts the AM at this interval to download AP to station associations, update policy configuration changes, and download AP and station statistics. |
| AP poll retries          | Maximum number of failed polling attempts before the polled AM is considered to be down.                                                                                                                                                          |
| AP ageout interval       | Time, in minutes, that an AP must remain unseen by any probes before it is deleted from the database.                                                                                                                                             |
| Adhoc AP ageout interval | Time, in minutes, that an adhoc (IBSS) AP remains unseen before it is deleted (ageout) from the database.                                                                                                                                         |
| Station ageout interval  | Time, in minutes, that a client must be unseen by any probes before it is deleted from the database.                                                                                                                                              |

| Column                                      | Description                                                                                               |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Statistics update                           | Shows the status of the statistics updates in the database.                                               |
| Persistent Neighbor APs                     | Shows the status of known AP neighbors.                                                                   |
| Persistent Valid STAs                       | Shows the status of known AP neighbors.                                                                   |
| AP learning                                 | Shows the status of “learning” of non-Dell APs.                                                           |
| Propagate Wired Macs                        | Shows if the controller has enabled or disabled the propagation of the gateway wired MACs.                |
| Collect Stats for Monitored APs and Clients | Shows if the master controller will collect up to 25,000 statistic entries for monitored APs and clients. |
| Learn System Wired Macs                     | Shows the status of “learning” of wired MACs at the controller.                                           |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show ifmap

```
show ifmap
 cppm
 state cppm
```

### Descriptions

Issue this command to show the CPPM IF-MAP configuration profile and the IP-MAP connection state.

### Syntax

| Parameter  | Description                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------|
| cppm       | Shows the CPPM IF-MAP profile parameters and their values.                                          |
| state cppm | Shows the CPPM IF-MAP connection state including if it is enabled, and the servers and their state. |

### Example

To configure this feature using the CLI:

```
(host) (config) #ifmap
(host) (config) #ifmap cppm
(host) (CPPM IF-MAP Profile) #server host <host>
(host) (CPPM IF-MAP Profile) #port <port>
(host) (CPPM IF-MAP Profile) #passwd <psswd>
(host) (CPPM IF-MAP Profile) #enable
```

This show command show if the CCPM interface is enable and the CPPM server IP address, username and password.

```
(host) (CPPM IF-MAP Profile) #show ifmap cppm
CPPM IF-MAP Profile

Parameter Value

CPPM IF-MAP Interface Enabled
CPPM IF-MAP Server 10.10.10.10:443 admin/*****
```

This show command shows if state of all enabled CPPM servers.

```
(host) (CPPM IF-MAP Profile) #show ifmap state cppm
CPPM IF-MAP Connection State [Interface: Enabled]

Server State

10.4.191.32:443 UP
```

## show ip interface brief

show ip interface brief

### Description

View IP-related information on all interfaces in summary format.

### Syntax

No parameters.

### Example

```
(host) #show ip interface brief
```

| Interface | IP Address / IP Netmask      | Admin | Protocol |
|-----------|------------------------------|-------|----------|
| vlan 1    | 172.16.0.254 / 255.255.255.0 | up    | up       |
| vlan 2    | 10.4.62.9 / 255.255.255.0    | up    | up       |
| loopback  | unassigned / unassigned      | up    | up       |
| mgmt      | unassigned / unassigned      | down  | down     |

The following table details the columns and content in the show command.

| Column                 | Description                                                                       |
|------------------------|-----------------------------------------------------------------------------------|
| Interface              | List the interface and interface identification, where applicable.                |
| IP Address /IP Netmask | List the IP address and netmask for the interface, if configured.                 |
| Admin                  | States the administrative status of the interface.<br>Enabled—up<br>Disabled—down |
| Protocol               | Status of the IP on the interface.<br>Enabled—up<br>Disabled—down                 |

|---------------|-----------------------|-----------------------------------------------------------|
| All platforms | Base operating system | Available in Config or Enable mode on master controllers. |

## show image version

### Description

Display the current system image version on both partition 0 and 1.

### Syntax

No parameters.

### Example

The following example shows that the controller is running ArubaOS 3.4 and booting off partition 0:0.

```
(host) #show image version

Partition : 0:0 (/dev/hda1) **Default boot**
Software Version : AOS-W 3.3.2.0
Build number : 18661
Label : 18661
Built on : 2008-06-12 04:24:34 PDT

Partition : 0:0 (/dev/hda1)
Software Version : AOS-W 3.3.2.0
Build number : 18661
Label : 18661
Built on : 2008-06-12 04:24:34 PDT
```

The output of this command includes the following parameters:

| Parameter        | Description                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------|
| Partition        | Partition number and name. The default boot partition will display a <b>**Default boot**</b> notice by the partition name. |
| Software Version | Version of ArubaOS software running on the partition.                                                                      |
| Build number     | Build number for the software version.                                                                                     |
| Label            | The label parameter can display additional information for the build. By default, this value is the software build number. |
| Built on         | Date the software build was created.                                                                                       |

### Command History

This command was available in ArubaOS 1.0.

## show interface cellular access-group

show interface cellular access-group

### Description

List the Access groups configured on the cellular interface.

### Example

```
(host) (config-cell)#show interface cellular access-group
```

Cell Interface:

```
session access list 3 is configured
```

### Command History

| Release     | Modification       |

|--------------|-----------------------|----------------------------------|
| W-600 Series | Base operating system | Configuration Mode (config-cell) |

## show interface counters

show interface counters

### Description

Displays a table of L2 interfaces counters.

### Syntax

No parameters

### Example

The example below shows the output of **show interface counters** on a W-650 controller.

| Port  | InOctets    | InUcastPkts | InMcastPkts | InBcastPkts |
|-------|-------------|-------------|-------------|-------------|
| GE1/0 | 250559459   | 1664878     | 0           | 16          |
| GE1/1 | 1615683022  | 1230973     | 0           | 16          |
| GE1/2 | 204909      | 1511        | 0           | 16          |
| GE1/3 | 2964355     | 22155       | 0           | 17          |
| GE1/4 | 1612815178  | 12509415    | 0           | 228         |
| GE1/6 | 23571170611 | 15545404    | 0           | 4           |
| GE1/7 | 23562566444 | 15530432    | 8236        | 146         |

| Port  | OutOctets   | OutUcastPkts | OutMcastPkts | OutBcastPkts |
|-------|-------------|--------------|--------------|--------------|
| GE1/0 | 2504472376  | 2645877      | 8243         | 16770        |
| GE1/1 | 169128719   | 820198       | 8243         | 17083        |
| GE1/2 | 1881584     | 25785        | 8243         | 16771        |
| GE1/3 | 5247669     | 47718        | 8245         | 16813        |
| GE1/4 | 26893373267 | 20838930     | 8243         | 16561        |
| GE1/6 | 539935348   | 8160008      | 8139         | 461          |
| GE1/7 | 23563612641 | 15531317     | 7            | 336          |

The output of this command includes the following parameters:

| Parameter    | Description                                            |
|--------------|--------------------------------------------------------|
| Port         | Port number.                                           |
| InOctets     | Number of octets received through the port.            |
| InUcastPkts  | Number of unicast packets received through the port.   |
| InMcastPkts  | Number of multicast packets received through the port. |
| InBcastPkts  | Number of broadcast packets received through the port. |
| OutOctets    | Number of octets sent through the port.                |
| OutUcastPkts | Number of unicast packets sent through the port.       |
| OutMcastPkts | Number of multicast packets sent through the port.     |
| OutBcastPkts | Number of broadcast packets sent through the port.     |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show interface fastethernet

show interface fastethernet <slot/port>

### Description

Displays information about a specified fast Ethernet port.

### Syntax

| Parameter      | Description                                                 |
|----------------|-------------------------------------------------------------|
| access-group   | Displays access groups configured on this interface.        |
| counters       | Displays L2 interface counters for the specified interface. |
| switchport     | Displays L2 interface information.                          |
| untrusted-vlan | Displays port member vlan untrusted status.                 |
| xsec           | Displays xsec configuration.                                |

### Examples

The example below shows the output of **show interface fastethernet 1/0**.

```
FE 1/0 is up, line protocol is up
Hardware is FastEthernet, address is 00:0B:86:51:14:D1 (bia 00:0B:86:51:14:D1)
Description: fe1/0
Encapsulation ARPA, loopback not set
Configured: Duplex (AUTO), speed (AUTO)
Negotiated: Duplex (Full), speed (100 Mbps)
MTU 1500 bytes, BW is 100 Mbit
Last clearing of "show interface" counters 15 day 21 hr 34 min 53 sec
link status last changed 15 day 21 hr 32 min 16 sec
 1122463 packets input, 196293018 bytes
 Received 661896 broadcasts, 0 runts, 0 giants, 0 throttles
 0 input error bytes, 0 CRC, 0 frame
 661881 multicast, 460567 unicast
 191428 packets output, 97063150 bytes
 0 output errors bytes, 0 deferred
 0 collisions, 0 late collisions, 0 throttles
This port is TRUSTED
POE Status of the port is OFF
```

The output of this command includes the following parameters:

| Parameter           | Description                                                     |
|---------------------|-----------------------------------------------------------------|
| FE 1/0 is...        | Displays the status of the specified port.                      |
| line protocol is... | Displays the status of the line protocol on the specified port. |
| Hardware is....     | Describes the hardware interface type.                          |

| Parameter                                  | Description                                                                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| address is...                              | Displays the MAC address of the hardware interface.                                                                                     |
| Description                                | The port type, name, and connector type.                                                                                                |
| Encapsulation                              | Encapsulation method assigned to this port.                                                                                             |
| loopback...                                | Displays whether or not loopback is set.                                                                                                |

Administrative Trunking Encapsulation: dot1q
Operational Trunking Encapsulation: dot1q
Access Mode VLAN: 0 ((Inactive))
Trunking Native Mode VLAN: 1 (Default)
Trunking Vlans Enabled: ALL
Trunking Vlans Active: 1-3
```

The output of this command includes the following parameters:

| Parameter                             | Description                                            |
|---------------------------------------|--------------------------------------------------------|
| Name                                  | Port name.                                             |
| Switchport                            | Whether or not switchport is enabled.                  |
| Administrative mode                   | Administrative mode.                                   |
| Operational mode                      | Operational mode.                                      |
| Administrative Trunking Encapsulation | Encapsulation method used for administrative trunking. |
| Operational Trunking Encapsulation    | Encapsulation method used for operational trunking.    |
| Access Mode VLAN                      | The access mode VLAN for the specified port.           |

| Parameter                 | Description                                           |
|---------------------------|-------------------------------------------------------|
| Trunking Native Mode VLAN | The trunking native mode VLAN for the specified port. |
| Trunking Vlans Enabled    | Number of trunking VLANs currently enabled.           |
| Trunking Vlans Active     | Number of trunking VLANs currently active.            |

```
#show interface fastethernet 1/0 untrusted-vlan
Name: FE1/0
Untrusted Vlan(s)
```

The output of this command includes the following parameters:

| Parameter         | Description                 |
|-------------------|-----------------------------|
| Name              | Name of the specified port. |
| Untrusted Vlan(s) | List of untrusted VLANs.    |

```
#show interface fastethernet 1/1 xsec
xsec vlan 7 is ACTIVE
```

The output of this command includes the following parameters:

| Parameter             | Description                                                                           |
|-----------------------|---------------------------------------------------------------------------------------|
| xsec vlan 7 is ACTIVE | This states that xsec is active on the specified port as well as the associated VLAN. |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show interface gigabitethernet

show interface gigabitethernet <slot/module/port>

### Description

Displays information about a specified Gigabit Ethernet port.

### Syntax

| Parameter      | Description                                                 |
|----------------|-------------------------------------------------------------|
| counters       | Displays L2 interface counters for the specified interface. |
| switchport     | Displays L2 interface information.                          |
| untrusted-vlan | Displays port member vlan untrusted status.                 |
| xsec           | Displays xsec configuration.                                |

### Examples

The example below shows the output of **show interface gigabitethernet 1/0**.

```
(host)# show interface gigabitethernet 0/0/0
GE 0/0/0 is up, line protocol is up
Hardware is Gigabit Ethernet, address is 00:1A:1E:00:0D:09 (bia 00:1A:1E:00:0D:09)
Description: GE0/0/0 (RJ45 Connector)
Encapsulation ARPA, loopback not set
Configured: Duplex (AUTO), speed (AUTO)
Negotiated: Duplex (Full), speed (1000 Mbps)
Jumbo Support is enabled on this interface MTU 9216
Last clearing of "show interface" counters 1 day 20 hr 32 min 38 sec
link status last changed 1 day 19 hr 37 min 57 sec
120719 packets input, 24577381 bytes
Received 84208 broadcasts, 0 runts, 0 giants, 780 throttles
0 input error bytes, 0 CRC, 0 frame
32939 multicast, 36511 unicast
19865402 packets output, 4953350248 bytes
0 output errors bytes, 0 deferred
0 collisions, 0 late collisions, 0 throttles
This port is TRUSTED
```

The output of this command includes the following parameters:

| Parameter           | Description                                                     |
|---------------------|-----------------------------------------------------------------|
| GE 1/0 is...        | Displays the status of the specified port.                      |

# show interface loopback

show interface loopback

## Description

Displays information about the loopback IP interface.

## Syntax

No parameters

## Example

The example below shows the output of **show interface loopback** on a W-650 controller.

```
#show interface loopback
loopback interface is up line protocol is up
Hardware is Ethernet, address is 00:0B:86:51:14:D0
Internet address is 10.3.49.100 255.255.255.255
```

The output of this command includes the following parameters:

| Parameter                | Description                                           |
|--------------------------|-------------------------------------------------------|
| loopback interface is... | Status of the loopback interface.                     |
| line protocol is...      | Status of the line protocol on the specified port.    |
| Hardware is...           | Hardware interface type.                              |
| address is...            | MAC address of the loopback interface.                |
| Internet address is...   | IP address and subnet mask of the loopback interface. |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers. |

# show interface port-channel

show interface port-channel

## Description

Displays information about a specified port-channel interface.

## Syntax

| Parameter      | Description                                                 |
|----------------|-------------------------------------------------------------|
| access-group   | Displays access groups configured on this interface.        |
| counters       | Displays L2 interface counters for the specified interface. |
| untrusted-vlan | Displays port member vlan untrusted status.                 |
| xsec           | Displays xsec configuration.                                |

## Example

The example below shows the output of **show interface port-channel 0** on a controller.

```
(host) #show interface port-channel 6
Port-Channel 6 is administratively up
Hardware is Port-Channel, address is 00:1A:1E:00:0D:08 (bia 00:1A:1E:00:0D:08)
Description: Link Aggregate (LACP)
Spanning Tree is forwarding
Switchport priority: 0
Jumbo Support is enabled on this interface MTU 9216
Member port:
GE 0/0/4, Admin is up, line protocol is up
GE 0/0/5, Admin is up, line protocol is up
Last clearing of "show interface" counters 1 day 20 hr 32 min 43 sec
link status last changed 1 day 20 hr 29 min 58 sec
69425936 packets input, 15102169223 bytes
Received 27578 broadcasts, 0 runts, 0 giants, 0 throttles
0 input error bytes, 0 CRC, 0 frame
27568 multicast, 69398358 unicast
270782 packets output, 37271325 bytes
0 output errors bytes, 0 deferred
0 collisions, 0 late collisions, 0 throttles
Port-Channel 6 is TRUSTED
```

The output of this command includes the following parameters:

| Parameter            | Description                                        |
|----------------------|----------------------------------------------------|
| Port-Channel 6 is... | Status of the specified port.                      |
| line protocol is...  | Status of the line protocol on the specified port. |

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hardware is....                            | Hardware interface type.                                                                                                                                                                                                                                                                                                                    |
| address is...                              | MAC address of the hardware interface.                                                                                                                                                                                                                                                                                                      |
| Description                                | The port type, name, and connector type. If the LAG is created by LACP, it is indicated as shown in the display output above. If the LAG is created by LACP, you can not statically add or delete any ports under that port channel. All other commands are allowed. If LACP is not shown, then the LAG is created by static configuration. |
| Spanning Tree is...                        | Spanning tree status on the specified port-channel.                                                                                                                                                                                                                                                                                         |
| VLAN membership                            | Number of VLANs the specified port-channel is associated with.                                                                                                                                                                                                                                                                              |
| Switchport priority                        | Switchport priority of the specified port-channel.                                                                                                                                                                                                                                                                                          |
| Jumbo Support is...                        | Displays the status of jumbo frame on a port channel.                                                                                                                                                                                                                                                                                       |
| Last clearing of "show interface counters" | Time since "show interface counters" was cleared.<br><br>Below the time, all current counters related to the specified port are listed.                                                                                                                                                                                                     |
| Port-channel 0 is...                       | Whether or not this port-channel is trusted.                                                                                                                                                                                                                                                                                                |

```
#show interface port-channel 0 access-group
```

```
Port-Channel 0:
```

```
Port-Vlan Session ACL
```

```

SessionACL Vlan Status

```

The output of this command includes the following parameters:

| Parameter  | Description       |
|------------|-------------------|
| SessionACL | Session ACL name. |
| Vlan       | VLAN number.      |
| Status     | ACL status.       |

```
#show interface port-channel 0 counters
```

```
Port InOctets InUcastPkts InMcastPkts InBcastPkts
PC 0: 0 0 0 0
Port OutOctets OutUcastPkts OutMcastPkts OutBcastPkts
```

PC 0: 0 0 0 0

The output of this command includes the following parameters:

| Parameter    | Description                                            |
|--------------|--------------------------------------------------------|
| PC           | Port number.                                           |
| InOctets     | Number of octets received through the port.            |
| InUcastPkts  | Number of unicast packets received through the port.   |
| InMcastPkts  | Number of multicast packets received through the port. |
| InBcastPkts  | Number of broadcast packets received through the port. |
| OutOctets    | Number of octets sent through the port.                |
| OutUcastPkts | Number of unicast packets sent through the port.       |
| OutMcastPkts | Number of multicast packets sent through the port.     |
| OutBcastPkts | Number of broadcast packets sent through the port.     |

```
#show interface port-channel 0 untrusted-vlan
```

```
Name: FE1/0
Untrusted Vlan(s)
```

The output of this command includes the following parameters:

| Parameter         | Description                 |
|-------------------|-----------------------------|
| Name              | Name of the specified port. |
| Untrusted Vlan(s) | List of untrusted VLANs.    |

```
#show interface port-channel 0 xsec
xsec vlan 7 is ACTIVE
```

The output of this command includes the following parameters:

| Parameter             | Description                                                                           |
|-----------------------|---------------------------------------------------------------------------------------|
| xsec vlan 7 is ACTIVE | This states that xsec is active on the specified port as well as the associated VLAN. |

## Command History

| Release       | Modification                              |
|---------------|-------------------------------------------|
| ArubaOS 3.4.1 | Modified to display LACP when applicable. |
| ArubaOS 3.0.  | Command introduced.                       |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show interface-profile voip-profile

show interface-profile voip-profile <profile-name>

### Description

This command displays the specified VoIP profile configuration information.

### Syntax

| Parameter      | Description               |
|----------------|---------------------------|
| <profile-name> | Name of the VoIP profile. |

### Examples

The following example shows configuration details for the VoIP profile:

```
(host) #show interface-profile voip-profile profile1
VOIP profile "profile1"

Parameter Value
----- -
VOIP VLAN 1
DSCP 0
802.1 UP 0
VOIP Mode auto-discover
```

The output of this command includes the following information:

| Parameter | Description                                                    |
|-----------|----------------------------------------------------------------|
| VOIP VLAN | The Voice VLAN ID.                                             |
| DSCP      | The DSCP value for the voice VLAN.                             |
| 802.1 UP  | The 802.11p priority level.                                    |
| VOIP Mode | The mode of VoIP operation. It can be auto-discover or static. |

### Command History

Command introduced in ArubaOS 6.2.

### Command Information

| Platforms     | Licensing              | Command Mode                                         |
|---------------|------------------------|------------------------------------------------------|
| All platforms | Base operating system. | Enable or Config mode on master or local controllers |

## show interface tunnel

show interface tunnel <id>

### Description

Displays information about tunnel interfaces.

### Syntax

| Parameter | Description              |
|-----------|--------------------------|
| id        | Tunnel interface number. |

### Example

The example below shows the output of **show interface tunnel** for IPv4.

```
#show interface tunnel 2000
Tunnel 2000 is up line protocol is up
Description: Tunnel Interface
Internet address is 3.3.3.1 255.255.255.0
Source 192.168.203.1
Destination 192.168.202.1
Tunnel mtu is set to 1100
Tunnel is an IP GRE TUNNEL
Tunnel is Trusted
Inter Tunnel Flooding is enabled
Tunnel keepalive is disabled
```

The example below shows the output of **show interface tunnel** for IPv6.

```
#show interface tunnel 21
Tunnel 21 is up line protocol is up
Description: Tunnel Interface
Internet address is 2005:81::1:2
Source 2082::802:1(Vlan 802)
Destination 2082::802:2
Tunnel mtu is set to 1280
Tunnel is an IPv6 GRE TUNNEL
Tunnel is Trusted
Inter Tunnel Flooding is enabled
Tunnel keepalive is disabled
```

The output of this command includes the following parameters:

| Parameter           | Description                                                       |
|---------------------|-------------------------------------------------------------------|
| Tunnel 2000 is...   | Status of the specified tunnel.                                   |
| line protocol is... | Displays the status of the line protocol on the specified tunnel. |
| Description         | Description of the specified interface.                           |

| Parameter                   | Description                                              |
|-----------------------------|----------------------------------------------------------|
| Internet address is...      | IP address of the specified interface.                   |
| Source                      | IP address of the tunnel's source.                       |
| Destination                 | IP address of the tunnel's destination.                  |
| Tunnel mtu is set to...     | Size of the specified tunnel's MTU.                      |
| Tunnel is an...             | Description of the specified tunnel.                     |
| Tunnel is...                | Whether or not the specified tunnel is trusted.          |
| Inter tunnel flooding is... | Status of inter tunnel flooding on the specified tunnel. |
| Tunnel keepalive is...      | Status of tunnel keepalive on the specified tunnel.      |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show interface vlan

show interface vlan

### Description

Displays information about a specified VLAN interface.

### Syntax

No parameters

### Example

The example below shows the output of **show interface vlan 1** on a W-650 controller.

```
#show interface vlan 1
```

```
VLAN1 is up line protocol is down
Hardware is CPU Interface, Interface address is 00:0B:86:61:82:40 (bia 00:0B:86:61:82:40)
Description: 802.1Q VLAN
Internet address is 10.3.49.50 255.255.255.0
Routing interface is enable, Forwarding mode is enable
Directed broadcast is disabled, BCMC Optimization disabled ProxyARP disabled Suppress ARP
disabled
Encapsulation 802, loopback not set
MTU 1500 bytes
Last clearing of "show interface" counters 4 day 0 hr 28 min 58 sec
link status last changed 4 day 0 hr 28 min 58 sec
Proxy Arp is disabled for the Interface
DHCP Option-82 AP name and ESSID are configured on this Interface
```

The output of this command includes the following parameters:

| Parameter               | Description                                                    |
|-------------------------|----------------------------------------------------------------|
| VLAN1 is...             | Status of the specified VLAN                                   |
| line protocol is...     | Displays the status of the line protocol on the specified port |
| Hardware is...          | Describes the hardware interface type                          |
| Interface address is... | Displays the MAC address of the hardware interface             |
| Description             | Description of the specified VLAN                              |
| Internet address is...  | IP address and subnet mask of the specified VLAN               |
| Routing interface is... | Status of the routing interface                                |
| Forwarding mode is...   | Status of the forwarding mode                                  |

| Parameter                                  | Description                                                                                                                                                  |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Directed broadcast is...                   | Displays whether or not directed broadcast is enabled                                                                                                        |
| Encapsulation                              | Encapsulation type                                                                                                                                           |
| loopback...                                | Loopback status                                                                                                                                              |
| MTU                                        | MTU size of the specified port in bytes                                                                                                                      |

# show inventory

show inventory

## Description

Displays hardware inventory of the controller.

## Syntax

No parameters.

## Example

Issue this command to display the hardware component inventory of the controller. The output of this command will vary, depending upon controller type.

The voltage displayed in the right column should match the corresponding value in the left column, generally with +/- 5%. |

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

```
show iostat
```

Displays IO statistics information. This command reports Central Processing Unit (CPU) statistics and input/output statistics for devices and partitions.

No parameters.

Issue this command to display the IO statistics of the controller.

[illegible]

| Parameter | Description                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cpu       | The number of jiffies (1/100th of a second) that the system spent in user mode, user mode with low priority, system mode, and the idle task, respectively. |
| page      | The number of pages the system paged in and the number that were paged out (from disk).                                                                    |
| swap      | The number of swap pages that have been brought in an out.                                                                                                 |
| intr      | The number of interrupts received from the system boot.                                                                                                    |
| disk_io   | (x,y) is (major, minor):(xx, xx, xxxx, x, x) is (noinfo, read_io_ops, blks_read, write_io_ops, blks_written)                                               |
| ctxt      | The number of context switches that the system underwent.                                                                                                  |

| Parameter | Description                     |
|-----------|---------------------------------|
| btime     | The boot time, in seconds.      |
| processes | The number of forks since boot. |

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show ip access-group

show ip access-group

### Description

Display access control lists (ACLs) configured for each port on the controller.

### Syntax

No parameters.

### Examples

The example below shows part of the output of this command. If a port does not have a defined session ACL, the *Port-Vlan Session ACL* table will be blank.

```
(host) # show ip access-group
FE 1/0:
Rx access list 200 is applied
session access list User14 is applied

Port-Vlan Session ACL

SessionACL Vlan Status

coltrane 22 configured
```

The output of this command includes the following parameters:

| Parameter   | Description                                                                                    |
|-------------|------------------------------------------------------------------------------------------------|
| Session ACL | Name of the ACL applied to the interface.                                                      |
| VLAN        | If the ACL was applied to a VLAN associated with this port, this column will show the VLAN ID. |
| Status      | Shows whether or not the session ACL is configured.                                            |

### Related Commands

| Command                                                                  | Description                                 |
|--------------------------------------------------------------------------|---------------------------------------------|
| <a href="#">interface fastethernet   gigabitethernet ip access-group</a> | Configure an access group for an interface. |

## show ip access-list

```
show ip access-list {brief|<string>}
```

### Description

Display a table of all configured access control lists (ACLs), or show details for a specific ACL.

### Syntax

| Parameter | Description                                                                   |
|-----------|-------------------------------------------------------------------------------|
| brief     | Display a table of information for all ACLs.                                  |
| <string>  | Specify the name of a single ACL to display detailed information on that ACL. |

### Examples

The example below shows general information for all ACLs in the Access List table.

```
(Host) #show ip access-list brief
```

Access list table

```

Name Type Use Count Roles
---- -
200 eth
33 standard
allowall session 2 trusted-ap default-vpn-role
ap-acl session 2 rap_role ap-role
captiveportal session 4 coltrane-logon wizardtest-logon test-logon logon
captiveportal6 session 2 guest-logon logon
control session 7 ap-role coltrane-logon wizardtest-logon guest stateful
test-logon logon
cplogout session 1 guest
default session
guest session
log-https session
srcnat session
stateful-dot1x session 2 stateful-dot1x logon
stateful-kerberos session
validuser session 1 test-24325
```

The output of this command includes the following parameters:

| Parameter | Description                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Name      | Name of an access-control list (ACL).                                                                                                   |
| Type      | Shows that the ACL is one of the following ACL policy types: <ul style="list-style-type: none"><li>Ethertype</li><li>Standard</li></ul> |

| Parameter | Description                                                                                    |
|-----------|------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>• Session</li> <li>• MAC</li> <li>• Extended</li> </ul> |
| Use Count | Number of rules defined in the ACL.                                                            |
| Roles     | Names of user roles associated with the ACL.                                                   |

Include the name of a specific ACL to show detailed configuration information for that ACL. The output in the example below has been divided into two sections to better fit into this document. The output in the command-line interface will appear in a single, long table.

```
(host)# show ip access-list captiveportal6
ip access-list session captiveportal6

The output of the **show ip access-list** command may include some or all of the following parameters:

| Parameter | Description                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Priority  | Name of an access-control list (ACL).                                                                                                                                                                                                                                                               |
| Source    | <p>The traffic source, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• <b>alias</b>: The network resource (use the <code>netdestination</code> command to configure aliases; use the <code>show netdestination</code> command to see configured aliases)</li> </ul> |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <ul style="list-style-type: none"> <li>• <b>any</b>: Matches any traffic.</li> <li>• <b>host</b>: A single host IP address.</li> <li>• <b>network</b>: The IP address and netmask.</li> <li>• <b>user</b>: The IP address of the user.</li> <li>• <b>localip</b>: The set of all local IP addresses on the system, on which the ACL is applied.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Destination | <p>The traffic destination, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• <b>alias</b>: The network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases)</li> <li>• <b>any</b>: Matches any traffic.</li> <li>• <b>host</b>: A single host IP address.</li> <li>• <b>network</b>: An IP address and netmask.</li> <li>• <b>user</b>: The IP address of the user.</li> <li>• <b>localip</b>: The set of all local IP addresses on the system, on which the ACL is applied.</li> </ul>                                                                                                                                                                                                                                                                                                                |
| Service     | <p>Network service, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• An IP protocol number (0-255).</li> <li>• The name of a network service (use the show netservice command to see configured services).</li> <li>• <b>any</b>: Matches any traffic.</li> <li>• <b>tcp</b>: A TCP port number (0-65535).</li> <li>• <b>destination port number</b>: specify the TCP port number (0-65535)</li> <li>• <b>source</b>: TCP/UDP source port number</li> <li>• <b>udp</b>: A UDP port number (0-65535).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                 |
| Application | <p>Name of the application to which the access control list is applied. (For a complete list of supported applications, issue the command <b>show dpi application all</b>.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Action      | <p>Action if rule is applied, which can be one of the following:</p> <p><b>deny</b>: Reject packets.</p> <p><b>dst-nat</b>: Perform destination NAT on packets.</p> <p><b>dual-nat</b>: Perform both source and destination NAT on packets.</p> <p><b>permit</b>: Forward packets.</p> <p><b>redirect</b>: Specify the location to which packets are redirected, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• Datapath destination ID (<b>0-65535</b>).</li> <li>• <b>esi-group</b>: Specify the ESI server group configured with the esi group command</li> <li>• <b>opcode</b>: Specify the datapath destination ID (0x33, 0x34, or 0x82). Do not use this parameter without proper guidance from Dell.</li> </ul> <p><b>tunnel</b>: Specify the ID of the tunnel configured with the interface tunnel command.</p> <p><b>src-nat</b>: Perform source NAT on packets.</p> |

| Parameter   | Description                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IpssecMap   | Packets can be redirected over a VPN tunnel by specifying the name of an IPsec map in the access control list. This column specifies the name of an IPsec map used by a router ACL. For more information on IPsec maps, see <a href="#">crypto-local ipsec-map</a> . |
| Timerange   | Any defined time range for this rule.                                                                                                                                                                                                                                |
| NextHopList | If the access rule uses policy-based routing to forwards packets to a nexthop device, then this column displays the next-hop list associated with the rule. More more information on next-hop lists, see <a href="#">ip nexthop-list on page 540</a> .               |
| Tunnel      | Packets can be redirected over an L3 GRE tunnel. If the ACL routes packets over a tunnel, this column specifies the tunnel used by the ACL.                                                                                                                          |
| TunnelGroup | Packets can be redirected over an L3 GRE tunnel group. If the ACL routes packets over a tunnel in a tunnel group, this column specifies the tunnel group used by the ACL. For more information on tunnel groups, see <a href="#">tunnel-group</a> .                  |
| Log         | Shows if the rule was configured to generate a log message when the rule is applied.                                                                                                                                                                                 |
| Expired     | Shows if the rule has expired.                                                                                                                                                                                                                                       |
| Queue       | Shows if the rule assigns a matching flow to a priority queue (high/low).                                                                                                                                                                                            |
| 8021p       | 802.11p priority level applied by the rule (0-7).                                                                                                                                                                                                                    |
| Blacklist   | Shows if the rule should blacklist any matching user.                                                                                                                                                                                                                |
| Mirror      | Shows if the rule was configured to mirror all session packets to datapath or remote destination.                                                                                                                                                                    |
| DisScan     | Shows if the rule was configured to pause ARM scanning while traffic is present.                                                                                                                                                                                     |
| IPv4/6      | Shows the IP version.                                                                                                                                                                                                                                                |

## show ip cp-redirect-address

show ip cp-redirect-address

### Description

Show the captive portal automatic redirect IP address.

### Syntax

No parameters.

### Examples

The example below shows the IP address to which captive portal users are automatically directed.

```
(host) # show ip cp-redirect-address
Captive Portal redirect Address... 10.3.63.11
```

## show ip dhcp

```
show ip dhcp {binding|database|statistics}
```

### Description

Show DHCP Server Settings.

### Syntax

| Parameter  | Description                |
|------------|----------------------------|
| binding    | Show DHCP server bindings. |
| database   | Show DHCP server settings. |
| statistics | Show DHCP pool statistics. |

### Examples

The example below shows DHCP statistics for two configured networks.

```
(host) # show ip dhcp statistics
```

```
DHCPv4 enabled; DHCPv6 enabled
```

```
DHCP Pools
```

```

```

| Network Name     | Type | Active | Configured leases | Active leases | Free leases | Expired leases |
|------------------|------|--------|-------------------|---------------|-------------|----------------|
| Abandoned leases |      |        |                   |               |             |                |
| -----            |      |        |                   |               |             |                |
| 2-2-2-nw         | v4   | Yes    | 242               | 0             | 242         | 0              |
| 3-2-2-nw         | v4   | Yes    | 254               | 0             | 254         | 0              |
| test             | v4   | Yes    | 254               | 0             | 254         | 0              |
| 2011             | v6   | No     | 5                 | -             | -           | -              |
| 2012             | v6   | No     | 5                 | -             | -           | -              |
| Current leases   |      |        | 750               |               |             |                |
| Total leases     |      |        | 512               |               |             |                |

The output of this command includes the following parameters:

| Parameter         | Description                                                      |
|-------------------|------------------------------------------------------------------|
| Network Name      | Range of addresses that the DHCP server may assign to clients.   |
| Type              | Indicates the IP version of the DHCP server. It can be v4 or v6. |
| Active            | Indicates if the DHCP server is active or not.                   |
| Configured leases | Number of leases configured on the DHCP server.                  |
| Active leases     | Number of active DHCP leases.                                    |

| Parameter        | Description                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------|
| Free leases      | Number of available DHCP leases.                                                                               |
| Expired leases   | Number of leases that have expired because they have extended past their valid lease period.                   |
| Abandoned leases | Number of abandoned leases. Abandoned leases will not be reassigned unless there are no free leases available. |

## show ip domain-name

show ip domain-name

### Description

Show the full domain name and server.

### Syntax

No parameters.

### Examples

The example below shows that the IP domain lookup feature is enabled, but that no DNS server has been configured on the controller.

```
(host) #show ip domain-name
```

```
IP domain lookup: Enabled
IP Host.Domain name: MyCompany2400.
```

```
No DNS server configured
```

## show ip health-check

### Description

Display the health-check status of the uplink interfaces of a branch-office controller.

### Syntax

No parameters.

### Example

The following example displays the status of two uplinks on a branch controller.

```
(host) #show ip health-check
IP Health-Check Entries

Probe IP Src Interface State Probe Profile Avg RTT (ms)

10.10.10.254 vlan 1 UP Default 20.4
10.10.10.254 Cellular DOWN Default 0
```

The output of this command includes the following data columns.

| Parameter       | Description                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Probe IP        | IP address of the master controller.                                                                                                                    |
| Src Interface   | IP address of the uplink gateway interface through which the probes were sent.                                                                          |
| State           | Shows if the uplink is in an UP or DOWN state.                                                                                                          |
| Probe-Profile   | A branch controller supports only the <b>default</b> IP probe profile. For information on configuring an IP probe profile, see <a href="#">ip probe</a> |
| Avt RTT (in ms) | The average round trip time, in milliseconds. If the round trip time is less than 1 millisecond, the average round trip time will appear as 0.          |

| proxy-group vlan <vlan>            | Show IGMP proxy group information for a specific interface.                                                                                                                                                                                                                                                                                                                 |
| proxy-mobility-group maddr <maddr> | Display the IGMP proxy group information stored for mobile clients which are away from the controller.                                                                                                                                                                                                                                                                      |
| proxy-mobiity-stats                | Display the most important messages exchanged between the mobility process and the IGMP proxy.                                                                                                                                                                                                                                                                              |
| proxy-stats                        | Display the number of messages transmitted and received by the IGMP proxy on the upstream interface                                                                                                                                                                                                                                                                         |

## Examples

The example below displays the IGMP interface table for all VLANs on the controller.

```
(host) # show ip igmp interface vlan 2
```

IGMP Interface Table

| VLAN        | Addr       | Netmask       | MAC Address       | IGMP     | Snooping | Querier    |       |
|-------------|------------|---------------|-------------------|----------|----------|------------|-------|
| Destination | IGMP       | Proxy         |                   |          |          |            |       |
| ----        | ----       | -----         | -----             | ----     | -----    | -----      | ----- |
| 64          | 10.6.4.252 | 255.255.255.0 | 00:0b:86:01:99:00 | disabled | disabled | 10.6.4.252 | CP    |
| 65          | 10.6.5.252 | 255.255.255.0 | 00:0b:86:01:99:00 | disabled | disabled | 10.6.5.252 | CP    |
| 1           | 10.6.2.252 | 255.255.255.0 | 00:0b:86:01:99:00 | disabled | disabled | 10.6.2.252 | CP    |
| 66          | 10.6.6.252 | 255.255.255.0 | 00:0b:86:01:99:00 | disabled | disabled | 10.6.6.252 | CP    |
| 63          | 10.6.3.252 | 255.255.255.0 | 00:0b:86:01:99:00 | disabled | disabled | 10.6.3.252 | CP    |

The output of this command includes the following parameters:

| Parameter   | Description                                                  |
|-------------|--------------------------------------------------------------|
| VLAN        | A VLAN ID number.                                            |
| Addr        | IP address of a VLAN router.                                 |
| Netmask     | Subnet mask for the IP address.                              |
| MAC Address | MAC destination address.                                     |
| IGMP        | Indicates if IGMP is enabled (or disabled) on the interface. |
| Snooping    | Indicates if IGMP snooping is enabled (or disabled).         |
| Querier     | IP address of an IGMP querier.                               |
| Destination | Traffic destination.                                         |
| IGMP Proxy  | Indicates if IGMP proxy is enabled (or disabled).            |

The following example displays the current IGMP configuration settings for the controller.

```
(host) #show ip igmp config
```

IGMP Config

-----

| Name                    | Value |
|-------------------------|-------|
| ----                    | ----- |
| robustness-variable     | 2     |
| query-interval          | 30    |
| query-response-interval | 100   |
| startup-query-interval  | 31    |
| startup-query-count     | 2     |

```

last-member-query-interval 10
last-member-query-count 2
version-1-router-present-timeout 400
version-2-router-present-timeout 400
max-members-per-group 300
quick-client-convergence enabled
ssm-range IANA standard range. 232.0.0.0/8

```

The output of this command includes the following parameters:

| Parameter                        | Description                                                                                                                                                                                      |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| robustness-variable              | This variable is increased from its default level of 2 to allow for expected packet loss on a subnetwork.                                                                                        |
| query-interval                   | Interval, in seconds, at which the controller sends host-query messages to the multicast group address 224.0.0.1 to solicit group membership information.                                        |
| query-response-interval          | Maximum time, in .1 second intervals, that can elapse between when the controller sends a host-query message and when it receives a response. This must be less than the <b>query-interval</b> . |
| startup-query-count              | Number of queries that the controller sends out on startup, separated by startup-query-interval. The default setting is the value of the <b>robustness-variable</b> parameter.                   |
| startup-query-interval           | Interval, in seconds, at which the controller sends general queries on startup. The default value of this parameter is 1/4 of the <b>query-interval</b> .                                        |
| last-member-query-count          | Number of group-specific queries that the controller sends before assuming that there are no local group members.                                                                                |
| last-member-query-interval       | Maximum time, in seconds, that can elapse between group-specific query messages.                                                                                                                 |
| version-1-router-present-timeout | Timeout, in seconds, if the controller detects a version 1 IGM router.                                                                                                                           |
| version-2-router-present-timeout | Timeout, in seconds, if the controller detects a version 2 IGM router.                                                                                                                           |

```

### Description

Display statistics and configuration information for the mobile protocol.

### Syntax

| Parameter        | Description                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| active domains   | IP mobility domains active on this switch                                                                                                      |
| binding          | Display a list of Home Agent Bindings                                                                                                          |
| [<host-ip>]      | Filter the Home Agent Bindings list to display data for a specific host IPv4 address.                                                          |
| [<host-ipv6>]    | Filter the Home Agent Bindings list to display data for a specific host IPv6 address.                                                          |
| [<host-macaddr>] | Filter the Home Agent Bindings list to display data for a specific host MAC address.                                                           |
| [brief]          | Limit the output of this command to show just two lines of data.                                                                               |
| domain [<name>]  | Display subnet, VLAN and home agent information for all mobility domains, or specify a mobility domain name to view data for that domain only. |
| global           | View the current Mobility Agents global configuration                                                                                          |
| hat              | Display the Active Home Agent Table                                                                                                            |

| Parameter                                   | Description                                                                                                                                                                                                                                                                    |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host                                        | Display a list of Mobile IP hosts.                                                                                                                                                                                                                                             |
| [<host-ip>]                                 | Filter the Mobile Host List to display data for a specific host IPv4 address.                                                                                                                                                                                                  |
| [<host-ipv6>]                               | Filter the Mobile Host List to display data for a specific host IPv6 address.                                                                                                                                                                                                  |
| [<host-macaddr>]                            | Filter the Mobile Host List to display data for a specific host MAC address.                                                                                                                                                                                                   |
| [brief]                                     | Limit the output of this command to show just two lines of data.                                                                                                                                                                                                               |
| multicast-vlan-table                        | Displays mobility multicast VLAN table information.                                                                                                                                                                                                                            |
| mac                                         | MAC address of the client.                                                                                                                                                                                                                                                     |
| packet-trace [<count>]                      | The output of this command shows when packets of different types were sent between a source IP or MAC address and a destination IP or MAC address.                                                                                                                             |
| remote <host-ip> <host-ipv6> <host-macaddr> | This is a debug command can be used to identify the controller associated with the specified client IPv4/IPv6 address or MAC address. The output of this command shows the home agent (HA) and foreign agent (FA) for a mobile client, as well as the client's roaming status. |
| trace                                       | Show if the Mobile IP feature will poll remote controllers for mobility status of station                                                                                                                                                                                      |
| <host-ip>                                   | Host IPv4 address.                                                                                                                                                                                                                                                             |
| <host-ipv6>                                 | Host IPv6 address.                                                                                                                                                                                                                                                             |

| tunnel                                     | Show the Mobile Tunnel Table for IPIP Tunnels.                                                                                                                                |
| visitor                                    | Display a list of mobile nodes visiting a foreign agent.                                                                                                                      |
| [<host-ip>]                                | Filter the Foreign Agent Visitor list to display data for a specific host IPv4 address.                                                                                       |
| [<host-ipv6>]                              | Filter the Foreign Agent Visitor list to display data for a specific host IPv6 address.                                                                                       |
| [<host-macaddr>]                           | Filter the Foreign Agent Visitor list to display data for a specific host MAC address.                                                                                        |
| [brief]                                    | Limit the output of this command to show just two lines of data.                                                                                                              |

## Examples

The example below lists mobility domains configured on the controller, and shows information for any subnets defined on these domains.

```
(host) #show ip mobile domain
Mobility Domains:, 2 domain(s)

```

```
Domain name default
Home Agent Table, 0 subnet(s)
```

```
Domain name newdomain
Home Agent Table, 2 subnet(s)
 subnet mask VlanId Home Agent Description

 10.2.124.76 255.255.255.255 1 10.4.62.2 Corporate mobility entry
 172.21.5.50 255.255.255.255 1 10.4.62.2 Reserved entries
```

The output of this command includes the following parameters:

| Parameter   | Description                                     |
|-------------|-------------------------------------------------|
| Home Agent  | IP address of the home agent or mobility agent. |
| Description | Description of the HAT entry.                   |

Use the **show ip mobile host** command to track mobile users.

```
(host) # show ip mobile host
Mobile Host List, 1 host(s)

9c:b7:0d:3f:a6:dd 10.16.23.219 mobil
IPv4: 10.16.23.219
IPv6: fe80::826:aa9a:fe35:53e0
2004:deed::34
Roaming Status: Home Switch/Home VLAN, Service time 0 days 01:34:19
Home VLAN 623 on network 10.16.23.0/24
DHCP lease for PC at Sun Dec 23 20:32:00 2012 for 86400 secs from 10.16.28.1
```

The output of this command includes the following parameters:

| Parameter            | Description                                                             |
|----------------------|-------------------------------------------------------------------------|
| <mac-addr> <ip-addr> | MAC and IP addresses of the host                                        |
| Roaming Status       | Displays how long the host has used its current controller and VLAN.    |
| Home VLAN            | VLAN ID, IP address and subnet of the home VLAN.                        |
| DHCP lease           | Displays the amount of time the station has had its current DHCP lease. |

# show ip nat pool

show ip nat pool

## Description

Display pools of IP addresses for network address translation (NAT).

## Syntax

No parameters

## Examples

The example below shows the current NAT pool configuration on the controller.

```
(host) # show ip nat pools
NAT Pools

Name Start IP End IP DNAT IP

2net 2.1.1.1 2.1.1.1 2.1.1.125
```

The output of this command includes the following parameters:

| Parameter | Description                                                                             |
|-----------|-----------------------------------------------------------------------------------------|
| Name      | Name of the NAT pool.                                                                   |
| Start IP  | IP address that defines the beginning of the range of source NAT addresses in the pool. |
| End IP    | IP address that defines the end of the range of source NAT addresses in the pool.       |
| DNAT IP   | Destination NAT IP address, if defined.                                                 |

## show ip nexthop-list

### Description

Display nexthop list settings for policy-based routing.

### Syntax

No parameters.

### Usage Guidelines

A nexthop IP is the IP address of a adjacent router or device with layer-2 connectivity to the controller. The Nexthop list provides redundancy for the nexthop devices by forwarding the traffic to a backup nexthop device in case of failures. If active nexthop device on the list becomes unreachable, traffic matching a policy-based routing ACL is forwarded using the highest-priority active nexthop on the list. For more information on this feature, see [ip nexthop-list on page 540](#).

### Example

The following command displays the configuration settings for the one configured nexthop list.

```
(host))# show ip nexthop-list

Nexthop-list Name Nexthop-list Id Preemptive Failover Active IP

NH_list_1 0x4401 Enabled 10.10.10.254

Nexthop IPs (Priority)

10.18.2.254 (2), 10.10.10.254 (1)
```

The output of this command displays the following information

| Parameter              | Description                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nexthop-list Name      | Name of the nexthop list                                                                                                                                                                                                 |
| Nexthop-list Id        | Nexthop list ID assigned by the controller.                                                                                                                                                                              |
| Preemptive Fail-over   | This column indicates whether preemptive failover is enabled or disabled.<br>If preemption is enabled and a higher priority nexthop becomes reachable again, packets are again forwarded to the higher priority nexthop. |
| Active IP              | IP address of the actively used nexthop device.                                                                                                                                                                          |
| Nexthop IPs (Priority) | List of the IP addresses of all nexthop IPs, including the priority assigned to each device when the list was configured.                                                                                                |

## show ip ospf

```
show ip ospf
 database
 debug route
 interface [tunnel|vlan] <id>
 neighbor
 rapng-vpn aggregate-routes <ip-addr>
 redistribute
 subnet
```

### Description

Display statistics and configuration information for the Open Shortest Path First (OSPF) routing protocol.

### Syntax

| Parameter                    | Description                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| database                     | Show database information for the OSPF protocol.                                                                                                    |
| debug route                  | Show debugging information for OSPF routes.                                                                                                         |
| interface [tunnel vlan] <id> | Display the status of OSPF on an individual interface by specifying a tunnel or VLAN ID number. The tunnel ID range is 1-16777215.                  |
| neighbor                     | Display data for OSPF neighboring routers.                                                                                                          |
| rapng-vpn                    | Display IAP-VPN information.                                                                                                                        |
| aggregate-routes <ip-addr>   | Display IAP-VPN aggregate route information.                                                                                                        |
| redistribute                 | Display OSPF route distribution information.                                                                                                        |
| subnet                       | Display the subnets manually added to the Subnet Exclude List via the <a href="#">router ospf subnet exclude &lt;addr&gt; &lt;mask&gt;</a> command. |

### Example

If you issue this command without any of the optional parameters described in the table above, the show ip ospf command will display general router and area settings for the OSPF.

```
(host) (config-subif)# show ip ospf
OSPF is currently running with Router ID 123.45.110.200
Number of areas in this router is 1
Area 10.1.1.0
 Number of interfaces in this area is 2
 Area is totally stub area
```

SPF algorithm executed 0 times

The output of this command includes the following parameters.

| Parameter       | Description                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OSPF Router ID  | Verifies that OSPF is running and the router ID that OSPF is running on.                                                                                                                                                                      |
| Number of areas | List the number of areas configured in the router.                                                                                                                                                                                            |
| Area            | Displays the Area ID followed by: <ul style="list-style-type: none"> <li>• number of interfaces in the area</li> <li>• indicates if the area is a totally stub area</li> <li>• number of times the SPF algorithm has been executed</li> </ul> |

To display OSPF settings for an individual interface, you must specify a VLAN or tunnel ID number. The example below displays part of the output of the **show ip ospf interface vlan** command.

```
(host) # show ip ospf interface vlan 10
Vlan 3 is up, line protocol is up
Internet Address 3.3.3.1, Mask 255.255.255.0, Area 10.1.1.1
Router ID 10.4.131.227, Network Type BROADCAST, Cost: 1
Transmit Delay is 1 sec, State WAIT, Priority 1
Designated Router id 0.0.0.0, Interface Address 3.3.3.1
Backup designated Router id 0.0.0.0, Interface Address 3.3.3.1
Timer intervals configured, Hello 10, Dead 40, Retransmit 5
Neighbor Count is 0
Tx Stat: Hellos 1 DbDescr 0 LsReq 0 LsUpdate 0 LsAck 0 Pkts 1
Rx Stat: Hellos 0 DbDescr 0 LsReq 0 LsUpdate 0 LsAck 0 Pkts 0
 DisCd 0 BadVer 0 BadNet 0 BadArea 0 BadDstAdr 0 BadAuType 0
 BadAuth 0 BadNeigh 0 BadPckType 0 BadVirtLink 0
```

...

The output may include some or all of the following parameters.

| Parameter                   | Description                                                                        |
|-----------------------------|------------------------------------------------------------------------------------|
| Vlan <number>               | Identifies that the interface type and ID are up and functional.                   |
| Internet Address            | Internet address, network mask, and area assigned to the interface.                |
| Router ID                   | Displays the router ID, that the network type is Broadcast, and the cost value.    |
| Transmit Delay              | Details of the transmit delay, state, and priority.                                |
| Designated Router           | Details of the designated router ID and interface address.                         |
| Backup Designated Router ID | Details of the backup router ID and interface address.                             |
| Timer intervals configured  | Details of elapse time intervals for Hello, Dead, Transmit (wait), and retransmit. |

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor Count | Details the number of neighbors and adjacent neighbors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## show ip pppoe-info

show ip pppoe-info

### Description

Display configuration settings for Point-to-Point Protocol over Ethernet (PPPoE).

### Syntax

No parameters.

### Examples

The example below shows the current PPPoE configuration.

```
(host) #show ip pppoe-info
```

```
PPPoE username: rudolph123
PPPoE password: <HIDDEN>
PPPoE service name: ppp2056
PPPoE VLAN: 22
```

The output of this command includes the following parameters:

| Parameter          | Description                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PPPoE username     | PAP username configured on the PPPoE access concentrator.                                                                                                                                                   |
| PPPoE password     | If this parameter displays the word <b>&lt;HIDDEN&gt;</b> , a PAP password is configured on the PPPoE access concentrator. If this parameter is <b>&lt;NONE&gt;</b> , there is no PPOE password configured. |
| PPPoE service name | PPPoE service name.                                                                                                                                                                                         |
| PPPoE VLAN         | VLAN configured to use PPPoE to obtain an IP address via the command <b>interface vlan &lt;id&gt; ip address pppoe</b> .                                                                                    |

### Command History

Introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                                      |
|---------------|-----------------------|-------------------------------------------------------------------|
| All platforms | Base operating system | Available in Config or Enable mode on master or local controllers |

## show ip probe

show ip probe

### Description

This command displays the settings for the WAN health-check ping-probes for measuring WAN reachability and latency.

### Syntax

No parameters

### Usage Guidelines

The health-check feature uses ping-probes for measuring WAN reachability and latency. Latency is calculated based on the round-trip time (RTT) of ping responses. Ping settings are configured globally using the **ip probe default** command.

### Examples

The following command displays the current IP probe settings for the WAN health-check feature

```
(host) #show ip probe
IP Probe Entries

Name Probe Mode Frequency(in sec) Retries Burst size

default Ping 5 3 5
```

The output of this command contains the following information:

| Column     | Description                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Name       | ArubaOS supports a single instance of ip probe profile, which is always named <b>default</b> .                                                      |
| Probe Mode | <b>Ping</b> is the only mode currently supported by this feature.                                                                                   |
| Frequency  | Probe interval, in seconds. The WAN health-check feature sends the number of probes in the <b>Burst Size</b> column during each frequency interval. |
| retries    | Number of times the controller attempts to resend a probe.                                                                                          |
| burst-size | Number of probes sent during the probe frequency interval that appears in the <b>Frequency</b> column.                                              |

## show ip radius

```
show ip radius nas-ip|source-interface
```

### Description

Display global parameters for configured RADIUS servers.

### Syntax

| Command                       | Description                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------|
| <code>nas-ip</code>           | Show the Network Access Server (NAS) IP address attribute sent in outgoing RADIUS requests |
| <code>source-interface</code> | Show the source address of outgoing RADIUS requests                                        |

### Examples

The example below shows the RADIUS client NAS IP address.

```
(host) #show ip radius nas-ip
```

```
RADIUS client NAS IP address = 10.168.254.221
```

## show ip route

```
show ip route
 counters
 static
 stats
```

### Description

View the Dell controller routing table.

### Syntax

| Command  | Description                                                    |
|----------|----------------------------------------------------------------|
| counters | Displays the number of routes present, categorized by type.    |
| static   | Include this optional parameter to display only static routes. |
| stats    | Displays route statistics.                                     |

### Usage Guidelines

This command displays static routes configured on the controller via the [ip route](#) command. Use the [ip default-gateway](#) command to set the default gateway to the IP address of the interface on the upstream router or switch to which you connect the controller.

### Examples

The example below shows the ip address of routers and the VLANs to which they are connected.

```
(host) #show ip route
Codes: C - connected, O - OSPF, R - RIP, S - static
M - mgmt, U - route usable, * - candidate default, V - RAPNG VPN
Gateway of last resort is Imported from DHCP to network 0.0.0.0 at cost 10

## show ipc statistics app-ap

```
show ipc statistics app-ap {am|sapd|sta} {ap-name <ap-name>} [{bssid <bssid>}] [{ip-addr <ip-addr>}]
```

### Description

Display Inter Process Communication (IPC) statistics for a specific AP or BSSID.

### Syntax

| Parameter         | Description                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| am                | Show IPC statistics for an air monitor.                                                                                 |
| sapd              | Show IPC statistics for the SAPD process.                                                                               |
| stm               | Show IPC statistics for station management communications.                                                              |
| ap-name <ap-name> | Show IPC statistics for an AP with a specific name.                                                                     |
| bssid <bssid>     | Show IPC statistics for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address. |
| ip-addr <ip-addr> | Show IPC statistics for an AP with a specific IP address. Enter the IP address in dotted-decimal format.                |

### Usage Guidelines

Issue this command at the request of Dell support to troubleshoot application errors.

### Example

The following example shows IPC statistics for the SAPD process on an AP named **mpp125**.

```
(host) #show ipc statistics app-ap sapd ap-name mpp125
```

#### Local Statistics

| To application | Tx Msg | Tx Blk | Tx Ret | Tx Fail | Rx Ack | Rx Msg | Rx Drop | Rx Err | Tx |

| 0                |        |        |        |         |        |        |         |        |    |

```
Allocated Buffers 0
Static Buffers 1
Static Buffer Size 1444
```

The output of this command includes the following data columns:

| Parameter          | Description                                        |
|--------------------|----------------------------------------------------|
| Tx Msg             | Number of transmitted messages.                    |
| Tx Blk             | Number of blocking messages transmitted.           |
| Tx Ret             | Number of transmitted messages that were returned. |
| Tx Fail            | Number of failure messages that were transmitted.  |
| Rx Ack             | Number of received acknowledgements.               |
| Rx Msg             | Number of received messages.                       |
| Rx Drop            | Number of received messages that were dropped.     |
| Rx Err             | Number of received messages with errors.           |
| Tx Ack             | Number of transmitted acknowledgements.            |
| Allocated Buffers  | Number of allocated buffers for IPC messages.      |
| Static Buffers     | Number of static buffers for IPC messages.         |
| Static Buffer Size | Size of the static buffer.                         |

| Allocated Buffers  | 0       |        |        |         |         |         |         |        |    |
| Static Buffers     | 4       |        |        |         |         |         |         |        |    |
| Static Buffer Size | 1400    |        |        |         |         |         |         |        |    |

The output of this command includes the following data columns:

| Parameter | Description                                        |
|-----------|----------------------------------------------------|
| Tx Msg    | Number of transmitted messages.                    |
| Tx Blk    | Number of blocking messages transmitted.           |
| Tx Ret    | Number of transmitted messages that were returned. |
| Tx Fail   | Number of failure messages that were transmitted.  |
| Rx Ack    | Number of received acknowledgements.               |

| Parameter          | Description                                    |
|--------------------|------------------------------------------------|
| Rx Msg             | Number of received messages.                   |
| Rx Drop            | Number of received messages that were dropped. |
| Rx Err             | Number of received messages with errors.       |
| Tx Ack             | Number of transmitted acknowledgements.        |
| Allocated Buffers  | Number of allocated buffers for IPC messages.  |
| Static Buffers     | Number of static buffers for IPC messages.     |
| Static Buffer Size | Size of the static buffer.                     |

## Command History

This command was available in ArubaOS 3.0.

```

### Description

Displays IPv4 user table entries. You can filter the output based on various parameters are described in table.

### Syntax

| Parameter             | Description                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group>   | Filter the output of this command by showing users connected to APs that belong to the specified AP group. |
| ap-name <ap-name>     | Filter the output of this command by showing users connected to an AP with the specified AP name.          |
| authentication-method | Filter the output of this command by the authentication method used for the device:                        |
| dot1x                 | Show data for devices using 802.1X authentication.                                                         |
| mac                   | Show data for devices using MAC authentication.                                                            |
| opensystem            | Show data for devices using open (no) authentication.                                                      |
| psk                   | Show data for devices that do not use authentication but use a pre-shared key for encryption.              |
| stateful-dot1x        | Show data for devices using stateful 802.1X authentication.                                                |
| via-vpn               | Show data for devices that authenticate using Dell VIA.                                                    |
| vpn                   | Show data for devices using VPN authentication.                                                            |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| web          | Show data for devices using captive portal authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| bssid        | Displays entries in the IPv4 user-table that are associated to the specified BSSID.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| debug        | Displays entries in the IPv4 user-table that are in debug mode.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| essid        | Displays entries in the IPv4 user-table that are associated to the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.                                                                                                                                                                                                                                                                                                                                           |
| internal     | Displays internal IPv4 users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ip <A.B.C.D> | Displays IPv4 users that match the specified IPv4 IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| log          | Displays the log information for the specified IPv4 client.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| mac          | Displays users with the specified MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| mobile       | Displays list of mobile users in the IPv4 user table. The following filters are available for this parameter: <ul style="list-style-type: none"> <li>• <b>bindings</b>—list of users that have moved away from the current controller.</li> <li>• <b>rows</b>—displays entries that match the specified row number.</li> <li>• <b>unique</b>—displays unique entries in the IPv6 user-table.</li> <li>• <b>visitors</b>—displays users that have associated with the current controller.</li> </ul> |
| name         | Displays IPv4 user table entries that match the specified name.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| phy-type     | Displays IPv4 user table entries that match <b>a</b> or <b>b</b> phy-type.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| role         | Displays IPv4 user table entries that match the specified role.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| rows         | Displays specific rows in the IPv4 user table. Enter the starting row number and the number of rows to be displayed.                                                                                                                                                                                                                                                                                                                                                                                |
| station      | Displays the station table information for the IPv4 user table entries.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| verbose      | Displays the complete IPv4 user table with all details.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Example

This example displays a list of users.

```
(host) #show ipv4 user-table
```

```
Users
```

```

```

| IP           | MAC     | Name      | Role            | Age (d:h:m) | Auth |
|--------------|---------|-----------|-----------------|-------------|------|
| VPN link     | AP name | Roaming   | Essid/Bssid/Phy | Profile     |      |
| Forward mode | Type    | Host Name |                 |             |      |

The output of this command includes the following parameters:

| Parameter       | Description                                                          |
|-----------------|----------------------------------------------------------------------|
| IP              | IP address of the client in that row that authenticating using dot1x |
| MAC             | MAC address of the client.                                           |
| Name            | Name of the client.                                                  |
| Role            | The role assigned to the client.                                     |
| Age (d:h:m)     | Total time that client is connected to controller.                   |
| Auth            | Authentication type.                                                 |
| AP name         | Name of the AP associated with the client.                           |
| Roaming         | Current roaming status of the client.                                |
| Essid/Bssid/Phy | ESSID/BSSID/Phy to which the client is associated.                   |
| Profile         | Displays the AAA profile.                                            |

|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 access-list (deprecated)

show ipv6 access-list [<string> | brief]

### Description

Displays IPv6 access list configured in the controller.

### Syntax

| Parameter | Description                         |
|-----------|-------------------------------------|
| string    | To view details of a specific ACL.  |
| brief     | To view a summary of all IPv6 ACLs. |

### Command History

| Version     | Modification                                                                                  |
|-------------|-----------------------------------------------------------------------------------------------|
| ArubaOS 3.3 | Command introduced                                                                            |
| ArubaOS 6.1 | Command deprecated. This command has been replaced by the <b>show ip access-list</b> command. |

## show ipv6 datapath session counters (deprecated)

show ipv6 datapath session counters

### Description

Displays datapath session table statistics.

### Command History

| Version     | Modification                                                                                                  |
|-------------|---------------------------------------------------------------------------------------------------------------|

| ArubaOS 6.1 | Command deprecated. This command has been replaced by the <b>show datapath session ipv6 counters</b> command. |

## show ipv6 datapath session table (deprecated)

show ipv6 datapath session table <IPv6 Address>

### Description

Displays current IPv6 session on the controller.

### Syntax

| Parameter         | Description                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IPv6 IP Address> | Optional parameter. If specified, displays IPv6 datapath session table for that IP address. By default, displays session table for all IPv6 addresses. |

### Command History

| Version     | Modification                                                                                               |
|-------------|------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                                                         |
| ArubaOS 6.1 | Command deprecated. This command has been replaced by the <b>show datapath session ipv6 table</b> command. |

## show ipv6 datapath user counters (deprecated)

show ipv6 datapath user counters

### Description

Displays datapath user table statistics.

### Command History

| Version     | Modification                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                                                |
| ArubaOS 6.1 | Command deprecated. This command has been replaced by the <b>show datapath user ipv6</b> command. |

## show ipv6 datapath user table (deprecated)

show ipv6 datapath user table

### Description

Displays ipv6 datapath user table entries.

### Command History

| Version     | Modification                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                                                |
| ArubaOS 6.1 | Command deprecated. This command has been replaced by the <b>show datapath user ipv6</b> command. |

## show ipv6 dhcp

```
show ipv6 dhcp
 binding
 database [pool<pool_name>]
```

### Description

Shows DHCPv6 server settings.

### Syntax

| Parameter  | Description                  |
|------------|------------------------------|
| binding    | Show DHCPv6 server bindings. |
| database   | Show DHCPv6 server settings. |
| statistics | Show DHCPv6 pool statistics. |

### Examples

The example below shows the DHCPv6 database:

```
(host)#show ipv6 dhcp database
```

DHCPv6 enabled

```
2001-feed-64-nw
subnet6 2001:feed::/120 {
 option vendor-class-identifier "ArubaAP";
 option dhcp6.vendor-opts "2001:feed::235";
 range6 2001:feed::1 2001:feed::234;
 range6 2001:feed::236 2001:feed::ffff:ffff:ffff:fffe;
}
2003-feed-64-nw
subnet6 2003:feed::/120 {
 option vendor-class-identifier "ArubaAP";
 option dhcp6.vendor-opts "2001:feed::235";
 range6 2003:feed::1 2003:feed::234;
 range6 2003:feed::236 2003:feed::ffff:ffff:ffff:fffe;
}
DHCPv6
subnet6 2001:470:faca:4::/120 {
 default-lease-time 43200;
 max-lease-time 43200;
 option dhcp6.domain-search "test.org";
 option vendor-class-identifier "ArubaAP";
 option dhcp6.vendor-opts "2001:feed::235";
 option dhcp6.name-servers 2001:470:20::2;
 option dhcp6.preference 25;
 option dhcp6.usr-opt-24-DHCPv6 "Domain Search List";
 range6 2001:470:20::1 2001:470:faca:4::1;
 range6 2001:470:20::3 2001:470:faca:4:ffff:ffff:ffff:fffe;
}
```

The example below shows the DHCPv6 database for a specific pool:

```
(host) (config) #show ipv6 dhcp database [pool <pool-name>]
(host) (config) #show ipv6 dhcp database pool DHCPv6

DHCPv6
subnet6 2001:470:faca:4::/120 {
 default-lease-time 43200;
 max-lease-time 43200;
 option dhcp6.domain-search "test.org";
 option vendor-class-identifier "ArubaAP";
 option dhcp6.vendor-opts "2001:feed::235";
 option dhcp6.name-servers 2001:470:20::2;
 option dhcp6.preference 25;
 option dhcp6.usr-opt-24-DHCPv6 "Domain Search List";
 range6 2001:470:20::1 2001:470:faca:4::1;
 range6 2001:470:20::3 2001:470:faca:4:ffff:ffff:ffff:fffe;
}
```

The example below shows the DHCPv6 binding information:

```
(host)# show ipv6 dhcp binding
Client: fe80::1cf:2e1:cd13:356b; IA ID 0x13001f3c
ia-na "\023\000\037<\000\001\000\001\030\223\211\242\000%\263J\372\364" {
 cltt epoch 1364206514; # Mon Mar 25 15:45:14 2013
 iaaddr 2001:470:faca:4:21a:1eff:fe00:9e6 {
 binding state expired;
 preferred-life 187;
 max-life 300;
 ends epoch 1364206814; # Mon Mar 25 15:50:14 2013
 }
}
```

The example below shows the DHCPv6 active pools:

```
(host) #show ipv6 dhcp active-pools

DHCPv6 Active Pools

Vlan Pool Name

10 DHCPv6
```

## Related Commands

|--------------------------------|----------------------------------------------------------|
| <a href="#">ipv6 dhcp pool</a> | This command configures a DHCPv6 pool on the controller. |

## Command History

Introduced in ArubaOS 6.3.

## show ipv6 firewall

show ipv6 firewall

### Example

This example displays the status of all firewall configurations.

```
(host) #show ipv6 firewall
```

```
Global IPv6 firewall policies
```

```

Policy Action Rate Slot/Port

Monitor ping attack Disabled
Monitor TCP SYN attack Disabled
Monitor IPv6 sessions attack Disabled
Deny inter user bridging Disabled
Deny all IPv6 fragments Disabled
Per-packet logging Disabled
Enforce TCP handshake before allowing data Disabled
Prohibit RST replay attack Disabled
Session Idle Timeout Disabled
Session mirror destination Disabled
Prohibit IPv6 Spoofing Disabled
Enable IPv6 Stateful Firewall Disabled
```

The output of this command includes the following parameters:

| Parameter                    | Description                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monitor ping attack          | If enabled, the controller monitors the number of ICMP pings per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack.                                                     |
| Monitor TCP SYN attack       | If enabled, the controller monitors the number of TCP SYN messages per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack.                                               |
| Monitor IPv6 sessions attack | If enabled, the controller monitors the number of TCP session requests per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack sessions.                                  |
| Deny inter user bridging     | If enabled this setting prevents the forwarding of Layer-2 traffic between wired or wireless users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic. |
| Deny all IPv6 fragments      | If enabled, all IPv6 fragments are dropped.                                                                                                                                                                                              |

| Parameter                                  | Description                                                                                                                                                                                                                                       |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Per-packet logging                         | If active, and logging is enabled for the corresponding session rule, this feature logs every packet.                                                                                                                                             |
| Enforce TCP handshake before allowing data | If enabled, this feature prevents data from passing between two clients until the three-way TCP handshake has been performed. Enabling this option causes mobility to fail. So, disable this option if you have mobile clients on the network as. |
| Prohibit RST replay attack                 | If enabled, this setting closes a TCP connection in both directions if a TCP RST is received from either direction.                                                                                                                               |
| Session Idle Timeout                       | Shows if a session idle timeout interval has been defined.                                                                                                                                                                                        |
| Session mirror destination                 | Destination to which mirrored packets are sent.                                                                                                                                                                                                   |
| Prohibit IPv6 Spoofing                     | Status on IPv6 spoofing. When this option is enabled, IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.                                                                                         |
| Enable IPv6 Stateful Firewall              | Shows if IPv6 stateful firewall is enabled.                                                                                                                                                                                                       |

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                          |

# show ipv6 interface

show ipv6 interface [brief]

## Description

View IPv6-related information on all interfaces.

## Syntax

| Parameter | Description                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------|
| brief     | Optional parameter. If specified, displays the IPv6-related information on all the interfaces in a summary format. |

## Example

```
(host) #show IPv6 interface
VLAN1 is up line protocol is down
IPv6 Router Advertisements are disabled
IPv6 is disabled
VLAN46 is up line protocol is up
IPv6 is enabled, link-local address is fe80::1a:1e00:2e00:9f0
Global unicast address(es):
2046:eab::25, subnet is 2046:eab::/64
IPv6 Router Advertisements are disabled
VLAN50 is up line protocol is up
IPv6 Router Advertisements are disabled
IPv6 is disabled
VLAN10 is up line protocol is up
IPv6 is enabled, link-local address is fe80::1a:1e00:a00:9f0
Global unicast address(es):
2010:eab::1, subnet is 2010:eab::/64
fc01:eab::1, subnet is fc01:eab::/64
IPv6 Router Advertisements are enabled
loopback is up line protocol is up
IPv6 is enabled, link-local address is fe80::1a:1e0f:ff00:9f0
Global unicast address:
2046:eab::2, subnet is 2046:eab::2/128
TUNNEL2 is up line protocol is up
tunnel mode is Layer2 IPv6 GRE, tunnel vlan 10
tunnel source ipv6 address is 2046:eab::25
tunnel destination ipv6 address is 2047:eab::25
```

```
(host) #show ipv6 interface brief
Interface [Status/Protocol]

## show ipv6 mld config

show ipv6 mld config

### Description

Displays Multicast Listener Discover (MLD) configuration details.

### Example

This example displays the current MLD configuration values.

```
(host) #show ipv6 mld config
```

MLD Config

-----

| Name                    | Value                          |
|-------------------------|--------------------------------|
| robustness-variable     | 2                              |
| query-interval          | 125                            |
| query-response-interval | 100                            |
| ssm-range               | FF3X::4000:1 - FF3X::FFFF:FFFF |

The output of this command includes the following parameters:

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| robustness-variable     | Denotes the value that is used to calculate the timeout value of an MLD client.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| query-interval          | Denotes the time interval at which the MLD query is sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| query-response-interval | Denotes the time interval at which the MLD query response should be received.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ssm-range               | <p>Denotes the source specific multicast range. When you enter the SSM Range ensure that the upstream router has the same range, else the multicast stream would be dropped.</p> <p><b>Note:</b> Only SSM enabled clients can subscribe to the multicast stream in the multicast range. The default ssm-range in case of IPv6 is FF3X::4000:1 - FF3X::FFFF:FFFF, this range is configurable.</p> <p>If MLDv1 or a non SSM client sends a report on a specified SSM range, it is rejected by the controller.</p> |

### Command History

| Release     | Modification                                   |
|-------------|------------------------------------------------|
| ArubaOS 3.3 | Command introduced.                            |
| ArubaOS 6.4 | The <b>ssm-range</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                          |

## show ipv6 mld counters

```
show ipv6 mld counters
```

### Description

Displays the statistics of MLD.

### Example

This example displays the MLD statistics for the following values.

```
(host) #show ipv6 mld counters
```

```
MLD Statistics
```

```

```

| Name                   | Value |
|------------------------|-------|
| ----                   | ----- |
| received-total         | 0     |
| received-queries       | 0     |
| received-v1-reports    | 0     |
| received-leaves        | 0     |
| received-unknown-types | 0     |
| len-errors             | 0     |
| checksum-errors        | 0     |
| not-vlan-dr            | 0     |
| transmitted-queries    | 0     |
| forwarded              | 0     |

The output of this command includes the following parameters:

| Parameter              | Description                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------|
| received-total         | The total number of MLD messages.                                                              |
| received-queries       | The total number of MLD queries.                                                               |
| received-v1-reports    | The total number of MLD v1 reports received.                                                   |
| received-leaves        | The total number of MLD v1 leave messages received.                                            |
| received-unknown-types | The total number of unrecognized messages received.                                            |
| len-errors             | The total number of error message where the length check has failed.                           |
| checksum-errors        | The total number of error message where the checksum has failed.                               |
| not-vlan-dr            | The number of messages received for which the current controller is not the designated router. |
| transmitted-queries    | The total number of transmitted MLD queries.                                                   |

| Parameter | Description                                 |
|-----------|---------------------------------------------|
| forwarded | The total number of MLD messages forwarded. |

## Command History

This command was available in ArubaOS 3.3.

## Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 mld group

show ipv6 mld group

### Example

This example displays MLD group details.

```
(host) #show ipv6 mld group
```

MLD Group Table

| Group             | Members | Mode    | Age |
|-------------------|---------|---------|-----|
| -----             | -----   | ----    | --- |
| ff02::1:ff00:0    | 2       | Exclude | 4   |
| ff02::1:ff00:1900 | 2       | Exclude | 1   |

| ff02::1:ff5b:aac4 | 2       | Exclude | 11  |
| ff02::1:ff9f:df01 | 2       | Exclude | 3   |
| Total Groups: 17  |         |         |     |

The output of this command includes the following parameters:

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Group     | Name of MLD groups.                                                                                                                                                                                                                                                                                                                                                         |
| Members   | Number of members in an MLD group.                                                                                                                                                                                                                                                                                                                                          |
| Mode      | Controller supports two IPv6 multicast source filtering modes - Include and Exclude. In Include mode, the reception of packets sent to a specified multicast address is enabled only from the source addresses listed in the source list. In Exclude mode, the reception of packets sent to a specific multicast address is enabled from all source addresses (MLDv1 mode). |
| Age       | This parameter specifies the aging time.                                                                                                                                                                                                                                                                                                                                    |

This example displays MLD group address details.

```
(host) #show ipv6 mld group maddr ff1e::2 mac 9c:b7:0d:3f:a8:fc
```

MLD member 9c:b7:0d:3f:a8:fc Table

| Source       | Age |
|--------------|-----|
| -----        | --- |
| 2001:feed::2 | 26  |

The output of the `show ipv6 mld group` command includes the following parameters:

| Parameter | Description                              |
|-----------|------------------------------------------|
| Source    | IP address of the multicast source.      |
| Age       | This parameter specifies the aging time. |

## Command History

| Release     | Modification                                              |

| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 mld interface

```
show ipv6 mld interface
```

### Example

This example displays MLD status on VLANs. To view details for a specific VLAN, you can specify the VLAN ID.

```
(host) #show ipv6 mld interface
```

MLD Interface Table

| VLAN | Link local address | Snooping | Proxy    | Querier | Querier-dest | Upstream querier | Upstream port |
|------|--------------------|----------|----------|---------|--------------|------------------|---------------|
| 1    | ::                 | disabled | disabled | ::      | unknown      | ::               | -             |
| 160  | ::                 | disabled | disabled | ::      | unknown      | ::               | -             |

The output of this command includes the following parameters:

| Parameter          | Description                                              |
|--------------------|----------------------------------------------------------|
| VLAN               | Denotes the VLAN ID.                                     |
| Link local address | IP address of the VLAN interface.                        |
| Snooping           | Status of MLD snooping.                                  |
| Proxy              | Status of MLD proxy configuration.                       |
| Querier            | IPv6 address of the MLD querier for the VLAN.            |
| Querier-dest       | Denotes the destination of MLD querier on VLAN.          |
| Upstream querier   | Denotes the address of upstream MLD querier on VLAN.     |
| Upstream port      | Denotes the destination of upstream MLD querier on VLAN. |

### Command History

This command was available in ArubaOS 3.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers. |

## show ipv6 mld proxy-group

```
show ipv6 mld proxy-group [vlan <vlan>]
```

### Example

This example displays MLD proxy-group details.

```
(host) #show ipv6 mld proxy-group
MLD Proxy Group Table

VLAN Addr Group Num Members
---- ---- -
10 fe80::b:8600:a61:cc5c ff1e::5 2
10 fe80::b:8600:a61:cc5c ff02::1:ff9e:dc4c 1
10 fe80::b:8600:a61:cc5c ff02::1:3 2
10 fe80::b:8600:a61:cc5c ff02::1:ff83:d718 1
10 fe80::b:8600:a61:cc5c ff02::1:ff13:356b 1
10 fe80::b:8600:a61:cc5c ff02::c 2
Total displayed proxy groups: 6
```

The output of this command includes the following parameters:

| Parameter   | Description                        |
|-------------|------------------------------------|
| VLAN        | Denotes the VLAN ID.               |
| Addr        | IP address of the VLAN interface.  |
| Group       | Name of MLD group.                 |
| Num Members | Number of members in an MLD group. |

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 mld proxy-stats

```
show ipv6 mld proxy-stats
```

### Example

This example displays the status of the MLD proxy.

```
(host) #show ipv6 mld proxy-stats
MLD Proxy Statistics(Upstream)

Name Sent Received
---- -
Queries - 39
Joins 51 112
Leaves 9 0
```

The output of this command includes the following parameters:

| Parameter | Description                 |
|-----------|-----------------------------|
| Name      | Type of packet.             |
| Sent      | Number of packets sent.     |
| Received  | Number of packets received. |

### Command History

This command was available in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 mld proxy-mobility-group

```
show ipv6 mld proxy-mobility-group [maddr <maddr>]
```

### Example

This example displays MLD proxy-mobility-group details.

```
(host) #show ipv6 mld proxy-mobility-group
MLD MIP Group Table

Group Members

ff1e::2 1
ff02::1:3 2
ff02::c 1
```

The output of this command includes the following parameters:

| Parameter | Description                                 |
|-----------|---------------------------------------------|
| Group     | Name of MLD mobility group.                 |
| Members   | Number of members in an MLD mobility group. |

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 mld proxy-mobility-stats

```
show ipv6 mld proxy-mobility-stats
```

### Example

This example displays the details of MLD proxy-mobility statistics.

```
(host) #show ipv6 mld proxy-mobility-stats
```

```
MLD Mobility Multicast Statistics
```

```

The output of this command includes the following parameters:

| Parameter | Description                 |
|-----------|-----------------------------|
| Name      | Type of packet.             |
| Sent      | Number of packets sent.     |
| Received  | Number of packets received. |

### Command History

This command was available in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show ipv6 neighbors

show ipv6 neighbors

### Description

Displays the IPv6 neighbors configured on a VLAN interface.

### Usage Guidelines

This command displays the IPv6 neighbors configured on a VLAN interface via the [ipv6 neighbor](#) command.

### Examples

The example below shows the ipv6 neighbors configured on VLAN 1 .

```
(host) #show ipv6 neighbors vlan 1
```

```
IPv6 Neighbors
```

```

```

| IPv6 Address         | Age | Link-layer Addr   | State     | Interface |
|----------------------|-----|-------------------|-----------|-----------|
| -----                | --- | -----             | ----      | -----     |
| 2cce:205:160:100::fe | -   | 00:0b:86:61:13:28 | PERMANENT | vlan 1    |

### Command History

Introduced in ArubaOS 6.1.

### Command Information

| Platforms     | Licensing             | Command Mode                                                      |
|---------------|-----------------------|-------------------------------------------------------------------|
| All platforms | Base operating system | Available in Config or Enable mode on master or local controllers |

## show ipv6 ra status

show ipv6 ra status

### Description

Displays the IPv6 RA status on the VLAN interfaces.

### Usage Guidelines

This command displays the IPv6 RA status on the VLAN interfaces.

### Examples

The example below shows the IPv6 RA status on the VLAN interfaces .

```
(host) #show ipv6 ra status
```

```
IPv6 RA Status
```

```

VlanId State Prefix(es)

1 enabled 2001:abcd:1234:dead::/64
220 enabled 2200:eab:feed:12::/64
230 enabled 2300:eab:feed::/64
7 enabled 2001:470:faca:2::/64
 2001:470:faca:3::/64
 2001:470:faca:4::/64
```

### Command History

Introduced in ArubaOS 6.2.

### Command Information

| Platforms     | Licensing             | Command Mode                                                      |
|---------------|-----------------------|-------------------------------------------------------------------|
| All platforms | Base operating system | Available in Config or Enable mode on master or local controllers |

## show ipv6 route

show ipv6 route [counters | static]

### Description

Displays the Dell controller IPv6 routing table.

### Syntax

| Command  | Description                                                         |
|----------|---------------------------------------------------------------------|
| counters | Displays the number of routes present, categorized by type.         |
| static   | Include this optional parameter to display only static IPv6 routes. |

### Usage Guidelines

This command displays static IPv6 routes configured on the controller via the [ipv6 route](#) command. Use the [ipv6 default-gateway](#) command to set the default gateway to the IPv6 address of the interface on the upstream router or switch to which you connect the controller.

### Examples

The examples below show the ipv6 address of routers and the VLANs to which they are connected.

```
(host) #show ipv6 route
```

```
Codes: C - connected, O - OSPF, R - RIP, S - static
 M - mgmt, U - route usable, * - candidate default
```

```
Gateway of last resort is 2001::3 to network ::/128 at cost 1
S* ::/0 [1/0] via 2001::3*
C 2001::/64 is directly connected, VLAN1
C 2010:abcd:1234:dead::/64 is directly connected, VLAN10
```

```
(host) #show ipv6 route static
```

```
Gateway of last resort is 2001::3 to network ::/128 at cost 1
S* ::/0 [1/0] via 2001::3*
```

### Command History

| Release     | Modification                          |
|-------------|---------------------------------------|
| ArubaOS 6.1 | Command introduced.                   |
| ArubaOS 6.3 | Introduced <b>counters</b> parameter. |

## Command Information

| Platforms     | Licensing             | Command Mode                                                      |
|---------------|-----------------------|-------------------------------------------------------------------|
| All platforms | Base operating system | Available in Config or Enable mode on master or local controllers |

## show ipv6 user-table

```
show ipv6 user-table
 ap-group <ap-group>
 ap-name <ap-name>
 authentication-method dot1x|mac|opensystem|psk|stateful-dot1x|via-vpn|vpn|web
 bssid <A:B:C:D:E:F>
 debug
 essid <STRING>
 internal
 ip <A.B.C.D> [log]
 mac <A:B:C:D:E:F>
 mobile {[bindings][visitors]}
 name <STRING>
 phy-type {[a]|[b]}
 role <STRING>
 rows <NUMBER> <NUMBER>
 station
 verbose
```

### Description

Displays IPv6 user table entries. You can filter the output based on various parameters are described in table.

### Syntax

| Parameter             | Description                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group>   | Filter the output of this command by showing users connected to APs that belong to the specified AP group. |
| ap-name <ap-name>     | Filter the output of this command by showing users connected to an AP with the specified AP name.          |
| authentication-method | Filter the output of this command by the authentication method used for the device:                        |
| dot1x                 | Show data for devices using 802.1X authentication.                                                         |
| mac                   | Show data for devices using MAC authentication.                                                            |
| opensystem            | Show data for devices using open (no) authentication.                                                      |
| psk                   | Show data for devices that do not use authentication but use a pre-shared key for encryption.              |
| stateful-dot1x        | Show data for devices using stateful 802.1X authentication.                                                |
| via-vpn               | Show data for devices that authenticate using Dell VIA.                                                    |
| vpn                   | Show data for devices using VPN authentication.                                                            |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| web          | Show data for devices using captive portal authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| bssid        | Displays entries in the IPv6 user-table that are associated to the specified BSSID.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| debug        | Displays entries in the IPv6 user-table that are in debug mode.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ssid         | Displays entries in the IPv6 user-table that are associated to the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.                                                                                                                                                                                                                                                                                                                                           |
| internal     | Displays internal IPv6 users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ip <A.B.C.D> | Displays IPv6 users that match the specified IPv6 IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| log          | Displays the log information for the specified IPv6 client.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| mac          | Displays users with the specified MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| mobile       | Displays list of mobile users in the IPv6 user table. The following filters are available for this parameter: <ul style="list-style-type: none"> <li>• <b>bindings</b>—list of users that have moved away from the current controller.</li> <li>• <b>rows</b>—displays entries that match the specified row number.</li> <li>• <b>unique</b>—displays unique entries in the IPv6 user-table.</li> <li>• <b>visitors</b>—displays users that have associated with the current controller.</li> </ul> |
| name         | Displays IPv6 user table entries that match the specified name.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| phy-type     | Displays IPv6 user table entries that match <b>a</b> or <b>b</b> phy-type.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| role         | Displays IPv6 user table entries that match the specified role.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| rows         | Displays specific rows in the IPv6 user table. Enter the starting row number and the number of rows to be displayed.                                                                                                                                                                                                                                                                                                                                                                                |
| station      | Displays the station table information for the IPv6 user table entries.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| verbose      | Displays the complete IPv6 user table with all details.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Example

This example displays a list of users.

```
(host)#show ipv6 user-table
```

```
Users
```

```

```

| IP        |         | MAC     | Name            | Role | Age (d:h:m) | Auth         | VPN  |
|-----------|---------|---------|-----------------|------|-------------|--------------|------|
| link      | AP name | Roaming | Essid/Bssid/Phy |      | Profile     | Forward mode | Type |
| Host Name |         |         |                 |      |             |              |      |

```

2010:eab::59ee:264a:a702:ca57 c0:14:3d:d9:e2:1b salz guest 00:04:30 802.1x
AP-105 Away IPv6-dot1x-7220/00:24:6c:11:88:40/g-HT default tunnel Win 7
User Entries: 1/1

```

This example displays 802.1X authenticated users in the IPv6 user table.

```
(host)#show ipv6 user-table authentication-method dot1x
```

Users

```

IP
Auth VPN link AP name MAC Roaming Essid/Bssid/Phy Name Role Age (d:h:m) Profile

```

The output of this command includes the following parameters:

| Parameter       | Description                                                          |
|-----------------|----------------------------------------------------------------------|
| IP              | IP address of the client in that row that authenticating using dot1x |
| MAC             | MAC address of the client.                                           |
| Name            | Name of the client.                                                  |
| Role            | The role assigned to the client.                                     |
| Age (d:h:m)     | Total time that client is connected to controller.                   |
| Auth            | Authentication type.                                                 |
| AP name         | Name of the AP associated with the client.                           |
| Roaming         | Current roaming status of the client.                                |
| Essid/Bssid/Phy | ESSID/BSSID/Phy to which the client is associated.                   |
| Profile         | Displays the AAA profile.                                            |

| Release     | Modification                                                                                                                                                                               |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.3 | Command introduced                                                                                                                                                                         |
| ArubaOS 6.3 | The optional <b>log</b> parameter was introduced to display log files for events triggered by a specific user. Only W-6000, W-3600 and W-7200 Series controllers support per-user logging. |

## Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show keys

show keys [all]

### Description

Show whether optional keys and features are enabled or disabled on the controller.

### Syntax

| Parameter | Description                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| all       | Include this optional parameter to display the status of all optional keys and features. If this parameter is omitted, the output displays the status of the most commonly used features and keys. |

### Example

The following example displays the status of the most commonly used keys and features on the controller.

```
(host) #show keys
Licensed Features

Feature Status

Access Points 64

## Related Commands

To view the license usage database (including the license key strings) use the command [show license on page 1658](#).

## Command History

This command was available in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show lacp

```
show lacp <group_number> {counters | internal | neighbor}
```

### Description

View the LACP configuration status.

### Syntax

| Parameter      | Description                                                              |
|----------------|--------------------------------------------------------------------------|
| <group_number> | Enter the Link aggregation group number.<br>Range: 0-7                   |
| counters       | Enter the keyword <b>counters</b> to view the LACP traffic.              |
| internal       | Enter the keyword <b>internal</b> to view the LACP internal information. |
| neighbor       | Enter the keyword <b>neighbor</b> to view the LACP neighbor information. |

### Example

The port uses the group number +1 as its “actor admin key”. By default, all the ports use the long timeout value (90 seconds).

```
(Host)#show lacp 0 neighbor
Flags: S - Device is requesting Slow LACPDUs
 F - Device is requesting fast LACPDUs
 A - Device is in active mode P - Device is in passive mode
Partner's information

Port Flags Pri OperKey State Num Dev Id

FE 1/1 SA 1 0x10 0x45 0x5 00:0b:86:51:1e:70
FE 1/2 SA 1 0x10 0x45 0x6 00:0b:86:51:1e:70
```

When a port, in a LAG, is misconnected (that is, the partner device is different than the other ports or the neighborhood times out or can not exchange LACPDUs with the partner), the port status is displayed as “DOWN” (see the following example).

```
(Host)#show lacp 0 internal
Flags: S - Device is requesting Slow LACPDUs
 F - Device is requesting fast LACPDUs
 A - Device is in active mode P - Device is in passive mode

Port Flags Pri AdminKey OperKey State Num Status

FE 1/1 SA 1 0x1 0x1 0x45 0x2 DOWN
FE 1/2 SA 1 0x1 0x1 0x45 0x3 UP
```

The “counters” option allows you to view LACP received (Rx) traffic, transmitting (Tx) traffic, data units (DU) received and transmitted by port.

```
(Host)#show lacp 0 counters
```

| Port   | LACPDUTx | LACPDURx | MarkrTx | MarkrRx | MrkrRspTx | MrkrRspRx |
|--------|----------|----------|---------|---------|-----------|-----------|
| FE 1/1 | 10       | 10       | 0       | 0       | 0         | 0         |
| FE 1/2 | 12       | 12       | 0       | 0       | 0         | 0         |

## show lacp sys-id

show lacp sys-id

### Description

View the LACP system MAC address and port priority.

### Example

This command returns the port priority and the MAC address (comma separated). In the example below, the port priority is the default value 32768 followed by the MAC address 00:0B:86:40:37:C0.

```
(Host)#show lacp sys-id
32768,00:0B:86:40:37:C0
```

## show lcd-menu

show lcd-menu

### Description

Displays the current LCD Menu configuration.

### Syntax

None.

### Example

An example output of the **show lcd-menu** command.

```
lcd-menu

Parameter Value

menu maintenance upgrade-image partition0 enabled
menu maintenance upgrade-image partition1 enabled
menu maintenance upgrade-image enabled
menu maintenance upload-config enabled
menu maintenance factory-default enabled
menu maintenance media-eject enabled
menu maintenance reload-system enabled
menu maintenance halt-system enabled
menu maintenance enabled
menu enabled
```

## show license aggregate

show license aggregate

### Description

Display the license limits sent from centralized licensing clients to the licensing server.

### Syntax

No Parameters.

### Usage Guidelines

If your deployment uses the centralized licensing feature, you can issue this command from the command-line interface of the centralized licensing server controller to view license limits sent by licensing clients.

### Example

Issue this command from the command-line interface of the centralized licensing server controller. The following example displays output of the **show license aggregate** command.

```
Aggregate License Table

Hostname IP Address AP PEF RF Protect xSec Module ACR Last update (secs. ago)

Spectrum14 172.3.21.10 3587 2432 1536 8192 0 6

Total AP License Count :3587
Total PEF License Count :2432
Total RF Protect License Count :1536
Total XSEC License Count :8192
Total ACR License Count :0
```

The output of this command includes the following data columns:

| Parameter   | Description                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------|
| Hostname    | Name of the licensing client controller.                                                                                |
| IP Address  | IP address of the licensing client controller.                                                                          |
| AP          | Total number of AP licenses sent from licensing clients associated with this controller.                                |
| PEF         | Total number of Policy Enforcement Firewall (PEF) licenses sent from licensing clients associated with this controller. |
| RF Protect  | Total number of RFprotect licenses sent from licensing clients associated with this controller.                         |
| xSec Module | Total number of Extreme Security (xSec) licenses sent from licensing clients associated with this controller.           |

| Parameter                     | Description                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACR                           | Total number of advanced Cryptography (ACR) licenses sent from licensing clients associated with this controller.                                                                                          |
| Last update (secs. ago)       | Time, in seconds, that has elapsed since the licensing table on the master licensing controller was updated.                                                                                               |
| Total <license> License Count | These rows display the total numbers of licenses available for each license type. These numbers include licenses sent from licensing clients and any licenses currently installed on the licensing master. |

## Related Commands

Issue this command from the command-line interface of the centralized licensing master controller.

## show license client-table

show license client-table

### Description

Display the centralized license limits applied to each licensing client.

### Syntax

No Parameters.

### Usage Guidelines

If your deployment uses the centralized licensing feature, issue this command from the command-line interface of a centralized licensing client to view license limits applied to that licensing client from the licensing table.

### Example

The following example displays output of the **show license client-table** command.

```
(host) #show license client-table
Built-in limit: 32
License Client Table

Service Type System Limit Server Lic. Used Lic. Contributed Lic.
Remaining Lic.

Access Points 256 5120 1 5120 255
Next Generation PEF Module 256 2047 1 2048 255
RF Protect 256 6143 1 6144 255
xSec Module 4096 16384 0 16384 4096
Advanced Cryptography 4096 1024 0 1024 1024
```

The output of this command includes the following data columns:

| Parameter        | Description                                                                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Type     | Type of license on the licensing client.                                                                                                                                                                                                                                                      |
| System Limit     | The maximum number of licenses supported by the controller platform.                                                                                                                                                                                                                          |
| Server Lic.      | Number of licenses available for use by the licensing client.<br><b>NOTE:</b> This number is limited by the total license capacity of the controller platform. A controller cannot use more licenses than is supported by that controller platform, even if additional license are available. |
| Used Lic.        | Total number of licenses of each license type used by the licensing client controller.                                                                                                                                                                                                        |
| Contributed Lic. | Total number of licenses of each license type contributed by the licensing client controller.                                                                                                                                                                                                 |

| Parameter      | Description                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remaining Lic. | Total number of remaining licensing available on this controller. This number is also limited by the total license capacity of the controller platform. |

| All platforms | Base operating system | Enable mode on centralized licensing client controllers |

## show license debug

show license debug

### Description

Displays a summary of the current settings of the centralized licensing feature.

### Syntax

No parameters

### Example

The following example shows the output of the **show license debug** command.

```
(host) # show license debug

Summary of licensing state
Centralized Licensing: Enabled
Switch Role: Master
License Role: License Server
Master IP: 192.0.2.100
Switch IP: 192.0.1.103
License Server IP: 0.0.0.0
```

The output of this command includes the following data columns:

| Parameter             | Description                                                                                                                                                                          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Centralized licensing | Shows if centralized licensing is enable or disabled                                                                                                                                 |
| Switch Role           | Role of the controller on which this command is run                                                                                                                                  |
| License Role          | Licensing role of the controller on which this command is run. A master controller can be a licensing client or a licensing server. Local controllers can be licensing clients only. |
| Master IP             | IP address used by the master controller. If the master controller is using VRRP, this parameter displays the VRRP virtual IP address.                                               |
| Switch IP             | IP address assigned to the controller on which this command is run.                                                                                                                  |
| License Server IP     | <Reserved for future use>                                                                                                                                                            |

### Related Commands

|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                 |
|---------------|-----------------------|----------------------------------------------|
| All platforms | Base operating system | Enable mode on local and master controllers. |

## show license heartbeat stats

show license heartbeat stats

### Description

Display the license heartbeat statistics between the centralized licensing server and the license client.

### Syntax

No Parameters.

### Usage Guidelines

If your deployment uses the centralized licensing feature, issue this command from the command-line interface of a centralized licensing server to view heartbeat requests to and responses from each licensing client associated to that licensing server. If you issue this command from a licensing client, the output displays information for that one client only.

### Example

The following example displays output of the **show license heartbeat stats** command issued from the licensing server.

```
(host) #show license heartbeat stats
```

License Heartbeat Table

-----

| IP Address  | HB Req | HB Resp | Total Missed | Last Update |
|-------------|--------|---------|--------------|-------------|
| 10.3.17.130 | 233    | 233     | 0            | 18          |
| 10.3.17.120 | 233    | 233     | 0            | 19          |
| 10.3.17.190 | 234    | 234     | 0            | 9           |
| 10.3.17.140 | 233    | 233     | 0            | 7           |

The output of this command includes the following data columns:

| Parameter    | Description                                                                         |
|--------------|-------------------------------------------------------------------------------------|
| IP address   | IP address of the licensing client.                                                 |
| HB Req       | Heartbeat requests sent from the licensing client.                                  |
| HB Resp      | Heartbeat responses received from the license server.                               |
| Total Missed | Total number of heartbeats that were not received by the licensing client.          |
| Last Update  | Number of seconds elapsed since the licensing client last sent a heartbeat request. |

### Related Commands

|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                                                 |
|---------------|-----------------------|------------------------------------------------------------------------------|
| All platforms | Base operating system | Enable mode on centralized licensing master or licensing client controllers. |

## show license profile

show license profile

### Description

Display the license profile to determine if centralized licensing is enabled on the controller.

### Syntax

No Parameters.

### Usage Guidelines

If your deployment uses the centralized licensing feature, issue this command from the command-line interface of a centralized licensing master or client to determine if centralized licensing is enabled on that controller. Note that each controller supports only one licensing profile.

### Example

The following example displays output of the **show license profile** command issued from a licensing master.

```
(host) #show license profile
License provisioning profile

Parameter Value

Centralized Licensing Enabled
```

### Related Commands

To view additional statistics for license usage on the licensing server master, use the command [show license aggregate](#).

### Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

### Command Information

| Platforms     | Licensing             | Command Mode                                                       |
|---------------|-----------------------|--------------------------------------------------------------------|
| All platforms | Base operating system | Enable mode on centralized licensing server or client controllers. |

## show license server-table

show license server-table

### Description

Display the license table as it appears on the centralized licensing server.

### Syntax

No Parameters.

### Usage Guidelines

If your deployment uses the centralized licensing feature, issue this command from the command-line interface of a centralized licensing server to view licensing counts for each supported license type..

### Example

The following example displays output of the **show license server-table** command issued from a licensing server.

```
(host) #show license server-table
License Server Table
```

```

Service Type Aggregate Lic. Used Lic. Remaining Lic.

Access Points 3587 0 3587
Next Generation Policy Enforcement Firewall Module 2432 3 2429
RF Protect 1536 3 1533
xSec Module 8192 0 8192
Advanced Cryptography 0 0 0
```

The output of this command includes the following data columns:

| Parameter      | Description                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------|
| Service Type   | Type of license on the licensing server.                                                                     |
| Available Lic. | Number of licenses in the licensing table on the licensing server.                                           |
| Used Lic.      | Total number of licenses of each license type reported as used by the licensing clients or licensing server. |
| Remaining Lic. | Total number of remaining licensing available in the licensing table.                                        |

### Related Commands

To view additional statistics for license usage on the licensing server master, use the command [show license aggregate](#).

# show license server-redundancy

show license server-redundancy

## Description

Display information about a redundant server used by the centralized licensing feature.

## Syntax

No Parameters.

## Usage Guidelines

If your deployment uses the centralized licensing feature, issue this command from the command-line interface of a centralized licensing server to view to information for the redundant server.

## Example

The following example displays output of the **show license server-redundancy** command issued from a licensing server.

```
(host) #show license server-redundancy
License Server redundancy configuration:
License VRRP Id 1 current state is BACKUP
License Peer's IP Address is 10.1.1.42
```

## Related Commands

For more information on configuring a redundant licensing server for the centralized licensing feature, see [license](#).

## Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.3 | Command introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                                                 |
|---------------|-----------------------|------------------------------------------------------------------------------|
| All platforms | Base operating system | Enable mode on centralized licensing master or licensing client controllers. |

## show license-usage

show license-usage acr | ap | user | xsec | client

### Description

Display license usage information.

### Syntax

| Parameter | Description                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------|
| acr       | Show ACR license usage                                                                                |
| ap        | Show AP license usage information.                                                                    |
| user      | Show Policy Enforcement Firewall (PEF) user license usage.                                            |
| xsec      | Show Extreme Security (xSec) user and tunnel license usage.                                           |
| client    | For deployments using centralized licensing, show the license usage by centralized licensing clients. |

### Examples

The following example displays the user license usage.

```
(host) #show license-usage user
```

```
User License Usage

Name Value
---- -
License Limit 2048
License Usage 12
License Available 2036
License Exceeded 0
```

The AP license usage is displayed below:

```
(host) #show license-usage AP
```

```

AP Licenses

Type Number
---- -
AP Licenses 512
RF Protect Licenses 512
PEF Licenses 512
Overall AP License Limit 512

```

```

AP Usage

Type Count
---- -
Active CAPs 3
Standby CAPs 0
RAPs 0
Remote-node APs 0
Tunneled nodes 0
Total APs 3

```

```

Remaining AP Capacity

Type Number
---- -
CAPs 509
RAPs 509

```

When you issue the **show license-usage client** command from the command-line interface of a controller configured as a centralized licensing server, the output displays license usage statistics for each licensing client associated to that server. The output in the example below is separated into two tables to better fit in this document. In the ArubaOS command-line interface, the output appears in a single wide table.

```

License Clients License Usage

Hostname IP Address AP Lic. Used PEF Lic. Used RF Protect Lic. Used

controller_corp11 192.0.2.10 16 1 1
controller_corp17 192.0.2.12 16 1 1

xSec Lic. Used ACR Lic. Used Last update (secs. ago)

0 0 16
1 0 18

Total AP Licenses Used :32
Total PEF Licenses Used :2
Total RF Protect Licenses Used :2
Total XSEC Licenses Used :1
Total ACR Licenses Used :0
Total no. of clients :2

```

The output of the **show license-usage client** command includes the following data columns:

| Parameter  | Description                                    |
|------------|------------------------------------------------|
| Hostname   | Name of the licensing client controller.       |
| IP Address | IP address of the licensing client controller. |

| Parameter               | Description                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------|
| AP                      | Total number of AP licenses used by a licensing client associated with this controller.                                |
| PEF                     | Total number of Policy Enforcement Firewall (PEF) licenses used by a licensing client associated with this controller. |
| RF Protect              | Total number of RFprotect licenses used by a licensing client associated with this controller.                         |
| xSec Module             | Total number of Extreme Security (xSec) licenses used by a licensing client associated with this controller.           |
| ACR                     | Total number of advanced Cryptography (ACR) licenses used by a licensing client associated with this controller.       |
| Last update (secs. ago) | Time, in seconds, that has elapsed since the licensing table on the licensing client was updated.                      |

## show lldp interface

```
show lldp interface [fastethernet <slot/port> | gigabitethernet <slot/port>]
```

### Description

This command displays the LLDP interfaces information.

### Syntax

| Parameter                   | Description                                                |
|-----------------------------|------------------------------------------------------------|
| fastethernet <slot/port>    | Displays LLDP information on a fastethernet port.          |
| gigabitethernet <slot/port> | .Displays LLDP information on a gigabitethernet interface. |

### Example

The example shows two commands. The output of the **show lldp interface** command displays information for all LLDP interfaces.

```
(host) #show lldp interface
LLDP Interfaces Information

Interface LLDP TX LLDP RX LLDP-MED TX interval Hold Timer

GE1/3 Enabled Enabled Enabled 30 120
```

The following example only shows information for the GE1/3 interface.

```
(host) #show lldp interface gigabitethernet 1/3
Interface: gigabitethernet1/3
LLDP Tx: Enabled, LLDP Rx: Enabled
LLDP-MED: Enabled
Transmit interval: 30, Hold timer: 120
```

| Parameter   | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| Interface   | Name of an LLDP interface.                                                        |
| LLDP TX     | Shows if LLDP Protocol Data Unit (PDU) transmission is enabled or disabled.       |
| LLDP RX     | Shows if the controller has enabled or disabled processing of received LLDP PDUs. |
| LLDP-MED    | Shows if LLDP MED protocol is enabled or disabled.                                |
| TX interval | The LLDP transmit interval, in seconds.                                           |
| Hold Timer  | The LLDP transmit hold multiplier.                                                |

## Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.4 | Command Introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show lldp neighbor

```
show lldp neighbor interfaces [fastethernet <slot/port> | gigabitethernet <slot/port>
[detail]]
```

### Description

This command displays information about LLDP peers.

### Syntax

| Parameter                   | Description                                               |
|-----------------------------|-----------------------------------------------------------|
| fastethernet <slot/port>    | Displays LLDP information on a fastethernet port.         |
| gigabitethernet <slot/port> | Displays LLDP information on a gigabitethernet interface. |
| detail                      | Include details.                                          |

### Example

The command in the first example below shows that the ports GE1/3 and GE1/4 recognize each other as an LLDP peers.

```
(host)#show lldp neighbor
Capability codes: (R)Router, (B)Bridge, (A)Access Point, (P)Phone, (O)Other
LLDP Neighbor Information

Local Intf Chassis ID Capability Remote Intf Expiry-Time (Secs)

GE1/3 00:0b:86:6a:25:40 B:R GE0/0/17 105
GE1/4 00:0b:86:6a:25:40 B:R GE0/0/18 105
System name

Dell W-3600
Dell W-3600
Number of neighbors: 2
(host) #show lldp neighbor interface gigabitethernet 1/3 detail
Interface: gigabitethernet1/3, Number of neighbors: 1

```

The output of the **show lldp neighbor** command includes the following information:

| Parameter   | Description                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------|
| Local Intf  | Slot and port number.                                                                                           |
| Chassis ID  | MAC address of the LLDP Peer.                                                                                   |
| Capability  | Shows the capabilities of the peer to operate as a router, bridge, access point, phone or other network device. |
| Remote Intf | Remote interface.                                                                                               |
| Expiry-time | Expiry time.                                                                                                    |
| System Name | Name of the peer system, as supplied by the peer.                                                               |

The output of the **show lldp neighbor interface gigabitethernet <slot/module/port> detail** command varies, depending upon the type of LLDP peer detected. The output in the example above contains the following information:

| Parameter             | Description                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Interface             | Name of the port for which you are viewing LLDP neighbor information.                                                       |
| Number of Neighbors   | Number of LLDP neighbors seen by the port.                                                                                  |
| Chassis id            | MAC address of the neighbor device.                                                                                         |
| Management address    | MAC address of the neighbor's management port.                                                                              |
| Interface description | Description of the LLDP neighbor interface.                                                                                 |
| ID                    | Interface ID of the LLDP neighbor interface.                                                                                |
| MTU                   | Maximum Transmission Unit size allowed by the neighbor device in bytes.                                                     |
| Device MAC            | Shows the MAC address of the IAP connected to the MAS port.                                                                 |
| Last Update           | Date and time the neighbor device's status changed.                                                                         |
| Time to live          | Time, in seconds, for which this information is valid.                                                                      |
| Expires in            | Time, in seconds, before this information is considered invalid.                                                            |
| System capabilities   | This column shows the capabilities of the peer to operate as a router, bridge, access point, phone or other network device. |

| Parameter                | Description                                                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enabled capabilities     | This column if the peer has been actively configured to operate as a router, bridge, access point, phone or other network device.                               |
| System name              | Name of the peer system, as supplied by the peer.                                                                                                               |
| System description       | Description of the peer system, as supplied by the peer.                                                                                                        |
| Auto negotiation         | Shows if link auto-negotiation is enabled for the peer interface.                                                                                               |
| Media attached unit type | This parameter displays additional details about an LLDP-MED device attached to the interface. The specific details depend upon the capabilities of the device. |
| VLAN                     | VLAN ID assigned to the peer interface.                                                                                                                         |
| pvid                     | Indicates if the VLAN ID is assigned to the peer access port.                                                                                                   |
| MAC                      | Shows the MAC address of the rogue AP detected by the Instant AP(IAP), which is blacklisted by the MAS.                                                         |
| LLDP-MED                 | Shows details for LLDP-MED (Media Endpoint Discovery), if applicable.                                                                                           |
| Device Type              | Type of LLDP-MED device connected to the peer interface.                                                                                                        |
| Capability               | Capabilities of the LLDP-MED device connected to the peer interface.                                                                                            |

## Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.4 | Command Introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show lldp statistics

```
show lldp statistics [interface fastethernet <slot/port> | gigabitethernet <slot/port>]
```

### Description

This command displays the LLDP statistics information.

### Syntax

| Parameter                   | Description                                               |
|-----------------------------|-----------------------------------------------------------|
| fastethernet <slot/port>    | Displays LLDP information on a fastethernet port.         |
| gigabitethernet <slot/port> | Displays LLDP information on a gigabitethernet interface. |

### Usage Guidelines

By default, this command displays LLDP statistics for the entire list of LLDP interfaces. Include a slot/port number to display statistics only for that one interface.

### Example

The example command below shows LLDP statistics for the Gigabit Ethernet interface **0/0**.

```
(host) #show lldp statistics interface gigabitethernet 0/0
```

LLDP Statistics

-----

| Interface          | Received | Unknow TLVs | Malformed | Transmitted |
|--------------------|----------|-------------|-----------|-------------|
| -----              | -----    | -----       | -----     | -----       |
| gigabitethernet0/0 | 1249     | 0           | 0         | 1249        |

The output of this command includes the following information:

| Parameter                   | Description                                                                        |
|-----------------------------|------------------------------------------------------------------------------------|
| Interface                   | Name of an LLDP interface.                                                         |
| Received                    | Number of packets received on that interface.                                      |
| Unknown TLVs                | Number of LLDP Protocol Data Units (PDUs) with an unknown type-length-value (TLV). |
| Number of Malformed packets | Number of malformed packets received on that interface.                            |
| Transmitted                 | Number of packets transmitted from that interface.                                 |

### Command History

| Release     | Modification        |
|-------------|---------------------|
| ArubaOS 6.4 | Command Introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master and local controllers |

## show local-cert-mac

```
show local-cert-mac
tag <mac>
```

### Description

Display the IP, MAC address and certificate configuration of local controllers in a master-local configuration.

### Syntax

| Parameter | Description                                                                            |
|-----------|----------------------------------------------------------------------------------------|
| tag <tag> | IP address of the local controller or MAC address of the local controller certificate. |

### Usage Guidelines

By default the output of this command shows each local controller's IP and MAC address and the type of certificate used by those local controllers (Custom or Factory). Use the optional **tag** parameter to display information for a single controller only.

### Example

The output of this command shows that two local controllers have a custom certificate installed.

```
(host) # show local-cert-mac
Local Switches configured by Local Certificate

Switch IP of the Local MAC address of the Local Certificate Cert-Type CA cert

10.4.62.3 0B:86:F0:12:AC:15
10.4.62.5 00:0B:86:F0:05:60 Custom Undefined
```

The output of this command includes the following information:

| Column                               | Description                                                                                                                                                                                     |

## Command History

Available in ArubaOS 6.1

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show localip

show localip

### Description

Displays the IP address and VPN shared key between master and local.

### Syntax

No parameters.

### Example

The output of this command shows the controller's IP address and shared key between master and local controllers.

```
(host) # show localip

Local Switches configured by Local Switch IP

Switch IP address of the Local Key
----- ---
0.0.0.0 *****
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show local-userdb

```
show local-userdb {[maximum-expiration][start <offset> page <page_size>]}
```

### Description

Shows information about user's accounts in the local user database.

### Syntax

| Parameter          | Description                                                                     |
|--------------------|---------------------------------------------------------------------------------|
| maximum-expiration | How long the account is valid, in minutes, in the internal database.            |
| <offset>           | The user account record's location (by number) as it is listed in the database. |
| <page_size>        | The number of user account records that display on one page.                    |

### Usage Guidelines

Issue this command without any parameters to display a general overview of user's accounts in the database. Use the **maximum-expiration** parameter to show how long the account is valid for in minutes. Use the **start <offset> page <page\_size>** parameters to control which user account records in the database display initially and the number of account records displayed on a page.

### Example

This example shows the basic summary of a user accounts in the database.

```
(host) #show local-userdb maximum-expiration start 5 page 4
```

```
local-userdb maximum-expiration 90
```

```
User Summary
```

```

```

```
User Entries: 11
```

The output of this command includes the following parameters:

| Parameter | Description          |
|-----------|----------------------|
| Name      | Name of the user.    |
| Password  | The user's password. |

| Parameter    | Description                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Role         | Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method. |
| E-mail       | Shows the email address of the user account.                                                                                                                                                                                                                           |
| Enabled      | Shows whether the account is enabled or disabled.                                                                                                                                                                                                                      |
| Expiry       | Shows the expiration date for the user account. If this is not set, the account does not expire.                                                                                                                                                                       |
| Status       | Shows whether the profile has enabled or disabled the ability to use the HTTP protocol to redirect users to the captive portal page.                                                                                                                                   |
| Sponsor-Name | Shows the sponsor's name.                                                                                                                                                                                                                                              |
| Grantor-Name | Shows the grantor's name.                                                                                                                                                                                                                                              |
| User Entries | Shows the number of user accounts in the database.                                                                                                                                                                                                                     |

## show local-userdb-ap

```
local-userdb-ap
 mac-address <macaddr>
 start
```

### Description

View detailed information for the obsolete RAP whitelist database used in ArubaOS 6.1 and earlier.

### Syntax

| Parameter              | Description                                                                    |
|------------------------|--------------------------------------------------------------------------------|
| mac-address <mac-addr> | MAC address of the remote AP to be removed from the Remote AP Whitelist table. |
| start <offset>         | Start displaying the table at the specified record in the database             |

### Usage Guidelines

When you upgrade from ArubaOS 5.0-6.1 to ArubaOS 6.2 or later, the remote AP whitelist table will automatically move from the legacy Remote AP whitelist to the newer Remote AP whitelist. Issue the **show local-userdb-ap** command to view and troubleshoot any AP entries that did not properly move to the new table during the upgrade procedure. In the example below, the command output has been divided into two tables to fit on a single page of this document. In the command-line interface, this output would appear in a single, wide table.

```
(host) #show local-userdb-ap
```

| Name             | MAC address of the AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| AP-Group         | Name of the AP group to which the AP has been assigned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| AP-name          | Name of the AP. If no name has been specified, this column will display the AP's MAC address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Full-name        | Text string used to identify the AP. This field often describes the AP's user, and corresponds to the <b>User Name</b> field in the RAP whitelist in the WebUI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Authen-Username  | User name of the user who authenticated the remote AP. This parameter holds the user name of the user who authenticated the remote AP. This is related to the zero touch authentication feature, as a user needs to authenticate an AP before it gets its complete configuration. Before the AP is authenticated, it is given a restricted configuration to allow users to perform captive portal authorization via the remote AP's ENET ports to authenticate the remote AP. The username used during captive portal authentication will be stored in this field. This cannot be added manually when creating a local-userdb-ap entry.                                                                                                                                                                                                                                                                                                                                                      |
| Revoke-Text      | The command <b>local-userdb-ap revoke</b> includes an optional <b>revoke-comment</b> parameter that allows network administrators to explain why the AP was revoked. If an AP is revoked, and a revoke comment entered, this text appears in the <b>revoke-text</b> column in the <b>show local-userdb-ap</b> command. When a local DB entry is reenabled via the command <b>local-userdb-ap modify mac-addr mode enable</b> , this field is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| AP_Authenticated | <p>This column indicates the authorization status of the AP. An AP can either be <b>Authenticated</b> or <b>Provisioned</b>.</p> <p>Remote APs that <i>do not</i> support certificate-based provisioning will always display a <b>Provisioned</b> status.</p> <p>Remote APs that support certificate-based provisioning can display either a <b>Authenticated</b> or <b>Provisioned</b> status, depending on their configuration and authentication status.</p> <ul style="list-style-type: none"> <li>• If the remote AP has a defined AP authorization profile, the remote AP will be in a "Provisioned" state with a limited configuration until it is authenticated. After it the remote AP has been authenticated, it will be in an "Authenticated" state.</li> <li>• If the remote AP does not have a defined AP authorization profile, the remote AP will be in a "Provisioned" state, but will still receive the full configuration assigned to that AP and its AP group.</li> </ul> |
| Description      | A text string used to further identify the remote AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Date-Added       | Date and time that the AP was added to the local user database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Enabled          | <p>This column shows if the entry in the database is enabled or disabled. Database entries can be enabled or disabled using the CLI commands:</p> <pre>local-userdb-ap {add modify} mac-address &lt;mac-addr&gt; mode {enable disable}</pre> <p>and</p> <pre>local-userdb-ap revoke mac-address &lt;mac-addr&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## show local-userdb-branch

```
show local-userdb-branch mac-address <mac-addr> start <offset>
```

### Description

The output of this command lists the MAC address and assigned branch config group for branch controllers associated with that master.

### Syntax

| Parameter              | Description                                                                     |
|------------------------|---------------------------------------------------------------------------------|
| mac-address <mac-addr> | Branch controller's MAC address in the local user database.                     |
| start                  | The user account record's location (by number) as it is listed in the database. |
| <page_size>            | The number of user account records that display on one page.                    |

### Usage Guidelines

If your network includes multiple master controller under a single root master controller, the output of this command shows all branch controllers and master controllers on the network. By default, this command displays all entries in the whitelist. To display only part of the branch controller whitelist, include the **start** <offset> parameters to start displaying the branch controller whitelist at the specified entry value. You can also include the optional **mac-address** <mac-addr> parameters to display values for a single branch controller entry.

### Example

This example shows the basic summary of a user accounts in the database.

```
(host) #show local-userdb-branch
```

```
Branch-controller-entry Details
```

```

Mac Branch-config-group Hostname
--- -
00:0b:86:bb:b5:47 eng 7024-242
00:0b:86:b8:a2:60 plm-2 7005-236
00:0b:86:99:89:97 it 7010-234
```

```
Branch Controller Entries: 3
```

The output of this command includes the following parameters:

| Parameter                   | Description                                                        |
|-----------------------------|--------------------------------------------------------------------|
| Name                        | Mac address of the branch controller                               |
| Branch-Config-Group profile | Name of the branch controller group                                |
| Branch controller entries   | Number of branch controllers associated to this master controller. |

## Command History

| Release         | Modification        |
|-----------------|---------------------|
| ArubaOS 6.0     | Command introduced. |
| ArubaOS 6.2     | Command deprecated. |
| ArubaOS 6.4.3.0 | Command reinstated. |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show local-userdb-guest

show local-userdb-guest

### Description

Shows information about guest accounts in the local user database.

### Syntax

| Parameter          | Description                                                                     |
|--------------------|---------------------------------------------------------------------------------|
| maximum-expiration | How long the account is valid, in minutes, in the internal database.            |
| <offset>           | The user account record's location (by number) as it is listed in the database. |
| <page_size>        | The number of user account records that display on one page.                    |

### Usage Guidelines

Issue this command without any parameters to display a general overview of guest accounts in the database. Use the **maximum-expiration** parameter to show how long the account is valid for in minutes. Use the **start <offset> page <page\_size>** parameters to control which guest account records in the database display initially and the number of account records displayed on a page.

### Example

This example shows the basic summary of a user accounts in the database.

```
(host) #show local-userdb-guest maximum-expiration start 5 page 4

local-userdb-guest maximum-expiration 90

Guest UserSummary

Name Password Role E-Mail Enabled Expiry Status Sponsor-Name Grantor-Name

guest-0657984 * guest Yes Yes Yes Active admin admin
guest-8330301 * guest Yes Yes Yes Active admin admin
guest-5433352 * guest Yes Yes Yes Active admin admin
guest-3469360 * guest Yes Yes Yes Active admin admin

User Entries: 11
```

The output of this command includes the following parameters:

| Parameter | Description          |
|-----------|----------------------|
| Name      | Name of the user.    |
| Password  | The user's password. |

| Parameter    | Description                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Role         | Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method. |
| E-mail       | Shows the email address of the user account.                                                                                                                                                                                                                           |
| Enabled      | Shows whether the account is enabled or disabled.                                                                                                                                                                                                                      |
| Expiry       | Shows the expiration date for the user account. If this is not set, the account does not expire.                                                                                                                                                                       |
| Status       | Shows whether the profile has enabled or disabled the ability to use the HTTP protocol to redirect users to the captive portal page.                                                                                                                                   |
| Sponsor-Name | Shows the sponsor's name.                                                                                                                                                                                                                                              |
| Grantor-Name | Shows the grantor's name.                                                                                                                                                                                                                                              |
| User Entries | Shows the number of user accounts in the database.                                                                                                                                                                                                                     |

## show local-userdb username

```
show local-userdb username <name>
```

### Description

Shows information about specific user account in the internal controller database.

### Usage Guidelines

Issue this command to display an overview of a particular user account in the database.

### Example

This example shows the basic summary of a user account **Paula** in the database.

```
(host) #show local-userdb username Paula

User Summary

Name Password Role E-Mail Enabled Expiry Status Sponsor-Name Grantor-Name

paula * guest Yes Inactive admin

User Entries: 1
```

## show localip

show localip

### Description

Displays the IP address and VPN shared key between master and local.

### Syntax

No parameters.

### Example

The output of this command shows the controller's IP address and shared key between master and local controllers.

```
(host) # show localip
```

```
Local Switches configured by Local Switch IP

Switch IP address of the Local Key

0.0.0.0 *****
```

### Command History

## show log arm-user-debug

show log arm-user-debug{ [<number>] [all] }

### Description

Show the controller's ARM user debug logs.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the ARM user debug logs for the controller.                                       |

### Example

This example shows the controller's last ten ARM user debug logs.

```
(host) #show log arm-user-debug 10
```

```

## show log bssid-debug

```
show log bssid-debug{ [<number>] [all] }
```

### Description

A Basic Service Set Identifier (BSSID) uniquely defines each wireless client and Wireless Broadband Router. This command shows the controller's BSSID debug logs.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the BSSID debug logs for the controller.                                          |

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                         |
|---------------|-----------------------|--------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes |

## show log errorlog

```
show log errorlog{[<number>][all]}
```

### Description

Show the controller's system errors and other critical information.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the error logs for the controller.                                                |

### Example

This example shows the ten most recent system log errors.

```
(host) #show log errorlog 10
```

```
Mar 5 10:30:34 <sapd 106007> <ERRS> |AP 1.1.1@10.3.49.253 sapd| AM 00:0b:86:a2:e7:40: Rogue

```

### Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                          |
|---------------|-----------------------|---------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes. |

## show log essid-debug

```
show log essid-debug{ [<number>] [all] }
```

### Description

Show the controller's ESSID debug logs.

An Extended Service Set Identifier (ESSID) is used to identify the wireless clients and Wireless Broadband Routers in a WLAN. All wireless clients and Wireless Broadband Routers in the WLAN must use the same ESSID.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the ESSID debug logs for the controller.                                          |

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                          |
|---------------|-----------------------|---------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes. |

## show log network

```
show log network{[<number>][all]}
```

### Description

Show the controller's system network errors.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the network logs for the controller.                                              |

### Example

This example shows the controller's recent network log errors

```
(host) #show log network all
```

```
Feb 17 14:47:14 :209801: <WARN> |fpapps| Physical link down: port 1/1
Feb 17 14:48:04 :209801: <WARN> |fpapps| Physical link down: port 1/1
```

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                          |
|---------------|-----------------------|---------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes. |

## show log security

```
show log security{[<number>][all]}
```

### Description

Show the controller's security logs.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the security logs for the controller.                                             |

### Example

This example shows the controller's last seven security logs.

```
(host) #show log security 7
```

```
Mar 5 11:53:43 :124004: <DEBUG> |authmgr| Local DB auth failed for user admin, error (User
not found in UserDB)
Mar 5 11:53:43 :124003: <INFO> |authmgr| Authentication result=Authentication failed(1),
method=Management, server=Internal, user=10.100.100.66
Mar 5 11:53:43 :124004: <DEBUG> |authmgr| Auth server 'Internal' response=1

Mar 5 11:53:58 :103060: <DEBUG> |ike| ipc.c:get_local_cfg_trigger_ike:2653 IKE got trigger
from CFGM : state :3
```

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                          |
|---------------|-----------------------|---------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes. |

## show log system

```
show log system{[<number>][all]}
```

### Description

Show the controller's system logs.

### Syntax

| Parameter | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| <number>  | Start displaying the log output from the specified number of lines from the end of the log. |
| all       | Shows all the system logs for the controller.                                               |

### Example

This example shows the controller's last ten system logs.

```
(host) #show log system 10
```

```

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                          |
|---------------|-----------------------|---------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes. |

## show logging

```
show logging facility|server|{level [verbose]}
```

### Description

the IP address of the remote logging server, as well as facility log types and their associated facility levels.

### Syntax

| Parameter       | Description                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| facility        | View the facility used when logging messages into the remote syslog server.                                                                                      |
| server          | Show the IP address of a remote logging server.                                                                                                                  |
| level [verbose] | Show logging levels at which the messages are logged. Include the optional verbose parameter to display additional data for logging subcategories and processes. |

### Usage Guidelines

The ArubaOS logging levels follow syslog convention:

- level 7: Emergency
- level 6: Alert
- level 5: Critical
- level 4: Errors.
- level 3: Warning
- level 2: Notices
- level 1: Informational
- level 0: Debug

The default logging level is **level 1**. You can change this setting via the **logging** command.

### Example

This example below displays defined logging levels for each logging facility.

```
(host) #show logging level
```

```
LOGGING LEVELS

Facility Level
----- -
network warnings
security warnings
system warnings
user warnings
wireless warnings
```

This example below displays the IP address of a remote log server. If a remote log server has not yet been defined, this command will not display any output.

```
(host) #show logging server

Remote Server: 1.1.1.1

FACILITY MAPPING TABLE

local-facility severity remote-facility

user debugging local1
```

## Related Commands

# show loginsessions

show loginsessions

## Description

Displays the current administrator login sessions statistics.

## Syntax

No parameters.

## Example

Issue this command to display the admin login session statistics.

Session Table

| ID | User Name | User Role | Connection From | Idle Time | Session Time |
|----|-----------|-----------|-----------------|-----------|--------------|
| 1  | admin     | root      | 10.100.102.43   | 00:00:00  | 00:27:59     |

The output includes the following parameters:

| Parameter       | Description                                               |
|-----------------|-----------------------------------------------------------|
| ID              | Sessions identification number                            |
| User Name       | Administrator's user name                                 |
| User Role       | Administrator's role                                      |
| Connection From | The IP address from which the administrator is connecting |
| Idle Time       | Amount of time the user has been idle                     |
| Session Time    | Total time the session has been open                      |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                |

| All platforms | Base operating system | Enable or config mode on master controllers |

## show mac-address-table

show mac-address-table

### Description

Displays a MAC forwarding table.

### Syntax

No parameters.

### Example

Issue this command to display the MAC forwarding table.

```
Dynamic Address Count: 0
Static Address (User-defined) Count: 0
System Self Address Count: 0
Total MAC Addresses : 6
Maximum MAC addresses : 6
MAC Address Table

Destination Address Address Type VLAN Destination Port

00:0b:86:00:00:00 Mgmt 1 vlan 1
00:0b:86:f0:05:60 Mgmt 1 vlan 1
00:0b:86:00:00:00 Mgmt 62 vlan 62
00:0b:86:f0:05:60 Mgmt 62 vlan 62
00:0b:86:00:00:00 Mgmt 4095 vlan 4095
00:0b:86:f0:05:60 Mgmt 4095 vlan 4095
```

The output includes the following parameters:

| Parameter                           | Description                                                            |
|-------------------------------------|------------------------------------------------------------------------|
| Dynamic Address Count               | Count of dynamic addresses currently associated with the controller    |
| Static Address (User-defined) Count | Count of static, user-defined addresses associated with the controller |
| System Self Address Count           | Number of self system addresses                                        |
| Total MAC Addresses                 | Total number of MAC addresses associated with the controller           |
| Maximum MAC Addresses               | Maximum number of MAC addresses                                        |
| Destination Address                 | Destination MAC address                                                |
| Address Type                        | Destination address type                                               |

| Parameter        | Description      |
|------------------|------------------|
| VLAN             | Associated VLAN  |
| Destination Port | Destination port |

## Related Commands

| Command           | Description                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| master-redundancy | This command associates a VRRP instance with master controller redundancy.                                                    |
| master-local      | This command displays the statistics between the local and the master controllers.                                            |
| switches          | This command provides the details on the switches connected to the master controller, including the master controller itself. |

## Command History

This command was introduced in ArubaOS 6.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                  |
|---------------|-----------------------|-----------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master controllers. |

## show master-local stats

show master-local stats [<ip-addr>] [<page>]

### Description

Display statistics for communication between master and local controllers.

### Syntax

| Parameter | Description                                                                        |
|-----------|------------------------------------------------------------------------------------|
| <ip-addr> | Include the IP address of a controller to display statistics that controller only. |
| <page>    | Start displaying the output of this command at the specified page number.          |

### Usage Guidelines

By default, master and Local controllers exchange heartbeat messages every 10 seconds. These "Heartbeats" include configuration timestamp. If a master controller has later timestamp than the local controller, the state of the local controller changes from 'Update Successful' to 'Update Required'.

### Example

This example below shows statistics for all communications between the master and local controller.

```
(host) #show master-local stats
```

```
Missed -> HB Resp from Master
```

```

IP Address HB Req HB Resp Total Missed Last Sent Missed Peer Reset Cfg Terminate
Last Synced

10.6.2.252 194721 194208 926 0 105 1
Thu Feb 26 21:12:04 2009
```

The output of this command includes the following data columns:

| Parameter    | Description                                                                |
|--------------|----------------------------------------------------------------------------|
| IP Address   | IP address of the local controller.                                        |
| HB Req       | Heartbeat requests sent from the local controller.                         |
| HB Resp      | Heartbeat responses sent from the master controller.                       |
| Total Missed | Total number of heartbeats that were not received by the local controller. |

| Parameter        | Description                                                                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Last Sent Missed | This counter will increment if controller misses the last heartbeat from the peer controller. This counter will keep on incrementing until the heartbeat message is received from peer. |
| Peer Reset       | The number of times the connection to peer is been reset. The connection could reset due to network connectivity problems or when the peer switch reboots.                              |
| Cfg Terminate    | Number of times the controller has failed to upgrade to a new configuration                                                                                                             |
| Last Synced      | Timestamp showing the last time the local controller synched its configuration from the master controller.                                                                              |

# show master-redundancy

show master-redundancy

## Description

Display the master controller redundancy configuration.

## Syntax

No parameters.

## Example

This example below shows the current master redundancy configuration, including the ID number of the master VRRP virtual router and the IP address of the peer controller for master redundancy.

```
(host) #show master-redundancy
Master redundancy configuration:
 VRRP Id 2 current state is MASTER
 Peer's IP Address is 2.1.1.4
```

### Description

Show the amounts of free and available memory on the controller, or include a process name to show memory information for a process on the AP or controller.

### Syntax

| Parameter         | Description                                                           |
|-------------------|-----------------------------------------------------------------------|
| aaa               | Display memory information for the AAA process on the controller.     |
| ap                | Display memory information for a process running on a specific AP.    |
| meshd             | Display memory information for the meshd process on the specified AP. |
| rfd               | Display memory information for the rfd process on the specified AP.   |
| sapd              | Display memory information for the rfd process on the specified AP.   |
| ap-name <ap-name> | Display memory information for an AP with the specified AP name.      |
| bssid <bssid>     | Display memory information for an AP with the specified BSSID.        |

| Parameter         | Description                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ip-addr <ip-addr> | Display memory information for an AP with the specified IP address.                                                                                          |
| auth              | Display memory information for the <b>auth</b> process on the controller.                                                                                    |
| certmgr           | Display the memory information for certmgr process.                                                                                                          |
| cfgm              | Display memory information for the <b>cfgm</b> process on the controller.                                                                                    |
| cpsec             | Displays memory information for the Control Plane Security process on the controller.                                                                        |
| dbsync            | Display memory information for the <b>dbsync</b> process on the controller.                                                                                  |
| debug [verbose]   | Display detailed memory information to debug memory errors the controller. This command should only be used under the supervision of Dell Technical Support. |
| dhcpd             | Display memory information for the DHCP process on the controller.                                                                                           |
| ecc               | Display the DRAM ecc counters on the controller.                                                                                                             |
| fpapps            | Display memory information for the <b>fpapps</b> process on the controller.                                                                                  |
| fpcli             | Display memory information for the <b>fpcli</b> process on the controller.                                                                                   |
| isakmpd           | Display memory information for the <b>isakmpd</b> process on the controller.                                                                                 |
| l2tpd             | Display memory information for the <b>l2tpd</b> process on the controller.                                                                                   |
| mdns              | Display memory information for the mDNS process on the controller.                                                                                           |
| mobileip          | Display memory information for the <b>mobileip</b> process on the controller.                                                                                |
| ospf              | Display memory information for the <b>ospf</b> process on the controller.                                                                                    |
| pim               | Display memory information for the <b>pim</b> process on the controller.                                                                                     |
| pptpd             | Display memory information for the <b>pptpd</b> process on the controller.                                                                                   |
| profmgr           | Display memory information for the <b>profmgr</b> process on the controller.                                                                                 |
| slb               | Display memory information for the <b>slb</b> process on the controller.                                                                                     |
| apsnmpd           | Display memory information for the <b>apsnmpd</b> process on the controller.                                                                                 |
| stm               | Display memory information for the <b>auth</b> process on the controller.                                                                                    |

| Parameter | Description                                                                    |
|-----------|--------------------------------------------------------------------------------|
| udbserver | Display memory information for the <b>udbserver</b> process on the controller. |
| wms       | Display memory information for the <b>wms</b> process on the controller.       |

## Usage Guidelines

Include the name of a process to show memory information for that process. Use this command under the supervision of Dell technical support to help debug process errors.

## Example

The command **show memory** displays, in Kilobytes, the total memory on the controller, the amount of memory currently being used, and the amount of free memory.

```
(host) # show memory
Memory (Kb): total: 256128, used: 162757, free: 93371
```

Include the name of a process to show memory statistics for that process. The example below shows memory statistics for **mobileip**.

```
(host) # show memory mobileip
```

| Type    | Num Allocs | Size Allocs | Total Allocs | Total Size |
|---------|------------|-------------|--------------|------------|
| default | 92         |             | 145622       |            |
|         |            | PC          |              |            |
|         | 0x1000be14 | 1           | 64           |            |
|         | 0x10016cb0 | 1           | 41000        |            |
|         | 0x10021604 | 1           | 80           |            |
|         | 0x10032e34 | 1           | 24           |            |
|         | 0x30019a24 | 1           | 2200         |            |
|         | 0x30019bd8 | 1           | 41000        |            |
|         | 0x30019bf0 | 1           | 41000        |            |
|         | 0x30019c28 | 1           | 11263        |            |
|         | 0x3001b134 | 2           | 1967         |            |
|         | 0x300326b8 | 9           | 72           |            |
|         | 0x30032738 | 4           | 64           |            |
|         | 0x3019dfdc | 1           | 44           |            |
|         | 0x3019ee60 | 3           | 48           |            |
|         | 0x3019ef18 | 1           | 784          |            |
|         | 0x301b63bc | 13          | 312          |            |
|         | 0x301b6470 | 10          | 200          |            |
|         | 0x301b648c | 10          | 920          |            |
|         | 0x301b7614 | 3           | 36           |            |
|         | 0x301b7770 | 8           | 128          |            |
|         | 0x301bd460 | 3           | 60           |            |

The output of this command includes the following columns:

| Column | Description                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------|
| Type   | The show memory command currently shows information for predefined processes only, so this column always displays the parameter default. |

| Column       | Description                                                                       |
|--------------|-----------------------------------------------------------------------------------|
| Num Alloc    | Current number of memory allocations.                                             |
| Size Allocs  | Total size of all memory allocations, in bytes.                                   |
| Total Allocs | Maximum number of allocations used throughout in the life of the process.         |
| Total Size   | Maximum size of allocations used throughout in the life of the process, in bytes. |
| PC           | Program counter: the address of a memory allocation. (For internal use only.)     |
| Allocs       | Number of memory allocations at that program counter. (For internal use only.)    |
| Size         | Size of all memory allocations at that program counter. (For internal use only.)  |

## Command History

| Release     | Modification                                                                                                                                                                         |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| ArubaOS 6.3 | <p>The following parameters were introduced:</p> <ul style="list-style-type: none"> <li>• <b>aaa</b></li> <li>• <b>cpsec</b></li> <li>• <b>ecc</b></li> <li>• <b>mdns</b></li> </ul> |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show mgmt-role

show mgmt-role

### Description

This command allows the user to view a list of management role configurations.

### Syntax

No parameters.

### Example

Issue this command to display a list of management user roles.

Management User Roles

```

ROLE DESCRIPTION
---- -
root Super user role
read-only Read only commands
network-operations network-operations
guest-provisioning guest-provisioning
location-api-mgmt location-api-mgmt
no-access Default role, no commands are accessible for this role
location-api-mgmt location-api-mgmt
```

The output includes the following parameters:

| Parameter   | Description                             |
|-------------|-----------------------------------------|
| ROLE        | Name of the management user role        |
| DESCRIPTION | Description of the management user role |

### Command History

This command was introduced in ArubaOS 1.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master controllers |

## show mgmt-server

```
show mgmt-server
 message-counters process {auth | fw_visibility | spectrum | stm | wms}
 profile <profile-name>
```

### Description

Displays the message counter information of management server.

### Syntax

| Parameter                                             | Description                                                                                                                                                                                           |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| message-counters                                      | Message counter in the recent past.                                                                                                                                                                   |
| process {auth   fw_visibility   spectrum   stm   wms} | Controller processes: <ul style="list-style-type: none"><li>• Authentication</li><li>• Firewall Visibility</li><li>• Spectrum</li><li>• Station Management</li><li>• WLAN Management System</li></ul> |
| profile <profile-name>                                | Displays the list of configuration profiles and the details of the specified configuration profiles for the management server.                                                                        |

### Example

The output of this command shows the message counter information of the WLAN Management System process in the controller.

```
(host) (config) #show mgmt-server message-counters process wms
```

Message Counter History

| Message Number     | Time                    | Packets | Monitored AP Info | Monitored AP Stats |
|--------------------|-------------------------|---------|-------------------|--------------------|
| Monitored STA Info | Monitored STA Stats     |         |                   |                    |
| 82                 | Tue Apr 2 14:56:43 2013 | 1       | 0                 | 0                  |
| 3                  |                         |         |                   | 3                  |
| 81                 | Tue Apr 2 14:56:13 2013 | 1       | 14                | 218                |
| 67                 |                         |         |                   | 2                  |
| 80                 | Tue Apr 2 14:55:43 2013 | 1       | 0                 | 0                  |
| 2                  |                         |         |                   | 0                  |
| 79                 | Tue Apr 2 14:55:13 2013 | 1       | 0                 | 0                  |
| 2                  |                         |         |                   | 0                  |

The output of the following command displays the details of the default-amp management configuration profile:

```
(host) #show mgmt-server profile default-amp
```

Mgmt Config profile "default-amp" (Predefined (editable))

```

Parameter Value

Stats Enabled
Tag Enabled
Sessions Enabled
Monitored Info Disabled
Monitored Stats Disabled
Misc Enabled
Location Enabled
Voice Info Disabled
```

## Command History

| Release       | Modification                                                                                   |
|---------------|------------------------------------------------------------------------------------------------|
| ArubaOS 3.4   | Command introduced.                                                                            |
| ArubaOS 6.3   | The <b>wms</b> process is introduced to track the Advanced Monitoring (AMON) message counters. |
| ArubaOS 6.3.1 | The <b>profile</b> parameter was introduced.                                                   |

## Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Enable mode on master or local controllers |

## show mgmt-servers

show mgmt-servers

### Description

Displays list of management servers that receive Advanced Monitoring (AMON) messages from the controller.

### Syntax

| Parameter    | Description                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| mgmt-servers | Management Servers. This could be W-AirWave Management Server or any other server that receive messages from the controller using AMON protocol. |

### Example

The output of this command shows list of management servers in the controller.

```
(host) (config) #show mgmt-servers
```

List of Management Servers

```

Type Primary Server Profile

AirWave 10.4.14.200 default-amp
ALE 1.1.1.1 default-ale
Num Rows:2
```

### Command History

| Release       | Modification                                                                   |
|---------------|--------------------------------------------------------------------------------|
| ArubaOS 3.4   | Command introduced.                                                            |
| ArubaOS 6.3.1 | The management server configuration profile column was included in the output. |

### Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Enable mode on master or local controllers |

## show mgmt-users

```
show mgmt-users [<username> |
 local-authentication-mode <username> |
 ssh-pubkey <username> |
 webui-cacert <username>]
```

### Description

Displays list of management users on the controller and also details of each management users.

### Syntax

| Parameter                 | Description                                           |
|---------------------------|-------------------------------------------------------|
| username                  | To view details of a specific management user.        |
| local-authentication-mode | Status of local-authentication mode.                  |
| ssh-pubkey                | Number of management users using the ssh-pubkey.      |
| webui-cacert              | Number of management users using web CA certificates. |

### Example

The output of this command shows the client certificate name, username, user role, and revocation checkpoint for management users using the ssh-pubkey in the controller.

```
(host) #show mgmt-user ssh-pubkey
```

SSH Public Key Management User Table

```

CLIENT-CERT USER ROLE STATUS REVOCATION CHECKPOINT

client1-rg test1 root ACTIVE ca-rg
client2-rg test2 root ACTIVE none
client3-rg test3 root ACTIVE ca-rg
client1-rg test4 root ACTIVE ca-rg
```

### Command History

| Release       | Modification                                                          |
|---------------|-----------------------------------------------------------------------|
| ArubaOS 3.3.2 | Command introduced                                                    |
| ArubaOS 6.3   | The ssh-pubkey <b>Revocation Checkpoint</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show tunneled-node config

show tunneled-node config

### Description

Displays wired tunneled node configuration details.

### Syntax

No parameters.

### Example

The output of this command shows the tunneled node configuration details.

```
(host) # show tunneled-node config
```

```

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show netdestination

```
show netdestination <netdestination name>
```

### Description

Displays IPv4 and IPv6 network destination information.

### Syntax

No parameters.

### Example

Issue this command to display all netdestination configured on this controller. The output below displays information for all configured IPv4 and IPv6 netdestinations. To display additional detailed information for an individual netdestinations, include the name of the netdestination at the end of the command.

```
(host) >enable
Password:*****
(host) #show netdestination
Name: white-list
Position Type IP addr Mask-Len/Range
----- --- -
Name: localnetwork
Position Type IP addr Mask-Len/Range
----- --- -
1 network 0.0.0.2 0.0.0.0
```

The output includes the following parameters:

| Parameter  | Description                               |
|------------|-------------------------------------------|
| Name       | Network destination name                  |
| Position   | Network destination position              |
| Type       | Network destination type                  |
| IP addr    | IP address of the network destination     |
| Mask/Range | Network destination subnet mask and range |

### Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing                                                            | Command Mode                                |
|---------------|----------------------------------------------------------------------|---------------------------------------------|
| All platforms | You must have a PEFNG license to configure or view a netdestination. | Enable or config mode on master controllers |

## show netexthdr

show netexthdr <alias-name>

### Description

This command displays the IPv6 extension header (EH) types that are denied.

### Syntax

| Parameter    | Description                | Default        |
|--------------|----------------------------|----------------|
| <alias-name> | Specify the EH alias name. | <b>default</b> |

### Usage Guidelines

#### Example

The following command displays the denied extended header types in the default EH:

```
(host) #show netexthdr default
```

```
Extended Header type(s) Denied

51,
```

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.1 | Command introduced |

### Command Information

| Platforms     | Licensing             | Command Mode                                    |
|---------------|-----------------------|-------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on the master controllers |

## show netservice

show netservice [<string>]

### Description

Show network services

### Syntax

| Parameter | Description                |
|-----------|----------------------------|
| <string>  | Name of a network service. |

### Usage guidelines

Issue this command without the optional **<string>** parameter to view a complete table of network services on the controller. Include the **<string>** parameter to display settings for a single network service only.

### Example

The following example shows the protocol type, ports and application-level gateway (ALG) for the DHCP service.

```
(host) #show netservice svc-dhcp
Services

Name Protocol Ports ALG
---- -
svc-dhcp udp 67 68
```

### Related Commands

To configure an alias for network protocols, use the command [netservice](#).

### Command History

This command was available in ArubaOS 1.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show netstat stats

show netstat stats

### Description

Show network statistics for current active network connections, filtered by protocol type.

### Syntax

No parameters

### Usage guidelines

Issue this command to display aggregate statistics for IP, ICMP, TCP and UDP protocols, and extended TCP statistics

### Example

The following example shows incoming and outgoing packet statistics for the controller.

```
(host) #show netstat stats
Ip:
 1084012095 total packets received
 2 with invalid headers
 3 forwarded
 426940 incoming packets discarded
 932097114 incoming packets delivered
 1004595164 requests sent out
 52847 fragments dropped after timeout
 201323411 reassemblies required
 50179757 packets reassembled ok
 53204 packet reassembles failed
 136827034 fragments created
Icmp:
 1969625 ICMP messages received
 5 input ICMP message failed.
 ICMP input histogram:
 destination unreachable: 1752058
 timeout in transit: 1684
 redirects: 70805
 echo requests: 145073
 echo replies: 5
 249806 ICMP messages sent
 0 ICMP messages failed
 ICMP output histogram:
 destination unreachable: 51944
 time exceeded: 52796
 redirect: 2
 echo replies: 145064
Tcp:
 3 active connections openings
 0 passive connection openings
 0 failed connection attempts
 0 connection resets received
 2 connections established
 1006383 segments received
 1147229 segments send out
 9603 segments retransmitted
 0 bad segments received.
```

```
2568 resets sent
Udp:
928478757 packets received
40767 packets to unknown port received.
426937 packet receive errors
910267627 packets sent
```

## Related Commands

To configure an alias for network protocols, use the command [netservice](#).

|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Config mode on local and master controllers |

## show network-printer

show network-printer [config | job <printer-name> | status]

### Description

Displays configuration, job status details, and printer status of USB printers connected to a W-600 Series controller.

### Syntax

| Parameter | Description                                                                    |
|-----------|--------------------------------------------------------------------------------|
| config    | Displays the configuration details of the printer service on the controller.   |
| job       | Displays the list of job in queue in all printers connected to the controller. |
| status    | Displays the status of all printers connected to the controller.               |

### Example

The output of this command shows the status of all printers connected to the controller.

```
(host) #show network-printer status
```

```
Networked Printer Status
```

```

```

| Printer Name                                              | Printer Alias | Status | Comment |
|-----------------------------------------------------------|---------------|--------|---------|
| -----                                                     | -----         | -----  | -----   |
| usb1p_Hewlett-Packard_HP_Color_LaserJet_CP3505_CNBj8B1003 | HPLJ_P3005    | idle   | enabled |
| usb1p_HP_Officejet_Pro_L7500_MY872231FX                   | HPOJ_L7500    | idle   | enabled |

### Command History

This command was available in ArubaOS 3.4

### Command Information

| Platforms               | Licensing             | Command Mode |
|-------------------------|-----------------------|--------------|
| W-600 Series controller | Base operating system | Enable mode  |

## show network-storage

```
show network-storage [files opened |
 shares {<file-system-path> | disk |
 status |
 users {disk <disk-name>}]
```

### Description

Displays details about the USB storage device connect to a W-600 Series controller.

### Syntax

| Parameter    | Description                                                                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| files opened | Displays the list of opened files in the USB storage device connected to the controller.                                                                                                                                                                                                               |
| shares       | Displays the list of shares that are created in the USB storage device. This option provides the following details: <ul style="list-style-type: none"><li>• name of the share</li><li>• name of the disk by alias.</li><li>• the folder associated with the share,</li><li>• the access mode</li></ul> |
| status       | Displays the status of the storage service on the controller.                                                                                                                                                                                                                                          |
| users        | Displays the list of users by IP address, connected share name and connection time.                                                                                                                                                                                                                    |

### Example

The output of this command shows the status of all printers connected to the controller.

```
(host) #show network-storage users
```

```
NAS Users
```

```

```

```
Share Name Machine Connected at

```

```
Documents 192.168.1.4 Fri Apr 21 14:28:59 2009
```

```
Documents 192.168.1.5 Fri Apr 21 14:17:09 2009
```

### Command History

This command was available in ArubaOS 3.4

### Command Information

| Platforms               | Licensing             | Command Mode |
|-------------------------|-----------------------|--------------|
| W-600 Series controller | Base operating system | Enable mode  |

## show ntp trusted-keys

show ntp trusted-keys

### Description

Show information for the NTP trusted key

### Syntax

No parameters.

### Example

The following example shows values for the NTP authentication keys, Key ID and Md5 secret key.

```
(host) #show ntp authentication-keys
```

```
Key Id md5 secret

12345 4567
```

The output of this command includes the following parameters:

| Parameter  | Description                                                                         |
|------------|-------------------------------------------------------------------------------------|
| Key ID     | The key identifier used to when you configured the NTP authentication key.          |
| md5 secret | The key value for the MD5 hash used when you configured the NTP authentication key. |

### Related Commands

To configure NTP authentication keys, use the command [ntp authentication-key](#).

### Command History

This command was available in ArubaOS 6.1.

### Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show ntp peer

show ntp peer <IPv4/IPv6 Address>

### Description

Show NTP peer information.

### Syntax

| Parameter           | Description                    |
|---------------------|--------------------------------|
| <IPv4/IPv6 Address> | IPv4/IPv6 Address of the peer. |

### Example

The output of this commands shows IPv4 and IPv6 address of the peer.

(host) #show ntp peer 2008::2

```

## Usage guidelines

The **show ntp peer** command is used for NTP server troubleshooting, and should only be used under the supervision of Dell technical support. Issue the [show ntp servers](#) command to view basic settings for currently configured NTP servers.

## Related Commands

To configure an NTP server, use the command [ntp server](#).

## Command History

| Release     | Modification                       |
|-------------|------------------------------------|
| ArubaOS 3.0 | Command introduced.                |
| ArubaOS 6.4 | The IPv6 parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show ntp servers

show ntp servers [brief]

### Description

Show information for Network Time Protocol (NTP) servers.

### Syntax

| Parameter | Description                                                                 |
|-----------|-----------------------------------------------------------------------------|
| brief     | Display the IP address of the defined NTP servers, iburst and key settings. |

### Examples

The following example shows values for the primary and backup NTP servers. The primary server is marked with an asterisk (\*) and the backup server is marked with an equals sign (=). Note that a backup server will not display delay, offset or dispersion data, as it is not currently in use.

```
(host) (config) #show ntp server
NTP Server Table Entries

Flags: * Selected for synchronization
+ Included in the final selection set
Selected for synchronization but distance exceeds maximum
- Discarded by the clustering algorithm
= mode is client
remote local st poll reach delay offset disp
=====
===
*2012::d63d:7eff:fe46:7309 2012::40 3 1024 377 0.00169 -0.001367
0.13815
```

The output of this command includes the following parameters:

| Parameter | Description                                                                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags     | The flags indicate the status of the server.                                                                                                                                                                                                                                                                    |
| remote    | IP address of the remote NTP server defined using the CLI command <a href="#">ntp server</a> .                                                                                                                                                                                                                  |
| local     | IP address of the local clock.                                                                                                                                                                                                                                                                                  |
| st        | NTP uses hierarchical levels of clock sources, or strata, and assigns each layer a number starting with zero at the root. The <b>st</b> column in the output of this command represents the number of servers between the configured NTP server and the root reference clock.                                   |
| poll      | Interval, in seconds, between the local NTP server's attempt to poll the remote NTP server.                                                                                                                                                                                                                     |
| reach     | An index that measures whether or not the remote NTP server could be reached at eight most recent polling intervals. If the NTP server has just been configured and hasn't yet been polled successfully, the value will be zero (0). A value of 377 indicates that the last eight poll queries were successful. |

| Parameter | Description                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| delay     | Delay, in seconds, between the time that the local clock polls the NTP server and the NTP server returns a reply.                                                                                                             |
| offset    | The difference in time, in seconds, between the local clock and the NTP server.                                                                                                                                               |
| disp      | Dispersion represents the maximum error of the local clock relative to the reference clock, and is a measurement of the time server and network quality. Lower dispersion values are preferred over higher dispersion values. |

The following example shows the **ntp servers** configuration. The NTP server IP address, key ID and iburst status are shown when the **ntp servers brief** command is used.

The following output is for IPv4:

```
(host) (config) #show ntp servers brief
server 1.1.1.1 key 1234
server 10.1.1.245 iburst key 12345
```

The following output is for IPv6:

```
(host) (config) #show ntp servers brief
server 2012::d63d:7eff:fe46:7309
```

## Related Commands

To configure an NTP server, use the command [ntp server](#).

## show ntp status

show ntp status

### Description

Show information for a NTP server.

### Syntax

No parameters.

### Example

The following example shows values for the primary NTP server.

```
(host) #show ntp status
```

```
Authentication: enabled
time since restart: 2347
time since reset: 7594
packets received: 4
packets processed: 0
current version: 0
previous version: 0
declined: 0
access denied: 0
bad length or format: 0
bad authentication: 0
rate exceeded: 0
system peer: 10.1.1.250
system peer mode: client
leap indicator: 00
stratum: 3
precision: -18
root distance: 0.03236 s
root dispersion: 0.06728 s
reference ID: [10.1.1.250]
reference time: cd45b701.bcbc05d5 Tue, Feb 17 2009 14:21:53.737
system flags: auth monitor ntp kernel stats
jitter: 0.005020 s
stability: 0.866 ppm
broadcastdelay: 0.003998 s
authdelay: 0.000000 s
```

The output of this command includes the following parameters:

| Parameter          | Description                                                                   |
|--------------------|-------------------------------------------------------------------------------|
| authentication     | Indicates if authentication is enabled for the NTP server.                    |
| time since restart | Time in hours since the system was last rebooted.                             |
| time since reset   | The number of seconds since the last time the local NTP server was restarted. |
| packets received   | Total number of packets received.                                             |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| packets processed    | Number of packets received in response to previous packets sent.                                                                                                                                                                                                                                                           |
| current version      | Number of packets matching the current NTP version.                                                                                                                                                                                                                                                                        |
| previous version     | Number of packets matching the previous NTP version.                                                                                                                                                                                                                                                                       |
| declined             | Number of packets declined.                                                                                                                                                                                                                                                                                                |
| access denied        | Number of packets for which access has been denied.                                                                                                                                                                                                                                                                        |
| bad length or format | Number of packets with invalid length, format or port number.                                                                                                                                                                                                                                                              |
| packets received     | Total number of packets received.                                                                                                                                                                                                                                                                                          |
| bad authentication   | Number of NTP packets that failed to be authenticated.                                                                                                                                                                                                                                                                     |
| rate exceeded        | Number of packets discarded due to rate limitation.                                                                                                                                                                                                                                                                        |
| system peer          | The IP address of the peer NTP server.                                                                                                                                                                                                                                                                                     |
| system peer mode     | The peer mode of this remote association: <ul style="list-style-type: none"> <li>• Symmetric Active</li> <li>• Symmetric Passive</li> <li>• Client</li> <li>• Server</li> <li>• Broadcast</li> </ul>                                                                                                                       |
| leap indicator       | This parameter indicates whether or not a leap-second should be inserted or removed at the end of the last day of the current month. <ul style="list-style-type: none"> <li>• 00 no warning</li> <li>• 01 +1 second (following minute has 61 seconds)</li> <li>• 10 -1 second (following minute has 59 seconds)</li> </ul> |
| stratum              | The stratum level of the peer                                                                                                                                                                                                                                                                                              |
| precision            | The advertised precision of the switch. This value can range from -4 and -20, inclusive.                                                                                                                                                                                                                                   |
| root distance        | Total round trip delay to the stratum 1 reference clock.                                                                                                                                                                                                                                                                   |
| root dispersion      | Total dispersion to the stratum 1 reference clock. This value is a cumulative measure of all errors associated with the network hops and servers between the NTP server and its stratum 1 server.                                                                                                                          |
| reference ID         | IPv4/IPv6 address of the remote NTP server.                                                                                                                                                                                                                                                                                |

| Parameter      | Description                                                                                                                                                                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Note: When NTP server is reachable through IPv4 address, use the address as is. If done through IPv6 address, the Reference ID is calculated instead of directly taking the IPV6 address on the NTP Server. The controller performs a MD5 checksum and the last 4 bytes are considered as the reference ID. |
| reference time | Time when the local system clock was last set or corrected, in NTP timestamp format.                                                                                                                                                                                                                        |
| system flags   | This parameter displays any flags configured for this NTP entity.                                                                                                                                                                                                                                           |
| jitter         | The average magnitude of jitter between several time queries.                                                                                                                                                                                                                                               |
| stability      | The average magnitude of offset between several time queries                                                                                                                                                                                                                                                |
| broadcastdelay | The broadcast delay of this NTP server association, in seconds.                                                                                                                                                                                                                                             |
| authdelay      | The authentication delay of this NTP server association, in seconds.                                                                                                                                                                                                                                        |

## show packet-capture

```
show packet-capture
 controlpath-pcap [hex]
 datapath-pcap [hex]
```

### Description

Displays packet capture status on the controller.

### Syntax

| Parameter              | Description                                                    |
|------------------------|----------------------------------------------------------------|
| controlpath-pcap [hex] | Displays controlpath packets captured in the local-filesystem. |
| datapath-pcap [hex]    | Displays datapath packets captured in the local-filesystem.    |

### Example

The output of this command shows the packet capture configuration details.

```
(host) #show packet-capture
Active Capture Destination

Destination IP 1.2.3.4
Active Capture (Controlpath)

Interprocess Disabled
Sysmsg Disabled
TCP Enabled Ports: 2
UDP Enabled Ports: 5
Other Enabled
Active Capture (Datapath)

Wifi-Client Enabled Mac: 00:0b:86:6d:47:6c Filter: Decrypted
Ipsec Enabled Peer: 10.1.1.1
(host) (config) #show packet-capture-defaults
Default Capture Destination

Destination Local-Filesystem
Default Capture (Controlpath)

Interprocess Disabled
Sysmsg Disabled
TCP Enabled Ports: 80 8080
UDP Enabled Ports: All
Other Disabled
Default Capture (Datapath)

Wifi-Client Enabled Mac: 00:0b:86:6d:47:6c Filter: Encrypted
Ipsec Disabled
```

# show packet-capture-defaults

show packet-capture-defaults

## Description

Displays the status of default packet capture options.

## Syntax

No parameters.

## Example

The output of this command shows packet capture status.

```
(host) # show packet-capture-defaults

Current Active Packet Capture Actions(current switch)
=====
Packet filtering for TCP ports disabled.
Packet filtering for UDP ports disabled.
Packet filtering for internal messaging opcodes disabled.
Packet filtering for all other packets disabled.

Packet Capture Defaults(across switches and reboots if saved)
=====
Packet filtering for TCP ports disabled.
Packet filtering for UDP ports disabled.
Packet filtering for internal messaging opcodes disabled.
Packet filtering for all other packets disabled.
```

## Command History

This command was available in ArubaOS 3.3.2

| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show pan active-profile

show pan active-profile

### Description

This command shows the active PAN firewall profile at the local controller level.

### Syntax

No syntax.

### Usage Guidelines

Issue this command to show the current active PAN firewall profile running on the controller.

```
(host) #show pan active-profile
Palo Alto Networks Active Profile

Parameter Value

Active Palo Alto Networks profile PAN-Group-1
```

### Command History

| All platforms | Base operating system | Enable or config mode on master or local controllers |

## show pan-options

show pan-options

### Description

This command displays configured settings for integrating a branch controller with a Palo Alto Networks (PAN) firewall.

### Syntax

No syntax.

### Usage Guidelines

Issue this command to see the connection status of the PAN firewalls associated with the controller.

```
(host)#show pan profile PAN-Group-1
```

```
Palo Alto Networks Servers Profile "PAN-Group-1"
```

```

Parameter Value

Palo Alto Networks Firewall 1.2.3.4:443 abc/*****
Palo Alto Networks Firewall 2.2.2.2:123 2222/*****
Palo Alto Networks Firewall 3.3.3.3:333 3333/*****
Palo Alto Networks Firewall 1.1.1.1:443 admin/*****
```

| All platforms | Base operating system | Enable or config mode on master or local controllers |

## show pan state

show pan state

### Description

This command shows the current connection status of PAN firewalls.

### Syntax

No syntax.

### Usage Guidelines

Issue this command to see the connection status of the PAN firewalls associated with the controller.

```
(host) #show pan state
Palo Alto Networks Servers Connection State[PAN-Group-1]

Firewalls State

1.2.3.4:443 DOWN
2.2.2.2:123 UP[11/25/13 12:45:49]Established
3.3.3.3:333 UP[11/25/13 12:45:48]Established
1.1.1.1:443 UP[11/25/13 12:45:50]Established
```

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master or local controllers |

## show pan statistics

show pan statistics

### Description

This command shows PAN firewall interface statistics.

### Syntax

No syntax.

### Usage Guidelines

Issue this command to see PAN firewall interface statistics.

```
(host) (config) #show pan statistics
Palo Alto Networks Interface Statistics Summary

Login Reqts Logout Reqts Refresh Reqts

0 0 0
Per-PAN server Statistics Summary

PAN Server User-ID Reqts Sent Skipped Success Failure Last Error

1.2.3.4:443 0 0 0 0 0
```

| Parameter                                       | Description                                             |
|-------------------------------------------------|---------------------------------------------------------|
| Palo Alto Networks Interface Statistics Summary |                                                         |
| Login Reqts                                     | Total number of login requests.                         |
| Logout Reqts                                    | Total number of logout requests.                        |
| Refresh Reqts                                   | Total number of refresh requests.                       |
| Per-PAN server Statistics Summary               |                                                         |
| PAN Server                                      | The PAN Server IP address.                              |
| User-ID Reqts                                   | Total number of login, logout, and refresh requests.    |
| Sent                                            | Number of requests sent.                                |
| Skipped                                         | Number of requests skipped.                             |
| Success                                         | Number of requests successfully handled.                |
| Failure                                         | Number of requests that were not successfully received. |
| Last Error                                      | The last failure error received.                        |

## show pan-gp

show pan-options

### Description

This command displays Palo Alto Networks portal or gateway settings on a branch or local controller.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to view GlobalProtect protocol settings for a Palo Alto Networks portal or gateway on a branch controller using the Palo Alto Networks firewall integration feature.

### Examples

The following example displays the portal information seen by a branch controller connected to a Palo Alto Networks portal.

```
(host) #show pan-gp portal-info
Global Protect Portal Information
=====
Portal Config..... 172.16.2.1:443

| ArubaOS 6.4.3.0 | Command introduced. |

## Command Information

| Platforms                                                                                                                                                        | Licensing             | Command Mode                               |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|--------------------------------------------|
| W-7000 Series controllers, when configured as a branch controller, or any controller model when used in conjunction with <a href="#">uplink manager</a> feature. | Base operating system | Config mode on master or local controllers |

## show pan-options

show pan-options

### Description

This command displays configured options to integrate a branch controller with a Palo Alto Networks (PAN) firewall.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to view Palo Alto Networks firewall integration settings for branch, standalone or local controllers. Note that the PAN firewall integration feature can only be used on standalone or local controllers when used in conjunction with the controller uplink VLAN manager feature, which must be enabled using the [uplink](#) command in the controller command-line interface.

### Examples

```
(host)# show pan-options
Configure Palo Alto Networks options

```

| Parameter                                       | Value                                   |
|-------------------------------------------------|-----------------------------------------|
| Portal IP for Palo Alto Networks Global Protect | portal-ip 172.16.2.1 cert cert_LSVPCert |

The output of this command contains the following parameters:

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Value     | <p>This column contains displays the following parameters for Palo Alto firewall integration feature:</p> <ul style="list-style-type: none"><li>• <b>portal-ip &lt;ip-addr&gt;</b>: The IP address of the firewall management portal</li><li>• <b>cert &lt;cert-name&gt;</b>: Name of the self-signed or external certification authority (CA) certificate to sign the controller and gateway server certificates</li></ul> |

# show papi kernel-socket-stats

show papi kernel-socket-stats

## Description

This command shows the state of UDP PAPI sockets in the kernel.

## Syntax

No syntax.

## Usage Guidelines

Issue this command to show the state of the UDP PAPI sockets in the kernel. The following example shows partial output of this command.

```
(host) #show papi-security
```

```
(7240-223) #show papi kernel-socket-stats Kernel PAPI Statistics
```

| Port                                | RxSockbufSize | RxSockbufHimark | CurRxQLen | MaxRxQLen | Drops |
|-------------------------------------|---------------|-----------------|-----------|-----------|-------|

## show perf-test reports

```
show perf-test reports
 ap {ap-name <ap-name>}|{ip-addr <ip>}|{ip6-addr <ip6>}
 controller
```

### Description

Use this command under the guidance of Dell technical support to view the results of an Iperf throughput test launched from an AP or controller.

### Syntax

| Parameter           | Description                                                                 |
|---------------------|-----------------------------------------------------------------------------|
| ap                  | Display the results of an Iperf throughput test launched from an AP.        |
| ap-name <ap-name>   | Name of the AP.                                                             |
| ip-addr <ip-addr>   | IPv4 address of the AP.                                                     |
| ip6-addr <ip6-addr> | IPv6 address of the AP.                                                     |
| controller          | Display the results of an Iperf throughput test launched from a controller. |

### Usage Guidelines

Issue this command to view a report file of test data from a client-mode Iperf throughput test launched from an AP or controller. Tests launched in server mode do not generate reports. Only W-AP130 Series, W-AP220 Series, and W-AP105 access points connected to a W-7200 Series or W-6000M3 controller support this feature.

## show poe

show poe [slot/port]

### Description

Displays the PoE status of all or a specific port on the controller.

### Syntax

No parameters.

### Example

The output of this command shows the PoE status of port 10 in slot 1.

```
(host) # show poe 1/10
```

PoE Status

```

Port Status Voltage (mV) Current (mA) Power (mW)

FE 1/10 Off N/A N/A N/A
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show policer-profile (deprecated)

```
show policer-profile <profile-name>
```

### Description

Displays the policer profile configuration.

### Command History

This command was deprecated in ArubaOS 6.2.

# show port link-event

show port link-event

## Description

Displays the link status on each of the port on the controller.

## Syntax

No parameters.

## Example

The output of this command shows the link status on all ports in the controller.

```
(host) # show port link-event
```

| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show port monitor

show port monitor

### Description

Displays the list of ports that are configured to be monitored.

### Syntax

No parameters.

### Example

The output of this command shows the link status on all ports in the controller.

```
(host) # show port monitor

Monitor Port Port being Monitored

FE 1/10 FE 1/20
```

### Command History

This command was available in ArubaOS 3.3.2

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show port stats

```
show port status
[<slot/port>]
```

### Description

Displays the activity statistics on each of the port on the controller.

### Syntax

| Parameter   | Description                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <slot/port> | <ul style="list-style-type: none"><li>Physical port in &lt;slot&gt;/&lt;port&gt; format for W-3000 Series controller.</li><li>Physical port in &lt;slot&gt;/&lt;module&gt;/&lt;port&gt; format for W-6000M3 and W-7200 Series controllers.</li></ul> |

### Example

The output of this command shows the link status on all ports in the controller.

```
(host) # show port stats
```

```
Port Statistics
```

| Port   | PacketsIn | PacketsOut | BytesIn | BytesOut | InputErrorBytes | OutputErrorBytes | CRCErrors |
|--------|-----------|------------|---------|----------|-----------------|------------------|-----------|
| GE 1/0 | 0         | 0          | 0       | 0        | 0               | 0                | 0         |
| GE 1/1 | 0         | 0          | 0       | 0        | 0               | 0                | 0         |
| GE 1/2 | 3142      | 176        | 170305  | 26266    | 0               | 0                | 0         |
| GE 1/3 | 0         | 0          | 0       | 0        | 0               | 0                | 0         |
| PC 0   | 0         | 0          | 0       | 0        | 0               | 0                | 0         |
| PC 1   | 0         | 0          | 0       | 0        | 0               | 0                | 0         |

The output of this command includes the following parameters:

| Parameter       | Description                                                           |
|-----------------|-----------------------------------------------------------------------|
| Port            | Displays the physical port on the controller.                         |
| PacketIn        | Indicates the total number of incoming packets to the port.           |
| PacketOut       | Indicates the total number of outgoing packets from the port.         |
| BytesIn         | Indicates the total number of incoming data (in bytes) to the port.   |
| BytesOut        | Indicates the total number of outgoing data (in bytes) from the port. |
| InputErrorBytes | Indicates input error bytes on the port.                              |

| Parameter        | Description                                                     |
|------------------|-----------------------------------------------------------------|
| OutputErrorBytes | Indicates the output error bytes on the port.                   |
| CRCErrors        | Indicates the Cyclic Redundancy Check (CRC) errors on the port. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

# show port trusted

show port trusted

## Description

Displays the list of ports configured with trusted profiles.

## Syntax

No parameters.

## Example

The output of this command shows the list of ports with trusted profile.

```
(host) # show port trusted
```

```
FE 1/0
FE 1/1
FE 1/2
FE 1/3
FE 1/4
FE 1/5
FE 1/6
FE 1/7

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show port xsec

show port xsec

### Description

Displays the list of xSec enabled ports.

### Syntax

No parameters.

### Example

The output of this command shows the list of xSec enabled ports.

```
(host) #show port xsec

Xsec Ports

Interface xsec vlan state

```

### Command History

This command was available in ArubaOS 3.3.2

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show priority-map

show priority-map

### Description

Displays the list of priority maps on a interface.

### Syntax

No parameters.

### Example

The output of this command shows the priority maps configured on all interfaces.

```
(host) # show priority-map
```

```
Priority Map
```

```

ID Name DSCP-TOS DOT1P-COS
-- ---
1 my-map 4-20,60 4-7
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show processes

show processes [sort-by {cpu | memory}]

### Description

Displays the list of all system process running on the controller. You can sort the list either by CPU intensive or memory intensive processes.

### Syntax

| Parameter | Description                                  |
|-----------|----------------------------------------------|
| sort-by   | Add a sort filter to the output              |
| cpu       | This will sort output based on CPU usage.    |
| memory    | This will sort output based on memory usage. |

### Example

The output of this command shows list of system processes sorted by CPU usage.

```
(host) # show priority-map
```

```

## show profile-errors

show profile-errors

### Description

Displays the list of invalid user-created profiles.

### Syntax

No parameters.

### Example

The output of this command shows list of profiles that are invalid and also displays the error in those profiles. In this example, the VLAN 1000 that is mapped to a virtual-ap that does not exist.

```
(host) #show profile-errors
```

```
Invalid Profiles

Profile Error

wlan virtual-ap "test-vap" VLAN 1000 does not exist
```

The following are the list of some profile errors:

| Error                                                                   | Description                                                                                                                                                                            |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Named VLAN [named_VLAN] is removed                                      | These errors are displayed if a virtual AP profile is configure with a VLAN that does not exist.                                                                                       |
| Named VLAN [named_VLAN] is not mapped                                   |                                                                                                                                                                                        |
| Named VLAN [named_VLAN] is invalid                                      |                                                                                                                                                                                        |

# show profile-hierarchy

show profile-hierarchy

## Description

Displays the profile hierarchy template.

## Syntax

No parameters.

## Usage Guidelines

The output of this command shows how profiles relate to each other, and how some higher-level profiles reference other lower-level profiles. The output of this command will vary, depending upon controller configuration and licenses.

## Command History

This command was available in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                                         |

| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list aaa

```
show profile-list aaa [{alias-group [page | start]} | {authentication [captive-portal | dot1x
| mac | stateful-ntlm | wispr]} | {authentication-server [ldap | radius | tacacs | windows]} |
{profile} | {rfc-3576-server} | {server-group} | {xml-api}]
```

### Description

Displays the list of AAA profiles.

### Syntax

| Parameter             | Description                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------|
| alias-group           | Lists all alias-groups.                                                                                   |
| page                  | Specify the number of items to display                                                                    |
| start                 | Specify the first item to display                                                                         |
| authentication        | List of aaa authentication profiles.                                                                      |
| captive-portal        | Captive portal authentication profiles.                                                                   |
| dot1x                 | 802.1X authentication profiles.                                                                           |
| mac                   | MAC authentication profiles.                                                                              |
| stateful-ntlm         | Stateful-NTLM authentication profiles.                                                                    |
| wispr                 | WISPr authentication profiles.                                                                            |
| authentication-server | List of aaa authentication servers                                                                        |
| ldap                  | List of servers using LDAP for AAA authentication.                                                        |
| radius                | List of servers using RADIUS for AAA authentication.                                                      |
| tacacs                | List of servers using TACACS+ for AAA authentication.                                                     |
| windows               | List of Windows servers used for AAA authentication.                                                      |
| profile               | Displays the AAA profile details.                                                                         |
| rfc-3576-server       | Displays IP address of RADIUS servers that use RFC 3576 specification to exchange authorization messages. |
| server-group          | List of server group used for RADIUS accounting.                                                          |
| xml-api               | List of servers configured in an external XML API server.                                                 |

## Example

The output of this command shows list of AAA profiles that use captive-portal authentication.

```
(host) # show profile-list aaa authentication captive-portal
```

```
Captive Portal Authentication Profile List
```

```

```

```
Name References Profile Status
```

```

```

```
default 1
```

## Command History

This command was available in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list ap

```
show profile-list ap [enet-link-profile | mesh-cluster-profile |
 mesh-ht-ssid-profile | mesh-radio-profile | regulatory-domain-profile |
 snmp-profile | snmp-user-profile | system-profile | wired-ap-profile]
```

### Description

Displays the list of AP profiles.

### Syntax

| Parameter                 | Description                                                              |
|---------------------------|--------------------------------------------------------------------------|
| enet-link-profile         | Display a list of AP Ethernet link profiles.                             |
| mesh-cluster-profile      | Display a list of mesh cluster profiles used by mesh nodes.              |
| mesh-ht-ssid-profile      | Display a list of mesh high-throughput SSID profiles used by mesh nodes. |
| mesh-radio-profile        | Display a list of mesh radio profiles used by mesh nodes.                |
| regulatory-domain-profile | Display a list of AP regulatory profiles.                                |
| snmp-profile              | Display a list of SNMP profiles.                                         |
| snmp-user-profile         | Display a list of SNMPv3 user profiles.                                  |
| system-profile            | Display a list of AP system profiles.                                    |
| wired-ap-profile          | Display a list of wired AP profiles.                                     |

### Example

The output of this command shows list of profiles that are invalid and also displays the error in those profiles.

```
(host) # show profile-list aaa authentication captive-portal
```

```
Captive Portal Authentication Profile List

Name References Profile Status
---- -
default 1
```

### Command History

This command was available in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list ap-group

show profile-list ap-group

### Description

Displays the status of AP groups profiles in the controller.

### Syntax

No parameters.

### Example

The output of this command shows the status of AP group profiles in the controller.

```
(host) # show profile-list ap-group
```

```
AP group List

Name Profile Status
---- -
default

Total:1
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list ap-name

show profile-list ap-name

### Description

Displays the status of AP profiles in the controller.

### Syntax

No parameters.

### Example

The output of this command shows status of AP profiles in the controller.

```
(host) # show profile-list ap-name
```

```
AP name List

Name Profile Status
---- -
```

```
Total:0
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list ha

```
show profile-list ha
 group-profile [page | start]
```

### Description

Displays the list of HA profiles.

### Syntax

| Parameter     | Description                            |
|---------------|----------------------------------------|
| group-profile | Lists all HA group information.        |
| page          | Specify the number of items to display |
| start         | Specify the first item to display      |

### Example

The output of this command shows list of HA group profile information.

```
(host) # show profile-list ha group-profile
```

```
HA group information List
```

```

```

```
Name Profile Status
```

```

```

```
Total:0
```

### Command History

This command was available in ArubaOS 6.3

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list ids

```
show profile-list ids [dos-profile | general-profile | impersonation-profile |
 profile | rate-thresholds-profile | signature-matching-profile |
 signature-profile | unauthorized-device-profile]
```

### Description

Displays the status of all IDS profiles in the controller.

### Syntax

| Parameter                   | Description                                         |
|-----------------------------|-----------------------------------------------------|
| dos-profile                 | Display a list of IDS DoS profiles.                 |
| general-profile             | Display a list of IDS generate profiles.            |
| impersonation-profile       | Display a list IDS impersonation profile.           |
| profile                     | Display a list of IDS profiles.                     |
| rate-thresholds-profile     | Display a list of IDS rate threshold profiles.      |
| signature-matching-profile  | Display a list of IDS signature-matching profiles.  |
| signature-profile           | Display a list of IDS signature profiles.           |
| unauthorized-device-profile | Display a list of IDS unauthorized device profiles. |

### Example

The output of this command shows a list of all IDS DoS profiles.

```
(host) # show profile-list ids dos-profile
```

```
IDS Denial Of Service Profile List
```

```

Name References Profile Status

default 1
ids-dos-disabled 1 Predefined
ids-dos-high-setting 1 Predefined
ids-dos-low-setting 1 Predefined
ids-dos-medium-setting 1 Predefined
```

```
Total:5
```

### Command History

This command was available in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list mgmt-server

show profile-list mgmt-server {profile <profile\_name>} [page <number>] [start <number>]

### Description

Displays all the Mgmt Config profiles in the controller.

### Syntax

| Parameter                            | Description                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------|
| mgmt-server {profile <profile_name>} | Specifies the name of the management server profile.                                                          |
| page <number>                        | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number>                       | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

The output of this command shows the management server profiles in the controller.

```
(host) (config) #show profile-list mgmt-server profile
Mgmt Config profile List

Name References Profile Status
---- -
default-ale 0 Predefined (editable)
default-amp 0 Predefined (editable)
Total:2
```

### Command History

This command was available in ArubaOS 6.3

### Command Information

| Platforms     | Licensing             | Command Mode           |
|---------------|-----------------------|------------------------|
| All platforms | Base operating system | Config or Enable mode. |

## show profile-list rf

```
show profile-list rf [arm-profile | dot11a-radio-profile | dot11g-radio-profile |
 event-thresholds-profile | ht-radio-profile | optimization-profile]
```

### Description

Displays the status of all radio profiles.

### Syntax

| Parameter                | Description                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| arm-profile              | Details of Adaptive Radio Management (ARM) Profile.                                                                                     |
| dot11a-radio-profile     | Details of AP radio settings for the 5GHz frequency band, including the ARM profile and the high-throughput (802.11n) radio profile.    |
| dot11g-radio-profile     | Details of AP radio settings for the 2.4 GHz frequency band, including the ARM profile and the high-throughput (802.11n) radio profile. |
| event-thresholds-profile | Details of events thresholds profile.                                                                                                   |
| ht-radio-profile         | Details of high-throughput AP radio settings                                                                                            |
| optimization-profile     | Details of the RF optimization profile                                                                                                  |

### Example

The output of this command shows status of ARM profile.

```
(host) # show profile-list rf arm-profile

Adaptive Radio Management (ARM) profile List

Name References Profile Status
---- -
default 2

Total:1
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show profile-list wlan

```
show profile-list wlan
 bcn-rpt-req-profile
 client-wlan-profile
 dot11k-profile
 dot11r-profile
 edca-parameters-profile
 handover-trigger-profile
 hotspot
 ht-ssid-profile
 ssid-profile
 traffic-management-profile
 virtual-ap
 voip-cac-profile
 wmm-traffic-management-profile]
```

### Description

Displays the status of WLAN profiles on the controller.

### Syntax

| Parameter                  | Description                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------|
| bcn-rpt-req-profile        | Shows a list of all Beacon Report Request profiles                                                      |
| client-wlan-profile        | Shows a list of all client WLAN profiles                                                                |
| dot11r-profile             | Shows a list of all 802.11r profiles                                                                    |
| dot11k-profile             | Show a list of all 802.11K profiles                                                                     |
| edca-parameters-profile    | Show a list of all enhanced distributed channel access (EDCA) profile for APs or for clients (stations) |
| handover-trigger-profile   | Shows a list of all Handover Trigger profiles                                                           |
| hotspot                    | Hotspot/Passpoint configuration settings                                                                |
| advertisement-profile      | Shows a list of all Advertisement profile                                                               |
| anqp-3gpp-nwk-profile      | Shows a list of all ANQP 3GPP Cellular Network profiles                                                 |
| anqp-domain-name-profile   | Shows a list of all ANQP Domain Name profiles                                                           |
| anqp-ip-addr-avail-profile | Shows a list of all ANQP IP Address Availability profiles                                               |
| anqp-nai-realm-profile     | Shows a list of all ANQP NAI Realm profiles                                                             |
| anqp-nwk-auth-profile      | Shows a list of all ANQP Network Authentication profiles                                                |
| anqp-roam-cons-profile     | Shows a list of all ANQP Roaming Consortium profiles                                                    |

| Parameter                      | Description                                                                   |
|--------------------------------|-------------------------------------------------------------------------------|
| anqp-venue-name-profile        | Shows a list of all ANQP Venue Name profiles                                  |
| h2qp-conn-capability-profile   | Shows a list of all H2QP Connection Capability profiles                       |
| h2qp-op-cl-profile             | Shows a list of all H2QP Operating Class Indication profiles                  |
| h2qp-operator-friendly-profile | Shows a list of all H2QP Operator Friendly Name profiles                      |
| h2qp-wan-metrics-profile       | Shows a list of all H2QP WAN Metrics profiles                                 |
| hs2-profile                    | Shows a list of all Hotspot 2.0 profiles                                      |
| ht-ssid-profile                | Show a list of all high-throughput SSID profiles                              |
| traffic-management-profile     | Show a list of all traffic management profiles                                |
| virtual-ap                     | Show a list of all the virtual AP profiles                                    |
| voip-cac-profile               | Show a list of all voice over IP (VoIP) call admission control (CAC) profiles |
| wmm-traffic-management-profile | Show a list of all WMM traffic management profiles                            |

## Example

The output of this command shows that the controller has a single ARM profile, “default”.

```
(host) # show profile-list rf arm-profile

Adaptive Radio Management (ARM) profile List

Name References Profile Status
---- -
default 2

Total:1
```

## Command History

| Release     | Modification                                   |
|-------------|------------------------------------------------|
| ArubaOS 3.0 | Command introduced                             |
| ArubaOS 6.3 | The <b>dot11r</b> parameter was introduced.    |
| ArubaOS 6.4 | The <b>hotspot</b> parameters were introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show provisioning-ap-list

show provisioning-ap-list

### Description

Displays the list of all APs that are in queue to be provisioned by the admin.

### Syntax

No parameters.

### Command History

| Release         | Modification                                                  |
|-----------------|---------------------------------------------------------------|

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

# show provisioning-params

show provisioning-params

## Description

Displays the list of parameters and the values used to provision the APs.

## Syntax

No parameters.

## Example

The output of this command shows list of all provisioning parameters and their values.

```
(host) # show provisioning-params
AP provisioning

| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show qos-profile (deprecated)

`show qos-profile <profile-name>`

### Description

Displays the QoS profile configuration.

### Command History

This command was deprecated in ArubaOS 6.2.

## show rap-wml

show rap-wml [cache <server-name> | server | wired-mac <bssid-of-AP>]

### Description

Displays the name and attributes of a MySQL database or a MySQL server.

### Syntax

| Parameter | Description                                                  |
|-----------|--------------------------------------------------------------|
| cache     | Displays the cache of all lookups for a database server.     |
| servers   | Displays the database server state.                          |
| wired-mac | Displays the wired MAC discovered on traffic through the AP. |

### Example

The output of this command shows status of all database servers.

```
(host) # #show rap-wml servers
```

```
WML DB Servers
```

```

```

```
name ip type user password db-name cache ageout(sec) in-service
```

```

```

```
WML DB Tables
```

```

```

```
server db table column timestamp-column lookup-time(sec) delimiter query-count
```

```

```

```
Mesh SAE sae-default
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show references aaa authentication

```
show references aaa authentication {captive-portal <profile-name>}|{dot1x <profile-name>}|{mac <profile-name>}|mgmt|stateful-dot1x|{stateful-ntlm <profile-name>}|vpn|wired|{wispr {profile-name}} [page <number>] [start <number>]
```

### Description

Show AAA profile references.

### Syntax

| Parameter                     | Description                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| captive-portal <profile-name> | Show the number of references to a captive-portal profile.                                                    |
| dot1x <profile-name>          | Show the number of references to a 802.1X authentication profile.                                             |
| mac <profile-name>            | Show the number of references to a MAC authentication profile.                                                |
| mgmt <profile-name>           | Show the number of references to a management authentication profile.                                         |
| stateful-dot1x                | Show the number of references to the stateful 802.1X authentication profile.                                  |
| stateful-ntlm <profile-name>  | Show the number of references to the specified stateful NTLM authentication profile.                          |
| vpn                           | Show the number of references to VPN authentication.                                                          |
| wired                         | Show the number of references to wired authentication.                                                        |
| wired                         | Show the number of references to a wispr authentication.                                                      |
| wispr <profile-name>          | Show the number of references to the specified WISPr authentication profile.                                  |
| page <number>                 | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number>                | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

Use this command to show where a specified AAA profile has been applied. The output of the example shown below indicates that the aaa profile **default-dot1x** contains a single reference to the 802.1X authentication profile **default**.

```
(host) #show references aaa authentication dot1x default
```

References to 802.1X Authentication Profile "default"

```

Referrer Count

aaa profile "default-dot1x" authentication-dot1x 1
Total References:1
```

## Command History

| Version       | Modification                                                          |
|---------------|-----------------------------------------------------------------------|
| ArubaOS 3.0   | Command introduced                                                    |
| ArubaOS 3.4.1 | The <b>stateful-ntlm</b> and <b>wispr</b> parameters were introduced. |

## Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references aaa authentication-server

```
show references aaa authentication-server {ldap <ldap-server-name>}|{radius <radius-server-name>}|{tacacs <tacacs-server-name>} [page <number>] [start <number>]
```

### Description

Display information about AAA authentication servers.

### Syntax

| Parameter                   | Description                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------|
| ldap <ldap-server-name>     | Show the number of server groups that include references to the specified LDAP server.               |
| radius <radius-server-name> | Show the number of server groups that include references to the specified RADIUS server.             |
| tacacs <radius-server-name> | Show the number of server groups that include references to the specified TACACS server.             |
| page <number>               | Include this parameter to limit output of this command to the specified number of items.             |
| start <number>              | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to show the AAA server groups that include references to the specified server. The example below shows that two server groups, **default** and **rad**, each include a single reference to the radius server **rad01**.

```
(host) #show references aaa authentication-server radius rad01
```

```
References to RADIUS Server "rad01"
```

```

Referrer Count

aaa server-group "default" server_group 1
aaa server-group "rad" server_group 1
Total References:2
```

### Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references aaa profile

```
show references aaa profile <profile-name>
```

### Description

Show references to an AAA Profile.

### Syntax

| Parameter              | Description                                                   |
|------------------------|---------------------------------------------------------------|
| profile <profile-name> | Name of an AAA profile for which you want to view references. |

### Example

Issue this command to show the wlan virtual AP profiles that include references to the specified AAA profile. The example below shows that seven different virtual AP profiles include a single reference to the AAA profile **default**.

```
(host) #References to AAA Profile "default"

Referrer Count

wlan virtual-ap "1.0.0_corporateHQ-wpa2" aaa-profile 1
wlan virtual-ap "110.0.corporateHQ-wpa2" aaa-profile 1
wlan virtual-ap "default" aaa-profile 1
wlan virtual-ap "corporateHQ-vocera" aaa-profile 1
wlan virtual-ap "corporateHQ-voip-wpa2" aaa-profile 1
wlan virtual-ap "Test123" aaa-profile 1
wlan virtual-ap "branch12" aaa-profile 1
Total References:7
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references aaa rfc-3576-server

```
show references aaa rfc-3576-server <server-ip>{page<page> start<start>}
```

### Description

Show information about the configuration profiles that reference a specific RFC 3576 server.

### Syntax

| Parameter     | Description                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------|
| <server-ip>   | IP address of an RFC-3576 server                                                                    |
| page <page>   | Include this parameter to limit output of this command to the specified number of items.            |
| start <start> | Include this parameter to start displaying the output of this command at the specified index number |

### Example

This first example shows that the **default** AAA profile and the AirGroup CPPM-server AAA profile reference an RFC 3567 Server with the IP address 10.1.1.41.

```
(host) # (host) (config) # show references aaa rfc-3576-server 10.1.1.41
References to RFC 3576 Server "10.1.1.41"

Referrer Count

aaa profile "default" rfc-3576-server 1
airgroup cppm-server aaa rfc-3576-server 1
Total References:2
```

### Related Commands

## show references aaa server-group

```
show references aaa server-group {<sg-name>[page][start]}
```

### Description

Show references to a server group.

### Syntax

| Parameter              | Description                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------|
| server-group <sg-name> | Name of the server group for which you want to show references                                       |
| page <number>          | Include this parameter to limit output of this command to the specified number of items.             |
| start <number>         | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to display a list of AAA profiles that include references to the specified server group.

```
(host) #show references aaa server-group default
```

```
References to Server Group "default"
```

```

```

| Referrer                                               | Count |

| Total References:16                                    |       |

### Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references activate-service-whitelist

```
show references activate-service-whitelist <server-ip>{page<page> start<start>}
```

### Description

Displays activate service whitelist profile references.

### Syntax

| Parameter                  | Description                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------|
| activate-service-whitelist | Name of the activate service whitelist profile for which you want to show references                 |
| page <number>              | Include this parameter to limit output of this command to the specified number of items.             |
| start <number>             | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to display a list of activate service whitelist profiles that include references to the specified profile

```
(host) #show references activate-service-whitelist
References to activate-service-whitelist

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references airgroup

```
show references airgroup
cppm-server aaa [page <number>] [start <number>]
```

### Description

Display information about AAA authentication servers.

### Syntax

| Parameter      | Description                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------|
| cppm-server    | Specifies the ClearPass Policy Server information.                                                            |
| aaa            | Specifies the AAA parameters for AirGroup.                                                                    |
| page <number>  | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number> | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

Use this command to show the AAA server groups that include references to the AirGroup.

```
References to Airgroup AAA profile

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references ap

```
show references ap
 enet-link-profile <profile-name>
 mesh-cluster-profile <profile-name>
 mesh-ht-ssid-profile <profile-name>
 mesh-radio-profile <profile-name>
 regulatory-domain-profile <profile-name>
 system-profile <profile-name>
 wired-ap-profile <profile-name>
 page <number>
 start <number>
```

### Description

Show the number of references to a specific AP profile.

### Syntax

| Parameter                                | Description                                                                                                   |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| enet-link-profile <profile-name>         | Show AP groups that include a references to this Ethernet link profile.                                       |
| mesh-cluster-profile <profile-name>      | Show AP groups that include a references to this mesh cluster profile.                                        |
| mesh-ht-ssid-profile <profile-name>      | Show AP groups that include a references to this mesh high-throughput SSID profile.                           |
| mesh-radio-profile <profile-name>        | Show AP groups that include a references to this mesh radio profile.                                          |
| regulatory-domain-profile <profile-name> | Show AP groups that include a references to this regulatory domain profile.                                   |
| system-profile <profile-name>            | Show AP groups that include a references to this system profile.                                              |
| wired-ap-profile <profile-name>          | Show AP groups that include a references to this wired AP profile.                                            |
| page <number>                            | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number>                           | Include this optional parameter to start displaying the output of this command at the specified index number. |

## Example

The example below shows that 10 different AP groups include links to the AP Ethernet link profile **Default**. These 10 AP groups reference the **Default** Ethernet link profile for both their Ethernet 0 and Ethernet 1 interfaces, for a total of 20 references altogether.

```
(host)#show references ap enet-link-profile default
```

```
References to AP Ethernet Link profile "default"
```

```

| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references guest-access-email

```
show references guest-access-email [page <number>] [start <number>]
```

### Description

Show references to the global guest access email profile.

### Syntax

| Parameter      | Description                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------|
| page <number>  | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number> | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

```
(host) #show references guest-access-email
```

```
References to Guest-access Email Profile

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references ha

```
show references ha group-profile <profile-name> {page<page> start<start>}
```

### Description

Displays HA group profile references.

### Syntax

| Parameter                    | Description                                                                                          |
|------------------------------|------------------------------------------------------------------------------------------------------|
| group-profile <profile-name> | Name of the HA group profile for which you want to show references                                   |
| page <number>                | Include this parameter to limit output of this command to the specified number of items.             |
| start <number>               | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to display a list of references for a specific HA group profile.

```
(host) (config) #show references ha group-profile newgroup
References to HA group information "newgroup"

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references ids

```
show references ids
dos-profilegeneral-profile
general-profile
impersonation-profile
profile
rate-thresholds-profile
signature-matching-profile
signature-profile
unauthorized-device-profile
```

### Description

Displays IDS profile references.

### Syntax

| Parameter                   | Description                                          |
|-----------------------------|------------------------------------------------------|
| dos-profilegeneral-profile  | Show references to an IDS Denial Of Service Profile  |
| general-profile             | Show references to an IDS General Profile            |
| impersonation-profile       |                                                      |
| profile                     |                                                      |
| rate-thresholds-profile     | Show references to an IDS Rate Thresholds Profile    |
| signature-matching-profile  | Show references to an IDS Signature Matching Profile |
| signature-profile           | Show references to an IDS Signature Profile          |
| unauthorized-device-profile | Show references to an IDS Signature Profile          |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references ifmap cppm

```
show references ifmap cppm {page<page> start<start>}
```

### Description

Displays the CPPM IF-MAP references.

### Syntax

| Parameter      | Description                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------|
| ifmap cppm     | Shows references to the CPPM IF-MAP profile.                                                         |
| page <number>  | Include this parameter to limit output of this command to the specified number of items.             |
| start <number> | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to display a list of references for the CPPM IF-MAP profile.

```
(host) #show references ifmap cppm
References to CPPM IF-MAP Profile

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references license profile

```
show references license profile {page<page> start<start>}
```

### Description

Displays the license provisioning profile references.

### Syntax

| Parameter      | Description                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------|
| license        | Shows references to the license provisioning profile.                                                |
| profile        | Enables or disables centralized licensing.                                                           |
| page <number>  | Include this parameter to limit output of this command to the specified number of items.             |
| start <number> | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to display a list of references for the license provisioning profile.

```
(host) #show references license profile
References to License provisioning profile

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references mgmt-server profile

```
show references mgmt-server profile <profile_name>
```

### Description

Shows the management server configuration profiles.

### Syntax

| Parameter           | Description                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------|
| mgmt-server profile | Specifies the management profile name.                                                                        |
| page <number>       | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number>      | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

```
(host) (config) #show references mgmt-server profile default
References to Mgmt Config profile "default"

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references papi-security

```
show references papi-security [page <number>] [start <number>]
```

### Description

Show references to a PAPI security profile.

### Syntax

| Parameter      | Description                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------|
| page <number>  | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number> | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

```
(host) #show references papi-security
```

```
References to PAPI Security Profile
```

```

```

```
Referrer Count
```

```
----- ----
```

```
Total References:0
```

### Command History

This command was introduced in ArubaOS 3.4.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references rf

```
show references rf
 dot11a-radio-profile <profile-name>
 dot11g-radio-profile <profile-name>
 event-thresholds-prof <profile-name>
 ht-radio-profile <profile-name>
 optimization-profile <profile-name>
```

### Description

Show RF profile references.

### Syntax

| Parameter             | Description                                        |
|-----------------------|----------------------------------------------------|
| dot11a-radio-profile  | Show references to a 802.11a radio profile         |
| dot11g-radio-profile  | Show references to a 802.11g radio profile         |
| event-thresholds-prof | Show references to an RF Event Thresholds Profile  |
| ht-radio-profile      | Show references to a High-throughput radio profile |
| optimization-profile  | Show references to an RF Optimization Profile      |

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references upgrade-profile

```
show references upgrade-profile {page<page> start<start>}
```

### Description

Displays the upgrade profile references.

### Syntax

| Parameter       | Description                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------|
| upgrade-profile | Shows references to the upgrade profile.                                                             |
| page <number>   | Include this parameter to limit output of this command to the specified number of items.             |
| start <number>  | Include this parameter to start displaying the output of this command at the specified index number. |

### Example

Issue this command to display a list of references for the upgrade profile.

```
(host) #show references upgrade-profile
References to Upgrade Profile

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references user-role

```
show references user-role <role_name>
```

### Description

Show access rights for user role.

### Syntax

| Parameter   | Description                       |
|-------------|-----------------------------------|
| <role_name> | The role name assigned to a user. |

### Example

```
(host) #show references user-role guest
```

```
References to User Role "guest"
```

```

```

```
aaa profile "airwave-office-ssid" mac-default-role
aaa profile "amigopod-guest" mac-default-role
aaa profile "corp1344-voip" mac-default-role
aaa profile "default" mac-default-role
aaa profile "default-airwave-office" mac-default-role
aaa profile "default-corp1344" mac-default-role
aaa profile "default-corp1344-no-okc" mac-default-role
aaa profile "default-corp1344-okc" mac-default-role
aaa profile "default-dot1x" mac-default-role
aaa profile "default-dot1x-psk" mac-default-role
aaa profile "default-dot1x-psk" dot1x-default-role
aaa profile "default-India" mac-default-role
aaa profile "default-india-hotel" mac-default-role
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show references web-server

```
show references web-server [page <number>] [start <number>]
```

### Description

Show the Web server configuration references.

### Syntax

| Parameter      | Description                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------|
| page <number>  | Include this optional parameter to limit output of this command to the specified number of items.             |
| start <number> | Include this optional parameter to start displaying the output of this command at the specified index number. |

### Example

```
(host) #show references web-server
```

```
References to Web Server Configuration

Referrer Count
----- -----
Total References:0
```

### Command History

This command was introduced in ArubaOS 3.0.

```

### Description

Show information about the different configuration profiles that reference a specific WLAN profile.

### Syntax

| Parameter                              | Description                                                     |
|----------------------------------------|-----------------------------------------------------------------|
| bcn-rpt-req-profile                    | Shows references to a Beacon Report Request profile.            |
| client-wlan-profile                    | Shows references for the Client WLAN profile.                   |
| dot11k-profile <profile-name>          | Shows references to a 802.11k profile.                          |
| dot11r-profile <profile-name>          | Shows references to a 802.11r profile.                          |
| edca-parameters-profile <profile-name> | Shows references to an EDCA parameters profile.                 |
| handover-trigger-profile               | Show references to a Handover Trigger profile.                  |
| hotspot                                | Shows references to one of the following hotspot profile types: |

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                      | <ul style="list-style-type: none"> <li>advertisement-profile</li> <li>anqp-3gpp-nwk-profile</li> <li>anqp-domain-name-profile</li> <li>anqp-ip-addr-avail-profile</li> <li>anqp-nai-realm-profile</li> <li>anqp-nwk-auth-profile</li> <li>anqp-roam-cons-profile</li> <li>anqp-venue-name-profile</li> <li>h2qp-conn-capability-profile</li> <li>h2qp-op-cl-profile</li> <li>h2qp-operator-friendly-name-profile</li> <li>h2qp-wan-metrics-profile</li> <li>hs2-profile</li> </ul> |
| ht-ssid-profile <profile-name>       | Shows references to a high-throughput SSID profile.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| rrm-ie-profile                       | Shows references to an RRM IE profile.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ssid-profile <profile-name>          | Shows references to an SSID management profile.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| traffic-management-pr <profile-name> | Shows references to a traffic management profile.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| virtual-ap <profile-name>            | Shows references to a virtual AP profile.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| tsm-req-profile                      | Show references to a TSM Report Request profile.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| voip-cac-profile <profile-name>      | Shows references to a VOIP Call Admission Control profile.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| wmm-traffic-management               | Shows references to a WMM Traffic management profile.                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Example

The following example shows that two different WLAN hotspot 2.0 profiles reference the **default** WLAN hotspot advertisement profile.

```
(host) #show references wlan hotspot advertisement-profile default
References to Advertisement Profile "default"

Referrer Count

wlan hotspot hs2-profile "deploytest" advertisement-profile 1
wlan hotspot hs2-profile "default" advertisement-profile 1
```

Total References:2

## Command History

|             | Modification                            |
|-------------|-----------------------------------------|
| ArubaOS 3.0 | Command introduced.                     |
| ArubaOS 6.4 | The <b>hotspot</b> parameter was added. |

## Command Information

| Platforms                  | Licensing             | Command Mode                                |
|----------------------------|-----------------------|---------------------------------------------|
| Available on all platforms | Base operating system | Config mode on master and local controllers |

## show rf am-scan-profile

show rf am-scan-profile [<profile-name>]

### Description

Display the Air Monitor (AM) scanning profile list. Optionally display parameter and values of a specified Air Monitor profile.

### Syntax

| Parameter      | Description                           |
|----------------|---------------------------------------|
| <profile-name> | Name of this instance of the profile. |

### Usage Guidelines

Enter the basic show command to view a list of profiles, the number of profiles and the profile status. For example:

```
(host) #show rf am-scan-profile

AM Scanning profile List

Name References Profile Status
---- -
default 9
north 0

Total:2
```

### Example

In the example above, there are two profile names; default and north. The Reference column indicates the number of references to this profile name. The Profile Status column is blank unless the profile is predefined.

Optionally, you can enter a profile name to view the parameters for that profile. For example:

```
(host) #show rf am-scan-profile default

AM Scanning profile "default"

Parameter Value

Scan Mode all-reg-domain
Dwell time: Active channels 500
Dwell time: Regulatory Domain channels 250
Dwell time: non-Regulatory Domain channels 200
Dwell time: Rare channels 100
```

The explanation of the display output is described in the table below.

| Parameter                                  | Description                                                      |
|--------------------------------------------|------------------------------------------------------------------|
| Scan-mode                                  | The scanning mode for the radio                                  |
| all-reg-domain                             | Scan channels in all regulatory domain                           |
| rare                                       | Scan all channels (all regulatory domains and rare channels)     |
| reg-domain                                 | Scan channels in the APs regulatory domain                       |
| Dwell time: Active channels                | Dwell time (in ms) for channels where there is wireless activity |
| Dwell time: Regulatory Domain channels     | Dwell time (in ms) for AP's Regulatory domain channels           |
| Dwell time: non-Regulatory Domain channels | Dwell time (in ms) for channels not in the APs regulatory domain |
| Dwell time: Rare channels                  | Dwell time (in ms) for rare channels                             |

## Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.0 | Command introduced |

## Command Information

| Platforms     | Licensing | Command Mode                |
|---------------|-----------|-----------------------------|
| All Platforms | RFProtect | Configuration Mode (config) |

## show rf arm-rf-domain-profile

```
show rf arm-rf-domain profile
```

### Description

This profile contains a non-editable key defined by the master controller, and used to sign over-the air (OTA) ARM updates exchanged between APs.

### Syntax

No parameters

### Example

The output of this command displays the OTA key defined by the master controller.

```
(host) # #show rf arm-rf-domain-profile

ARM RF domain

Parameter Value

ARM RF domain key 27f71ad66f28c374a8904b4a82177e2c
```

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.2 | Command introduced |

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## show rf arm-profile

```
show rf arm-profile [<profile>]
```

### Description

Show an Adaptive Radio Management (ARM) profile.

### Syntax

| Parameter | Description             |
|-----------|-------------------------|
| <profile> | Name of an ARM profile. |

### Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire ARM profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has five configured ARM profiles. The **References** column lists the number of other profiles with references to the ARM profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show rf arm-profile
Adaptive Radio Management (ARM) profile List

Name References Profile Status

airwave 2
default 4
default-AP85 2
no-scanning 1
Wireless-rf-profile 1

Total:5.
```

This example displays the configuration settings for the profile **Wireless\_rf\_profile**.

```
(host) #show rf arm-profile default
Adaptive Radio Management (ARM) profile "Wireless_rf_profile"

Parameter Value

Assignment single-band
Allowed bands for 40MHz channels a-only
80MHz support Enabled
Client Aware Enabled
Max Tx EIRP 127 dBm
Min Tx EIRP 9 dBm
Rogue AP Aware Disabled
Scan Interval 10 sec
Aggressive scanning true
Active Scan Disabled
ARM Over the Air Updates Enabled
```

```

Scanning Enabled
Multi Band Scan Enabled
VoIP Aware Scan Enabled
Power Save Aware Scan Disabled
Video Aware Scan Enabled
Ideal Coverage Index 10
Acceptable Coverage Index 4
Free Channel Index 25
Backoff Time 240 sec
Error Rate Threshold 50 %
Error Rate Wait Time 30 sec
Channel Quality Aware Arm Disabled
Channel Quality Threshold 70 %
Channel Quality Wait Time 120 sec
Minimum Scan Time 8
Load aware Scan Threshold 1250000 Bps
Mode Aware Arm Disabled
Scan Mode all-reg-domain
Client Match Enabled
Client Match report interval (sec) 30
Client Match Unsteerable Client Ageout Enabled
Client Match Unsteerable Client Ageout Interval 2 0
Client Match Sticky Client Check Interval (sec) 3
Client Match Sticky client check SNR (dB) 25
Client Match SNR threshold(dB) 99
Client Match Sticky Min Signal 70
Client Match Restriction timeout (sec) 255
Client Match Load Balancing threshold (%) 20
Client Match VBR Stale Entry Age (sec) 120
Client Match Max steer failures 5
Client Match Load Balancing client threshold 10
Client Match Load Balancing SNR threshold (dB) 77

```

The output of this command includes the following parameters:

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Assignment                       | Displays the current ARM channel/power assignment mode.                                                                                                                                                                                                                                                                                      |
| Allowed bands for 40MHz channels | Shows if 40 MHz mode of operation is allowed on the 5 GHz (802.11a) or 2.4 GHz (802.11b/g) frequency band only, on all frequency bands, or on neither frequency band.                                                                                                                                                                        |
| Client Aware                     | Shows if the client aware feature is enabled or disabled. When enabled, the AP does not change channels when there are active clients.                                                                                                                                                                                                       |
| Max Tx Power                     | The highest transmit power levels for the AP, from 0-30 dBm in 3 dBm increments. Higher power level settings may be constrained by local regulatory requirements and AP capabilities. In the event that an AP is configured for a Max Tx Power setting it cannot support, this value will be reduced to the highest supported power setting. |
| Min Tx Power                     | The lowest transmit power levels for the AP, from 0-30 dBm, in 3 dBm increments. Note that power settings will not change if the Assignment option is set to disabled or maintain.                                                                                                                                                           |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multi Band Scan           | If enabled, single-radio APs will try to scan across bands for rogue AP detection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Rogue AP Aware            | <p>If enabled, Dell APs may change channels to contain off-channel rogue APs with active clients. This security features allows APs to change channels even if the Client Aware setting is disabled.</p> <p>This setting is disabled by default, and should only be enabled in high-security environments where security requirements are allowed to consume higher levels of network resources. You may prefer to receive Rogue AP alerts via SNMP traps or syslog events.</p>                                                                          |
| Scan Interval             | <p>If Scanning is enabled, the Scan Interval defines how often the AP will leave its current channel to scan other channels in the band.</p> <p>Off-channel scanning can impact client performance. Typically, the shorter the scan interval, the higher the impact on performance. If you are deploying a large number of new APs on the network, you may want to lower the Scan Interval to help those APs find their optimal settings more quickly. Raise the Scan Interval back to its default setting after the APs are functioning as desired.</p> |
| Aggressive Scanning       | When the aggressive scanning feature is enabled, an AP radio with no clients will scan channels every second.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Active Scan               | If enabled, the AP initiates active scanning via probe request. This option elicits more information from nearby APs, but also creates additional management traffic on the network. Active Scan is disabled by default, and should not be enabled except under the direct supervision of Dell Support.                                                                                                                                                                                                                                                  |
| Scanning                  | Shows if the AP has enabled or disabled AP scanning of other channels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Scan Time                 | The amount of time, in milliseconds, an AP will drift out of the current channel to scan another channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| VoIP Aware Scan           | Shows if Dell's VoIP Call Admission Control (CAC) prevents any single AP from becoming congested with voice calls. If CAC is enabled, you should also enable VoIP Aware Scan in the ARM profile, so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call.                                                                                                                                                                                                                                                   |
| Power Save Aware Scan     | When enabled, the AP will not scan if Power Save is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Video Aware Scan          | If Video Aware Scan is enabled in the ARM profile, the AP will not attempt to scan a different channel if one of its clients has an active video session.                                                                                                                                                                                                                                                                                                                                                                                                |
| Ideal Coverage Index      | The coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Acceptable Coverage Index | The minimal coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be.                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Free Channel Index        | The difference in the interference index between the new channel and current channel must exceed this value for the AP to move to a new channel. The higher this value, the lower the chance an AP will move to the new channel.                                                                                                                                                                                                                                                                                                                                                                  |
| Backoff Time              | Time, in seconds, an AP backs off after requesting a new channel or power level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error Rate Threshold      | The percentage of errors in the channel that triggers a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Error Rate Wait Time      | Time, in seconds, that the error rate has to maintain or surpass the error rate threshold before it triggers a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Channel Quality Aware Arm | Shows if ARM changes are based on on channel quality and noise floor values. If this parameter is disabled, only noise-floor values will be used to change channels. Default: Disabled                                                                                                                                                                                                                                                                                                                                                                                                            |
| Channel Quality Threshold | Displays the hannel quality percentage below which ARM initiates a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Channel Quality Wait Time | If channel quality is below the specified channel quality threshold for this wait time period, ARM initiates a channel change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Minimum Scan Time         | Time, in seconds, that a channel must be scanned before it is considered for assignment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Load aware Scan Threshold | The traffic throughput level an AP must reach before it stops scanning, in bytes/second. A value of 0 to disables this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Mode Aware Arm            | If enabled, ARM will turn APs into Air Monitors (AMs) if it detects higher coverage levels than necessary. This helps avoid higher levels of interference on the WLAN. Although this setting is disabled by default, you may want to enable this feature if your APs are deployed in close proximity (e.g. less than 60 feet apart).                                                                                                                                                                                                                                                              |
| Scan Mode                 | This parameter defines the scan mode for the AP. <ul style="list-style-type: none"> <li>all-reg-domain: The AP scans channels within all regulatory domains. This is the default setting.</li> <li>reg-domain: Limit the AP scans to just the regulatory domain for that AP.</li> </ul>                                                                                                                                                                                                                                                                                                           |
| Client Match              | The client match feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.<br><br>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Dell AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is enabled by default |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client Match report interval (sec)              | This interval defines how often an AP sends an updated client probe report to the controller. Each client probe report contains a list of MAC addresses for clients that have been active in the last two minutes, and the AP radio SNR values seen by those clients.                                                                                                                                                                                             |
| Client Match Unsteerable Client Ageout Interval | The client entries in an unsteerable client list remain in effect for the interval defined by this parameter before they age out.                                                                                                                                                                                                                                                                                                                                 |
| Client Match Unsteerable Client Ageout          | When client match and the client match unsteerable client ageout feature are enabled, the controller periodically sends APs that are not a desired AP match for a client in a list of unsteerable clients. These lists contain a list of MAC addresses for up to 128 clients that should not be steered to that AP.                                                                                                                                               |
| Client Match Sticky Client Check Interval (sec) | Frequency at which the AP checks for client's received SNR values. If the SNR value drops below the threshold defined by the <b>cm-sticky-snr</b> parameter for three consecutive check intervals, that client may be moved to an different AP.                                                                                                                                                                                                                   |
| Client Match Sticky Client Check SNR (dB)       | If the client's received signal strength indicator (RSSI) is above this signal-to-noise ratio (SNR) threshold, that client will be allowed to stay associated to its current AP. If the client's received signal strength is below this threshold, it may be moved to a different AP.                                                                                                                                                                             |
| Client Match SNR threshold (dB)                 | A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the AP radio is stronger than its current radio by the dB level defined by the <b>cm-sticky-snr-thresh</b> parameter, and the candidate radio also has a minimum signal level defined by the <b>cm-sticky-min-signal</b> parameter.                                                                                               |
| Client Match Sticky Min Signal                  | A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the candidate AP radio is at or higher than the minimum signal level defined by this parameter <i>and</i> the candidate radio has a higher signal strength than the radio to which the client is currently associated. (The required improvement in signal strength can be defined using the <b>cm-sticky-snr-delta</b> command.) |
| Client Match Restriction timeout (sec)          | When a client is steered from one AP to a more desirable AP, the steer timeout feature helps facilitate the move by defining the amount of time that any APs to which the client should NOT associate will not respond to the AP.                                                                                                                                                                                                                                 |
| Client Match Load Balancing threshold (%)       | When the client match feature is enabled, clients may be steered from a highly utilized channel on an AP to a channel with fewer clients. If a channel on an AP radio has this percentage fewer clients than another channel supported by the client, the client match feature may move clients from the busier channel to the channel with fewer clients.                                                                                                        |
| Client Match VBR Stale Entry Age (sec)          | The controller maintains client match data for up to 4096 clients showing the detected SNR values for up to 16 candidate APs per client. This table is periodically updated as APs send client probe reports to the controller. This parameter defines the amount of time that the controller should retain client match data from each client probe report.                                                                                                      |
| Client Match Max Steer Failures                 | The controller keeps track of the number of times the client match feature failed to steer a client to a different radio, and the reason that each steer                                                                                                                                                                                                                                                                                                          |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                | <p>attempt was triggered. If the client match feature attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as unsteerable for that specific trigger.</p> <p>This parameter defines the maximum allowed number of client match steering fails with the same trigger before the client is marked as unsteerable for that trigger.</p> |
| Client Match Load Balancing Client Threshold   | If an AP radio has fewer clients than the client match load balancing threshold defined by this parameter, the AP will not participate in load balancing.                                                                                                                                                                                                                                                                                                      |
| Client Match Load Balancing SNR Threshold (dB) | Clients must detect a SNR from an underutilized AP radio at or above this threshold before the client match feature considers load balancing a client to that radio.                                                                                                                                                                                                                                                                                           |

## show rf dot11a-radio-profile

```
show rf dot11a-radio-profile [<profile>]
```

### Description

Show an 802.11a Radio profile.

### Syntax

| Parameter | Description                 |
|-----------|-----------------------------|
| <profile> | Name of an 802.11a profile. |

### Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire 802.11a Radio profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has three configured 802.11a Radio profiles. The **References** column lists the number of other profiles with references to the 802.11a Radio profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show rf dot11a-radio-profile
802.11a radio profile List

Name References Profile Status

default 18
default-AP85 1
test 1
```

Total:3.

This example displays the configuration settings for the profile default.

```
(host) # show rf dot11a-radio-profile default
802.11a radio profile "default"
Parameter Value

Radio enable Enabled
Mode ap-mode
High throughput enable (radio) Enabled
Very high throughput enable (radio) Enabled
Channel N/A
Transmit EIRP 15 dBm
Non-Wi-Fi Interference Immunity 2
Enable CSA Disabled
CSA Count 4
Spectrum Monitoring Enabled
Spectrum Monitoring Profile default-a
Advertise 802.11d and 802.11h Capabilities Disabled
Spectrum Load Balancing Disabled
Spectrum Load Balancing Mode channel
```

```

Spectrum Load Balancing Update Interval (sec) 30 seconds
Spectrum Load Balancing Threshold (%) 20 percent
Spectrum Load Balancing Domain N/A
Beacon Period 100 msec
Beacon Regulate Disabled
Advertized regulatory max EIRP 0
ARM/WIDS Override OFF
Reduce Cell Size (Rx Sensitivity) 0 dB
Management Frame Throttle interval 1 sec
Management Frame Throttle Limit 20
Maximum Distance 0 meters
RX Sensitivity Threshold 0 dB
RX Sensitivity Tuning Based Channel Reuse disable
Adaptive Radio Management (ARM) Profile default
High-throughput Radio Profile default-a
AM Scanning Profile default

```

The output of this command includes the following parameters:

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Radio enable                   | Shows if the AP has enabled or disabled transmissions on this radio band.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Mode                           | Access Point operating mode. Available options are: <ul style="list-style-type: none"> <li>• am-mode: Air Monitor mode</li> <li>• ap-mode: Access Point mode</li> <li>• apm-mode: Access Point Monitor mode</li> <li>• sensor-mode: RFprotect sensor mode</li> </ul>                                                                                                                                                                                                                                                        |
| High throughput enable (radio) | Shows if high-throughput (802.11n) is enabled on the radio.<br><br>A high-throughput profile manages 40 Mhz tolerance settings, and controls whether or not APs using this profile will advertise intolerance of 40 MHz operation. (This option is disabled by default, allowing 40 MHz operation.)<br><br>A high-throughput profile also determines whether an AP radio using the profile will stop using the 40 MHz channels surrounding APs or stations advertise 40 Mhz intolerance. This option is enabled by default. |
| Very High Throughput-Enable    | Enable or disable support for Very High Throughput (802.11ac) on the radio. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Channel                        | Channel number for the AP 802.11a, 802.11n, or 802.11ac physical layer.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Beacon Period                  | Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.                                                                                                                                                                                                                                                                                                                                                           |
| Beacon Regulate                | If enabled, this option introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air. This option is disabled by default.                                                                                                                                                                                                                                                                                             |
| Transmit EIRP                  | Maximum transmit power (EIRP) in dBm from 0 to 51 in .5 dBm increments. Further limited by regulatory domain constraints and AP capabilities.                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Advertise 802.11d and 802.11h Capabilities   | If enabled, the radio advertises its 802.11d (Country Information) and 802.11h (Transmit Power Control) capabilities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TPC Power                                    | The transmit power advertised in the TPC IE of beacons and probe responses                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Spectrum load balancing                      | <p>The Spectrum load balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Dell AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p>                                                                                                                                                                                                                                |
| Spectrum load balancing mode                 | SLB Mode allows control over how to balance clients. Channel-based load-balancing balances clients across channels. Radio-based load-balancing distributes clients across radios on the same band, independent of channels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Spectrum load balancing mode update interval | This parameter specifies how often spectrum load balancing calculations are made (in seconds). The default value is 30 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Spectrum load balancing threshold            | If the spectrum load balancing feature is enabled, this parameter controls the percentage difference between number of clients on a channel channel that triggers load balancing. The default value is 20%, meaning that spectrum load balancing is activated when there are 20% more clients on one channel than on another channel used by the AP radio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Advertised Regulatory Max EIRP               | <p>Shows if the radio is configured to work around a known issue on Cisco 7921G telephones by capping for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.</p> <p>The supported value is 1–31 dBm.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| Spectrum load balancing domain               | <p>Define a spectrum load balancing domain to manually create RF neighborhoods.</p> <p>Use this option to create RF neighborhood information for networks that have disabled Adaptive Radio Management (ARM) scanning and channel assignment.</p> <ul style="list-style-type: none"> <li>• If spectrum load balancing is enabled in a 802.11a radio profile but the spectrum load balancing domain is <i>not</i> defined, ArubaOS uses the ARM feature to calculate RF neighborhoods.</li> <li>• If spectrum load balancing is enabled in a 802.11a radio profile and a spectrum load balancing domain <i>is/also</i> defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by the ARM feature.</li> </ul> |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RX Sensitivity Tuning Based Channel Reuse | <p>Shows if the channel reuse feature's current operating mode, static, dynamic or disable.</p> <ul style="list-style-type: none"> <li>• <b>Static:</b> This mode of operation is a coverage-based adaptation of the Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa.</li> <li>• <b>Dynamic:</b> In this mode, the Clear Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client.</li> <li>• <b>Disable:</b> This mode does not support the tuning of the CCA Detect Threshold.</li> </ul> |
| RX Sensitivity Threshold                  | <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (-dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength. For example, if the RX sensitivity threshold was set to -65 dBm, the AP would ignore signals with a strength from -1 dBm to -64 dBm. If the value is set to zero, the feature will automatically determine an appropriate threshold.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Enable CSA                                | <p>Shows if Channel Switch Announcements (CSAs) are enabled or disabled. CSAs, as defined by IEEE 802.11h, enable an AP to announce that it is switching to a new channel before it begins transmitting on that channel. This allows clients that support CSA to transition to the new channel with minimal downtime.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| CSA Count                                 | <p>Number of channel switch announcements that must be sent prior to switching to a new channel. The default CSA count is 4 announcements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Management Frame Throttle Interval        | <p>Averaging interval for rate limiting mgmt frames from this radio, in seconds. A management frame throttle interval of 0 seconds disables rate limiting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Management Frame Throttle Limit           | <p>Maximum number of management frames that can come in from this radio in each throttle interval.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ARM/WIDS Override                         | <p>If enabled, this option disables Adaptive Radio Management (ARM) and Wireless IDS functions and slightly increases packet processing performance. If a radio is configured to operate in Air Monitor mode, then the ARM/WIDS override functions are always enabled, regardless of whether or not this check box is selected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Reduce Cell Size (Rx Sensitivity)         | <p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Adaptive Radio Management (ARM) Profile | Name of an Adaptive Radio Management profile associated with this 802.11a profile.                                                                                                                                                                                                                            |
| High-throughput Radio Profile           | Name of a High Throughput Radio profile associated with this 802.11a profile.                                                                                                                                                                                                                                 |
| Maximum Distance                        | Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.. |
| Spectrum Monitoring                     | If enabled, the AP operates as a hybrid AP that can simultaneously serve clients and monitor a single channel for spectrum analysis data.                                                                                                                                                                     |
| Spectrum Monitoring Profile             | The spectrum monitoring profile referenced by APs using this 802.11a radio profile. For details, see <a href="#">rf spectrum-profile on page 784</a>                                                                                                                                                          |
| AM Scanning Profile                     | The AM scanning profile referenced by APs using this 802.11a radio profile. For details, see <a href="#">rf am-scan-profile on page 734</a>                                                                                                                                                                   |

## Command History

| Release       | Modification                                                                                                                                                                                                                                             |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0   | Command introduced.                                                                                                                                                                                                                                      |
| ArubaOS 3.3.2 | Introduced support for the high-throughput IEEE 802.11n standard.                                                                                                                                                                                        |
| ArubaOS 3.4.0 | Support for the following parameters: <ul style="list-style-type: none"> <li>• Spectrum load balancing</li> <li>• RX Sensitivity Tuning Based Channel Reuse</li> <li>• RX Sensitivity Threshold</li> <li>• ARM/WIDS Override</li> </ul>                  |
| ArubaOS 3.4.2 | Support for the <b>Beacon Regulate</b> parameter                                                                                                                                                                                                         |
| ArubaOS 6.0   | Support for the following parameters: <ul style="list-style-type: none"> <li>• AM Scanning Profile</li> <li>• Advertised regulatory max EIRP</li> <li>• Spectrum Load balancing mode</li> <li>• Spectrum load balancing update interval (sec)</li> </ul> |
| ArubaOS 6.1   | Support for the following parameters: <ul style="list-style-type: none"> <li>• Spectrum Monitoring</li> </ul>                                                                                                                                            |

| Release         | Modification                                                                            |

| All platforms | Base operating system | Enable and Config mode on local and master controllers |

# show rf dot11g-radio-profile

show rf dot11g-radio-profile [<profile>]

## Description

Show an 802.11g Radio profile.

## Syntax

| Parameter | Description                |
|-----------|----------------------------|
| <profile> | Name of a 802.11g profile. |

## Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire 802.11g profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has four configured 802.11g profiles. The **References** column lists the number of other profiles with references to the 802.11g profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show rf arm-profile
Adaptive Radio Management (ARM) profile List

Name References Profile Status
---- -
airwave 4
default 4
no-scanning 1
nokia-rf-profile 1
```

Total:4.

This example displays the configuration settings for the profile airwave.

```
(host) # show rf dot11g-radio-profile default
Parameter Value

Radio enable Enabled
Mode ap-mode
High throughput enable (radio) Enabled
Channel N/A
Beacon Period 100 msec
Beacon Regulate Disabled
Transmit EIRP 15 dBm
Advertise 802.11d and 802.11h Capabilities Disabled
TPC Power 15 dBm
Spectrum load balancing Disabled
Spectrum Load balancing mode channel
Spectrum load balancing update interval (sec) 30 seconds
Advertised regulatory max EIRP 0
Spectrum Load Balancing domain N/A
```

```

RX Sensitivity Tuning Based Channel Reuse disable
RX Sensitivity Threshold 0 -dBm
Non 802.11 Interference Immunity Level-2
Enable CSA Disabled
CSA Count 4
Management Frame Throttle interval 1 sec
Management Frame Throttle Limit 20
ARM/WIDS Override Disabled
Reduce Cell Size (Rx Sensitivity) 0 dB
Protection for 802.11b Clients Enabled
Adaptive Radio Management (ARM) Profile default
High-throughput Radio Profile default-g
Maximum Distance 0 meters
Spectrum Monitoring Disabled
Spectrum Monitoring Profile default-a
AM Scanning Profile default

```

The output of this command includes the following parameters:

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Radio enable                               | Shows if the AP has enabled or disabled transmissions on this radio band.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Mode                                       | Access Point operating mode. Available options are: <ul style="list-style-type: none"> <li>• am-mode: Air Monitor mode</li> <li>• ap-mode: Access Point mode</li> <li>• apm-mode: Access Point Monitor mode</li> <li>• sensor-mode: RFprotect sensor mode</li> </ul>                                                                                                                                                                                                                                                             |
| High throughput enable (radio)             | Shows if high throughput (802.11n) is enabled or disabled on this radio.<br>A high-throughput profile manages 40 Mhz tolerance settings, and controls whether or not APs using this profile will advertise intolerance of 40 MHz operation. (This option is disabled by default, allowing 40 MHz operation.)<br>A high-throughput profile also determines whether an AP radio using the profile will stop using the 40 MHz channels surrounding APs or stations advertise 40 Mhz intolerance. This option is enabled by default. |
| Channel                                    | Channel number for the AP 802.11a/802.11n physical layer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Beacon Period                              | Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.                                                                                                                                                                                                                                                                                                                                                                |
| Beacon Regulate                            | If enabled, this option introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air. This option is disabled by default.                                                                                                                                                                                                                                                                                                  |
| Transmit EIRP                              | Maximum transmit power (EIRP) in dBm from 0 to 51 in .5 dBm increments. Further limited by regulatory domain constraints and AP capabilities.                                                                                                                                                                                                                                                                                                                                                                                    |
| Advertise 802.11d and 802.11h Capabilities | If enabled, the radio advertises its 802.11d (Country Information) and 802.11h (Transmit Power Control) capabilities.                                                                                                                                                                                                                                                                                                                                                                                                            |

| Spectrum load balancing                      | <p>The Spectrum load balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Dell AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p>                                                                                                                                                                                                                                |
| Spectrum load balancing mode                 | SLB Mode allows control over how to balance clients. Channel-based load-balancing balances clients across channels. Radio-based load-balancing distributes clients across radios on the same band, independent of channels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Spectrum load balancing mode update interval | This parameter specifies how often spectrum load balancing calculations are made (in seconds). The default value is 30 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Spectrum load balancing threshold            | If the spectrum load balancing feature is enabled, this parameter controls the percentage difference between number of clients on a channel channel that triggers load balancing. The default value is 20%, meaning that spectrum load balancing is activated when there are 20% more clients on one channel than on another channel used by the AP radio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Advertised Regulatory Max EIRP               | <p>Shows if the radio is configured to work around a known issue on Cisco 7921G telephones by capping for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.</p> <p>The supported value is 1–31 dBm.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| Spectrum load balancing domain               | <p>Define a spectrum load balancing domain to manually create RF neighborhoods.</p> <p>Use this option to create RF neighborhood information for networks that have disabled Adaptive Radio Management (ARM) scanning and channel assignment.</p> <ul style="list-style-type: none"> <li>• If spectrum load balancing is enabled in a 802.11g radio profile but the spectrum load balancing domain is <i>not</i> defined, ArubaOS uses the ARM feature to calculate RF neighborhoods.</li> <li>• If spectrum load balancing is enabled in a 802.11g radio profile and a spectrum load balancing domain <i>is also</i> defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by the ARM feature.</li> </ul> |
| RX Sensitivity Tuning Based Channel Reuse    | <p>Shows if the channel reuse feature's current operating mode, static, dynamic or disable.</p> <ul style="list-style-type: none"> <li>• <b>Static:</b> This mode of operation is a coverage-based adaptation of the</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    | <p>Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa.</p> <ul style="list-style-type: none"> <li>• <b>Dynamic:</b> In this mode, the Clear Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client.</li> <li>• <b>Disable:</b> This mode does not support the tuning of the CCA Detect Threshold.</li> </ul> |
| RX Sensitivity Threshold           | <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (-dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength. For example, if the RX sensitivity threshold was set to -65 dBm, the AP would ignore signals with a strength from -1 dBm to -64 dBm. If the value is set to zero, the feature will automatically determine an appropriate threshold.</p>                                                                                                                                                                                                                                                                                                                                                                   |
| Non 802.11 Interference Immunity   | <p>Show the current value for 802.11 Interference Immunity on the 2.4 Ghz band.</p> <p>The default setting for this parameter is level 2. When performance drops due to interference from non-802.11 interferers (such as DECT or Bluetooth devices), the level can be increased up to level 5 for improved performance. However, increasing the level makes the AP slightly "deaf" to its surroundings, causing the AP to lose a small amount of range.</p> <p>The levels for this parameter are:</p> <ul style="list-style-type: none"> <li>• Level-0: no ANI adaptation.</li> <li>• Level-1: noise immunity only.</li> <li>• Level-2: noise and spur immunity.</li> <li>• Level-3: level 2 and weak OFDM immunity.</li> <li>• Level-4: level 3 and FIR immunity.</li> <li>• Level-5: disable PHY reporting.</li> </ul>                                                 |
| Enable CSA                         | <p>Shows if Channel Switch Announcements (CSAs) are enabled or disabled. CSAs, as defined by IEEE 802.11h, enable an AP to announce that it is switching to a new channel before it begins transmitting on that channel. This allows clients that support CSA to transition to the new channel with minimal downtime.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| CSA Count                          | <p>Number of channel switch announcements that must be sent prior to switching to a new channel. The default CSA count is 4 announcements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Management Frame Throttle Interval | <p>Averaging interval for rate limiting mgmt frames from this radio, in seconds. A management frame throttle interval of 0 seconds disables rate limiting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Management Frame Throttle Limit         | Maximum number of management frames that can come in from this radio in each throttle interval.                                                                                                                                                                                                                                                                                                            |
| ARM/WIDS Override                       | If enabled, this option disables Adaptive Radio Management (ARM) and Wireless IDS functions and slightly increases packet processing performance. If a radio is configured to operate in Air Monitor mode, then the ARM/WIDS override functions are always enabled, regardless of whether or not this check box is selected.                                                                               |
| Reduce Cell Size (Rx Sensitivity)       | The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value. |
| Protection for 802.11b Clients          | Shows if the profile has enabled or disabled protection for 802.11b clients.                                                                                                                                                                                                                                                                                                                               |
| Adaptive Radio Management (ARM) Profile | Name of an Adaptive Radio Management profile associated with this 802.11a profile.                                                                                                                                                                                                                                                                                                                         |
| High-throughput Radio Profile           | Name of a High Throughput Radio profile associated with this 802.11a profile.                                                                                                                                                                                                                                                                                                                              |
| Maximum Distance                        | Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.                                                                                               |
| Spectrum Monitoring                     | If enabled, the AP operates as a hybrid AP that can simultaneously serve clients and monitor a single channel for spectrum analysis data.                                                                                                                                                                                                                                                                  |
| Spectrum Monitoring Profile             | The spectrum monitoring profile referenced by APs using this 802.11g radio profile. For details, see <a href="#">rf spectrum-profile on page 784</a>                                                                                                                                                                                                                                                       |
| AM Scanning Profile                     | The AM scanning profile referenced by APs using this 802.11g radio profile. For details, see <a href="#">rf am-scan-profile on page 734</a>                                                                                                                                                                                                                                                                |

## Command History

| Release       | Modification                                                                                        |
|---------------|-----------------------------------------------------------------------------------------------------|
| ArubaOS 3.0   | Command introduced                                                                                  |
| ArubaOS 3.3.2 | Introduced protection for 802.11b clients and support for the high-throughput IEEE 802.11n standard |
| ArubaOS 3.4   | Support for the following parameters:                                                               |

| Release         | Modification                                                                                                                                                                                                                                             |

| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show rf event-thresholds-profile

```
show rf event-thresholds-profile [<profile>]
```

### Description

Show an Event Thresholds profile.

### Syntax

| Parameter | Description                         |
|-----------|-------------------------------------|
| <profile> | name of an Event Thresholds profile |

### Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire Event Thresholds profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has two configured Event Thresholds profiles. The **References** column lists the number of other profiles with references to the Event Thresholds profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show rf event-thresholds-profile
```

```
RF Event Thresholds Profile List

Name References Profile Status
---- -
default 6
event1 2
```

```
Total: 2.
```

This example displays the configuration settings for the profile **default**.

```
(host) # show rf event-thresholds-profile default
RF Event Thresholds Profile "default"

Parameter Value

Detect Frame Rate Anomalies Disabled
Bandwidth Rate High Watermark 0 %
Bandwidth Rate Low Watermark 0 %
Frame Error Rate High Watermark 0 %
Frame Error Rate Low Watermark 0 %
Frame Fragmentation Rate High Watermark 16 %
Frame Fragmentation Rate Low Watermark 8 %
Frame Low Speed Rate High Watermark 16 %
Frame Low Speed Rate Low Watermark 8 %
Frame Non Unicast Rate High Watermark 0 %
Frame Non Unicast Rate Low Watermark 0 %
Frame Receive Error Rate High Watermark 16 %
Frame Receive Error Rate Low Watermark 8 %
```

```

Frame Retry Rate High Watermark 16 %
Frame Retry Rate Low Watermark 8 %

```

The output of this command includes the following parameters:

| Parameter                               | Description                                                                                                                                                                                                                                                                               |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detect Frame Rate Anomalies             | Shows of the profile enables or disables detection of frame rate anomalies.                                                                                                                                                                                                               |
| Bandwidth Rate High Watermark           | If bandwidth in an AP exceeds this value, it triggers a <b>bandwidth exceeded condition</b> . The value represents the percentage of maximum for a given radio. (For 802.11b, the maximum bandwidth is 7 Mbps. For 802.11 a and g, the maximum is 30 Mbps.) The recommended value is 85%. |
| Bandwidth Rate Low Watermark            | If an AP triggers a <b>bandwidth exceeded</b> condition, the condition persists until bandwidth drops below this value.                                                                                                                                                                   |
| Frame Error Rate High Watermark         | If the frame error rate (as a percentage of total frames in an AP) exceeds this value, it triggers a <b>frame error rate exceeded</b> condition.                                                                                                                                          |
| Frame Error Rate Low Watermark          | If an AP triggers a <b>frame error rate exceeded</b> condition, the condition persists until the frame error rate drops below this value.                                                                                                                                                 |
| Frame Fragmentation Rate High Watermark | If the frame fragmentation rate (as a percentage of total frames in an AP) exceeds this value, it triggers a <b>frame fragmentation rate exceeded</b> condition.                                                                                                                          |
| Frame Fragmentation Rate Low Watermark  | If an AP triggers a <b>frame fragmentation rate exceeded</b> condition, the condition persists until the frame fragmentation rate drops below this value.                                                                                                                                 |
| Frame Low Speed Rate High Watermark     | If the rate of low-speed frames (as a percentage of total frames in an AP) exceeds this value, it triggers a <b>low-speed rate exceeded</b> condition.                                                                                                                                    |
| Frame Low Speed Rate Low Watermark      | After a <b>low-speed rate exceeded condition</b> exists, the condition persists until the percentage of low-speed frames drops below this value.                                                                                                                                          |
| Frame Non Unicast Rate High Watermark   | If the non-unicast rate (as a percentage of total frames in an AP) exceeds this value, it triggers a <b>non-unicast rate exceeded</b> condition. This value depends upon the applications used on the network.                                                                            |
| Frame Non Unicast Rate Low Watermark    | If an AP triggers a <b>non-unicast rate exceeded</b> condition, the condition persists until the non-unicast rate drops below this value.                                                                                                                                                 |
| Frame Receive Error Rate High Watermark | If the frame receive error rate (as a percentage of total frames in an AP) exceeds this value, it triggers a <b>frame receive error rate exceeded</b> condition.                                                                                                                          |
| Frame Receive Error Rate Low Watermark  | If an AP triggers a <b>frame receive error rate exceeded</b> condition, the condition persists until the frame receive error rate drops below this value.                                                                                                                                 |

| Parameter                       | Description                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame Retry Rate High Watermark | If the frame retry rate (as a percentage of total frames in an AP) exceeds this value, it triggers a <b>frame retry rate exceeded</b> condition. |
| Frame Retry Rate Low Watermark  | If an AP triggers a <b>frame retry rate exceeded</b> condition exists, the condition persists until the frame retry rate drops below this value. |

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show rf ht-radio-profile

```
show rf ht-radio-profile [<profile>]
```

### Description

Show a High-throughput Radio profile.

### Syntax

| Parameter | Description                              |
|-----------|------------------------------------------|
| <profile> | Name of a High-throughput Radio profile. |

### Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire High-throughput Radio profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has five configured High-throughput Radio profiles. The **References** column lists the number of other profiles with references to the High-throughput Radio profile, and the **Profile Status** column indicates whether the profile is predefined and editable, and if that predefined profile has been changed from its default settings. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show rf ht-radio-profile
High-throughput radio profile List

Name References Profile Status

default 0
default-a 8 Predefined (editable)
default-g 3 Predefined (changed)
legacystation 1
test 1
```

Total:5

This example displays the configuration settings for the predefined profile **default-a**.

```
(host) #show rf ht-radio-profile default-a
High-throughput radio profile "default-a" (Predefined (editable))

Parameter Value

40 MHz intolerance Disabled
Honor 40 MHz intolerance Enabled
Diversity spreading workaround Disabled
CSD Override Disabled
```

The output of this command includes the following parameters:

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 40 MHz intolerance                             | Shows whether or not APs using this radio profile will advertise intolerance of 40 MHz operation. By default, 40 MHz operation is allowed.                                                                                                                                                                              |
| Honor 40 MHz intolerance                       | If this parameter is enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.                                                                                                                                                                |
| CSD Override<br>Diversity Spreading Workaround | When this feature is enabled, all legacy transmissions will be sent using a single antenna. This enables interoperability for legacy or high-throughput stations that cannot decode 802.11n cyclic shift diversity (CSD) data.<br><br>This feature is disabled by default and should be kept disabled unless necessary. |

## show rf optimization-profile

show rf optimization-profile [<profile>]

### Description

Show an Optimization profile.

### Syntax

| Parameter | Description            |
|-----------|------------------------|
| <profile> | name of an ARM profile |

### Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire Optimization profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has two configured Optimization profiles. The **References** column lists the number of other profiles with references to the Optimization profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show rf optimization-profile
RF Optimization Profile List

Name References Profile Status
---- -
default 6
profile2 1
```

Total:2

This example displays the configuration settings for the profile **profile2**.

```
(host) #show rf optimization-profile profile2
RF Optimization Profile "profile2"

Parameter Value

Station Handoff Assist Disabled
Detect Association Failure Disabled
Coverage Hole Detection Disabled
Hole Good RSSI Threshold 20
Hole Good Station Ageout 30 sec
Hole Detection Interval 180 sec
Hole Idle Station Ageout 90 sec
Hole Poor RSSI Threshold 10
Detect interference Disabled
Interference Threshold 90 %
Interference Threshold Exceed Time 25 sec
Interference Baseline Time 25 sec
RSSI Falloff Wait Time 4
Low RSSI Threshold 10
```

The output of this command includes the following parameters:

| Parameter                          | Description                                                                                                                                                                              |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Station Handoff Assist             | If enabled, this parameter allows the controller to force a client off an AP when the RSSI drops below a defined minimum threshold.                                                      |
| Detect Association Failure         | Shows if the profile enables or disables STA association failure detection.                                                                                                              |
| Coverage Hole Detection            | Shows if the profile enables or disables coverage hole detection.                                                                                                                        |
| Hole Good RSSI Threshold           | Time, in seconds, after a coverage hole is detected until a coverage hole event notification is generated.<br><br>This parameter requires the RF Protect license.                        |
| Hole Good Station Ageout           | Stations with signal strength above this value are considered to have good coverage.<br><br>This parameter requires the RF Protect license.                                              |
| Hole Detection Interval            | Time, in seconds, after which a station with good coverage is aged out.<br><br>This parameter requires the RF Protect license.                                                           |
| Hole Idle Station Ageout           | Time, in seconds, after which a station in a poor coverage area is aged out.<br><br>This parameter requires the RF Protect license.                                                      |
| Hole Poor RSSI Threshold           | Stations with signal strength below this value will trigger detection of a coverage hole.<br><br>This parameter requires the RF Protect license.                                         |
| Detect interference                | Enables or disables interference detection.                                                                                                                                              |
| Interference Threshold             | Percentage increase in the frame retry rate (FRR) or frame receive error rate (FRER) before interference monitoring begins on a given channel.                                           |
| Interference Threshold Exceed Time | Time, in seconds, the FRR or FRER exceeds the threshold before interference is reported.                                                                                                 |
| Interference Baseline Time         | Time, in seconds, the air monitor should learn the state of the link between the AP and client to create frame retry rate (FRR) and frame receive error rate (FRER) baselines.           |
| RSSI Falloff Wait Time             | Number of times the detected client RSSI level must fall below the minimum RSSI threshold the before the AP sends a deauthorization message to the client. The maximum value is 8 times. |
| Low RSSI Threshold                 | Minimum RSSI above which deauthorization messages should never be sent.                                                                                                                  |

| Parameter            | Description                           |
|----------------------|---------------------------------------|
| RSSI Check Frequency | Interval, in seconds, to sample RSSI. |

# show rf spectrum-profile

rf spectrum-profile <profile-name>

## Description

Show a spectrum profile used by the spectrum analysis feature.

## Syntax

| Parameter | Description                 |
|-----------|-----------------------------|
| <profile> | Name of a spectrum profile. |

## Usage Guidelines

Issue this command without the **<profile>** parameter to display the entire spectrum profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has three configured spectrum profiles. The **References** column lists the number of other profiles with references to the spectrum profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show rf spectrum-profile
```

```
Spectrum profile List
```

```

Name References Profile Status
---- -
spectrum1 1
default-a 2 Predefined (editable)
default-g 2 Predefined (editable)
```

This example displays the configuration settings for the profile spectrum1.

```
(host) #show rf spectrum-profile default
```

```
Spectrum profile "default"
```

```

Parameter Value

Age Out: WIFI 600 sec
Age Out: Generic Interferer 30 sec
Age Out: Microwave 15 sec
Age Out: Microwave (Inverter type) 15 sec
Age Out: Video Device 60 sec
Age Out: Audio Device 10 sec
Age Out: Cordless Phone Fixed Frequency 10 sec
Age Out: Generic Fixed Frequency 10 sec
Age Out: Bluetooth 25 sec
Age Out: Xbox 25 sec
Age Out: Cordless Network Frequency Hopper 60 sec
Age Out: Cordless Base Frequency Hopper 240 sec
Age Out: Generic Frequency Hopper 25 sec
```

The output of this command includes the following information:

| Parameter                               | Description                                                                                                                                                                                                                                                                                       |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Age Out: WIFI                           | The number of seconds for which a wifi device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 600 seconds.                                                                                                     |
| Age Out: Generic Interferer             | The number of seconds for which an unknown device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 30 seconds.                                                                                                  |
| Age Out: Microwave                      | <p>The number of seconds for which a microwave device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 15 seconds.</p> <p>Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.</p>    |
| Age Out: Microwave (inverter type)      | <p>The number of seconds for which an inverter microwave must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 15 seconds.</p> <p>Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.</p> |
| Age Out: Video Device                   | The number of seconds for which a video device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 60 seconds.                                                                                                     |
| Age Out: Audio Device                   | The number of seconds for which an audio device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 10 seconds.                                                                                                    |
| Age Out: Cordless Phone Fixed Frequency | The number of seconds for which a fixed frequency cordless phone must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 10 seconds.                                                                                   |
| Age Out: Generic Fixed Frequency        | The number of seconds for which a generic fixed frequency device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 10 seconds.                                                                                   |

| Parameter                                  | Description                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Age Out: Xbox                              | <p>The number of seconds for which an Xbox device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 25 seconds.</p> <p>Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.</p>     |
| Age Out: Bluetooth                         | <p>The number of seconds for which a bluetooth device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 25 seconds.</p> <p>Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.</p> |
| Age Out: Cordless Network Frequency Hopper | <p>The number of seconds for which a frequency-hopping cordless network device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 60 seconds.</p>                                                              |
| Age Out: Cordless Base Frequency Hopper    | <p>The number of seconds for which a frequency-hopping cordless phone base must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 240 seconds.</p>                                                                 |
| Age Out: Generic Frequency Hopper          | <p>The number of seconds for which a generic frequency-hopping device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 25 seconds.</p>                                                                       |

## show rft profile

```
show rft profile {all|antenna-connectivity|link-quality|raw}
```

### Description

Show parameters for the predefined RF test profiles.

### Syntax

| Parameter            | Description                                                                             |
|----------------------|-----------------------------------------------------------------------------------------|
| all                  | Show all predefined profiles.                                                           |
| antenna-connectivity | Show configured parameters for the predefined <b>Antenna Connectivity</b> test profile. |
| link-quality         | Show configured parameters for the predefined <b>Link Quality</b> test profile.         |
| raw                  | Show configured parameters for the predefined <b>RAW</b> test profile.                  |

### Usage guidelines

The [rft](#) command is used for RF troubleshooting, and should only be used under the supervision of Dell technical support. Issue the **show rft profile** command to view the profiles used for these RF tests.

### Example

The following example shows the testing parameters for the predefined link-quality RF test profile.

```
(host) #show rft profile link-quality

Profile LinkQuality: Built-in profile

Parameter Value

Antenna 1 and/or 2
Frame Type Null Data
Num Packets 100 for each data-rate
Packet Size 1500
Num Retries 0
Data Rate All rates are tried
```

### Related Commands

To view the results of an RF test, use the command [show rft result](#).

### Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show rft result

```
show rft result all|{trans-id <trans-id>}
```

### Description

Show the results of an RF test.

### Syntax

| Parameter           | Description                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| all                 | Show the most recent test result for each test type (antenna-connectivity, link-quality or raw).                                                          |
| trans-id <trans-id> | Each RF test is assigned a transaction ID. Include the <b>trans-id &lt;trans-id&gt;</b> parameters to show the test result for a specific transaction ID. |

### Usage guidelines

The [rft](#) command is used for RF troubleshooting, and should only be used under the supervision of Dell technical support.

### Related Commands

To view a list of the most recent transaction IDs for each test type, use the command [show rft transactions](#).

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show rft transactions

show rft transactions

### Description

Show transaction IDs of RF tests.

### Syntax

No parameters.

### Usage guidelines

The [rft](#) command is used for RF troubleshooting, and should only be used under the supervision of Dell technical support. Issue the **show rft transaction** command to view the transaction IDs for the most recent test of each test type.

### Example

The following example shows the transaction IDs for the latest RAW, link-quality and antenna-connectivity tests.

```
(host) #show rft transactions

RF troubleshooting transactions

Profile Transaction ID

RAW 2001
LinkQuality 2101
AntennaConnectivity 1801
```

### Related Commands

Use transaction IDs with the command [show rft result](#) to view results for individual RF tests.

### Command History

This command was available in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show rights

show rights [<name-of-a-role>]

### Description

Displays the list of user roles in the roles table with high level details of role policies. To view role policies of a specific role specify the role name.

### Syntax

| Parameter      | Description                                     |
|----------------|-------------------------------------------------|
| name-of-a-role | Enter the role name to view its policy details. |

### Example

The output of this command shows the list of roles in the role table.

```
(host) # show rights
```

```
RoleTable

Name ACL Bandwidth ACL List Type

ap-role 4 Up: No Limit,Dn: No Limit control/,ap-acl/ System
authenticated 39 Up: No Limit,Dn: No Limit allowall/,v6-allowall/ User
default-vpn-role 37 Up: No Limit,Dn: No Limit allowall/,v6-allowall/ User
guest 3 Up: No Limit,Dn: No Limit http-acl/,https-acl/,dhcp-acl/ User
guest-logon 6 Up: No Limit,Dn: No Limit logon-control/,captiveportal/ User
logon 1 Up: No Limit,Dn: No Limit logon-control/,captiveportal/ User
stateful-dot1x 5 Up: No Limit,Dn: No Limit System
voice 38 Up: No Limit,Dn: No Limit sip-acl/,noe-acl/,svp-acl/,vocera-acl/ User
```

### Command History

This command was available in ArubaOS 3.0

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show roleinfo

show roleinfo

### Description

Displays the role of the controller.

### Syntax

No parameters.

### Example

The output of this command shows the role of the controller.

```
(host) # show roleinfo
switchrole:master
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show route-access-list

show route-access-list

### Description

This command displays information about access control lists (ACLs) for policy-based routing (PBR).

### Syntax

No Parameters

### Usage Guidelines

Policy-based routing is an optional feature that allows packets to be routed based on access control lists (ACLs) configured by the administrator. By default, when a controller receives a packet for routing, it looks up the destination IP in the routing table and forwards the packet to the nexthop router. If policy-based routing is configured, the nexthop device can be chosen based on a defined access control list.

In a typical deployment scenario with multiple uplinks, the default route only uses one of the uplink next-hops for forwarding packets. If a nexthop becomes unreachable, the packets will not reach their destination. If your deployment uses policy-based routing based on a nexthop list, any of the uplink nexthops could be used for forwarding traffic. This requires a valid ARP entry (Route-cache) in the system for all the policy-based routing nexthops.

### Example

The following command displays a list of configured routing access lists.

```
(host)(config)# (host) #show route-access-list
Router Access list table

Name Use Count Roles
---- -
attempt1 0
pbr 0
name 1 test
Tuesday 0
```

The output of this command includes the following parameters:

| Parameter | Description                                               |
|-----------|-----------------------------------------------------------|
| Name      | Name of the access list                                   |
| Use Count | Number of VLANs associated with this routing access list. |
| Roles     | User role associated with the routing access list.        |

## Related Commands

## show rrm dot11k admission-capacity

show rrm dot11k admission-capacity

### Description

Displays the available admission capacity for voice traffic on an AP.

### Syntax

No parameters.

### Example

The output of this command shows the available admission capacity for voice traffic on all APs.

```
(host) # show rrm dot11k admission-capacity
```

```
802.11K Available Admission Capacity for Voice
```

```

Flags: B: Bandwidth based CAC, C: Call-count based CAC
 D: CAC Disabled, E: CAC Enabled
```

| AP Name   | IP Address   | Freq Band | Chan | Total | Available | Flags |
|-----------|--------------|-----------|------|-------|-----------|-------|

## show rrm dot11k ap-channel-report

```
show rrm dot11k ap-channel-report [ap-name <name-of-an-ap> |
 bssid <bssid-of-an-ap> | ip-addr <ip-address-of-an-ap> | ip6-addr <ip-addr> | essid
 <ssid>]
```

### Description

Displays the channel information gathered by the AP. You can either specify an ap-name, bssid or ip-address of an AP to see more details.

### Syntax

| Parameter | Description                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-name   | Enter the name of the AP.                                                                                                                        |
| bssid     | Enter the BSSID address of the AP.                                                                                                               |
| ip-addr   | Enter the IP address of the AP.                                                                                                                  |
| ip6-addr  | Enter the IPv6 address of the AP                                                                                                                 |
| ssid      | Entries in the IPv4 user-table that are associated to the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks. |

### Example

The output of this command shows the channel information for r-wing-94:94.

```
(host) # show rrm dot11k ap-channel-report ap-name r-wing-94
```

```

## show rrm dot11k neighbor-report

```
show rrm dot11k neighbor-report [ap-name |
 bssid <bssid-of-an-ap> | ip-addr <ip-address-of-an-ap>]
```

### Description

Displays the neighbor information for a particular AP. If the AP name or the AP's IP address is specified, the user should specify the ESSID to get the neighbor information. If the ESSID is not specified, the command will display the neighbor information for all the Virtual AP's configured on the AP.

### Syntax

| Parameter       | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| ap-name         | Identify the AP for which you want to view information.                                |
| <name-of-an-ap> | Name of an AP.                                                                         |
| <ssid>          | ESSID of the AP. If the ESSID includes spaces, you must enclose it in quotation marks. |
| bssid           | Enter the BSSID address of the AP.                                                     |
| ip-addr         | Enter the IP address of the AP.                                                        |

### Example

The output of this command shows the neighbor information for r-wing-94.

```
(host) # show rrm dot11k neighbor-report ap-name r-wing-94
```

```
802.11K Neighbor Report Details
```

```
Flags: S: Spectrum Management, Q: QoS, A: APSD, R: Radio Measurement
```

| ESSID        | BSSID             | Channel | Reachability | Security | Authenticator | Preference |

|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced.                                                                                                                     |
| ArubaOS 6.4.2.5 | The default <b>dot1x high-watermark</b> and <b>dot1x low-watermark</b> values were removed from the <b>show running-config</b> command. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show session-acl-list

show session-acl-list

### Description

Displays the list of configured session ACLs in the controller.

### Syntax

No parameters.

### Example

The output of this command shows the session ACLs in the controller.

```
(host) # show session-access-list
v6-icmp-acl
allow-diskservices
control
validuser
v6-https-acl
vocera-acl
icmp-acl
v6-dhcp-acl
captiveportal
v6-dns-acl
allowall
test
sip-acl
https-acl
...
...
...
v6-http-acl
dhcp-acl
http-acl
stateful-dot1x
ap-acl
svp-acl
noe-acl
stateful-kerberos
v6-logon-control
h323-acl
```

### Command History

This command was available in ArubaOS 3.4

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show slots

show slots

### Description

Displays the list of slots in the controller, including the status and card type.

### Syntax

No parameters.

### Example

The output of this command shows slot details on the controller.

```
(host) # show slots
```

```
Slots

Slot Status Card Type
---- -
1 Present A2400
```

### Command History

This command was available in ArubaOS 3.4

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

# show snmp community

show snmp community

## Description

Displays the SNMP community string details.

## Syntax

No parameters.

## Example

The output of this command shows slot details on the controller.

```
(host) # show snmp community

SNMP COMMUNITIES

COMMUNITY ACCESS VERSION

public READ_ONLY V1, V2c
```

## Command History

This command was available in ArubaOS 3.0

## Command Information

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show snmp inform

show snmp inform

### Description

Displays the length of SNMP inform queue.

### Syntax

No parameters.

### Example

The output of this command shows slot details on the controller.

```
(host) # show snmp inform stats

Inform queue size is 100

SNMP INFORM STATS

HOST PORT INFORMS-INQUEUE OVERFLOW TOTAL INFORMS
---- -

```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show snmp trap-hosts

show snmp trap-hosts

### Description

Displays the configured SNMP trap hosts.

### Syntax

No parameters.

### Example

The output of this command shows details of a SNMP trap host.

```
(host) # show snmp trap-hosts
```

```
SNMP TRAP HOSTS
```

```

HOST VERSION SECURITY NAME PORT TYPE TIMEOUT RETRY

10.16.14.1 SNMPv2c public 162 Trap N/A N/A
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show snmp trap-list

show snmp trap-list

### Description

Displays the list of SNMP traps.

### Syntax

No parameters.

### Example

The output of this command shows the list of SNMP traps and the status.

```
(host) # show snmp trap-list
```

```
SNMP TRAP LIST

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show snmp trap-queue

show snmp trap-queue

### Description

Displays the list of SNMP traps in queue.

### Syntax

No parameters.

### Example

The output of this command shows the list of SNMP traps sent to host.

```
(host) # show snmp trap-queue

a)wlsxMgmtUserAuthenticationFailed
The trap indicates that a management user authentication failed.
2013-10-29 08:08:10 Management user authentication failed for user commonuser1 with IP address
10.20.102.79 usermac 00:00:00:00:00:00 server name CiscoACS-2 serverip 10.15.28.41
b)wlsxNUserAuthenticationFailed :
The trap indicates that a user authentication has failed.
2013-10-29 07:47:07 User Authentication failed for user commonuser1 userip 0.0.0.0 usermac
00:5f:12:00:00:00 servername CiscoACS-1 serverip 10.15.28.40 bssid 00:d2:5d:80:00:08 apname
v5rapsim_000_000
c)wlsxNAuthServerReqTimeOut:
The trap indicates that the authentication server req timeout
2013-10-29 07:44:58 Authentication request timed out for server CiscoACS-1 serveip 10.15.28.4
username commonuser1 userip 0.0.0.0 usermac 00:5f:12:00:00:00 bssid 00:d2:5d:80:00:08 apname
v5rapsim_000_000
d)wlsxNAuthServerTimeOut :
The trap indicates the server taken out of service.
2013-10-29 07:45:48 Authentication server CiscoACS-1 serverip 10.15.28.4 timed out. Time out
value is 1383012948 for user commonuser1 ip 0.0.0.0 mac 00:5f:12:00:00:00 bssid
00:d2:5d:80:00:08 apname v5rapsim_000_000
e)wlsNAuthServerIsDown
The trap indicates that an authentication server is down.
2013-10-29 07:44:11 Authentication Server CiscoACS-1 with ip 10.15.28.4 is down.
f)wlsNAuthServerUp
The trap indicates that an authentication server is up.
2013-10-29 07:45:48 Authentication server CiscoACS-1 with ip 10.15.28.4 is up
```

### Command History

| Release     | Modification                                                                                                                                                                                              |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced.                                                                                                                                                                                       |
| ArubaOS 6.4 | Added more information to the output: Server IP address, user MAC, AP name, authentication failure details, authentication request time out, auth server down and up traps messages sending to the host . |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show snmp user-table

```
show snmp user-table [user <username> auth-prot [sha | md5] <value> priv-prot [aes | des] <value>]
```

### Description

Displays the list of SNMP user profile for a specified username.

### Syntax

| Parameter | Description                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| auth-prot | Authentication protocol for the user, either HMAC-MD5-98 Digest Authentication Protocol (MD5) or HMAC-SHA-98 Digest Authentication Protocol (SHA), and the password for use with the designated protocol. |
| priv-prot | Privacy protocol for the user, either Advanced Encryption Standard (AES) or CBC-DES Symmetric Encryption Protocol (DES), and the password for use with the designated protocol.                           |

### Example

The output of this command shows the list of SNMP traps sent to host.

```
(host) # show snmp user-table
```

```
SNMP USER TABLE
```

```

USER AUTHPROTOCOL PRIVACYPROTOCOL FLAGS

Sam SHA AES
fire SHA AES
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show spanning-tree

```
show spanning-tree
```

```
<interface [fastethernet slot/port | gigabitethernet slot/port | port-channel id]
<vlan vlan-id>
```

### Description

View the RSTP and PVST+ configuration.

### Syntax

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| vlan      | Enter the keyword <b>vlan</b> follow by the VLAN ID.<br>Range: 1 to 4094<br>Default: 1                                                                                                                                                                                                                                                                                                                                                       |

### Example—show spanning-tree

```
(host) # show spanning-tree
```

```
Spanning tree instance for vlan 10
Spanning Tree is executing the IEEE compatible Rapid Spanning Tree protocol
Bridge Identifier has priority 32768, address 00:0b:86:f0:20:00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag is not set, detected flag not set, changes 1
Times: hold 1, topology change 35 hello 2, max age 20, forward delay 15
Timers: hello 0, notification 0
Last topology change: 2 days, 0 hours, 31 mins, 21 secs
```

```
Spanning tree instance for vlan 20
Spanning Tree is executing the IEEE compatible Rapid Spanning Tree protocol
Bridge Identifier has priority 32768, address 00:0b:86:f0:20:00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag is not set, detected flag not set, changes 1
Times: hold 1, topology change 3 hello 2, max age 20, forward delay 15
Timers: hello 0, notification 0
Last topology change: 1 days, 0 hours, 3 mins, 2 secs
```

### Example—show spanning-tree vlan

```
(host) # show spanning-tree vlan 2
```

```

Spanning Tree is executing the IEEE compatible Rapid Spanning Tree protocol
Bridge Identifier has priority 32768, address 00:0b:86:f0:20:00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag is not set, detected flag not set, changes 1
Times: hold 1, topology change 35 hello 2, max age 20, forward delay 15
Timers: hello 0, notification 0
Last topology change: 2 days, 0 hours, 31 mins, 21 secs

```

## Example—show spanning-tree interface fastethernet

```
(host) (config-if)#show spanning-tree interface fastethernet 1/1
```

```

Interface FE 1/1 (port 2) in Spanning tree is FORWARDING
Port path cost 19, Port priority 128 Role DISNIGNATED
PortFast DISABLED P-to-P ENABLED
Designated root has priority 0 address 00:01:e8:d5:a3:6d
Designated bridge has priority 32768 address 00:0b:86:50:58:30
Designated port is 2, path cost 0
Timers: message age 0, forward delay 20, hold 0
Counts: BPDUs received 0, sent 0

```

## Command History

| Release     | Modification                                           |
|-------------|--------------------------------------------------------|
| ArubaOS 6.0 | PVST+ added                                            |
| ArubaOS 3.4 | Upgraded STP to RSTP with full backward compatibility. |

## Command Information

| Platform      | Licensing             | Command Mode                                                      |
|---------------|-----------------------|-------------------------------------------------------------------|
| All platforms | Base operating system | Enable mode and Configuration mode (config) on master controllers |

## show spantree

```
show spantree
 <blocking> | <enable> | <forwarding> | <off> | <vlan>
```

### Description

View the global RSTP and PVST+ topology.

### Syntax

| Parameter  | Description                                           |
|------------|-------------------------------------------------------|
| blocking   | View the spanning tree ports in the Blocking state.   |
| enable     | View the spanning tree ports in the Enable state.     |
| forwarding | View the spanning tree ports in the Forwarding state. |
| off        | View the ports with spanning tree disabled            |
| vlan       | View the spanning tree instance for the VLAN.         |

### Example

```
(host) # show spantree
```

```
Spanning tree instance vlan 1
Designated Root MAC 00:0b:86:6b:57:80
Designated Root Priority 32768
Root Cost 20000
Root Max Age 20 sec Hello Time 2 sec Forward Delay 15 sec

Bridge MAC 00:1a:1e:00:89:b8
Bridge Priority 32768
Configured Max Age 20 sec Hello Time 2 sec Forward Delay 15 sec
```

```
Rapid Spanning Tree port configuration
```

```

Port State Cost Prio PortFast BpduGuard P-to-P Role

```

## Command History

| Release         | Modification                                                              |
|-----------------|---------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced.                                                       |
| ArubaOS 6.0     | The <b>PVST+</b> parameter added.                                         |
| ArubaOS 6.3     | Upgraded STP to RSTP with full backward compatibility.                    |
| ArubaOS 6.4.3.0 | The <b>BpduGuard</b> field was introduced as part of this command output. |

## Command Information

| Platform      | Licensing             | Command Mode                                                      |
|---------------|-----------------------|-------------------------------------------------------------------|
| All platforms | Base operating system | Enable mode and Configuration mode (config) on master controllers |

## show ssh

show ssh

### Description

Displays the SSH configuration details.

### Syntax

No parameters.

### Example

The output of this command shows SSH configuration details.

```
(host) # show ssh
```

```
SSH Settings:
```

```

```

```
DSA Enabled
Mgmt User Authentication Method username/password
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show sso idp-profile

```
show sso idp-profile
```

### Description

Displays all SSO IDP profiles.

### Syntax

No parameters.

### Example

The output of this command lists all SSO IDP profiles on the controller.

```
((host) (config) #show sso idp-profile
SSO Profile List

Name References Profile Status

sso-example 0
```

### Command History

This command was available in ArubaOS 6.4

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

# show startup-config

show startup-config

## Description

Displays the configuration which will be used the next time the controller is rebooted. It contains all the options last saved using the write memory command. Any unsaved changes are not included.

## Syntax

No parameters.

## Example

The output of this command shows slot details on the controller.

```
(host) # show startup-config

version 3.4

This command was available in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show station-table

```
show station-table [mac <mac_address> | verbose]
```

### Description

Displays the internal station table entries and also details of a station table entry.

### Syntax

| Parameter         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| mac <mac_address> | Displays the details of the AP that matches the specified MAC address. |
| verbose           | Displays the details of all the APs in a table format.                 |

### Example

The output of this command shows details of an entry in the station table.

```
(host) # show station-table mac 00:1f:6c:7a:d4:fd
```

Association Table

```

 BSSID IP Essid AP name Phy Age

00:0b:86:6d:3e:30 10.15.20.252 sam - a 01:03:41
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show storage

show storage

### Description

Displays the storage information on the controller.

### Syntax

No parameters.

### Example

The output of this command shows the storage details on the controller.

```
(host) # show storage
Filesystem Size Used Available Use% Mounted on
/dev/root 57.0M 54.6M 2.3M 96% /
none 70.0M 2.0M 68.0M 3% /tmp
/dev/hda3 149.7M 9.3M 132.6M 7% /flash
/dev/usb/flash3 1.5G 168.6M 1.3G 12% /flash
/dev/usbdisk/2 3.5G 71.4M 3.2G 2% /mnt/usbdisk/2
/dev/usbdisk/1 3.9G 131.0M 3.8G 3% /mnt/usbdisk/1
```

The number at the end of the USB device's name is the partition. Unlike the controller's flash, the USB device has more than two partitions; not just 0 and 1. When copying a file from a USB device, you must know which partition the target file is on.

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show switch ip

show switch ip

### Description

Displays the IP address of the controller and VLAN ID.

### Syntax

No parameters.

### Example

The output of this command shows the IP address and VLAN ID of the controller.

```
(host) # show switch ip

Switch IP Address: 10.16.15.1

Switch IP is from Vlan Interface: 1
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show switch software

show switch software

### Description

Displays the details of the software running in the controller.

### Syntax

No parameters.

### Example

The output of this command shows the details of software running in the controller.

```
(host) # show switch software
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show switches

```
show switches [all | regulatory | state {complete | incomplete | inprogress | required} |
summary]
```

### Description

Displays the details of controllers connected to the master controller, including the master controller itself.

### Syntax

| Parameter  | Description                                                      |
|------------|------------------------------------------------------------------|
| all        | List of all controllers.                                         |
| regulatory | Displays information about the currently active regulatory file. |
| state      | Configuration status of all controllers.                         |
| summary    | Status of all controllers connected to the master.               |

### Example

The output of this command shows that there is a single local controller connected to the master controller.

```
(host) # show switches all
```

```
All Switches
```

```

IP Address Name Location Type Version Status Configuration State
Config Sync Time (sec)

10.16.12.1 r-wing-94 Building1.floor1 master 6.0.0.0_13782 up UPDATE SUCCESSFUL
0192.0.2.12 CorpA2400 Building1.floor1 master 6.0.0.0_13782 up UPDATE SUCCESSFUL
0
```

The following command displays information about branch controllers defined using a branch config group on a master controller. In the example below, the table in the command output has been divided into two sections to better fit on this document. In the ArubaOS command-line interface, this output appears in a single, wide table.

```
(host) (config) #show switches branch
```

```
All Branch Controllers
```

```

IP Address MAC Hostname Model Version Status

172.16.0.254 00:1a:1e:00:56:68 host DellW-7210 6.4.3.0_48786 up

Branch Group Configuration State Branch Config ID Uptime

branch1 UPDATE SUCCESSFUL 3 7d 21h 20m
```

The output of the previous command includes the following parameters:

| Parameter           | Description                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP address          | IP address of the controller                                                                                                                                                                                                                                            |
| MAC                 | MAC address of the controller                                                                                                                                                                                                                                           |
| Hostname            | hostname of the master controller                                                                                                                                                                                                                                       |
| Model               | Controller model type.                                                                                                                                                                                                                                                  |
| Version             | Software version running on the controller                                                                                                                                                                                                                              |
| Status              | A status of up indicates that the controller is active on the network. A status of down indicates that the controller is inactive or unreachable by the master controller                                                                                               |
| Branch Group        | Name of the branch config group assigned to the branch controller.                                                                                                                                                                                                      |
| Configuration State | Status of the configuration assigned to the branch controller,                                                                                                                                                                                                          |
| Branch Config ID    | The branch config ID increments every time the branch config group settings are updated. All branch controllers assigned to the same branch config group should display the same branch config ID, indicating that they are all running the same configuration version. |
| Uptime              | Amount of time the controller has been active on the network.                                                                                                                                                                                                           |

The output of the following command shows the regulatory file active on the controller.

```
(host) #show switches regulatory
```

All Switches

```

IP Address Name Location Type Model File Version File Build

172.16.0.254 host Building1.floor1 master W-7210 1.0_43859 21/4/2014

```

## Command History

| Version       | Description                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0   | Command introduced.                                                                                                                                                           |
| ArubaOS 6.0   | The <b>version</b> column in the output of this command was expanded to include both the version and the build number for controllers running ArubaOS 6.0 and later releases. |
| ArubaOS 6.4.1 | The <b>regulatory</b> parameter was added.                                                                                                                                    |
| ArubaOS 6.4.3 | The <b>branch</b> parameter was added to display settings for branch office controllers.                                                                                      |

## Command Information

| Platforms     | Licensing             | Command Mode                                |
|---------------|-----------------------|---------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master controllers |

## show switchinfo

show switchinfo

### Description

Displays the latest and complete summary of controller details including role, last configuration change, hostname, reason for last reboot.

### Syntax

No parameters.

### Example

The output of this command lists all controllers connected to the master controller including the master controller.

```
(host) # show switchinfo
Hostname is Techpubs
Console Baudrate: 115200
Location not configured
System Time:Tue Nov 27 16:22:14 PST 2012
Compiled on 2012-11-26 at 17:06:31 PST (build 36290) by p4build
ROM: System Bootstrap, Version CPBoot 1.2.0.9 (build 35873)
Built: 2012-10-24 13:51:09
Built by: p4build@re_client_35873
Switch uptime is 9 hours 34 minutes 3 seconds
Reboot Cause: User reboot.
Built: 2012-10-24 13:51:0
Built by: p4build@re_client_35873

Internet address is 172.16.0.254 255.255.255.0
Routing interface is enable, Forwarding mode is enable
Directed broadcast is disabled
Encapsulation 802, loopback not set
Last clearing of "show interface" counters 0 day 9 hr 34 min 3 sec
link status last changed 0 day 9 hr 34 min 3 sec
Proxy Arp is disabled for the Interface
switchrole:master
Configuration unchanged since last save
Crash information available.
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show syscontact

show syscontact

### Description

Displays the contact information for support.

### Syntax

No parameters.

### Example

The output of this command shows the contact information for technical support.

```
(host) # show syscontact
```

```
admin@mycompany.com
```

### Command History

This command was available in ArubaOS 3.1

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show syslocation

show syslocation

### Description

Displays the location details of the controller.

### Syntax

No parameters.

### Example

The output of this command location of the controller.

```
(host) # show syslocation
```

```
Building 1, Floor 1
```

### Command History

This command was available in ArubaOS 3.1

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show tech-support

```
show tech-support
<filename>
user
```

### Description

Displays all information about the controller required for technical support purposes.

### Syntax

| Parameter  | Description                                                                                 |
|------------|---------------------------------------------------------------------------------------------|
| <filename> | Stores the output in specified file name. Maximum length of the file name is 127 characters |
| user       | Run a user specific tech-support command.                                                   |

### Command History

| Release     | Modification                                              |
|-------------|-----------------------------------------------------------|
| ArubaOS 3.1 | Command available.                                        |
| ArubaOS 6.2 | <b>User</b> and <b>&lt;filename&gt;</b> parameters added. |

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show telnet

show telnet

### Description

Displays the status of telnet access using the command line interface (CLI) or Serial over Ethernet (SOE) to the controller.

### Syntax

No parameters.

### Example

The output of this command shows the status of CLI and SOE access to the controller.

```
(host) # show telnet
```

```
telnet cli is enabled
```

```
telnet soe is enabled
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show threshold

```
show threshold
 all|controlpath-cpu|controlpath-memory|datapath-cpu|
 no-of-aps|no-of-locals|total-tunnel-capacity|user-capacity|
```

### Description

This command shows controller capacity thresholds which, when exceeded, will trigger alerts.

### Syntax

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| all                   | Display all alert thresholds.                                                                                                                                                                                                                                                                                                                                                                          |
| controlpath-cpu       | <p>Display the alert threshold for controlpath CPU capacity. The output of this command shows the percentage of the total controlpath CPU capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 80%.</p>                                                                                                                                         |
| controlpath-memory    | <p>Display the alert threshold for controlpath memory consumption. The output of this command shows the percentage of the total memory capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 85%.</p>                                                                                                                                            |
| datapath-cpu          | <p>Display the alert threshold for datapath CPU capacity. The output of this command shows the percentage of the total datapath CPU capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 30%.</p>                                                                                                                                               |
| no-of-APs             | <p>The maximum number of APs that can be connected to a controller is determined by that controller's model type and installed licenses. This threshold triggers an alert when the number of APs currently connected to the controller exceeds a specific percentage of its total AP capacity.</p> <p>The default threshold for this parameter is 80%.</p>                                             |
| no-of-locals          | <p>Display the alert threshold for the master controller's capacity to support branch and local controllers.</p> <p>A master controller can support a combined total of 256 branch and local controllers. The output of this command shows the percentage of the total master controller capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 80%.</p> |
| total-tunnel-capacity | <p>Display the alert threshold for the controller's tunnel capacity. The output of this command shows the percentage of the controller's total tunnel capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 80%</p>                                                                                                                              |

| Parameter     | Description                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user-capacity | <p>Display the alert threshold for the controller's user capacity. The output of this command shows the percentage of the total resource capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 80%.</p> |

## Usage Guidelines

The controller will send a *wlsxThresholdAbove* SNMP trap and a syslog error message when the controller has exceeded a set percentage of the total capacity for that resource. A *wlsxThresholdBelow* SNMP trap and error message will be triggered if the resource usage drops below the threshold once again.

## Example

```
(host) (config) #show threshold all
Controller Capacity Threshold Values

RESOURCE THRESHOLD (%)

Datapath-Cpu 30 %
Controlpath-Cpu 80 %
Controlpath-Memory 85 %
Total-Tunnel-Capacity 80 %
Ap-Tunnel-Capacity 80 %
User-Capacity 80 %
No-of-APs 80 %
No-of-locals 80 %
```

## Command History

The command was introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master and local controllers |

## show threshold-limits

```
show threshold-limits
 controlpath-memory|fan-speed|no-of-aps|no-of-locals|total-tunnel-capacity|user-capacity
```

### Description

This command shows current values of the different resources monitored by the controller.

### Syntax

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| controlpath-memory    | The output of this command displays the default memory threshold which, when exceeded, will trigger an alert, the current configured threshold, the total memory (in MB) and the currently available memory (in MB).                                                                                                                                                                                                                                                                 |
| fan-speed             | The output of this command displays the fan alert threshold. This parameter is only available for controllers with fans, such as the W-6000M3 and W-7200 series.                                                                                                                                                                                                                                                                                                                     |
| no-of-aps             | The output of this command displays the following values: <ul style="list-style-type: none"><li>• The default threshold for the number of APs, which, when exceeded, will trigger an alert</li><li>• The current configured threshold.</li><li>• The maximum number of APs supported by the controller,</li><li>• The number of available licenses for campus and remote APs,</li><li>• The total number of APs, and the current number of campus, remote and virtual APs.</li></ul> |
| no-of-locals          | The output of this command displays the default threshold for the number of local controllers which, when exceeded, will trigger an alert, and the current configured threshold. The output also displays the maximum number of local controllers that can be connected to this master controller, and the number of local controllers currently connected.                                                                                                                          |
| total-tunnel-capacity | The output of this command displays the default tunnel capacity threshold which, when exceeded, will trigger an alert, as well as the current configured tunnel threshold. The output also includes the maximum number of tunnels supported by the controller, as well as the number of tunnels currently used by the controller.                                                                                                                                                    |
| user-capacity         | The output of this command displays the default user capacity threshold which, when exceeded, will trigger an alert, as well as the current configured user threshold. The output also includes the maximum number of users supported by the controller, as well as the number of users currently associated with the controller.                                                                                                                                                    |

### Usage Guidelines

The controller will send a *wlsxThresholdAbove* SNMP trap and a syslog error message when the controller has exceeded a set percentage of the total capacity for that resource. A *wlsxThresholdBelow* SNMP trap and error message will be triggered if the resource usage drops below the threshold once again.

## Example

The following command shows the current alert thresholds for controlpath memory resources:

```
(host) (config) #show threshold-limits controlpath-memory
```

Threshold Values For Controlpath Memory

```

Default(%) Current(%) Total Memory (MB) Available Memory (MB)

85 77 679 225
```

The following command shows the current alert thresholds for all monitored controller resources:

## Command History

The command was introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master and local controllers |

## show time-range

show time-range [<name>|summary]

### Description

Displays the list of time range configured in the system and rules affected by the time range.

### Syntax

No parameters.

### Example

The output of this command shows the absolute time range details.

```
(host) # show time-range
```

```
Time-Range monitoring, Absolute

StartDate Start-time EndDate End-time Applied

4/29/2009 23:00 4/30/2009 12:00 No
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show timer debug statistics app-name

```
show ipc statistics app-name <name>
```

### Description

Display timer debugging statistics for a specific application.

### Syntax

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Example

The following example shows IPC statistics for the **STM** process.

```
(host) #show timer debug statistics app-name stm
```

```
Granularity=100
Wheel Size=512
Tick Count=5744522
Spoke Index=394
Active timers=21
Expired timers=886374
Hiwater mark=49
Started timers=109893
```

Cancelled timers=4425

Timer info

## Command History

This command was available in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show tpm cert-info

show tpm cert-info

### Description

Displays the TPM and Factory Certificate information on MIPS controllers (W-6000M3, W-3000 Series, and W-600 Series).

### Syntax

No parameters.

### Usage Guidelines

Use this command to verify that TPM and factory certificates are installed as expected. This command should be executed *before* enabling CPSec on MIPS controllers (W-6000M3, W-3000 Series, and W-600 Series).

### Example

In the example below, the TPM and certificates are installed.

```
(host)#show tpm cert-info

subject= /CN=AF0000168::00:0b:86:f0:33:e0
issuer= /DC=com/DC=arubanetworks/DC=ca/CN=DEVICE-CA2
serial=1F023F05000000015087
notBefore=Jan 30 01:38:57 2009 GMT
notAfter=Jan 25 01:38:57 2029 GMT
```

In the example below, the controller is not able to verify the TPM or Factory Certificate information.

```
(host)#show tpm cert-info

Cannot get TPM and Factory Certificate Info
TPM and/or Factory Certificates might be missing.
```

### Command History

## show trunk

show trunk

### Description

Displays the list of trunk ports on the controller.

### Syntax

No parameters.

### Example

The output of this command shows details of a trunk port.

```
(host) # show trunk
```

```
Trunk Port Table
```

```

Port Vlans Allowed Vlans Active Native
Vlan
---- -
FE2/12 1, 613, 615-617, 632-633, 636-640, 667-668 1, 613, 615-617, 632-633, 636-640, 667-668 1
```

### Command History

This command was available in ArubaOS 3.0

## show tunnel-group

show tunnel-group <tunnel-group-name>

### Description

Displays the operational status of the tunnel-groups configured on the controller.

### Syntax

| Parameter           | Description                                                    |
|---------------------|----------------------------------------------------------------|
| <tunnel-group-name> | Displays the operational status of the specified tunnel-group. |

### Example

The output of this command shows the status of the configured tunnel-groups:

```
(host) #show tunnel-group
```

```
Tunnel-Group Table Entries
```

```

Tunnel Group Type Tunnel Group Id Preemptive Failover Active Tunnel Id Tunnel Members

tgroup1 L3 16385 enabled 10 10 20
tgroup2 L2 16387 enabled 10 10 20 40
```

The output of the following command shows the status of the specified tunnel-group:

```
(host) #show tunnel-group tgroup1
```

```
Tunnel-Group Table Entries
```

```

Tunnel Group Type Tunnel Group Id Preemptive Failover Active Tunnel Id Tunnel Members

tgroup1 L3 16385 enabled 10 10 20
```

The output of the following command shows the datapath Tunnel-Group table entries:

```
(host) #show datapath tunnel-group
```

```
Datapath Tunnel-Group Table Entries
```

```

Tunnel-Group Active Tunnel Members

16385 10 10 20
```

## show tunneled-node

show tunneled-node [state|database]

### Description

Displays the state of the tunneled node and lists all tunneled nodes connected to the controller.

### Syntax

No parameters.

### Example

The output of this command shows the tunneled node state.

```
(host) # show tunneled-node state
```

Tunneled Node State

-----

IP MAC s/p state vlan tunnel inactive-time

-----

```
192.168.123.14 00:0b:86:40:32:40 1/23 complete 10 9 1
192.168.123.14 00:0b:86:40:32:40 1/22 complete 10 10 1
192.168.123.14 00:0b:86:40:32:40 1/20 complete 10 11 1
```

On the tunneled node client:

```
(host) #show tunneled-node state
```

Tunneled Node State

-----

| IP             | MAC               | s/p  | state    | vlan | tunnel | inactive-time |
|----------------|-------------------|------|----------|------|--------|---------------|

## show ucc call-info cdrs

```
show ucc call-info cdrs
 ap <ap_name> [app [h323 | lync | noe | sccp | sip | svp | vocera]]
 app {h323 [detail] | lync [detail] | noe [detail] | sccp [detail] | sip [detail] | svp
 [detail] | vocera [detail]}
 cid <cid>
 detail
 <cr>
```

### Description

This command displays the Call Detailed Records (CDR) statistics for Unified Communication and Collaboration (UCC).

When VoIP calls are prioritized using media classification, the **UCC Call ID**, **Client Name**, **Called to**, **Dir** (direction of the call), **End-to-End Delay(ms)/Jitter(ms)/PktLoss(%)**, **Codec**, **MOS**, and **MOS-Band** values are not available.

### Syntax

| Parameter                                                                                                          | Description                                                                          |
|--------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| ap <ap_name> [app [h323   lync   noe   sccp   sip   svp   vocera]]                                                 | Displays the CDR statistics of an AP for a specific Application Layer Gateway (ALG). |
| app {h323 [detail]   lync [detail]   noe [detail]   sccp [detail]   sip [detail]   svp [detail]   vocera [detail]} | Displays the CDR statistics based on a specific ALG.                                 |
| cid <cid>                                                                                                          | Displays CDR statistics for a specific CDR-ID.                                       |
| detail                                                                                                             | Displays detailed CDR statistics.                                                    |

### Example

The following command displays the CDR statistics:

```
(host) #show ucc call-info cdrs
CDRS:

CDR ID UCC Call ID Client IP Client MAC Client Name ALG Dir Called to Dur
(sec)

43 12 192.0.2.22 00:23:33:41:c8:b8 Alex Lync IC Joe 50

Jan 8 06:16:49 SUCC Terminated Voice/Conf Call 86 86.34 Good

```

```

MOS MOS-Band
--- -
4.17 Good
4.15 Good
4.19 Good

```

The output of this command includes the following information:

| Column      | Description                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CDR ID      | Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.                                                                                                                                                                                              |
| UCC Call ID | Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session.                                                                                                                                                                                |
| Client IP   | Displays the IP address of the VoIP client.                                                                                                                                                                                                                                                                       |
| Client MAC  | Displays the MAC address of the VoIP client.                                                                                                                                                                                                                                                                      |
| Client Name | Displays the username of the VoIP client.                                                                                                                                                                                                                                                                         |
| ALG         | Displays the VoIP protocol used by the VoIP client.                                                                                                                                                                                                                                                               |
| Dir         | Displays the direction of the call. Possible values are: <ul style="list-style-type: none"> <li>● <b>OG</b>—Outgoing</li> <li>● <b>IG</b>—Incoming</li> </ul>                                                                                                                                                     |
| Called to   | Displays the username of the VoIP client being called.                                                                                                                                                                                                                                                            |
| Dur (sec)   | Displays the duration of the VoIP call in seconds.                                                                                                                                                                                                                                                                |
| Orig Time   | Displays the time at which the VoIP call originated.                                                                                                                                                                                                                                                              |
| Status      | Displays the status of the VoIP call. Possible values are: <ul style="list-style-type: none"> <li>● <b>SUCCESS</b></li> <li>● <b>FAILED</b></li> <li>● <b>ABORTED</b></li> <li>● <b>BLOCKED</b></li> <li>● <b>FORWARDED</b></li> <li>● <b>ALERTING</b></li> <li>● <b>HOLD</b></li> <li>● <b>ACTIVE</b></li> </ul> |
| Reason      | Displays the reason code for call termination. Possible values are:                                                                                                                                                                                                                                               |

| Column    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Column        | Description                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <ul style="list-style-type: none"> <li>• <b>Video/Conf Call</b></li> <li>• <b>Desktop-Sharing/Conf Call</b></li> <li>• <b>File-Transfer/Conf Call</b></li> </ul>                                                                            |
| Client Health | Displays the ratio of ideal air time required for transmitting a packet from an AP to a client to the actual air time taken for the packet transmission in percentage. Ideal air time assumes highest data rate without any retransmission. |
| UCC Score     | Displays the UCC score based on the quality of the voice call or desktop sharing session. This is an AP-to-client score (wireless) of the VoIP call.                                                                                        |
| UCC-Band      | Displays the quality band of the VoIP call based on the UCC score.                                                                                                                                                                          |
| MOS           | Displays the Mean Opinion Score of the VoIP call.                                                                                                                                                                                           |
| MOS-Band      | Displays the Mean Opinion Score of the VoIP call. This is an end-to-end score (wired and wireless) of the VoIP call. MOS-Band is the quality band of the VoIP call based on the MOS of the voice call.                                      |

The following command displays the CDR statistics for an AP.

```
(host) #show ucc call-info cdrs ap AP225-1
```

CDR-AP:

| CDR ID<br>(msec) | UCC Call ID | AP Name | Re-Assoc | CAC-Denied | Utilization(%) | Codec | Quality | Delay |
|------------------|-------------|---------|----------|------------|----------------|-------|---------|-------|
| 18               | 7           | AP225-1 | 0        | No         | 37             | G711  | Good    | 0.74  |
| 17               | 7           | AP225-1 | 0        | No         | 37             | G711  | Fair    | 19.00 |
| 16               | 6           | AP225-1 | 1        | No         | 34             | NA    | Good    | 0.55  |

| Jitter(msec) | Packet Loss(%) | Orig WMM-AC |
|--------------|----------------|-------------|
| 0.21         | 0.00           | NA          |
| 0.37         | 14.93          | 0           |
| 0.05         | 0.00           | 0           |

Max Concurrent Calls: 2 At Jan 14 03:54:15

The output of this command includes the following information:

| Column      | Description                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------|
| CDR ID      | Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.               |
| UCC Call ID | Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session. |

| Column          | Description                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AP Name         | Displays the name that uniquely identifies the AP.                                                                                                                                                                    |
| Re-Assoc        | Displays the number of times the client re-associated while on an active call.                                                                                                                                        |
| CAC-Denied      | Displays the status of the Call Admission Control (CAC). Possible values are: <ul style="list-style-type: none"> <li>• <b>Yes</b>—CAC denied</li> <li>• <b>No</b>—CAC allowed</li> </ul>                              |
| Utilization(%)  | Displays the channel utilization of the AP during the call.                                                                                                                                                           |
| Codec           | Displays the compression protocol used for voice and video calls, desktop sharing, or file transfer session.                                                                                                          |
| Quality         | Displays the quality of the VoIP call based on the UCC score. Possible values are: <ul style="list-style-type: none"> <li>• <b>Good</b></li> <li>• <b>Fair</b></li> <li>• <b>Poor</b></li> <li>• <b>NA</b></li> </ul> |
| Delay (msec)    | Displays the average delay in milliseconds.                                                                                                                                                                           |
| Jitter (msec)   | Displays the average jitter in milliseconds.                                                                                                                                                                          |
| Packet Loss (%) | Displays the loss of packet in percentage.                                                                                                                                                                            |
| Orig WMM-AC     | Displays the original client value of the Wi-Fi Multimedia Access Category.                                                                                                                                           |

The following command displays detailed CDR statistics.

```
(host) #show ucc call-info cdrs detail
```

CDRS-Detail:

| CDR ID | UCC Call ID | AP Name | Re-Assoc | UCC Score | UCC-Band | WLAN Delay (ms) /Jitter (ms) /PktLoss (%) |
|--------|-------------|---------|----------|-----------|----------|-------------------------------------------|
| 29     | 11          | AP135-1 | 0        | 82.70     | Good     | 0.57/0.01/0.42                            |
| 22     | 9           | AP135-1 | 0        | 83.93     | Good     | 0.30/0.00/0.00                            |

The output of this command includes the following information:

| Column                                      | Description                                                                                                                                                                                         |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CDR ID                                      | Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.                                                                                |
| UCC Call ID                                 | Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session.                                                                  |
| AP Name                                     | Displays the name that uniquely identifies the AP.                                                                                                                                                  |
| Re-Assoc                                    | Displays the number of times the client re-associated while on an active call.                                                                                                                      |
| UCC Score                                   | Displays the UCC score based on the quality of the voice call or desktop sharing.                                                                                                                   |
| UCC-Band                                    | Displays the quality band of the VoIP call based on the UCC score.                                                                                                                                  |
| WLAN Delay (ms) / Jitter (ms) / PktLoss (%) | Displays the WLAN delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage).<br><b>NOTE:</b> This field takes only the wireless network QoS parameters into consideration. |
| SNR                                         | Displays the Signal-to-noise (SNR) ratio. SNR is the power ratio between an information signal and the level of background noise.                                                                   |
| Avg Tx Rate (Mbps)                          | Displays the average transmission rate in Mbps.                                                                                                                                                     |
| Tx Drop (%)                                 | Displays the transmission packet drop in percentage.                                                                                                                                                |
| Tx Retry (%)                                | Displays the transmission retry in percentage.                                                                                                                                                      |
| Avg Rx Rate (Mbps)                          | Displays the average receive rate in Mbps.                                                                                                                                                          |
| Rx Retry (%)                                | Displays the receive retry in percentage.                                                                                                                                                           |
| MOS                                         | Displays the Mean Opinion Score of the VoIP call. This is an end-to-end score (wired and wireless) of the VoIP call.                                                                                |
| MOS-Band                                    | Displays the quality band of the VoIP call based on the Mean Opinion Score.                                                                                                                         |

| Column                                             | Description                                                                                                                                                                                                    |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| End-to-End Delay (ms)<br>/Jitter (ms) /PktLoss (%) | Displays the end-to-end delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage).<br><b>NOTE:</b> This field takes the wired and wireless network QoS parameters into consideration. |

## show ucc client-info

```
show ucc client-info
 app {h323 [detail] | lync [detail] | noe [detail] | sccp [detail] | sip [detail] | svp
 [detail] | vocera [detail]}
 detail
 sta <mac>
 <cr>
```

### Description

This command displays the UCC client status and CDR statistics.

When VoIP calls are prioritized using media classification, the **Client Name** value is not available.

### Syntax

| Parameter                                                                                                          | Description                                                                  |
|--------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| app {h323 [detail]   lync [detail]   noe [detail]   sccp [detail]   sip [detail]   svp [detail]   vocera [detail]} | Displays the UCC client status and CDR statistics based on a specific ALG.   |
| detail                                                                                                             | Displays UCC client status details.                                          |
| sta <mac>                                                                                                          | Displays the detailed record for a specific client based on its MAC address. |

### Example

The following command displays the UCC client status and record:

```
(host) # show ucc client-info
Client Status:
```

| Client IP  | Client MAC        | Client Name | ALG  | Server(IP) | Registration State | Call |
|------------|-------------------|-------------|------|------------|--------------------|------|
| 192.0.2.22 | 00:23:33:41:c8:b8 | Alex        | Lync | 192.0.2.1  | REGISTERED         | Idle |
| 192.0.2.26 | 24:77:03:9a:6c:dc | John        | Lync | 192.0.2.1  | REGISTERED         | Idle |

| AP Name | Flags | Device Type |
|---------|-------|-------------|
| W-AP105 |       | Windows     |
| W-AP135 |       | Win 7       |

Flags: V - Visitor, A - Away, W - Wired, R - Remote, B - Blocked, E - External

The output of this command includes the following information:

| Column             | Description                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client IP          | Displays the IP address of the VoIP client.                                                                                                                                                                                                                     |
| Client MAC         | Displays the MAC address of the VoIP client.                                                                                                                                                                                                                    |
| Client Name        | Displays the username of the VoIP client.                                                                                                                                                                                                                       |
| ALG                | Displays the Application Layer Gateway protocol used by the VoIP client.                                                                                                                                                                                        |
| Server (IP)        | Displays the IP address of call server the client is registered to.                                                                                                                                                                                             |
| Registration State | Displays the registration status of the VoIP call. Possible values are: <ul style="list-style-type: none"> <li>• <b>Registered</b></li> <li>• <b>Registering</b></li> <li>• <b>Unregistered</b></li> <li>• <b>Rejected</b></li> <li>• <b>Unknown</b></li> </ul> |
| Call Status        | Displays the VoIP call status of the client. Possible values are: <ul style="list-style-type: none"> <li>• <b>Idle</b></li> <li>• <b>In-Call</b></li> </ul>                                                                                                     |
| AP Name            | Displays the name of the AP to which the VoIP client is associated.                                                                                                                                                                                             |
| Flags              | Displays if the client is a visitor, away, wired, remote, blocked, or external.                                                                                                                                                                                 |
| Device Type        | Displays the device type identification of the client.                                                                                                                                                                                                          |

The following command displays the UCC client status details:

```
(host) #show ucc client-info detail
```

Client Status Details(Average):

```

| Client IP             | Displays the IP address of the VoIP client.                                                                                                                                                                                                                                                       |
| Client MAC            | Displays the MAC address of the VoIP client.                                                                                                                                                                                                                                                      |
| Client Name           | Displays the username of the VoIP client.                                                                                                                                                                                                                                                         |
| AP-Name               | Displays the name of the AP handling the VoIP call.                                                                                                                                                                                                                                               |
| SNR                   | Displays the Signal-to-noise (SNR) ratio. SNR is the power ratio between an information signal and the level of background noise.                                                                                                                                                                 |
| Avg Tx Rate (Mbps)    | Displays the average transmission rate in Mbps.                                                                                                                                                                                                                                                   |
| Tx Drop (%)           | Displays the transmission packet drop in percentage.                                                                                                                                                                                                                                              |
| Tx Retry (%)          | Displays the transmission retry in percentage.                                                                                                                                                                                                                                                    |
| Avg Rx Rate (Mbps)    | Displays the average receive rate in Mbps.                                                                                                                                                                                                                                                        |
| Rx Retry (%)          | Displays the receive retry in percentage.                                                                                                                                                                                                                                                         |
| Un-steerable (reason) | Displays the reason for steering/not steering the client to another band. Possible values are: <ul style="list-style-type: none"> <li>• <b>Sticky</b></li> <li>• <b>Load Balance</b></li> <li>• <b>Band Steer</b></li> <li>• <b>Band Balance</b></li> <li>• <b>Administrator Added</b></li> </ul> |

| Column              | Description                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | <ul style="list-style-type: none"> <li>• <b>(IOS)</b></li> <li>• <b>NA</b></li> </ul>                                                                                                                                                                                                                             |
| <b>Active Calls</b> |                                                                                                                                                                                                                                                                                                                   |
| CDR ID              | Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.                                                                                                                                                                                              |
| UCC Call ID         | Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session.                                                                                                                                                                                |
| Client IP           | Displays the IP address of the VoIP client.                                                                                                                                                                                                                                                                       |
| Client Name         | Displays the username of the VoIP client.                                                                                                                                                                                                                                                                         |
| ALG                 | Displays the Application Layer Gateway protocol used by the VoIP client.                                                                                                                                                                                                                                          |
| Dir                 | Displays the direction of the call. Possible values are: <ul style="list-style-type: none"> <li>• <b>OG</b>—Outgoing</li> <li>• <b>IG</b>—Incoming</li> </ul>                                                                                                                                                     |
| Called To           | Displays the username of the VoIP client being called.                                                                                                                                                                                                                                                            |
| Dur (sec)           | Displays the duration of the VoIP call in seconds.                                                                                                                                                                                                                                                                |
| Orig-Time           | Displays the time at which the VoIP call originated.                                                                                                                                                                                                                                                              |
| Status              | Displays the status of the VoIP call. Possible values are: <ul style="list-style-type: none"> <li>• <b>SUCCESS</b></li> <li>• <b>FAILED</b></li> <li>• <b>ABORTED</b></li> <li>• <b>BLOCKED</b></li> <li>• <b>FORWARDED</b></li> <li>• <b>ALERTING</b></li> <li>• <b>HOLD</b></li> <li>• <b>ACTIVE</b></li> </ul> |
| Call Type           | Displays the type of VoIP call or session. Possible values are: <ul style="list-style-type: none"> <li>• <b>Not Available</b></li> <li>• <b>Voice</b></li> <li>• <b>Video</b></li> <li>• <b>Desktop Sharing</b></li> </ul>                                                                                        |

| Column              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | <ul style="list-style-type: none"> <li>• <b>File Transfer</b></li> <li>• <b>Voice/Conf Call</b></li> <li>• <b>Video/Conf Call</b></li> <li>• <b>Desktop-Sharing/Conf Call</b></li> <li>• <b>File-Transfer/Conf Call</b></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Client Health       | Displays the ratio of ideal air time required for transmitting a packet from an AP to a client to the actual air time taken for the packet transmission in percentage. Ideal air time assumes highest data rate without any retransmission.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| UCC Score           | Displays the UCC score based on the quality of the voice call or desktop sharing session. This is an AP-to-client score (wireless) of the VoIP call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| UCC-Band            | Displays the quality band of the VoIP call based on the UCC score.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| MOS                 | Displays the Mean Opinion Score of the VoIP call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| MOS-Band            | Displays the Mean Opinion Score of the VoIP call. This is an end-to-end score (wired and wireless) of the VoIP call. MOS-Band is the quality band of the VoIP call based on the MOS of the voice call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|---------------------------------------|------------------------------------------------------------------------------------------|
| cac-alg                               | Displays the CAC profiles configured in the controller.                                  |
| dialplan-profile [<profile-name>]     | Displays the dialplan profile configured in the controller.                              |
| logging                               | Displays the MAC address of the voice client that has logging enabled.                   |
| midcall-timeout                       | Displays the status of the SIP mid-call request timeout configuration on the controller. |
| realtime-analysis                     | Displays the status of real-time call quality analysis configuration.                    |
| rtcp-inactivity                       | Displays the Real Time Control Protocol (RTCP) inactivity timer status.                  |
| sip                                   | Displays the Session Initiation Protocol (SIP) settings in the controller.               |
| traffic-control lync [<profile-name>] | Displays the Lync traffic control profile configuration in the controller.               |

### Example

The following command displays the overall UCC configuration in the controller:

```
(host) #show ucc configuration

Voice firewall policies

Policy Action

Stateful SIP Processing Enabled
WMM content enforcement Disabled
Session VOIP Timeout Enabled
Stateful H.323 Processing Enabled
Stateful SIPs Processing Enabled
Stateful SCCP Processing Enabled
Stateful VOCERA Processing Enabled
Stateful UA Processing Enabled
```

## SSID Profiles

| Profile Name           | WMM      | WMM-UAPSD | TSPEC Min Inactivity(msec) | DSCP-vo |
|------------------------|----------|-----------|----------------------------|---------|
| AP01-SSID-PROFILE-WPA2 | Disabled | Enabled   | 0                          | 56      |
| default                | Disabled | Enabled   | 0                          | 56      |

| DSCP-vi | DSCP-be | DSCP-bk | Battery Boost | EDCA STA prof | EDCA AP prof | Strict SVP |
|---------|---------|---------|---------------|---------------|--------------|------------|
| 40      | 24      | 8       | Disabled      | N/A           | N/A          | Disabled   |
| 34      | 24      | 8       | Disabled      | N/A           | N/A          | Disabled   |

## AP Group Profiles

| Profile Name | VoIP CAC Profile |
|--------------|------------------|
| default      | default          |
| employee     | default          |

## Virtual AP Group Profiles

| Profile Name | 802.11K Profile | HA Discovery on-assoc. |
|--------------|-----------------|------------------------|
| default      | default         | Enabled                |
| VoIP-net     | default         | Enabled                |

## VoIP Call Admission Control Profiles

| Profile Name | VoIP CAC |
|--------------|----------|
| default      | Disabled |
| voip_cac     | Disabled |

## 802.11K Profiles

| Profile Name | Advertise 802.11K Capability |
|--------------|------------------------------|
| default      | Disabled                     |

## SIP settings

| Parameter        | Value    |
|------------------|----------|
| Session Timer    | Disabled |
| Session Expiry   | 300 sec  |
| Dialplan Profile | N/A      |

Voice rtcp-inactivity:disable  
Voice sip-midcall-req-timeout:disable

The following command displays the Lync traffic control profile configuration in the controller:

```
(host) #show ucc configuration traffic-control lync default
```

## Traffic Control Prioritization Profile "default"

| Parameter                  | Value   |
|----------------------------|---------|
| prioritize voice           | Enabled |
| prioritize video           | Enabled |
| prioritize desktop-sharing | Enabled |
| prioritize file-transfer   | Enabled |

## Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.4 | Command introduced. |

## Command Information

| Platforms     | Licensing                                | Command Mode                                          |
|---------------|------------------------------------------|-------------------------------------------------------|
| All platforms | This command requires the PEFNG license. | Config or Enable mode on master or local controllers. |

## show ucc statistics

```
show ucc statistics
 counter cac | call {client [app {h323 | lync | noe | sccp | sip | svp | vocera}]] global
 [app {h323 | lync | noe | sccp | sip | svp | vocera}]]
 dialplan-hits
 remote wmm-flow {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
 tspec-enforcement
 wmm-flow
```

### Description

This command displays the UCC call statistics in the controller.

### Syntax

| Parameter                                                                                                                                        | Description                                                                                        |
|--------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| counter cac   call {client [app {h323   lync   noe   sccp   sip   svp   vocera}]] global [app {h323   lync   noe   sccp   sip   svp   vocera}]]} | Displays CAC, global, and client call counters.                                                    |
| dialplan-hits                                                                                                                                    | Displays dialplan hits for UDP-based SIP calls.                                                    |
| remote wmm-flow {ap-name <ap-name>   bssid <bssid>   ip-addr <ip-addr>}                                                                          | Displays Wi-Fi Multimedia (WMM) flows active on the AP based on the AP name, BSSID, or IP address. |
| tspec-enforcement                                                                                                                                | Displays the number of TSPEC requests accepted, rejected, or denied.                               |
| wmm-flow                                                                                                                                         | Displays Wi-Fi Multimedia (WMM) flows active on the AP.                                            |

### Example

The following command displays the global call counters:

```
(host) # show ucc statistics counter call global
```

System-wide Call Counters:

```

Call Originated Call Terminated Active Success Failed Blocked Aborted Forwarded WMM
AC-VI

33 21 0 53 0 0 1 0 37
```

```

0 3 0 11 0 0 0

```

WMM (VI, VO, BK, BE):total calls with received priority

The output of this command includes the following information:

| Column          | Description                                                                           |
|-----------------|---------------------------------------------------------------------------------------|
| Client IP       | Displays the IP address of the VoIP client.                                           |
| Client MAC      | Displays the MAC address of the VoIP client.                                          |
| Call Originated | Displays the number of times a call originated from the VoIP client.                  |
| Call Terminated | Displays the number of times a call terminated on the VoIP client.                    |
| Active          | Displays the number of active calls on the VoIP client.                               |
| Success         | Displays the number of successful calls.                                              |
| Failed          | Displays the number of failed call setup calls.                                       |
| Blocked         | Displays the number of blocked calls due to CAC.                                      |
| Aborted         | Displays the number of terminated calls due to inactivity.                            |
| Forwarded       | Displays the number of times a call is forwarded for a VoIP client.                   |
| WMM AC-VI       | Displays the number of calls where the client sent RTP with WMM AC set to Video (VI). |

| Column    | Description                                                                                 |
|-----------|---------------------------------------------------------------------------------------------|
| WMM AC-VO | Displays the number of calls where the client sent RTP with WMM AC set to Voice (VO).       |
| WMM-BK    | Displays the number of calls where the client sent RTP with WMM AC set to Background (BK).  |
| WMM-BE    | Displays the number of calls where the client sent RTP with WMM AC set to Best Effort (BE). |

## Command History

| Version     | Description         |

## show ucc trace-buffer

```
show ucc trace-buffer
 lync [count <count>]
 sccp [count <count>]
 sip [count <count>]
```

### Description

This command displays the UCC call message trace buffer for Lync, SCCP, and SIP ALGs. Call signaling events such as establishing voice, video, desktop sharing, and file transfer are recorded.

### Syntax

| Parameter            | Description                              |
|----------------------|------------------------------------------|
| lync [count <count>] | Displays Lync call message trace buffer. |
| sccp [count <count>] | Displays SCCP call message trace buffer. |
| sip [count <count>]  | Displays SIP call message trace buffer.  |

### Example

The following command displays Lync call message trace buffer:

```
(host) #show ucc trace-buffer lync
```

Lync Voice Client(s) Message Trace

```

# show upgrade configuration

show upgrade configuration

## Description

The output of this command shows the current upgrade configuration, including profile settings, image files and targets.

## Syntax

No parameters

## Usage Guidelines

The centralized image upgrade feature allows a master controller to automatically upgrade its associated local controllers by sending an image from an image server to one or more local controllers. This feature can and supports up to 100 simultaneous image downloads, and is enabled and configured on a master controller only.

## Example

```
(host) #show upgrade configuration
Upgrade configuration

Parameter Value

Protocol scp
Server IP address 10.1.1.41
Username tftp
Password *****
File path /tftpboot
Max downloads 100
Reboot automatically true
Image file ArubaOS_W-620_6.3.0.0_37916 (verified)
 ArubaOS_W-3000 Series_6.3.0.0_37916 (not verified)
 ArubaOS_W-7200 Series_6.3.0.0_37916 (verified)

Upgrade target

IP address Netmask

192.0.2.0 255.255.255.0
```

The output of this command includes the following information:

| Parameter | Description                                                                                                                                                                        | Range | Default |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| protocol  | Specify the protocol used to send the software upgrade from the image server to the local controller. <ul style="list-style-type: none"><li>TFTP</li><li>FTP</li><li>SCP</li></ul> | -     | TFTP    |
| Server IP | IP address of the image server.                                                                                                                                                    | -     | -       |
| Username  | If the <b>protocol</b> parameter is set to <b>FTP</b> or <b>SCP</b> , this parameter displays the username that ArubaOS uses to connect to the image server                        | -     | -       |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                   | Range | Default  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| Password             | If the <b>protocol</b> parameter is set to <b>FTP</b> or <b>SCP</b> , this parameter displays the password that ArubaOS will use to connect to the image server                                                                                                                                                                               | -     | -        |
| File path            | Location on the image server where the image file(s) are located                                                                                                                                                                                                                                                                              | -     | -        |
| Max downloads        | Maximum number of local controllers that can simultaneously download a file from a file server. The centralized image downloading feature supports up to 100 simultaneous downloads. If this field is left blank, ArubaOS will use its default value of 10 downloads.                                                                         | 1-100 | 10       |
| Reboot automatically | If true, the local controllers reboot after they download their new images.<br><br><b>NOTE:</b> If you enable this option, local controllers will reboot without saving any changes to their current configuration. If you have any unsaved configuration changes on your local controller that you want to retain, do not enable this option | -     | Disabled |
| Image File           | Name of image files available for download by controllers using the centralized image upgrade feature. The output of this parameter also shows whether or not these image files have been verified as valid by the controller.                                                                                                                | -     | -        |
| Target               | IP address and netmask of controllers that should download the image from the image server.                                                                                                                                                                                                                                                   | -     | -        |

## show upgrade status

show upgrade status[summary]

### Description

The output of this command shows the status of controllers using the centralized upgrade feature.

### Syntax

| Parameter | Description                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| summary   | Display a summary of all local controllers using the centralized image upgrade, including the numbers of controllers currently in each upgrade state. |

### Usage Guidelines

The centralized image upgrade feature allows the master controller to automatically upgrade its associated local controllers by sending an image from an image server to one or more local controllers. The centralized image upgrade feature can be configured on a master controller only, and supports up to 100 simultaneous downloads.

### Example

```
(host) #show upgrade status
All Controllers
```

```

IP Address Hostname Type Model Version Upgrade Status

192.0.2.103 corp-203 master DellW-7240 6.3.1.0_39600 N/A

192.0.2.110 corp-210 local DellW-3400 6.3.1.0_39600 Up-to-date
```

The output of this command includes the following information:

| Parameter | Description                                                                                                                                                                        | Range | Default |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| protocol  | Specify the protocol used to send the software upgrade from the image server to the local controller. <ul style="list-style-type: none"><li>TFTP</li><li>FTP</li><li>SCP</li></ul> | -     | TFTP    |
| Server IP | IP address of the image server.                                                                                                                                                    | -     | -       |
| Username  | If the <b>protocol</b> parameter is set to <b>FTP</b> or <b>SCP</b> , this parameter displays the user name that ArubaOS uses to connect to the image server.                      | -     | -       |
| Password  | If the <b>protocol</b> parameter is set to <b>FTP</b> or <b>SCP</b> , this                                                                                                         | -     | -       |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                   | Range | Default  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
|                      | parameter displays the password that ArubaOS will use to connect to the image server.                                                                                                                                                                                                                                                         |       |          |
| File path            | File path to the location on the image server where the image file(s) reside.                                                                                                                                                                                                                                                                 | -     | -        |
| Max downloads        | Maximum number of local controllers that can simultaneously download a file from a file server. The centralized image downloading feature supports up to 100 simultaneous downloads. If this field is left blank, ArubaOS will use its default value of 10 downloads.                                                                         | 1-100 | 10       |
| Reboot automatically | If true, the local controllers reboot after they download their new images.<br><br><b>NOTE:</b> If you enable this option, local controllers will reboot without saving any changes to their current configuration. If you have any unsaved configuration changes on your local controller that you want to retain, do not enable this option | -     | Disabled |
| Image File           | Name of image files available for download by controllers using the centralized image upgrade feature. The output of this parameter also shows whether or not these image files have been verified as valid by the controller.                                                                                                                | -     | -        |
| Target               | IP address and netmask of controllers that should download the image from the image server.                                                                                                                                                                                                                                                   | -     | -        |

If you include the optional **summary** parameter, the output of the **show upgrade status summary** command includes the following information.

| Parameter                      | Description                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Total Number of Local Switches | Number of local controllers using the centralized image upgrade feature.                                                          |
| Up-to-date                     | Number of local controllers with a current image that does not need to be upgraded.                                               |
| Upgrade in progress            | Number of local controllers downloading a new image.                                                                              |
| Rebooting                      | Number of local controllers rebooting after downloading a new image.                                                              |
| Waiting                        | Number of local controllers waiting to download a new image.                                                                      |
| Failed                         | If a local controller fails to download its new image, it goes into this state momentarily before it waits to retry the download. |
| Failed, waiting                | A local controller has failed to upgrade its image and is waiting 15 minutes before it attempts the download again.               |
| Down                           | The local controller cannot upgrade because it is down or not reachable.                                                          |
| Upgraded, reboot               | The local controller has upgraded its image, and is waiting to reboot. If you did not                                             |

| Parameter                     | Description                                                                                                                                     |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| required                      | enable the auto-reboot feature in the upgrade profile, you must manually reboot each controller after it downloads its new image.               |
| Not supported                 | The local controller is running a version of ArubaOS that does not support centralized image downloads.                                         |
| Waiting, image not verified   | The image must be verified as valid before the local controller can download that image.                                                        |
| Not part of target            | The local controller is associated with a master controller using the centralized image upgrade feature, but is not part of the upgrade target. |
| All target Configured         | All local controllers are on the target list defined by the <b>upgrade target</b> command.                                                      |
| Total Number of host target   | Total number of controller IP address added to the upgrade target list.                                                                         |
| Total Number of subnet target | Total number of controller subnets added to the upgrade target list.                                                                            |

## Command History

|---------------|-----------------------|-----------------------------------|
| all platforms | Base operating system | Enable mode on master controllers |

## show upgrade-profile

### Description

The settings in this centralized image upgrade profile allow the master controller to automatically upgrade its associated local controllers by sending an image from an image server to one or more local controllers.

### Syntax

No parameters

### Usage Guidelines

The centralized image upgrade feature is enabled and configured on a master controller only, and supports up to 100 simultaneous image downloads.

### Example

```
(host) (config) # show upgrade-profile
Upgrade Profile

Parameter Value

Enable software upgrade false
Max downloads 10
Reboot automatically true
Protocol tftp
Server IP address N/A
Username N/A
Password N/A
File path N/A
```

The output of this command includes the following information:

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                    | Range | Default  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| Enable software upgrade | If <b>true</b> , the centralized image upgrade feature has been enabled. Note that this feature is disabled by default.                                                                                                                                                                                                                        | -     | Disabled |
| Max downloads           | Maximum number of local controllers that can simultaneously download a file from a file server. The centralized image downloading feature supports up to 100 simultaneous downloads. If this field is left blank, ArubaOS will use its default value of 10 downloads.                                                                          | 1-100 | 10       |
| Reboot automatically    | If true, the local controllers reboot after they download their new images.<br><br><b>NOTE:</b> If you enable this option, local controllers will reboot without saving any changes to their current configuration. If you have any unsaved configuration changes on your local controller that you want to retain, do not enable this option. | -     | Disabled |
| Protocol                | Specify the protocol used to send the software upgrade from the image server to the local controller.                                                                                                                                                                                                                                          | -     | TFTP     |

| Parameter         | Description                                                                                                                                                      | Range | Default |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
|                   | <ul style="list-style-type: none"> <li>TFTP</li> <li>FTP</li> <li>SCP</li> </ul>                                                                                 |       |         |
| Server IP address | IP address of the image server.                                                                                                                                  | -     | -       |
| Username          | If the <b>protocol</b> parameter is set to <b>FTP</b> or <b>SCP</b> , this parameter displays the user name that ArubaOS uses to connect to the image server.    | -     | -       |
| Password          | If the <b>protocol</b> parameter is set to <b>FTP</b> or <b>SCP</b> , this parameter displays the password that ArubaOS will use to connect to the image server. | -     | -       |
| File path         | File path to the location on the image server where the image file(s) reside.                                                                                    | -     | -       |

| all platforms | Base operating system | Enable mode on master or local controllers |

## show uplink

```
show uplink [config|{connection <link_id>}|signal|{stats <link_id>}]
```

### Description

Displays uplink manager configuration details.

### Syntax

| Parameter  | Description                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------|
| config     | Enter the keyword <b>config</b> to display the uplink manager, the default wired priority and default cellular priority          |
| connection | Enter the keyword <b>connection</b> followed by the uplink ID number to display the connection details.                          |
| signal     | Enter the keyword <b>signal</b> to display the cellular uplink signal strength.                                                  |
| stats      | Enter the keyword <b>stats</b> followed by the uplink ID number to display the statistical information on the designated uplink. |

### Example

The output of this command displays the controller uplink status .

```
(host) #show uplink
Uplink Manager: Enabled
```

Uplink Management Table

| Id | Uplink Type | Properties   | Priority | State        | Status           |
|----|-------------|--------------|----------|--------------|------------------|
| 1  | Wired       | vlan 1       | 200      | Initializing | Waiting for link |
| 2  | Cellular    | Novatel_U727 | 100      | Standby      | Ready            |

### Command History

Introduced in ArubaOS 3.4.

### Command Information

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master and local controllers |

## show usb

```
show usb [cellular|ports|test|verbose]
```

### Description

Display detailed USB device information.

### Syntax

| Parameter | Description                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cellular  | Enter the keyword <b>cellular</b> to display cellular devices.                                                                                                                            |
| ports     | Enter the keyword <b>ports</b> to display detailed TTY port information such as signal strength.                                                                                          |
| test      | Enter the keyword <b>test</b> to test the USB TTY ports.<br><b>NOTE:</b> Testing an invalid modem port may cause the controller to "hang". To resolve this, unplug and re-plug the modem. |
| verbose   | Enter the keyword <b>verbose</b> to display detailed USB information including serial number and USB type.                                                                                |

### Examples

The USB Device table, in the example below, displays the USB port is in the 'Device Ready' state, meaning that the port has passed the diagnostic test and is ready to send and receive data.

```
(host) (config-cellular new_modem)# show usb
USB Device Table

Address Product Vendor ProdID Serial Type Profile State
----- -
18 Novatel Wireless CDMA 1410 4100 091087843891000 Cellular new_modem Device
ready
```

Below is an example of the **show usb verbose** display output (partial).

```
(host) #show usb verbose
...

 role <STRING>
 rows <NUMBER> <NUMBER>
```

### Description

Displays detailed information about user in terms of AP group, authentication method, role and so on.

### Syntax

| Parameter             | Description                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group>   | Filter the output of this command by showing users connected to APs that belong to the specified AP group. |
| ap-name <ap-name>     | Filter the output of this command by showing users connected to an AP with the specified AP name.          |
| authentication-method | Filter the output of this command by the authentication method used for the device:                        |
| dot1x                 | Show data for devices using 802.1X authentication.                                                         |
| mac                   | Show data for devices using MAC authentication.                                                            |
| opensystem            | Show data for devices using open (no) authentication.                                                      |
| psk                   | Show data for devices that do not use authentication but use a pre-shared key for encryption.              |
| stateful-dot1x        | Show data for devices using stateful 802.1X authentication.                                                |
| via-vpn               | Show data for devices that authenticate using Dell VIA.                                                    |
| vpn                   | Show data for devices using VPN authentication.                                                            |

| Parameter              | Description                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| web                    | Show data for devices using captive portal authentication.                                                                                                                                                    |
| bssid <A:B:C:D:E:F>    | Show user data for a specific device BSSID.                                                                                                                                                                   |
| devtype <device>       | Show output for a specified device type, if identified. If the device name includes spaces, you must enclose it in quotation marks.                                                                           |
| essid <STRING>         | Show user data for a specific ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.                                                                                                    |
| internal               | Display internal user entries only. Include the <b>rows</b> options to filter the output of this command by specifying the number of rows from the end of the output and the total number of rows to display/ |
| ip <A.B.C.D>           | Show user data for a specific IP address .                                                                                                                                                                    |
| log                    | If per-user logging is enabled using the <a href="#">aaa log</a> command, include the optional <b>log</b> parameter to display authentication log files for a user with the specified MAC address.            |
| mac <A:B:C:D:E:F>      | Show user data for a specific MAC address                                                                                                                                                                     |
| log                    | If per-user logging is enabled using the <a href="#">aaa log</a> command, include the optional <b>log</b> parameter to display authentication log files for a user with the specified MAC address.            |
| mobile                 | Filter the output of this command to show data for Mobile users.                                                                                                                                              |
| bindings               | Show data for users that have moved away from their home network.                                                                                                                                             |
| visitors               | Show data for mobility users that are visiting the network.                                                                                                                                                   |
| name <STRING>          | User's name.                                                                                                                                                                                                  |
| phy-type               | 801.11 type                                                                                                                                                                                                   |
| a                      | Matches PHY type a.                                                                                                                                                                                           |
| g                      | Matches PHY type b or g.                                                                                                                                                                                      |
| role <STRING>          | User role such as employee, visitor and so on.                                                                                                                                                                |
| rows <NUMBER> <NUMBER> | Filter the output of the show user command by specifying the number of rows from the end of the output and the total number of rows to display/                                                               |

## Usage Guidelines

Use the **show user** command to show detailed user statistics and roles.

## Example

```
(host) #show user
Users
```

```

IP MAC Name Role Age(d:h:m) Auth VPN link AP name Roaming
Essid/Bssid/Phy Profile Forward mode Type Host Name

```

```
User Entries: 0/0
```

```
Curr/Cum Alloc:0/0 Free:0/0 Dyn:0 AllocErr:0 FreeErr:0
```

## Command History

| Release     | Modification                                                                                                                                                                               |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                                                                                                                                         |
| ArubaOS 6.1 | The <b>devtype</b> parameter was introduced, and the output of this command expanded to include the <b>Type</b> column.                                                                    |
| ArubaOS 6.2 | Output for the IP address shows if it is derived using DHCP.                                                                                                                               |
| ArubaOS 6.3 | The optional <b>log</b> parameter was introduced to display log files for events triggered by a specific user. Only W-6000, W-3600 and W-7200 Series controllers support per-user logging. |

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                          |
|---------------|-----------------------|---------------------------------------|
| All platforms | Base operating system | Available in Enable and Config modes. |

## show user\_session\_count (deprecated)

show user\_session\_count

### Description

Show the number of users using an ESSID for different time intervals.

### Syntax

No parameters

### Command History

| Version     | Modification       |
|-------------|--------------------|
| ArubaOS 3.0 | Command introduced |
| ArubaOS 6.0 | Command deprecated |

## show user-table

```
show user-table
 ap-group <ap-group>
 ap-name <ap-name>
 authentication-method dot1x|mac|opensystem|psk|stateful-dot1x|via-vpn|vpn|web
 bssid <A:B:C:D:E:F>
 devtype <device>
 debug
 essid <STRING>
 internal
 ip <A.B.C.D> [log][detail]
 mac <A:B:C:D:E:F> [log]
 mobile {[bindings][visitors]}
 name <STRING>
 phy-type {[a][b]}
 role <STRING>
 rows <NUMBER> <NUMBER>
 station
 summary
 unique
 verbose
```

### Description

Displays detailed information about the controller's connection to a user device, in regards to mobility state and statistics, authentication statistics, VLAN assignment method, AP datapath tunnel info, radius accounting statistics, user name, user-role derivation method, datapath session flow entries, and 802.11 association state and statistics. The **show user** command allows you to filter specific information by parameter.

### Syntax

| Parameter             | Description                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------|
| ap-group <ap-group>   | Filter the output of this command by showing users connected to APs that belong to the specified AP group. |
| ap-name <ap-name>     | Filter the output of this command by showing users connected to an AP with the specified AP name.          |
| authentication-method | Filter the output of this command by the authentication method used for the device:                        |
| dot1x                 | Show data for devices using 802.1X authentication.                                                         |
| mac                   | Show data for devices using MAC authentication.                                                            |
| opensystem            | Show data for devices using open (no) authentication.                                                      |
| psk                   | Show data for devices that do not use authentication but use a pre-shared key for encryption.              |

| Parameter           | Description                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stateful-dot1x      | Show data for devices using stateful 802.1X authentication.                                                                                                                                                   |
| via-vpn             | Show data for devices that authenticate using Dell VIA.                                                                                                                                                       |
| vpn                 | Show data for devices using VPN authentication.                                                                                                                                                               |
| web                 | Show data for devices using captive portal authentication.                                                                                                                                                    |
| bssid <A:B:C:D:E:F> | Show user data for a specific device BSSID.                                                                                                                                                                   |
| debug               | Show all user data for debugging purposes.                                                                                                                                                                    |
| devtype <device>    | Show output for a specified device type, if identified. If the device name includes spaces, you must enclose it in quotation marks.                                                                           |
| essid <STRING>      | Show user data for a specific ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.                                                                                                    |
| internal            | Display internal user entries only. Include the <b>rows</b> options to filter the output of this command by specifying the number of rows from the end of the output and the total number of rows to display/ |
| ip <A.B.C.D>        | Show user data for a specific IP address .                                                                                                                                                                    |
| log                 | If per-user logging is enabled using the <a href="#">aaa log</a> command, include the optional <b>log</b> parameter to display authentication log files for a user with the specified MAC address.            |
| detail              | Show detailed user data for a specific IP address including role-derivation.                                                                                                                                  |
| mac <A:B:C:D:E:F>   | Show user data for a specific MAC address                                                                                                                                                                     |
| log                 | If per-user logging is enabled using the <a href="#">aaa log</a> command, include the optional <b>log</b> parameter to display authentication log files for a user with the specified MAC address.            |
| mobile              | Filter the output of this command to show data for Mobile users.                                                                                                                                              |
| bindings            | Show data for users that have moved away from their home network.                                                                                                                                             |
| visitors            | Show data for mobility users that are visiting the network.                                                                                                                                                   |
| name <STRING>       | User's name.                                                                                                                                                                                                  |
| phy-type            | 801.11 type                                                                                                                                                                                                   |

| Parameter              | Description                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| a                      | Matches PHY type a.                                                                                                                             |
| g                      | Matches PHY type b or g.                                                                                                                        |
| role <STRING>          | User role such as employee, visitor and so on.                                                                                                  |
| rows <NUMBER> <NUMBER> | Filter the output of the show user command by specifying the number of rows from the end of the output and the total number of rows to display/ |
| station                | For internal use only.                                                                                                                          |
| summary                | Shows the authentication and encryption type used by wired or wireless clients.                                                                 |
| unique                 | Displays only information for users with a valid IP address.                                                                                    |
| verbose                | Displays all information about the user table.                                                                                                  |

## Usage Guidelines

Use the **show user-table** command to show detailed user statistics which includes the entire output of the user-table, mobility state and statics, authentication statistics, VLAN assignment method, AP datapath tunnel information, radius accounting statistics, user-role derivation method, datapath session flow entries and 802.11 association state and statistics.

## Examples

This example displays users currently in the **employee** role. The output of this command is split into two tables in this document, however it appears in one table in the CLI.

```
(host) (config) show user role employee
```

Users

-----

The **role-how** and **vlan-how** parameters in the output of this command display a code that corresponds to the following values:

| Role Derivation Code | Description                               |
|----------------------|-------------------------------------------|
| 0                    | Default logon role                        |
| 1                    | Default user role for authentication type |
| 2                    | Role derived from server rules            |
| 3                    | Role derived from user rules              |
| 4                    | Predefined Guest role                     |
| 5                    | Role inherited from station               |

| Role Derivation Code | Description                                                       |
|----------------------|-------------------------------------------------------------------|
| 6                    | Forced role                                                       |
| 7                    | Role derived from Dell vendor-specific attribute (VSA)            |
| 8                    | RFC 3576 (Change of Authorization) role                           |
| 9                    | Role derived from external captive portal                         |
| 10                   | Default role from AAA profile                                     |
| 11                   | Role assigned by an Extended Service Interface (ESI) server group |

| VLAN Derivation Code | Description                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| 1                    | VLAN derived from user rule                                                                                  |
| 2                    | VLAN derived from user role                                                                                  |
