| 3                    | VLAN derived from server rule                                                                                |
| 4                    | VLAN derived from Dell vendor-specific attribute (VSA)                                                       |
| 5                    | VLAN derived from Microsoft Tunnel attributes (Tunnel-Type, Tunnel Medium Type, and Tunnel Private Group ID) |
| 6                    | VLAN assigned from derived role                                                                              |

## Command History

| Release         | Modification                                                                                                                                                                               |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced.                                                                                                                                                                        |
| ArubaOS 6.1     | The <b>devtype</b> parameter was introduced, and the output of this command expanded to include the <b>Type</b> column.                                                                    |
| ArubaOS 6.2     | Output for the IP address shows if it is derived using DHCP.                                                                                                                               |
| ArubaOS 6.3     | The optional <b>log</b> parameter was introduced to display log files for events triggered by a specific user. Only W-6000, W-3600 and W-7200 Series controllers support per-user logging. |
| ArubaOS 6.4.3.0 | The <b>detail</b> sub-parameter was introduced as part of the <b>ip</b> parameter.                                                                                                         |

## Command Information

| Platforms     | Licensing             | Command Mode             |
|---------------|-----------------------|--------------------------|
| All platforms | Base operating system | Enable and Config modes. |

## show util\_proc

```
show util_proc guest-email counters
```

### Description

Show counters for the guest email process.

### Syntax

No parameters.

### Usage Guidelines

As part of guest provisioning, the guest access email feature allows you to define the SMTP port and server that processes guest provisioning email. This server sends email to the guest or the sponsor when a guest user manually sends email from the Guest Provisioning page, or when a user creates a guest account.

### Example

The output of this command shows the numbers of guest emails received, sent and dropped since the controller was last reset

```
(host) #show util_proc guest-email counters
```

```
Guest Email Counters

Name Value
---- -
Email Received 14
Email Sent 3
Email Dropped 0.
```

### Related Commands

To configure SMTP servers and server ports for guest email, use the command [guest-access-email](#).

### Command History

This command was available in ArubaOS 1.0.

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show valid-network-oui-profile

show valid-network-oui-profile

### Description

This command displays the Valid Equipment OUI Profile table

### Syntax

No parameters

### Usage Guidelines

If you used the valid-networkoui-profile to add a new OUI to the controller, issue the show valid-network-oui-profile command to see a list of current OUIs.

### Example

```
(Host) (config) #show valid-network-oui-profile
```

```
Valid Equipment OUI profile
```

```

```

```
Parameter Value
```

```
----- ----
```

```
OUI 00:1A:1E
```

### Command History

|----------------------------|-----------------------|-----------------------------------|
| Available on all platforms | Base operating system | Config mode on master controllers |

## show version

show version

### Description

Show the system software version.

### Syntax

No parameters.

### Example

```
(host) #show version
Aruba Operating System Software.
ArubaOS (MODEL: Dell Networking W-650 Controller-US), Version 6.1.0.0
Website: http://www.dell.com
Copyright (c) 2002-2011, Aruba Networks, Inc.
Compiled on 2011-04-28 at 00:18:36 PDT (build 28106) by p4build
```

```
ROM: System Bootstrap, Version CPBoot 1.0.0.0 (build 23274)
Built: 2010-01-19 11:11:41
Built by: p4build@re_client_23274
```

```
Switch uptime is 1 days 6 hours 2 minutes 4 seconds
Reboot Cause: User reboot.
Supervisor Card
Processor XLS 408 (revision B1) with 890M bytes of memory.
32K bytes of non-volatile configuration memory.
256M bytes of Supervisor Card System flash (model=NAND 256MB).
```

The output of this command includes the following information

| Parameter       | Description                                                   |
|-----------------|---------------------------------------------------------------|
| Model           | Controller model type.                                        |
| Version         | Version of ArubaOS software.                                  |
| ROM             | System bootstrap version.                                     |
| Switch Uptime   | Switch uptime (time elapsed since the last controller reset). |
| Reboot Cause    | Reason the controller was last rebooted.                      |
| Supervisor Card | Details for the controller's internal supervisor card.        |

### Command History

| All platforms | Base operating system | Enable and Config mode on local and master controllers |

## show via

```
show via
 version
 websessions
```

### Description

Displays VIA version and web session details.

### Syntax

| Parameter   | Description                                                                      | Range | Default |
|-------------|----------------------------------------------------------------------------------|-------|---------|
| version     | Displays the version of VIA client available on the controller.                  | —     | —       |
| websessions | Displays the list of users connected to the VIA controller using the VIA client. | —     | —       |

### Example

The following example displays the version of VIA client available on the controller.

```
(host) # show via version(host) (VIA Client WLAN Profile "example") #show via version
Default VIA Installer:

<aruba>
 <via>
 <platform>win32</platform>
 <version>1.0.0.23373</version>
 </via>
</aruba>
```

### Command History

This command was available in ArubaOS 5.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show vlan

show vlan <id>

### Description

This command shows a configured VLAN interface number, description and associated ports.

### Syntax

| Parameter | Description                         | Range  | Default |
|-----------|-------------------------------------|--------|---------|
| <id>      | Identification number for the VLAN. | 1-4094 | 1       |

### Usage Guidelines

Issue this command to show the selected VLAN configuration. The **VLAN** column lists the VLAN ID. The **Description** column provides the VLAN name or number and the **Ports** column shows the VLAN's associated ports. The **AAA Profile** column shows if a wired AAA profile has been assigned to a VLAN, enabling role-based access for wired clients connected to an untrusted VLAN or port on the controller.

```
(host) #show vlan
```

VLAN CONFIGURATION

| VLAN | Description | Ports                         | AAA Profile       |
|------|-------------|-------------------------------|-------------------|
| 1    | Default     | GE0/3-7 GE0/9 XG0/10-11 Pc0-7 | N/A               |
| 10   | VLAN0010    | GE0/8                         | N/A               |
| 20   | RAP_VLAN    |                               | N/A               |
| 25   | VLAN0025    | GE0/0                         | mac-auth-aaa-prof |
| 30   | VLAN0030    |                               | N/A               |
| 56   | VLAN0056    |                               | default           |
| 57   | VLAN0057    |                               | default           |
| 58   | VLAN0058    |                               | default           |

### Related Commands

```

# show vlan-assignment

show vlan-assignment

## Description

This command shows the number of clients assigned to a VLAN.

## Syntax

No parameters.

## Usage Guidelines

Issue this command to show the number of clients that are assigned to a VLAN.

```
(host) #show vlan-assignment
```

```
VLAN Assignment

VLAN #CLIENTS
---- -
10 0
```

## Related Commands

| All platforms | Base operating system | Enable or config mode on master or local controllers |

## show vlan-assignment-auth

show vlan-assignment-auth

### Description

This command shows the VLAN usage in the user authentication module.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to view all the VLAN IDs that are configured along with the current client count that uses that VLAN ID.

```
(host) #show vlan-assignment-auth
```

```
Vlan usage in AUTH
```

```

```

```
VLAN ID Usage
```

```
----- -
```

```
10 0
```

### Related Commands

```
(host) (config) #vlan
```

### Command History

This command was introduced in ArubaOS 6.3.

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master or local controllers |

# show vlan mapping

show vlan mapping

## Description

This command shows a configured VLAN name, its pool status, assignment type and the VLAN IDs assigned to the pool.

## Syntax

| Parameter | Description                         | Range  | Default |
|-----------|-------------------------------------|--------|---------|
| <id>      | Identification number for the VLAN. | 1-4094 | 1       |

## Usage Guidelines

Issue this command to show the selected VLAN configuration. The **VLAN Name** column displays the name of the VLAN pool. The **VLAN IDs** column lists the VLANs that are part of the pool.

```
(host) #show vlan mapping
```

Vlan Mapping Table

| VLAN Name    | Assignment Type | VLAN IDs |
|--------------|-----------------|----------|
| mygroup      | Hash            | 62, 94   |
| newpoolgroup | Even            |          |
| vlannametest | Even            | 62, 1511 |
| yourvlan     | N/A             | 62       |

## Related Commands

```

(host) (config) #vlan-name
```

## Command History

| Release     | Modification                                         |
|-------------|------------------------------------------------------|
| ArubaOS 3.0 | Command introduced.                                  |
| ArubaOS 6.2 | The <b>Assignment Type</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or config mode on master or local controllers |

## show vlan status

```
show vlan status <id>
```

### Description

This command shows the current status of all VLANs on the controller.

### Syntax

No parameters.

### Usage Guidelines

Issue this command to show the status of VLANs on the controller. The **VLANID** column displays the VLAN ID name or number. The **IP Address** column provides the VLAN's IP address. The **Adminstate** column indicates if the VLAN is enabled or disabled. The **Operstate** column indicates if the VLAN is currently up and running. The **PortCount** column shows how many ports are associated with the VLAN. The **Nat Inside** column displays whether source Nat is enabled for the VLAN interface. If Nat is enabled, all the traffic passing through this VLAN interface is the source natted to the outgoing interface's IP address.

```
(host) #show vlan status
```

Vlan Status

| VlanId  |       | IPAddress                   | Adminstate | Operstate | PortCount | Nat Inside | Mode    |
|---------|-------|-----------------------------|------------|-----------|-----------|------------|---------|
| Ports   |       |                             | AAA        | Profile   |           |            |         |
| -----   |       | -----                       | -----      | -----     | -----     | -----      | ----    |
| 1       |       | unassigned/unassigned       | Enabled    | Up        | 9         | Disabled   | Regular |
| GE1/0   | GE1/2 | GE1/5-9                     | XG1/10-11  | Pc0       | Pc2-5     | Pc7        | N/A     |

# show vlan summary

show vlan summary

## Description

This command shows the number of existing VLANs.

## Syntax

| Parameter                | Description                                     |
|--------------------------|-------------------------------------------------|
| Number of existing VLANs | The number of existing VLANs on the controller. |

## Usage Guidelines

Issue this command to show the number of existing VLANs on the controller.

```
(host) #show vlan summary
```

```
Number of existing VLANs :13
```

## show vlan-bwcontract-explist

show vlan-bwcontract-explist [internal]

### Description

Show entries in the VLAN bandwidth contracts MAC exception lists.

### Syntax

| Parameter | Description                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| internal  | Include the optional <b>internal</b> parameter to display the MAC addresses in the internal, preconfigured VLAN bandwidth contracts MAC exception list. |

### Example

The following command displays the MAC addresses in the internal MAC exception list.

```
(host) (config) #show vlan-bwcontract-explist internal
```

```
VLAN BW Contracts Internal MAC Exception List
```

```

```

```
MAC address
```

```

```

```
01:80:C2:00:00:00
```

### Command History

Command introduced in ArubaOS 6.0.

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Enable or Config mode on master or local controllers |

## show voice alg-based-cac

show voice alg-based-cac

### Description

Displays the status of the VoIP signaling based Call Admission Control (CAC).

### Syntax

No parameters.

### Example

The output of this command shows the status of the ALG based CAC.

```
(host) #show voice alg-based-cac
```

WARNING: This command will be deprecated, please use show ucc commands instead.

```
Voice alg-based-cac:enable
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.2 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice call-cdrs

```
show voice call-cdrs
 bssid <bssid_string>
 cid <cid>
 count <count>
 detail
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 proto <proto_id>
 rtpa
 sta <mac>
```

### Description

Displays detailed call records of voice client.

### Syntax

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid_string> | Filter records based on BSSID of voice clients.                                                                                                                                                                                                                                                                                                                                                             |
| cid <cid>            | View the detailed call records for a specific client based on the Call Detail Record (CDR) ID.                                                                                                                                                                                                                                                                                                              |
| count <count>        | Specify the number of records to be displayed by entering a number.                                                                                                                                                                                                                                                                                                                                         |
| detail               | <p>Include this parameter to view the following additional information for each call record.</p> <ul style="list-style-type: none"><li>• Reason</li><li>• Codec</li><li>• Band</li><li>• Setup Time (sec)</li><li>• Re-Assoc</li><li>• Initial-BSSID</li><li>• Initial-ESSID</li><li>• Initial-AP Name</li><li>• Call Type</li><li>• Src port</li><li>• Dest port</li><li>• DSCP</li><li>• WMM AC</li></ul> |
| essid <essid_string> | Filter records based on ESSID of voice clients.                                                                                                                                                                                                                                                                                                                                                             |

| Parameter          | Description                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extn <extn_string> | Filter records based on the extension of a voice client.                                                                                                                                                                                         |
| ip <ipaddr>        | Filter records based on the IP address of a voice client.                                                                                                                                                                                        |
| proto <proto_id>   | View detailed records filtered on protocol including all of the following: <ul style="list-style-type: none"> <li>• sip</li> <li>• svp</li> <li>• noe</li> <li>• sccp</li> <li>• vocera</li> <li>• h323</li> <li>• lync</li> </ul>               |
| rtpa               | Include this parameter to view the voice call quality reports based on the call quality analysis from the RTP media streams.<br><b>NOTE:</b> This parameter is applicable only if Real Time Call Quality Analysis is enabled on the voice calls. |
| sta <mac>          | Filter records based on the MAC address of a voice client.                                                                                                                                                                                       |

## Example

The first example shows the breakdown of Lync data transfer sessions into voice, video, desktop-sharing, and file-transfer. For Lync ALG calls, if there are other sessions in addition to voice, details of such sessions are shown in a different row with the same CDR ID.

```
(host) #show voice call-cdrs proto lync
```

Voice Client(s) CDRs

```

CDR Id Client IP Client Name ALG Dir Called to Status

18 10.16.33.62 1000 lync IC 1001 SUCC
17 10.16.33.61 1001 lync OG 1000 SUCC
16 10.16.33.62 1000 lync IC 1001 ABORTED
 10.16.33.62 1000 lync IC 1001 ABORTED
15 10.16.33.61 1001 lync OG 1000 ABORTED
 10.16.33.61 1001 lync OG 1000 ABORTED
```

```

## show voice call-counters

show voice call-counters

### Description

Displays outgoing, incoming and terminated call counter details. The total calls equals the sum of the calls originated and terminated. It also equals the sum of the active, success, failed, blocked, aborted, and forwarded calls.

### Syntax

No parameters.

### Example

The output of this command shows call counter statistics.

```
(host) # show voice call-counters
```

```
System Wide Voice Call Counters
```

```

Total Call Originated Call Terminated Active Success Failed Blocked Aborted Forwarded

31 16 15 0 29 0 0 2 0
```

## show voice call-density

```
show voice call-density
 bssid <bssid_string>
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 proto <proto_id>
```

### Description

Displays call density report for voice calls.

### Syntax

| Parameter            | Description                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid_string> | Filter records based on BSSID of voice clients.                                                                                                                                                                |
| essid <essid_string> | Filter records based on ESSID of voice clients.                                                                                                                                                                |
| extn <extn_string>   | Filter records based on the extension of a voice client.                                                                                                                                                       |
| ip <ipaddr>          | Filter records based on the IP address of an AP.                                                                                                                                                               |
| proto <proto_id>     | Filter records based on a VOIP protocol. Supported values are: <ul style="list-style-type: none"><li>• sip</li><li>• svp</li><li>• noe</li><li>• sccp</li><li>• vocera</li><li>• h323</li><li>• lync</li></ul> |

### Example

The output of this command shows call density report for extension 3015.

```
(host) # show voice call-density extn 3015
```

VoIP Call Density Report for Client '3015'

## show voice call-perf

```
show voice call-perf
 bssid <bssid_string>
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 proto <proto_id>
```

### Description

Displays the performance of voice calls of all clients connected to the controller. You can filter the report based on BSSID, ESSID, extension, IP address or the VOIP protocol type.

### Syntax

| Parameter            | Description                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid_string> | Filter records based on BSSID of voice clients.                                                                                                                                                                |
| essid <essid_string> | Filter records based on ESSID of voice clients.                                                                                                                                                                |
| extn <extn_string>   | Filter records based on the extension of a voice client.                                                                                                                                                       |
| ip <ipaddr>          | Filter records based on the IP address of an AP.                                                                                                                                                               |
| proto <proto_id>     | Filter records based on a VOIP protocol. Supported values are: <ul style="list-style-type: none"><li>• sip</li><li>• svp</li><li>• noe</li><li>• sccp</li><li>• vocera</li><li>• h323</li><li>• lync</li></ul> |

### Example

The output of this command shows call performance report for extension 3015.

```

## show voice call-quality

```
show voice call-quality
 bssid <bssid_string>
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 proto <proto_id>
 rtpa
 sta <mac>
```

### Description

Displays voice call quality for each call over a period of time.

### Syntax

| Parameter            | Description                                                                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid_string> | Filter records based on BSSID of voice clients.                                                                                                                                                                                                  |
| essid <essid_string> | Filter records based on ESSID of voice clients.                                                                                                                                                                                                  |
| extn <extn_string>   | Filter records based on the extension of a voice client.                                                                                                                                                                                         |
| ip <ipaddr>          | Filter records based on the IP address of a voice client.                                                                                                                                                                                        |
| proto <proto_id>     | View detailed records filtered on protocol including all of the following: <ul style="list-style-type: none"><li>• sip</li><li>• svp</li><li>• noe</li><li>• sccp</li><li>• vocera</li><li>• h323</li><li>• lync</li></ul>                       |
| rtpa                 | Include this parameter to view the voice call quality reports based on the call quality analysis from the RTP media streams.<br><b>NOTE:</b> This parameter is applicable only if Real Time Call Quality Analysis is enabled on the voice calls. |
| sta <mac>            | Filter records based on the MAC address of a voice client.                                                                                                                                                                                       |

### Example

The output of this command shows call quality report for calls made by extension 3015.

```
(host) # show voice call-quality extn 3015
```

```
Voice Client(s) Call Quality Reports
```

```

```

## Command History

| Version       | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| ArubaOS 3.3.1 | Command introduced.                                                       |
| ArubaOS 6.0   | The rtpa and sta parameters were introduced.                              |
| ArubaOS 6.3   | Under the <b>proto</b> parameter, the <b>lync</b> protocol is introduced. |

## Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice call-stats

```
show voice call-stats
 bssid <bssid_string>
 cip <cipaddr>
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 proto <proto_id>
 sta <mac>
```

### Description

Displays voice call statistics for each client.

### Syntax

| Parameter            | Description                                                                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bssid <bssid_string> | Filter records based on BSSID of a voice client.                                                                                                                                                                           |
| cip <cipaddr>        | Filter records based on a client's IP address.                                                                                                                                                                             |
| essid <essid_string> | Filter records based on ESSID of a voice client.                                                                                                                                                                           |
| extn <extn_string>   | Filter records based on the extension of a voice client.                                                                                                                                                                   |
| ip <ipaddr>          | Filter records based on the IP address of an AP.                                                                                                                                                                           |
| proto <proto_id>     | View detailed records filtered on protocol including all of the following: <ul style="list-style-type: none"><li>• sip</li><li>• svp</li><li>• noe</li><li>• sccp</li><li>• vocera</li><li>• h323</li><li>• lync</li></ul> |
| sta <mac>            | Filter records based on the MAC address of a voice client.                                                                                                                                                                 |

### Example

The output of this command shows call quality report for calls made by extension 6210.

```
(host) # show voice call-stats
```

```
Voice Client(s) Call Statistics
```

| Client IP    | Client MAC        | Client Name | ALG  | Originated | Terminated | Active | Failed |
|--------------|-------------------|-------------|------|------------|------------|--------|--------|

## show voice client-status

```
show voice client-status
 active-only
 bssid <bssid_string>
 essid <essid_string>
 extn <extn_string>
 ip <ipaddr>
 proto <proto_id>
 sta <mac>
```

### Description

Displays list of voice clients and their status. You can also view details of a specific voice client.

### Syntax

| Parameter            | Description                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| active-only          | Filter records based on active voice clients                                                                                                                                                                   |
| bssid <bssid_string> | Filter records based on BSSID of a voice client.                                                                                                                                                               |
| essid <essid_string> | Filter records based on ESSID of a voice client.                                                                                                                                                               |
| extn <extn_string>   | Filter records based on the extension of a voice client.                                                                                                                                                       |
| ip <ipaddr>          | Filter records based on the IP address of a voice client.                                                                                                                                                      |
| proto <proto_id>     | Filter records based on a VOIP protocol. Supported values are: <ul style="list-style-type: none"><li>• sip</li><li>• svp</li><li>• noe</li><li>• sccp</li><li>• vocera</li><li>• h323</li><li>• lync</li></ul> |
| sta <mac>            | Filter records based on the MAC address of a voice client.                                                                                                                                                     |

### Example and Usage Guidelines

The output of this command shows details about all the voice clients on the controller.

In case of Lync voice clients, before each call leg is created, Call Admission Control (CAC) is performed if enabled. If CAC, which can be either call-count based or bandwidth based, is within limit, then the call leg is created with QoS enabled. If the call leg is not created the traffic for this call goes in best effort mode, signified by a **b** flag in the output shown in the second example . Note that during a call, if CAC is available, and if any message received from the Lync Network Enlightenment (LNE) senses the availability of CAC, the call leg is created, the media is prioritized, and the **b** flag is removed.

```
(host) #show voice client-status
```

#### Voice Client(s) Status

```

Client(IP) Client(MAC) Client Name ALG Server(IP) Registration State

# show voice dialplan-profile

show voice dialplan-profile <profile>

## Description

Displays list of SIP voice dialplan. You can also specify a dialplan to view configuration.

## Syntax

No parameter.

## Example

The output of this command shows list of all dialplans and the configuration of long distance dialplan.

```
(host) (config) #show voice dialplan-profile
Dialplan Profile List

Name References Profile Status
---- -
default 1
extenstion 0
local 0
longDistance 0
Total:4

(host) (config) #show voice dialplan-profile longDistance
Dialplan Profile "longDistance"

Parameter Value

dialplan 102 +1XXXXXXXXXX 9%e
```

## Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 5.0 | Command introduced. |

## show voice logging

show voice logging

### Description

Displays the MAC address of the voice client that has logging enabled.

### Syntax

No parameters.

### Example

The output of this command shows the MAC address of the voice client that has logging enabled.

```
(host) #show voice logging

VoIP Logging

Parameter Value

Client's MAC Address for Logging 11:22:33:44:55:67
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice msg-stats

```
show voice msg-stats
 lync {bssid <bssid_string> | cip <cipaddr> | essid <essid_string> | ip <ipaddr> | sta
 <mac>}
 sccp {bssid <bssid_string> | cip <cipaddr> | essid <essid_string> | ip <ipaddr> | sta
 <mac>}
 sip {bssid <bssid_string> | cip <cipaddr> | essid <essid_string> | ip <ipaddr> | sta <mac>}
```

### Description

Displays voice client message statistics for each client using either Lync ALG, Signaling Connection Control Part (SCCP), or Session Initiation Protocol (SIP).

### Syntax

| Parameter            | Description                                                |
|----------------------|------------------------------------------------------------|
| bssid <bssid_string> | Filter records based on BSSID of a voice client.           |
| cip <cipaddr>        | Filter records based on a client's IP address.             |
| essid <essid_string> | Filter records based on ESSID of a voice client.           |
| ip <ipaddr>          | Filter records based on the IP address of an AP.           |
| sta <mac>            | Filter records based on the MAC address of a voice client. |

### Example

The output of the command in the first example below shows voice message statistics for essid 'test' filtered on SCCP protocol. In both examples, the output is divided into multiple sections to better fit on the pages of this document. In the actual command-line interface, it appears in a single, long table.

```
(host) # show voice msg-stats sccp essid test
```

#### SCCP Voice Client(s) Msg Statistics

```

Client Name Client IP AP Name BSSID ESSID Register Register Ack

## show voice real-time-analysis

show voice real-time-analysis [sta <client MAC address>]

### Description

Displays the call quality parameters based on the call quality analysis on the RTP media streams for voice calls.

### Syntax

| Parameter | Description                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sta       | View the detailed real time call quality analysis report for a voice client based on the MAC address. You can also view the average call quality values for all the clients without passing the MAC address.<br><b>NOTE:</b> The real time call quality reports are supported and applicable only for clients in decrypt-tunnel and split-tunnel modes. |

### Example

The output of this command shows the detailed call quality parameters based on the RTP media stream for a specific voice client.

```
(host) #show voice real-time-analysis sta 1c:ab:a7:2d:75:6b
```

WARNING: This command will be deprecated, please use show ucc commands instead

Real-Time Analysis Detailed Report

| Time            | Jitter (D) (usec) | Pkt-loss (D) (%) | Delay (D) (usec) | UCC Score (D) | Forward mode |
|-----------------|-------------------|------------------|------------------|---------------|--------------|
| Mar 15 17:05:34 | 2.000             | 1.000            | 255.000          | 88.360        | tunnel       |

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice real-time-analysis-config

show voice real-time-analysis-config

### Description

Displays the status of Real Time Call Quality Analysis configuration.

### Syntax

No parameters.

### Example

The output of this command shows the status of Real Time Call Quality Analysis configuration on a controller.

```
(host) #show voice real-time-config
```

```
Configure Real-Time Analysis
```

```

```

```
Parameter Value
```

```

```

```
Real-Time Analysis of voice calls Enabled
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice rtcp-inactivity

`show voice rtcp-inactivity`

### Description

Displays the status of RTCP protocol.

### Syntax

No parameters.

### Example

The output of this command shows the status of RTCP protocol.

```
(host) #show voice rtcp-inactivity
```

```
Voice rtcp-inactivity:disable
```

### Command History

| Version       | Description         |
|---------------|---------------------|
| ArubaOS 3.3.1 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice sip

show voice sip

### Description

Displays the SIP settings on the controller.

### Syntax

No parameters.

### Example

The output of this command shows the SIP settings on a controller.

```
(host) #show voice sip
```

```
SIP settings
-----s
Parameter Value

Session Timer Enabled
Session Expiry 300 sec
Dialplan Profile N/A
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice sip-midcall-req-timeout

show voice sip-midcall-req-timeout

### Description

Displays the status of the SIP mid-call request timeout configuration on the controller.

### Syntax

No parameters.

### Example

The output of this command shows the status of the SIP mid-call request timeout configuration on a controller.

```
(host) #show voice sip-midcall-req-timeouts
```

```
Voice sip-midcall-req-timeout:disable
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |

| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice statistics

```
show voice statistics [cac | sip-dialplan-hits | tspec-enforcement]
```

### Description

Displays the CAC, UDP SIP dial plan hits, and TSPEC enforced voice statistics.

### Syntax

| Parameter         | Description                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cac               | Displays the dropped SIP Invites and SIP Status Code for both server and the client side.<br><b>Note:</b> This filter supports only the SIP protocol and will work only if CAC is enabled for the parameters. |
| sip-dialplan-hits | Displays the statistics of SIP dialplan hits.                                                                                                                                                                 |
| tspec-enforcement | Displays the statistics of the number of TSPEC requests accepted, rejected, or denied.                                                                                                                        |

### Example

The output of this command shows statistics for TSPEC enforced calls.

```
(host) # show voice statistics tspec-enforcement
```

```
TSPEC Enforcement statistics
```

```

```

| Name                                        | Value |
|---------------------------------------------|-------|
| ----                                        | ----- |
| TSPEC ADDTS Request                         | 16    |
| TSPEC accepted                              | 16    |
| TSPEC denied due to CAC                     | 0     |
| TSPEC enforcement timer events              | 2     |
| Calls established within enforcement period | 0     |
| TSPEC deleted after enforcement period      | 1     |

### Command History

| Version       | Description         |
|---------------|---------------------|
| ArubaOS 3.3.1 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                                         |
|---------------|-----------------------------------------|------------------------------------------------------|
| All platforms | This command requires the PEFNG license | Config or Enable mode on master or local controllers |

## show voice trace

```
show voice trace
 lync [count <num> | ip <ipaddr> | mac <macaddr>]
 sccp [count <num> | ip <ipaddr> | mac <macaddr>]
 sip [count <num> | ip <ipaddr> | mac <macaddr>]
```

### Description

Displays the signaling message trace details for either Lync ALG, Signaling Connection Control Part (SCCP), or Session Initiation Protocol (SIP) clients.

### Syntax

| Parameter     | Description                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------|
| count <num>   | View the specified number of the latest SIP, SCCP, or Lync voice client messages. Specify an integer value. |
| ip <ipaddr>   | Specify the IP address of a client to display its SIP, SCCP, or Lync voice client messages.                 |
| mac <macaddr> | Specify the IP address of a client to display its SIP, SCCP, or Lync voice client messages.                 |

### Example

The output of this command shows signaling message trace. The first example shown is for a SIP client.

```
(host) #show voice trace sip count 4
```

SIP Voice Client(s) Message Trace

```

ALG Client Name Client(MAC) Client(IP) Event Time
--- -
SIP 6201 00:24:7d:99:49:01 10.15.20.59 Aug 17 10:21:22

## show vpdn pptp configuration

show vpdn pptp configuration

### Description

Displays the PPTP configuration on the controller.

### Syntax

No parameters.

### Example

The output of this command shows the L2TP tunnel configuration.

```
(host) # show vpdn pptp configuration
```

```
Enabled
Hello timeout: 30 seconds
DNS primary server: 10.15.1.1
DNS secondary server: 10.15.1.200
WINS primary server: 0.0.0.0
WINS secondary server: 0.0.0.0
PPP client authentication methods:
 MSCHAP
 MSCHAPv2
MPPE Configuration
 128 bit encryption enabled
IP LOCAL POOLS
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |

## show vpdn pptp local pool

```
show vpdn pptp local pool <pool_name>
```

### Description

Displays the IP address pool for VPN users using Point-to-Point Tunneling Protocol.

### Syntax

No parameters.

### Example

The output of this command shows the all IP address pools for VPN users.

```
(host) # show vpdn pptp local pool

IP addresses used in pool localgroup
0 IPs used - 11 IPs free - 11 IPs configured
```

### Command History

This command was available in ArubaOS 3.0

### Command Information

| Platforms     | Licensing             | Command Mode                                         |
|---------------|-----------------------|------------------------------------------------------|
| All platforms | Base operating system | Config or Enable mode on master or local controllers |

## show vpn-dialer

```
show vpn-dialer <dialer_name>
```

### Description

Displays the VPN dialer configuration for users using VPN dialers.

### Syntax

No parameters.

### Example

The output of this command shows the VPN dialer configuration for remote Users.

```
(host) # show vpn-dialer remoteUser
```

```
remoteUser

Attribute Value

PPTP disabled
L2TP enabled
DNETCLEAR disabled
WIREDNOWIFI disabled
PAP enabled
CHAP enabled
MSCHAP enabled

## show vrrp

```
show vrrp {{<vrid>[statistics]}}|ipv6{{<vrid>|stats[all]}}|stats[all]|summary}
```

### Description

Displays the list of all VRRP configuration on the controller. To view a specific VRRP configuration, specify the VRID number.

### Syntax

| Parameter | Description                                              | Range | Default |
|-----------|----------------------------------------------------------|-------|---------|
| <vrid>    | Displays the Virtual Router Id.                          | 1-255 | —       |
| ipv6      | Display VRRP information for IPv6 address.               | —     | —       |
| stats     | Displays the operational statistics of the VRRP.         | —     | —       |
| summary   | Displays the number of vrrp instances for IPv4 and IPv6. | —     | —       |

### Example

The output of the following command shows the VRRP IPv4 instance with vrid 1.

```
(host) (config-vrrp)#show vrrp
Virtual Router 1:
Description
Admin State UP, VR State BACKUP
IP Address 0.0.0.0, MAC Address 00:00:5e:00:01:01, vlan 99
Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
Hold time 45 sec
Auth type NONE *****
tracking is not enabled
```

The output of the following command shows the statistics for IPv4 vrrp instance with vrid 10.

```
(host) # show vrrp 10 statistics
Virtual Router 10:
Admin State UP, VR State MASTER
Advertisements:
Sent: 249562 Received: 475
Zero priority sent: 0 Zero priority received: 0
Lower IP address received 475 Lower Priority received 3
Tracking priority overflow: 0
Advertisements received errors:
Interval mismatch 0 Invalid TTL 0
Invalid packet type 0 Authentication failure 0
Invalid auth type 0 Mismatch auth type 0
Invalid VRRP IP address 0 Invalid packet length 0
VRRP Up timestamp: Fri Aug 23 15:49:27 2013
Master Up timestamp: Mon Aug 26 11:59:44 2013
Last advertisement sent timestamp: Mon Aug 26 16:38:55 2013
Last advertisement received timestamp: Mon Aug 26 11:59:44 2013
Current time: Mon Aug 26 16:38:55 2013
Number times became VRRP Master: 2
```

The output of the following command provides information about IPv6 VRRP instances.

```
(host) (config) # show vrrp ipv6
Virtual Router 1:
 Description
 Admin State DOWN, VR State INIT
 IPv6 Address ::
 MAC Address 00:00:5e:00:02:01, vlan 0
 Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
 tracking is not enabled
Virtual Router 23:
 Description
 Admin State DOWN, VR State INIT
 IPv6 Address ::
 MAC Address 00:00:5e:00:02:17, vlan 0
 Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
 tracking is not enabled
Virtual Router 255:
 Description
 Admin State UP, VR State MASTER
 IPv6 Address 2006::25
 MAC Address 00:00:5e:00:02:ff, vlan 521
 Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
 tracking is not enabled
```

The output of the following command shows the statistics for IPv6 VRRP instances.

```
(host) #show vrrp ipv6 stats all
Virtual Router 1:
Admin State DOWN, VR State INIT
Advertisements:
Sent: 0 Received: 0
Zero priority sent: 0 Zero priority received: 0
Lower IP address received 0 Lower Priority received 0
Tracking priority overflow: 0
Advertisements received errors:
Interval mismatch 0 Invalid TTL 0
Invalid packet type 0
Invalid VRRP IP address 0 Invalid packet length 0
VRRP Up timestamp: N/A, DOWN
Master Up timestamp: N/A, not MASTER
Last advertisement sent timestamp: never
Last advertisement received timestamp: never
Current time: Wed Sep 25 19:40:42 2013
Number times became VRRP Master: 0
Virtual Router 23:
Admin State DOWN, VR State INIT
Advertisements:
Sent: 0 Received: 0
Zero priority sent: 0 Zero priority received: 0
Lower IP address received 0 Lower Priority received 0
Tracking priority overflow: 0
Advertisements received errors:
Interval mismatch 0 Invalid TTL 0
Invalid packet type 0
Invalid VRRP IP address 0 Invalid packet length 0
VRRP Up timestamp: N/A, DOWN
Master Up timestamp: N/A, not MASTER
Last advertisement sent timestamp: never
Last advertisement received timestamp: never
Current time: Wed Sep 25 19:40:42 2013
Number times became VRRP Master: 0
```

The output of the following command shows VRRP IPv4 and IPv6 instances.

```
(host) (config) #show vrrp summary
```

Number of existing VRRP IPv4 instances : 2  
Number of existing VRRP IPv6 instances : 3

The output of the following command shows the configuration for all IPv6 VRRP instances.

```
(host) #show vrrp ipv6
Virtual Router 1:
 Description
 Admin State DOWN, VR State INIT
 IPv6 Address ::
 MAC Address 00:00:5e:00:02:01, vlan 0
 Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
 tracking is not enabled
Virtual Router 23:
 Description
 Admin State DOWN, VR State INIT
 IPv6 Address ::
 MAC Address 00:00:5e:00:02:17, vlan 0
 Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
 tracking is not enabled
Virtual Router 255:
 Description
 Admin State UP, VR State MASTER
 IPv6 Address 2006::25
 MAC Address 00:00:5e:00:02:ff, vlan 521
 Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
 tracking is not enabled
```

The output of the following command shows the statistics for IPv4 VRRP instances.

```
(host) #show vrrp stats all
Virtual Router 1:
Admin State DOWN, VR State INIT
Advertisements:
Sent: 0 Received: 0
Zero priority sent: 0 Zero priority received: 0
Lower IP address received 0 Lower Priority received 0
Tracking priority overflow: 0
Advertisements received errors:

## show web-cc

```
show web-cc
 categories
 reputation
 stats
 status
 global-bandwidth-contract all|{web-cc-category <category>}|{web-cc-reputation <reputation>}
```

### Description

Display information about web content (web-cc) classification settings, category and reputation types, classification statistics and bandwidth contracts.

### Syntax

| Parameter                         | Description                                                                                                                  |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| categories                        | Display the category index number and the category name for each category type.                                              |
| reputation                        | Display the different reputation levels, and the range of reputation scores associated with each level.                      |
| stats                             | Display counters for web content traffic and web content classification table statistics                                     |
| status                            | Display information about the current operational status of the web content classification feature.                          |
| global-bandwidth-contract         | Display settings for global bandwidth contracts assigned to web content classification category types and reputation levels. |
| all                               | Show all bandwidth contracts                                                                                                 |
| web-cc-category<br><category>     | Display information for the specified web-cc category bandwidth contract.                                                    |
| web-cc-reputation<br><reputation> | Display information for the specified web-cc reputation bandwidth contract.                                                  |

### Usage Guidelines

The web content classification feature classifies all (HTTP) web traffic on the network. The output of the **show web-cc** command displays information about Webroot classification categories and risk reputation levels, bandwidth contracts, and the web content classification cache and database.

### Example

The following command shows the global bandwidth contracts applied to upstream and downstream traffic matching the **music** content category.

```
(host)#show web-cc global-bandwidth-contract web-cc-category music
Web-cc Global Bandwidth Contract

Web-cc Category/Reputation Direction Rate (bits/second) Contract Id

```

```

web-cc-category music Upstream 55000000 music-2126 2
web-cc-category music Downstream 20000000 music-745c 1

```

The output of the **show web-cc** command varies, depending upon the parameters specified. The following table describes the information displayed in the output of this command when that parameter is included.

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| categories                | <p>Include this parameter to display the following information categories in the command output:</p> <ul style="list-style-type: none"> <li>• <b>Name:</b> names of the available web content classification categories</li> <li>• <b>Web Category ID:</b> ID number associated with a category name.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| reputation                | <p>Include this parameter to display the following information categories in the command output:</p> <ul style="list-style-type: none"> <li>• <b>RiskLevel:</b> names of the available web content classification risk levels</li> <li>• <b>Score:</b> Range of risk scores associated with a risk level</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## show web-server

```
show web-server
 profile
 statistics
```

### Description

Displays the configuration and statistics of the controller's web server.

### Syntax

| Parameter  | Description                                                                                         | Range | Default |
|------------|-----------------------------------------------------------------------------------------------------|-------|---------|
| profile    | Displays the web server configuration profile.                                                      | —     | —       |
| statistics | Displays the web server statistics. This command helps to troubleshoot Captive Portal scale issues. | —     | —       |

### Example

The output of this command shows the web-server configuration.

```
(host) # show web-server profile
```

```
Web Server Configuration
```

```

```

| Parameter                                     | Value             |
|-----------------------------------------------|-------------------|
| -----                                         | -----             |
| Cipher Suite Strength                         | high              |
| SSL/TLS Protocol Config                       | sslsv3 tlsv1      |
| Switch Certificate                            | default           |
| Captive Portal Certificate                    | default           |
| Management user's WebUI access method         | username/password |
| User session timeout <30-3600> (seconds)      | 900               |
| Maximum supported concurrent clients <25-320> | 25                |
| Enable WebUI access on HTTPS port (443)       | false             |
| Web Lync Listen Port <1024-65535>             | 0                 |
| Enable bypass captive portal landing page     | false             |

The output of this command displays the web-server statistics.

```
(host) #show web-server statistics
```

```

### Usage Guidelines

Use this command to display the contents of the control plane security whitelist. To view information for a single AP, use the command **show whitelist-db cpsec mac-address <mac-address>**. To view a list of all secure APs on your controller, use the command **show whitelist-db cpsec**. If your deployment includes both master and local controllers, then the campus AP whitelist on every controller contains an entry for every secure AP on the network, regardless of the controller to which it is connected.

### Example

The output of the following command shows the campus AP whitelist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) #show whitelist-db cpsec mac-address 00:16:CF:AF:3E:E1
```

# Control-Plane Security Whitelist-entry Details

```

MAC-Address AP-Group AP-Name Enable State

00:16:CF:AF:3E:E1 employee ap-office1 Enabled cert-cont-cert

```

```

Cert-Type Description Revoke Text Last Updated

switch-cert Fri Oct 16 01:21:09 2009

```

Whitelist Entries: 1

The output of this command includes the following parameters:

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## show whitelist-db cpsec-local-switch-list

```
show whitelist-db cpsec-local-switch-list [mac-address <mac-address>]
```

### Description

Display the list of local controllers with APs using the control plane security feature.

### Syntax

| Parameter                 | Description                                                      |
|---------------------------|------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the local controller whose data you want to view. |

### Usage Guidelines

When you use the control plane feature on a network with both master and local controllers, the master controller maintains a whitelist of local controllers with APs using control plane security. When you change a campus AP whitelist on any controller, that controller contacts the master controller to check the local switch whitelist, then contacts every other controller on the local switch whitelist to notify it of the change. This allows an AP to move between local controllers and still stay connected to the secure network.

To view information for a single local controller, use the command **show whitelist-db cpsec-local-switch-list mac-address <mac-address>**. To view a list of all local controllers, use the command **show whitelist-db cpsec-local-switch-list**.

### Example

The following command shows information for all local controllers in the local controller whitelist:

```
(host) #show whitelist-db cpsec-local-switch-list
Registered Local Switch Details

MAC-Address IP-Address Sequence Number Remote Sequence Number NULL Update Count

00:0b:86:51:a5:4c 10.3.53.2 3 1

Local Purge Remote Purge Remote Last-Seq Last Update Sent Last Update Received

0 0 2 Mon May 4 13:33:29 2013 Mon May 4 13:33:18 2013
0 0 2 Mon May 4 13:32:55 2013 Mon May 4 13:32:19 2013

Whitelist Entries: 2
```

The output of this command includes the following information:

| Parameter   | Description                          |
|-------------|--------------------------------------|
| MAC-Address | MAC address of the local controller. |
| IP-Address  | IP address of the local controller.  |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sequence Number        | The number of times the local controller in the whitelist received and acknowledged a campus AP whitelist change from the master controller. In the example above, both local controllers received and acknowledged three campus AP whitelist changes sent from the master controller.                                                                                                                                                                                                                     |
| Remote Sequence Number | The number of times that the master controller has received and acknowledged a campus AP whitelist change from the local controller in the whitelist. In the example above, the master controller received and acknowledged a single campus AP whitelist change from the local controller with the MAC address 00:0b:86:51:a5:4c.                                                                                                                                                                          |
| Null Update Count      | The number of times the controller has checked its control plane security whitelist and found nothing to synchronize with the remote controller. By default, the controller compares its control plane security whitelist against whitelists on other controllers every minute. If the null update count reaches 5, the controller will send an "empty sync" heartbeat to the remote controller to ensure the sequence numbers on both controllers are the same, then reset the null update count to zero. |

## show whitelist-db cpsec-master-switch-list

```
show whitelist-db cpsec-master-switch-list [mac-address <mac-address>]
```

### Description

Display the master switch list whitelist on local controllers with APs using the control plane security feature.

### Syntax

| Parameter                 | Description                           |
|---------------------------|---------------------------------------|
| mac-address <mac-address> | MAC address of the master controller. |

### Usage Guidelines

When you use the control plane feature on a network with both master and local controllers, each local controller has a master switch whitelist which contains the IP and MAC addresses of its master controller. If your network has a redundant master controller, then this whitelist will contain more than one entry.

To view information for a single master controller, use the command **show whitelist-db cpsec-master-switch-list mac-address <mac-address>**. To view a list of all master controllers, use the command **show whitelist-db cpsec-master-switch-list**.

### Example

The following command shows that the local controllers have a single master controller with the IP address 10.3.53.3:

```
(host) #show whitelist-db cpsec-master-list
Registered Master Switch Details

Active MAC-Address IP-Address Sequence Number Remote Sequence Number NULL Update
Count

1 00:0b:86:61:ed:6c 10.3.53.11 1 3 1
Local Purge Remote Purge Remote Last-Seq Last Update Sent Last Update Received

0 0 1 Tue Aug 2 13:33:29 2012 Tue Aug 2 13:33:18 2012
```

The output of this command includes

### Syntax

| Parameter   | Description                           |
|-------------|---------------------------------------|
| MAC-Address | MAC address of the master controller. |
| IP-Address  | IP address of the master controller.  |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sequence Number        | The number of times the master controller in the whitelist received and acknowledged a campus AP whitelist change from the local controller. In the example above, the master controller received and acknowledged one campus AP whitelist change from the local controller.                                                                                                                                                                                                                               |
| Remote Sequence Number | The number of times that the local controller has received and acknowledged a campus AP whitelist change from the master controller in the whitelist. In the example above, the local controller received and acknowledged three campus AP whitelist updates from the master controller.                                                                                                                                                                                                                   |
| Null Update Count      | The number of times the controller has checked its control plane security whitelist and found nothing to synchronize with the master controller. By default, the controller compares its control plane security whitelist against whitelists on other controllers every minute. If the null update count reaches 5, the controller will send an "empty sync" heartbeat to the remote controller to ensure the sequence numbers on both controllers are the same, then reset the null update count to zero. |

## show whitelist-db cpsec-seq

show whitelist-db cpsec-seq

### Description

Display the current sequence number for the master or local controller whitelists.

### Syntax

No Parameters

### Usage Guidelines

The current sequence number in the **Sequence Number Details** table shows the number of changes to the campus AP whitelist made on this controller.

Each controller compares its campus AP whitelist against whitelists on other controllers every two minutes. If a controller detects a difference, it will send its changes to the other controllers on the network. If all other controllers on the network have successfully received and acknowledged all whitelist changes made on this controller, every entry in the **sequence number** column in the controller whitelist will have the same value as the number displayed in the **Sequence Number Details** table. If a controller in the master or local controller whitelist has a lower sequence number, that controller may still be waiting to complete its update, or its update acknowledgement may not have yet been received.

### Example

The output of the first command below shows that the campus AP whitelist has been updated 3 times on the master controller. The second command shows the local controller list on the master controller, and verifies that both local controllers have received and acknowledged all three of these changes.

```
(host) #show whitelist-db cpsec-seq
```

```
Sequence Number Details
```

```

```

| Table Name | Current Seq Number |
|------------|--------------------|
|------------|--------------------|

```

```

|                 |   |
|-----------------|---|
| cpsec_whitelist | 3 |
|-----------------|---|

Whitelist Entries: 97

```
(host) # show whitelist-db cpsec-local-list
```

```
Registered Local Controller Details
```

```

```

## show whitelist-db cpsec-status

```
show whitelist-db cpsec-status
[lms-list]
```

### Description

Display aggregate status information APs in the campus AP whitelist.

### Syntax

| Parameter | Description                          |
|-----------|--------------------------------------|
| lms-list  | Displays a list of LMS IP addresses. |

### Example

The output of the following command shows current status information for all APs in the campus AP whitelist:

```
(host) #show whitelist-db cpsec-status
```

```
My Mac-Address 00:1a:1e:00:89:b8
My IP-Address 192.0.2.1
Master IP-Address 192.0.2.1
Switch-Role Master
Whitelist-sync is enabled
```

Entries in Whitelist database

```
Total entries: 41
Approved entries: 0
Unapproved entries: 0
Certified entries: 40
Certified hold entries: 0
Revoked entries: 1
Marked for deletion entries: 0
Current Sequence Number: 0
```

The output of this command includes:

|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total entries               | Total number of entries in the campus AP whitelist                                                                                                                                                                                                                                                                                                                      |
| Approved entries:           | Number of APs that are valid, but is waiting to receive a certificate.                                                                                                                                                                                                                                                                                                  |
| Unapproved entries          | Number of APs that have certificate that was not not approved.                                                                                                                                                                                                                                                                                                          |
| Certified entries           | Number of APs that have an approved certificate.                                                                                                                                                                                                                                                                                                                        |
| Certified hold entries      | Number of APs in the certified hold state. An AP is put in this state when the controller thinks the AP a certified certificate yet the AP requests to be certified again. Since this is not a normal condition, the AP will not be reapproved as a secure AP until a network administrator manually changes the status of the AP to verify that it is not compromised. |
| Revoked entries             | Number of APs whose entries have been revoked                                                                                                                                                                                                                                                                                                                           |
| Marked for deletion entries | Number of APs whose entries have been marked for deletion. An entry will not be permanently deleted until all other controllers on the network acknowledge the deletion.                                                                                                                                                                                                |

## show whitelist-db rap

```
show whitelist-db rap
 apgroup <ap-group>
 apname <ap-name>
 export-css <filename>
 fullname <full-name>
 long
 mac-address <address>
 page <num>
 start <offset>
```

### Description

View detailed information for the remote AP whitelist database.

### Syntax

| Parameter              | Description                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apgroup <ap-group>     | Display specific AP-entries for this AP-group.                                                                                                                                     |
| apname <ap-name>       | Display specific AP-entry for this AP-name.                                                                                                                                        |
| export-css             | Export the remote AP white list to a file in the controller's /flash/config/ folder. This file can be given to a content security provider to manage the remote AP database.       |
| fullname <full-name>   | Display specific AP-entry for this full-name in the RAP whitelist database.                                                                                                        |
| long                   | Display additional debugging information about an entry in the RAP whitelist, including when it was last updated, the sequence number for the update, and any flags for the entry. |
| mac-address <mac-addr> | Display a whitelist entry for the specified RAP MAC address.                                                                                                                       |
| page                   | ArubaOS CLI displays 50 whitelist database entries per page. Filter the output of this command by displaying information starting at the specified page number.                    |
| start <offset>         | Start displaying the table at the specified record in the database                                                                                                                 |

### Example

In the example below, the command output has been divided into two tables to fit on a single page of this document. In the command-line interface, this output would appear in a single, wide table.

```
(host) #show whitelist-db rap
```

```
AP-entry Details

```

| Name              | AP-Group | AP-Name | Full-Name | Authen-Username | Revoke-Text |
|-------------------|----------|---------|-----------|-----------------|-------------|
| ----              | -----    | -----   | -----     | -----           | -----       |
| 00:0b:86:c3:58:38 | local    | AP-5B   | chucks_AP | Dev\Sarah       |             |
| 00:0b:86:66:01:aa | default  | AP-5C   | upstairs  | Dev             | AP invalid  |
| 00:1a:1e:c0:1b:e0 | default  | AP-99   |           | Dev\Chris       |             |
| 00:0b:86:66:03:3f | default  | LAB-AP  | addtl_rap | PM\Kumar        |             |

| AP_Authenticated | Description | Date-Added               | Enabled | Remote-IP  |
|------------------|-------------|--------------------------|---------|------------|
| -----            | -----       | -----                    | -----   | -----      |

| Authenticated    |             | Tue May 19 07:53:29 2009 | Yes     | 192.0.2.12 |
| Provisioned      |             | Fri May 8 10:37:40 2009  | Yes     | 192.0.2.13 |

AP Entries: 5

The output of this command includes the following information:

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name             | MAC address of the remote AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| AP-Group         | Name of the AP group to which the remote AP has been assigned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| AP-name          | Name of the remote AP. If no name has been specified, this column will display the remote AP's MAC address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Full-name        | Text string used to identify the remote AP. This field often describes the AP's user, and corresponds to the <b>User Name</b> field in the RAP whitelist in the WebUI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Authen-Username  | User name of the user who authenticated the remote AP. This parameter holds the user name of the user who authenticated the remote AP. This is related to the zero touch authentication feature, as a user needs to authenticate an AP before it gets its complete configuration. Before the AP is authenticated, it is given a restricted configuration to allow users to perform captive portal authorization via the remote AP's ENET ports to authenticate the remote AP. The username used during captive portal authentication will be stored in this field. This cannot be added manually when creating a local-userdb-ap entry.                                                                                                                                                                                                                                                                                                                                                |
| Revoke-Text      | The command <b>whitelist-db rap revoke</b> includes an optional <b>revoke-comment</b> parameter that allows network administrators to explain why the remote AP was revoked. If a remote AP is revoked, and a revoke comment entered, this text appears in the <b>revoke-text</b> column in the <b>show whitelist-db rap</b> command. When a local DB entry is reenabled via the command <b>whitelist-db rap modify mac-addr mode enable</b> , this field is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| AP_Authenticated | <p>This column indicates the authorization status of the RAP. A RAP can either be <b>Authenticated</b> or <b>Provisioned</b>.</p> <p>Remote APs that <i>do not</i> support certificate-based provisioning will always display a <b>Provisioned</b> status.</p> <p>Remote APs that support certificate-based provisioning can display either a <b>Authenticated</b> or <b>Provisioned</b> status, depending on their configuration and authentication status.</p> <ul style="list-style-type: none"> <li>If the remote AP has a defined AP authorization profile, the remote AP will be in a "Provisioned" state with a limited configuration until it is authenticated. After the remote AP has been authenticated, it will be in an "Authenticated" state.</li> <li>If the remote AP does not have a defined AP authorization profile, the remote AP will be in a "Provisioned" state, but will still receive the full configuration assigned to that AP and its AP group.</li> </ul> |

| Parameter   | Description                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | A text string used to further identify the remote AP.                                                                                                                                                                                                                                                    |
| Date-Added  | Date and time that the AP was added to the local user database                                                                                                                                                                                                                                           |
| Enabled     | <p>This column shows if the entry in the database is enabled or disabled. Database entries can be enabled or disabled using the CLI commands:</p> <pre> whitelist-db rap {add modify} mac-address &lt;mac-addr&gt; mode {enable disable} and whitelist-db rap revoke mac-address &lt;mac-addr&gt; </pre> |

## show whitelist-db rap-local-switch-list

```
show whitelist-db rap-local-switch-list [mac-address <mac-address>]
```

### Description

Display the remote AP whitelist local switch list on a master controller.

### Syntax

| Parameter                 | Description                                                      |
|---------------------------|------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the local controller whose data you want to view. |

### Usage Guidelines

When you have remote APs on a network with both master and local controllers, the master controller maintains a whitelist of local controllers with remote APs. When you change a remote AP whitelist on any controller, that controller contacts the master controller to check the local switch whitelist, then contacts every other controller on the local switch whitelist to notify it of the change. This allows a remote AP to move between local controllers and still stay connected to the secure network.

To view information for a single local controller, use the command **show whitelist-db rap-local-switch-list mac-address <mac-address>**. To view a list of all local controllers, use the command **show whitelist-db rap-local-switch-list**.

### Example

The following command shows information for all local controllers in the local controller whitelist. The output in the example below has been divided into sections to better fit on the pages of this document. In the ArubaOS CLI, the output appears in a single, long table.

```
(host) #show whitelist-db rap-local-switch-list
```

| Active | MAC-Address       | IP-Address | Sequence Number | Remote Sequence Number |
|--------|-------------------|------------|-----------------|------------------------|
| -----  | -----             | -----      | -----           | -----                  |
| 1      | 00:0b:86:51:a5:4c | 10.3.53.2  | 3               | 1                      |
| 1      | 00:A0:C9:14:C8:29 | 10.3.53.4  | 3               | 0                      |

| MAC-Address            | MAC address of the local controller.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| IP-Address             | IP address of the local controller.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Sequence Number        | The number of times the local controller in the whitelist received and acknowledged a remote AP whitelist change from the master controller. In the example above, both local controllers received and acknowledged three remote AP whitelist changes sent from the master controller.                                                                                                                                                                                           |
| Remote Sequence Number | The number of times that the master controller has received and acknowledged a remote AP whitelist change from the local controller in the whitelist. In the example above, the master controller received and acknowledged a single remote AP whitelist change from the local controller with the MAC address 00:0b:86:51:a5:4c.                                                                                                                                                |
| Null Update Count      | The number of times the controller has checked its remote AP whitelist and found nothing to synchronize with the remote controller. By default, the controller compares its remote AP whitelist against whitelists on other controllers every minute. If the null update count reaches 5, the controller will send an "empty sync" heartbeat to the remote controller to ensure the sequence numbers on both controllers are the same, then reset the null update count to zero. |

## show whitelist-db rap-master-switch-list

```
show whitelist-db rap-local-switch-list [mac-address <mac-address>]
```

### Description

Display the remote AP whitelist master switch list on local controllers with remote APs

### Syntax

| Parameter                 | Description                                                      |
|---------------------------|------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the local controller whose data you want to view. |

### Usage Guidelines

When your network has with both master and local controllers, each local controller with associated remote APs has a master switch whitelist which contains the IP and MAC addresses of its master controller. If your network has a redundant master controller, then this whitelist will contain more than one entry.

To view information for a single master controller, use the command **show whitelist-db rap-master-switch-list mac-address <mac-address>**. To view a list of all master controllers, use the command **show whitelist-db rap-master-switch-list**.

### Example

The following command shows that the local controllers have a single master controller with the IP address 192.0.2.143. The output in the example below has been divided into sections to better fit on the pages of this document. In the ArubaOS CLI, the output appears in a single, long table.

| Active | MAC-Address       | IP-Address | Sequence Number | Remote Sequence Number |
|--------|-------------------|------------|-----------------|------------------------|
| 1      | 00:0b:86:51:a5:4c | 192.0.2.14 | 2               | 2                      |

| NULL Update Count | Local Purge | Remote Purge | Remote Last-Seq | Last Update Sent   |
|-------------------|-------------|--------------|-----------------|--------------------|
| 0                 | 0           | 0            | 1               | Mon May 4 12:44:24 |
| 0                 |             |              |                 |                    |

## show whitelist-db rap-status

show whitelist-db rap-status

### Description

Display aggregate status information APs in the remote AP whitelist.

### Syntax

No parameters.

### Example

The output of the following command shows current status information for all APs in the remote AP whitelist:

```
(host) #show whitelist-db rap-status
Entries in Whitelist database

Total entries: 41
Revoked entries: 1
Marked for deletion entries: 0
```

The output of this command includes

### Syntax

| Parameter                   | Description                                                                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total entries               | Total number of entries in the remote AP whitelist                                                                                                                              |
| Revoked entries             | Number of remote APs whose entries have been revoked                                                                                                                            |
| Marked for deletion entries | Number of remote APs whose entries have been marked for deletion. An entry will not be permanently deleted until all other controllers on the network acknowledge the deletion. |

| Platforms     | Licensing              | Command Mode                               |
|---------------|------------------------|--------------------------------------------|
| All platforms | Base operating system. | Enable mode on master or local controllers |

## show wlan anyspot-profile

show wlan anyspot-profile [<profile-name>]

### Description

The output of this command displays configuration settings for a WLAN anyspot profile.

### Syntax

| Parameter | Description                |
|-----------|----------------------------|
| <profile> | Name of an anyspot profile |

### Usage Guidelines

The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks. Issue this command without the **<profile>** parameter to display the entire anyspot profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Example

The following command displays configuration information for an active (enabled) anyspot profile with two excluded ESSIDs, and one preset ESSID.

```
Anyspot profile "default"
```

```

```

| Parameter                               | Value       |
|-----------------------------------------|-------------|
| -----                                   | -----       |
| Enable Anyspot                          | true        |
| Exclude ESSID(s) (exact match)          | corp_dev_1  |
| Exclude ESSID(s) (exact match)          | corp_voip_1 |
| Exclude ESSID(s) (containing string(s)) | N/A         |
| Preset ESSID(s)                         | corpGuest   |

| Parameter                           | Description                                                                                                                                                                                                                                      |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable-anyspot                      | Indicates if the anyspot feature is enabled or disabled.                                                                                                                                                                                         |
| exclude-ssid <exclude-ssid>         | An anyspot-enabled radio will not respond to client probe requests using an ESSID in the <b>Exclude ESSID</b> lists. ESSIDs from neighboring APs will automatically appear in this list as long as the anyspot-enabled AP can detect that ESSID. |
| exclude-wildcard <exclude-wildcard> | An anyspot-enabled radio will not respond to client probe requests using an ESSID that matches a string in the <b>Exclude ESSID (containing string) list</b> .                                                                                   |
| preset-ssid <preset-ssid>           | If a client sends a probe request without an ESSID (that is, the probe request is not looking for a specific network) then the anyspot-enabled AP will respond to the probe request with an ESSID from this list.                                |

## show wlan bcn-rpt-req-profile

show wlan bcn-rpt-req-profile <profile-name>

### Description

Shows configuration and other information about the parameters for the Beacon Report Request frames.

### Syntax

| Parameter | Description                                   |
|-----------|-----------------------------------------------|
| <profile> | Name of a WLAN beacon report request profile. |

### Usage Guidelines

Issue this command without the <profile> parameter to display the entire Beacon Report Request profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

For this profile to take effect, the 802.11K feature needs to be enabled.

### Examples

```
(host) #show wlan bcn-rpt-req-profile
Beacon Report Request Profile List

Name References Profile Status
---- -
default 1
test 0
Total:2
(host) #
(host) #show wlan bcn-rpt-req-profile default

Beacon Report Request Profile "default"

Parameter Value

Interface 1
Regulatory Class 12
Channel 9
Randomization Interval 100
Measurement Duration 100
Measurement Mode for Beacon Reports active-all-ch
Reporting Condition 2
ESSID Name aruba-ap
Reporting Detail Disabled
Measurement Duration Mandatory Disabled
Request Information values 0/21/22
```

The output of this command includes the following parameters:

| Parameter                           | Description                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface                           | Specifies the Radio interface for transmitting the Beacon Report Request frame. It can have a value of either 0 or 1.                                                                                                                                                                                            |
| Regulatory Class                    | Specifies the Regulatory Class field in the Beacon Report Request frame.                                                                                                                                                                                                                                         |
| Channel                             | Specifies the Channel field in the Beacon Report Request frame.                                                                                                                                                                                                                                                  |
| Randomization Interval              | Specifies the Randomization Interval field in the Beacon Report Request frame. The Randomization Interval is used to specify the desired maximum random delay in the measurement start time. It is expressed in units of TUs (Time Units).                                                                       |
| Measurement Duration                | Specifies the Measurement Duration field in the Beacon Report Request frame. The Measurement Duration is set to the duration of the requested measurement. It is expressed in units of TUs.                                                                                                                      |
| Measurement Mode for Beacon Reports | Specifies the mode used for the measurement. The valid measurement modes are: <ul style="list-style-type: none"> <li>• active-all-ch</li> <li>• active-ch-rpt</li> <li>• beacon-table</li> <li>• passive</li> </ul>                                                                                              |
| Reporting Condition                 | Specifies the value for the "Reporting Condition" field in the Beacon Reporting Information sub-element present in the Beacon Report Request frame.                                                                                                                                                              |
| ESSID Name                          | Specifies the value for the "SSID" field in the Beacon Report Request frame.                                                                                                                                                                                                                                     |
| Reporting Detail                    | Indicates the value for the "Detail" field in the Reporting Detail sub-element present in the Beacon Report Request frame.                                                                                                                                                                                       |
| Measurement Duration Mandatory      | Specifies the "Duration Mandatory" bit of the Measurement Request Mode field of the Beacon Report Request frame.                                                                                                                                                                                                 |
| Request Information values          | Indicates the contents of the Request Information IE that could be present in the Beacon Report Request frame. The Request Information IE is present for all Measurement Modes except the 'Beacon Table' mode. It consists of a list of Element IDs that should be included by the client in the response frame. |

## Command History

The command is introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Enable mode on master or local controllers |

# show wlan dot11k-profile

show wlan dot11k-profile [<profile>]

## Description

Show a list of all 802.11k profiles, or display detailed configuration information for a specific 802.11k profile.

## Syntax

| Parameter | Description                 |
|-----------|-----------------------------|
| <profile> | Name of an 802.11k profile. |

## Usage Guidelines

Issue this command without the <profile> parameter to display the 802.11k profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has two configured 802.11k profiles. The **References** column lists the number of other profiles with references to the 802.11k profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan dot11k-profile
```

```
802.11K Profile List
```

```

```

| Name        | References | Profile Status |
|-------------|------------|----------------|
| ----        | -----      | -----          |
| default     | 8          |                |
| 11kprofile2 | 1          |                |
| Total: 2    |            |                |

The following example shows configuration settings defined for the profile **default**.

```
(host) #show wlan dot11k-profile default
```

```
802.11K Profile "default"
```

```

```

| Parameter                                                              | Value        |
|------------------------------------------------------------------------|--------------|
| -----                                                                  | -----        |
| Advertise 802.11K Capability                                           | Disabled     |
| Forcefully disassociate on-hook voice clients                          | Disabled     |
| Measurement Mode for Beacon Reports                                    | beacon-table |
| Configure specific channel for Beacon Requests                         | Disabled     |
| Channel requested for Beacon Reports in 'A' band                       | 36           |
| Channel requested for Beacon Reports in 'BG' band                      | 1            |
| Time duration between consecutive Beacon Requests                      | 60 sec       |
| Time duration between consecutive Link Measurement Requests            | 60 sec       |
| Time duration between consecutive Transmit Stream Measurement Requests | 90 sec       |

The output of this command includes the following data columns:

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Advertise 802.11K Capability                  | Shows if the profile has enabled or disabled the 802.11K feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Forcefully disassociate on-hook voice clients | If enabled, the AP may forcefully disassociate clients that reach the maximum CAC peak capacity or call handoff reservation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Measurement Mode for Beacon Reports           | Shows the profile's beacon measurement mode: <ul style="list-style-type: none"> <li>● <b>active:</b> In this mode, the client sends a probe request to the broadcast destination address on all supported channels, sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.</li> <li>● <b>beacon-table:</b> In this mode, the client measures beacons and returns a report with stored beacon information for any supported channel with the requested SSID and BSSID. The client does not perform any additional measurements. This is the default beacon measurement mode.</li> <li>● <b>passive:</b> In this mode, the client sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.</li> </ul> |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

# show wlan dot11r-profile

show wlan dot11r-profile [<profile>]

## Description

Show a list of all 802.11r profiles, or display detailed configuration information for a specific 802.11r profile.

## Syntax

| Parameter | Description                 |
|-----------|-----------------------------|
| <profile> | Name of an 802.11r profile. |

## Usage Guidelines

Issue this command without the <profile> parameter to display the 802.11r profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has two configured 802.11r profiles. The **References** column lists the number of other profiles with references to the 802.11r profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan dot11r-profile

802.11r Profile List

Name References Profile Status
---- -
default 8
voice-enterprise 1

Total: 2
```

The following example shows configuration settings defined for the profile **default**.

```
(host) #show wlan dot11r-profile default
802.11r Profile "default"

Parameter Value

Advertise 802.11r Capability Disabled
802.11r Mobility Domain ID 1
802.11r R1 Key Duration 3600
802.11r R1 Key Assignment dynamic
```

The output of this command includes the following data columns:

| Parameter                    | Description                                                       |
|------------------------------|-------------------------------------------------------------------|
| Advertise 802.11r Capability | Shows if the profile has enabled or disabled the 802.11r feature. |

| Parameter                  | Description                                                                  |
|----------------------------|------------------------------------------------------------------------------|
| 802.11r Mobility Domain ID | Shows the unique ID that identifies the mobility domain.                     |
| 802.11r R1 Key Duration    | Shows the r1 key timeout value in seconds for decrypt-tunnel or bridge mode. |
| 802.11r R1 Key Assignment  | Shows if the r1 key assignment is static or dynamic.                         |

## Command History

This command was introduced in ArubaOS 6.3.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

## show wlan edca-parameters-profile

```
show wlan edca-parameters-profile ap|station [<profile>]
```

### Description

Display an Enhanced Distributed Channel Access (EDCA) profile for APs or for clients (stations). EDCA profiles are specific either to APs or clients.

### Syntax

| Parameter | Description                        |
|-----------|------------------------------------|
| <profile> | Name of a EDCA Parameters profile. |

### Usage Guidelines

Issue this command without the <profile> parameter to display a EDCA Parameters profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has three EDCA Parameters profiles configured for stations. The **References** column lists the number of other profiles with references to the EDCA Parameters profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan edca-parameters-profile station
EDCA Parameters profile (Station) List
```

```

Name References Profile Status
---- -
station-corp1 3
station-corp2 1
testprofile 0
```

```
Total:3
```

The following example shows configuration settings defined for the profile **station-corp1**.

```
(host) #show wlan edca-parameters-profile ap station-corp1
EDCA Parameters
```

```

AC ECWmin ECWmax AIFSN TXOP ACM
-- -
Best-effort 4 6 3 0 0
Background 4 10 7 0 0
Video 3 4 1 94 0
Voice 2 3 1 47 0
```

The output of this command includes the following data columns:

| Parameter | Description                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| AC        | Name of an Access channel queue ( <b>Best-effort, Background, Video</b> or <b>Voice</b> ).                                                            |
| ECWmin    | The exponential (n) value of the minimum contention window size, as expressed by $2^n - 1$ . A value of 4 computes to $2^4 - 1 = 15$ .                |
| ECWmax    | The exponential (n) value of the maximum contention window size, as expressed by $2^n - 1$ . A value of 4 computes to $2^4 - 1 = 15$ .                |
| AIFSN     | Arbitrary inter-frame space number.                                                                                                                   |
| TXOP      | Transmission opportunity, in units of 32 microseconds.                                                                                                |
| ACM       | If this column displays a 1, the profile has enabled mandatory admission control. If this column displays a 0, the profile has disabled this feature. |

## Command History

This command was introduced in ArubaOS 3.1.

## Command Information

| Platforms     | Licensing                                                                                                                                                  | Command Mode                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| All platforms | This show command is available in the base operating system, but the controller must have the PEFNG license in order to configure EDCA Parameter Profiles. | Enable and Config mode on master or local controllers |

## show wlan handover-trigger-profile

show wlan handover-trigger-profile [<profile-name>]

### Description

Displays the current configuration settings for a handover trigger profile.

### Usage Guidelines

Issue this command without the <profile> parameter to display a handover trigger profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

For this profile to take effect, the 802.11K feature needs to be enabled.

### Example

```
(host) #show wlan handover-trigger-profile default
Handover Trigger Profile "default"

Parameter Value

Enable Handover Trigger feature
Enabled
Threshold signal strength value at which Handover Trigger should be sent to the client 25 -
dBm
```

The output of this command includes the following information:

| Parameter                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable Handover Trigger feature                                                        | Shows if the handoff trigger feature is enabled or disabled. If enabled, the controller will initiate the handover of a voice client (for example: dual mode handsets) roaming at the edge of Wi-Fi coverage to an alternate carrier or connection. The handover trigger is initiated if the Wi-Fi signal strength reported by the voice client (received from all APs) is equal to or less than the threshold value. |
| Threshold signal strength value at which Handover Trigger should be sent to the client | Shows the threshold RSSI value below which a handover trigger message will be sent to an associated client by the AP.                                                                                                                                                                                                                                                                                                 |

### Command History

This command was introduced in ArubaOS 6.2.

### Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Enable mode on master or local controllers |

# show wlan hotspot advertisement-profile

show wlan hotspot advertisement-profile [<profile-name>]

## Description

The output of this command displays settings for a WLAN ANQP advertisement profile.

## Syntax

| Parameter | Description                                   |
|-----------|-----------------------------------------------|
| <profile> | Name of a wlan hotspot advertisement profile. |

## Usage Guidelines

Access Network Query Protocol (ANQP) profiles and Hotspot 2.0 Query Protocol (H2QP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to view the ANQP and H2QP profiles to be associated with the advertisement profile.

Issue this command without the **<profile>** parameter to display the entire ANQP advertisement profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has two configured advertisement profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show wlan hotspot advertisement-profile
Advertisement Profile List

Name References Profile Status

default 1
Westgate_Mall 2
Total:2.
```

This example displays the configuration settings for the profile **Wireless\_rf\_profile**.

```
(host) (config) #show wlan hotspot advertisement-profile Wireless_rf_profile
Advertisement Profile "default"

Parameter Value

ANQP Venue Name Profile venue_mall
ANQP Network Authentication Profile auth1
ANQP Roaming Consortium Profile default
ANQP NAI Realm Profile Realm2
ANQP 3GPP Cellular Network Profile default
ANQP IP Address Availability Profile ipv4_Profile
H2QP WAN Metrics Profile default
H2QP Operator Friendly Name Profile default
H2QP Connection Capability Profile default
H2QP Operating Class Indication Profile default
```

The output of this command includes the following parameters:

| Parameter                               | Description                                                                                          |
|-----------------------------------------|------------------------------------------------------------------------------------------------------|
| ANQP Venue Name Profile                 | Name of the ANQP Venue Name profile associated with this WLAN advertisement profile.                 |
| ANQP Network Authentication Profile     | Name of the ANQP Network Authentication profile associated with this WLAN advertisement profile.     |
| ANQP Roaming Consortium Profile         | Name of the ANQP Roaming Consortium profile associated with this WLAN advertisement profile.         |
| ANQP NAI Realm Profile                  | Name of the ANQP NAI Realm profile associated with this WLAN advertisement profile.                  |
| ANQP 3GPP Profile                       | Name of the ANQP 3GPP Cellular Network profile associated with this WLAN advertisement profile.      |
| ANQP IP Address Availability Profile    | Name of the ANQP IP Address Availability profile associated with this WLAN advertisement profile.    |
| H2QP WAN Metrics Profile                | Name of the H2QPWAN Metrics profile associated with this WLAN advertisement profile.                 |
| H2QP Operator Friendly Name Profile     | Name of the H2QP Operator Friendly Name profile associated with this WLAN advertisement profile.     |
| H2QP Connection Capability Profile      | Name of the H2QP Connection Capability profile associated with this WLAN advertisement profile.      |
| H2QP Operating Class Indication Profile | Name of the H2QP Operating Class Indication profile associated with this WLAN advertisement profile. |
| ANQP Domain Name Profile                | Name of the ANQP domain name profile associated with this WLAN advertisement profile.                |

## show wlan hotspot anqp-3gpp-nwk-profile

show wlan hotspot anqp-3gpp-nwk-profile [<profile-name>]

### Description

This profile shows the configuration settings for for a 3rd Generation Partnership Project (3GPP) Cellular Network profile.

### Syntax

| Parameter | Description                              |
|-----------|------------------------------------------|
| <profile> | Name of a 3GPP Cellular Network profile. |

### Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Issue this command without the **<profile>** parameter to display the entire list of 3GPP profiles, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has two configured 3GPP profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) (config)# show wlan hotspot anqp-3gpp-nwk-profile
ANQP 3GPP Cellular Network Profile List

Name References Profile Status
---- -
default 1
Updated_PLMN 2
Total:2.
```

This example displays the configuration settings for the profile **Updated\_PLMN**.

```
(host) (config)# show wlan hotspot anqp-3gpp-nwk-profile Updated_PLMN
ANQP 3GPP Cellular Network Profile "Updated_PLMN"

Parameter Value

ANQP 3GPP network profile enable Enabled
3GPP PLMN1 310026
3GPP PLMN2 208000
3GPP PLMN3 208001
3GPP PLMN4 N/A
3GPP PLMN5 N/A
3GPP PLMN6 N/A
```

The output of this command includes the following parameters:

| Parameter                        | Description                                                                                                                                                                                       |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ANQP 3GPP network profile enable | Shows if this profile has been enabled ANQP 3GPP Cellular Network profiles are disabled by default.                                                                                               |
| 3gpp PLMN1                       | The Public Land Mobile Networks (PLMN) value of the highest-priority network.<br><br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).        |
| 3gpp PLMN2                       | The Public Land Mobile Networks (PLMN) value of the second-highest priority network.<br><br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC). |
| 3gpp PLMN3                       | The Public Land Mobile Networks (PLMN) value of the third-highest priority network.<br><br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).  |
| 3gpp PLMN4                       | The Public Land Mobile Networks (PLMN) value of the fourth-highest priority network.<br><br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC). |
| 3gpp PLMN5                       | The Public Land Mobile Networks (PLMN) value of the fifth-highest priority network.<br><br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).  |
| 3gpp PLMN6                       | The Public Land Mobile Networks (PLMN) value of the sixth-highest priority network.<br><br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).  |

## Usage Guidelines

The 3GPP Cellular Network Profile defines an ANQP information element (IE) to be sent in a Generic Advertisement Service (GAS) query response from an AP in a hotspot with a roaming relationship with a cellular operator. The 3GPP Mobile Country Code (MCC) and the 12-bit Mobile Network Code data in the IE can help the client select a 3GPP network.

Values configured in this profile will not be sent to clients unless you:

1. Associate the 3GPP Cellular Network profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-3gpp-nwk-profile <profile-name>`)
2. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)
3. Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

# show wlan hotspot anqp-domain-name-profile

show wlan hotspot anqp-domain-name-profile [<profile-name>]

## Description

The output of this command displays settings for a WLAN ANQP Domain Name profile.

## Syntax

| Parameter | Description                    |
|-----------|--------------------------------|
| <profile> | Name of a Domain Name profile. |

## Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Issue this command without the **<profile>** parameter to display the entire ANQP Domain Name profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Domain Name profile an ANQP advertisement profile. (wlan hotspot advertisement-profile <profile-name> anqp-domain-name-profile)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

## Examples

The example below shows that the controller has two configured Domain Name profiles. The **References** column lists the number of other profiles with references to the Domain Name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show wlan hotspot anqp-domain-name
ANQP Domain Name Profile List

Name References Profile Status

corp_domain 2
default 1
Total:2.
```

This example displays the configuration settings for the profile **corp\_domain**.

```
(host) #show wlan hotspot anqp-domain-name-profile corp_domain
ANQP Domain Name Profile "corp_domain"

Parameter Value

Domain Name example.com
```

The output of this command includes the following parameters:

| Parameter   | Description                          |
|-------------|--------------------------------------|
| Domain Name | Domain name of the hotspot operator. |

## show wlan hotspot anqp-ip-addr-avail-profile

show wlan hotspot anqp-ip-addr-avail-profile [<profile-name>]

### Description

The output of this command displays settings for a WLAN ANQP IP Address Availability profile.

### Syntax

| Parameter | Description                                 |
|-----------|---------------------------------------------|
| <profile> | Name of an IP Address Availability profile. |

### Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Issue this command without the **<profile>** parameter to display the entire ANQP IP Address Availability profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP IP Address Availability profile an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-ip-addr-avail-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

### Examples

The example below shows that the controller has three configured IP Address Availability profiles. The **References** column lists the number of other profiles with references to the IP Address Availability profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show wlan hotspot anqp-ip-addr-avail-profile
ANQP IP Address Availability Profile List

Name References Profile Status

default 0
ipv4_Profile 2
ipv6_profile 1
Total:3.
```

This example displays the configuration settings for the profile **ipv4\_Profile**.

```
(host) #show rf anqp-ip-addr-avail-profile ipv4_Profile
ANQP IP Address Availability Profile "ipv4_Profile"

Parameter Value
```

```

IPv4 Address Availability Type public
IPv6 Address Availability Type not-available
The output of this command includes the following parameters:
```

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

# show wlan hotspot anqp-nai-realm-profile

show wlan hotspot anqp-nai-realm-profile [<profile-name>]

## Description

The output of this command displays settings for a WLAN ANQP Network Access Identifier (NAI) Realm profile.

## Syntax

| Parameter | Description                   |
|-----------|-------------------------------|
| <profile> | Name of an NAI Realm profile. |

## Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Issue this command without the **<profile>** parameter to display the entire ANQP NAI Realm profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP NAI Realm profile an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-nai-realm-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name>hotspot-enable)

## Examples

The example below shows that the controller has three configured NAI Realm profiles. The References column lists the number of other profiles with references to the NAI Realm profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host) # show wlan hotspot anqp-nai-realm-profile
```

```
ANQP NAI Realm Profile List
```

```

Name References Profile Status
---- -
default 0
Realm1 2Realm2 2
```

```
Total:3.
```

This example displays the configuration settings for the profile **Realm2**.

```
(host) #show wlan hotspot anqp-nai-realm-profile Realm2
```

```
ANQP NAI Realm Profile "Realm2"
```

```

Parameter Value
```

```

NAI Realm name example.com
NAI Realm EAP Method eap-ttls
NAI Realm Authentication Parameter Type expanded-eap
```

The output of this command includes the following parameters:

| Parameter                               | Description                                                                             |
|-----------------------------------------|-----------------------------------------------------------------------------------------|
| NAI Realm name                          | Name of the NAI realm. The realm name is often the domain name of the service provider. |
| NAI Realm EAP Method                    | The NAI Realm Authentication types sent as an ANQP IE in an GAS response                |
| NAI Realm Authentication Parameter Type | The EAP authentication method supported by the hotspot realm.                           |

## show wlan hotspot anqp-nwk-auth-profile

show wlan hotspot anqp-nwk-auth-profile [<profile-name>]

### Description

The output of this command displays settings for a WLAN ANQP network authentication profile.

### Syntax

| Parameter | Description                                     |
|-----------|-------------------------------------------------|
| <profile> | Name of an ANQP Network Authentication profile. |

### Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Issue this command without the **<profile>** parameter to display the entire ANQP network authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has two configured network authentication profiles. The **References** column lists the number of other profiles with references to the network authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show wlan hotspot anqp-nwk-auth-profile
```

ANQP Network Authentication Profile List

```

Name References Profile Status

auth1 0
default 0
```

Total:2.

The following example displays the configuration settings for the profile **default**.

```
(host) #show wlan hotspot anqp-nwk-auth-profile default
```

ANQP Network Authentication Profile "default"

```

Parameter Value

Type of Network Authentication acceptance
Redirect URL N/A
```

The output of this command includes the following parameters:

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type of Network Authentication | <p>Network Authentication Type being used by the hotspot network. This parameter can be any of the following values:</p> <ul style="list-style-type: none"> <li>• acceptance: Network requires the user to accept terms and conditions.</li> <li>• dns-redirection: Additional information on the network is provided through DNS redirection.</li> <li>• http-https-redirection : Additional information on the network is provided through HTTP/HTTPS redirection.</li> <li>• online-enroll : Network supports online enrollment.</li> </ul> |
| Redirect URL                   | If information on the network is provided through DNS redirection, this parameter displays the redirection URL.                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Platforms     | Licensing             | Command Mode                                          |
|---------------|-----------------------|-------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers |

# show wlan hotspot anqp-roam-cons-profile

show wlan hotspot anqp-roam-cons-profile [<profile-name>]

## Description

The output of this command displays settings for a WLAN ANQP Roaming Consortium profile.

## Syntax

| Parameter | Description                                 |
|-----------|---------------------------------------------|
| <profile> | Name of an ANQP Roaming Consortium profile. |

## Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Issue this command without the <profile> parameter to display the entire ANQP Roaming Consortium profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Roaming Consortium profile an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-roam-cons-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

## Examples

The example below shows that the controller has two configured Roaming Consortium profiles. The **References** column lists the number of other profiles with references to the Roaming Consortium profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show wlan hotspot anqp-roam-cons-profile
ANQP Roaming Consortium Profile List

Name References Profile Status

default 1
Roam_OI2 1
Total:2.
```

This example displays the configuration settings for the profile **Roam\_OI2**.

```
(host) #show wlan hotspot anqp-roam-cons-profile Roam_OI2
ANQP Roaming Consortium Profile "Roam_OI2"

Parameter Value

Roaming consortium OI Len 3
```

Roaming consortium OI Len b32af0

The output of this command includes the following parameters:

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Roaming consortium OI Len | Length of the OI. The roaming consortium OI length parameter is based upon the number of octets of the Roaming consortium OI. This parameter can have the following values: <ul style="list-style-type: none"><li>• <b>0:</b> 0 Octets in the OI (Null)</li><li>• <b>3:</b> OI length is 24-bit (3 Octets)</li><li>• <b>5:</b> OI length is 36-bit (5 Octets)</li></ul> |
| Roaming Consortium OI     | The roaming consortium OI sent in a GAS query response.                                                                                                                                                                                                                                                                                                                 |

## show wlan hotspot anqp-venue-name-profile

```
show wlan hotspot anqp-venue-name-profile [<profile-name>]
```

### Description

The output of this command displays settings for a WLAN ANQP Venue Name profile.

### Syntax

| Parameter | Description                         |
|-----------|-------------------------------------|
| <profile> | Name of an ANQP Venue Name profile. |

### Usage Guidelines

Access Network Query Protocol (ANQP) profiles define the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Issue this command without the <profile> parameter to display the entire ANQP Venue Name profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Venue Name profile an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-venue-name-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

### Examples

The example below shows that the controller has two configured Venue Name profiles. The **References** column lists the number of other profiles with references to the Venue Name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show wlan hotspot anqp-venue-name-profile
ANQP Venue Name Profile List

Name References Profile Status

default 0
venue_mall 0
Total:2.
```

This example displays the configuration settings for the profile venue\_mall.

```
(host) #show wlan hotspot anqp-venue-name-profile venue_mall
ANQP Venue Name Profile "venue_mall"

Parameter Value

Venue Group mercantile
```

Type of Venue   mercantile-shopping-mall  
Venue Name       Westfield\_Mall

The output of this command includes the following parameters:

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Venue Group   | The venue group to be advertised in the ANQP Information Elements (IEs) from APs associated with this profile. This parameter can have any of the following values: <ul style="list-style-type: none"><li>• assembly</li><li>• business</li><li>• educational</li><li>• factory-or-industrial</li><li>• institutional</li><li>• mercantile</li><li>• outdoor</li><li>• reserved</li><li>• residential</li><li>• storage</li><li>• unspecified</li><li>• Utility-Misc</li><li>• Vehicular</li></ul> |
| Type of Venue | The venue type to be advertised in the IEs from APs associated with this hotspot profile. The complete list of supported venue types is described in <a href="#">Venue Types on page 2294</a> .                                                                                                                                                                                                                                                                                                    |
| Venue Name    | The venue name to be advertised in the ANQP IEs from APs associated with this profile.                                                                                                                                                                                                                                                                                                                                                                                                             |

## show wlan hotspot hs2-profile

```
show wlan hotspot h2-profile [<profile-name>]
```

### Description

The output of this command displays settings for a Hotspot profile.

### Syntax

| Parameter | Description                |
|-----------|----------------------------|
| <profile> | Name of a Hotspot profile. |

### Usage Guidelines

Organization Identifiers (OIs) are assigned to service providers when they register with the IEEE registration authority. The Roaming Consortium Information Elements (IEs) contain information identifying the network and service provider, whose security credentials can then be used to authenticate with the AP transmitting this element.

The OI for the service provider is defined in the ANQP Roaming Consortium profile using the [wlan hotspot anqp-roam-cons-profile](#) command. This Hotspot profile allows you to define and send up to three additional OIs to a client. The configurable values for each additional OI include the Organization Identifier itself, the OI length, and the venue group and venue type associated with those OIs.

Issue this command without the **<profile>** parameter to display the entire ANQP advertisement profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has two configured Hotspot profiles. The **References** column lists the number of other profiles with references to the Hotspot profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) # show wlan hotspot h2-profile
Hotspot Profile List

Name References Profile Status
---- -
default 1
Hotspot_1 2
Total:2.
```

The following example shows configuration settings defined for the profile **Hotspot1**.

```
(host) #show wlan hotspot h2-profile Hotspot1
Hotspot 2.0 Profile "default"

Parameter Value

Advertise Hotspot 2.0 Capability Enabled
Additional Steps required for Access Enabled Enabled
Network Internet Access Enabled
Length of Query Response 255 octets
Access network Type public-chargeable
```

|                                                                        |                      |

| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

## show wlan hotspot h2qp-conn-capability-profile

show wlan hotspot h2qp-conn-capability-profile [<profile>]

### Description

The output of this command displays settings for a WLAN Hotspot 2.0 Query Protocol (H2QP) connection capability profile.

### Syntax

| Parameter | Description                                                             |
|-----------|-------------------------------------------------------------------------|
| <profile> | Name of Hotspot 2.0 Query Protocol (H2QP) connection capability profile |

### Usage Guidelines

The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about the IP protocols and associated port numbers that are available and open for communication.

Values configured in this profile will not be sent to clients unless you:

1. Associate the H2QP profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> h2qp-conn-cap-profile <profile-name> )
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name> )
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable )

### Examples

Issue this command without the optional <profile> parameter to display a list of all configured connection capability profiles. Include the <profile> parameter to display details for a specific profile.

The example below shows that the controller has four configured connection capability profiles. The **References** column lists the number of other profiles with references to the connection capability profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
H2QP Connection Capability Profile List

Name References Profile Status
---- -
branch-hotspot-1 6
branch-hotspot-2 5
default 1
downtown-hotspot 1
Total:4
```

The following example displays the current configuration settings for the default H2QP connection capability profile.

```
(host) (config) #show wlan hotspot h2qp-conn-capability-profile default
H2QP Connection Capability Profile "default"

Parameter Value

```

```

H2QP Connection Capability ICMP port Disabled
H2QP Connection Capability FTP port(TCP Protocol) Disabled
H2QP Connection Capability SSH port(TCP Protocol) Disabled
H2QP Connection Capability HTTP port(TCP Protocol) Disabled
H2QP Connection Capability TLS VPN port(TCP Protocol) Disabled
H2QP Connection Capability PPTP VPN port(TCP Protocol) Disabled
H2QP Connection Capability VOIP port(TCP Protocol) Disabled
H2QP Connection Capability VOIP port(UDP Protocol) Disabled
H2QP Connection Capability IKEv2 port for IPSec VPN Disabled
H2QP Connection Capability May be used by IKEv2 port for IPSec VPN Disabled
H2QP Connection Capability ESP port(Used by IPSec VPN) Disabled

```

The output of this command includes the following information:

| Parameter                                                          | Description                                                                     |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| H2QP Connection Capability ICMP port                               | Shows if the ICMP port is enabled and available. (port 0)                       |
| H2QP Connection Capability FTP port                                | Shows if the FTP port is enabled and available. (port 20)                       |
| H2QP Connection Capability SSH port                                | Shows if the SSH port is enabled and available. (port 22)                       |
| H2QP Connection Capability HTTP port                               | Shows if the HTTP port is enabled and available. (port 80)                      |
| H2QP Connection Capability TLS VPN port                            | Shows if the TCP TLS port used VPNs is enabled and available. (port 80)         |
| H2QP Connection Capability PPTP VPN port                           | Shows if the PPTP port used by IPSec VPNs is enabled and available. (port 1723) |
| H2QP Connection Capability VoIP port (UDP)                         | Shows if the UDP VoIP port is enabled and available. (port 5060)                |
| H2QP Connection Capability VoIP port (TCP)                         | Shows if the TCP VoIP port is enabled and available. (port 5060)                |
| H2QP Connection Capability IKEv2 port for IPSec VPN                | Shows if the IKEv2 port 4500 is enabled and available                           |
| H2QP Connection Capability May be used by IKEv2 port for IPSec VPN | Shows if the IKEv2 port 500 is enabled and available                            |
| H2QP Connection Capability ESP port(Used by IPSec VPN)             | Shows if the ESP port used by IPsec VPNs is enabled and available. (port 0)     |

## Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |

| All platforms | Base operating system | Config mode on master controllers |

## show wlan hotspot h2qp-op-cl-profile

```
show wlan hotspot h2qp-op-cl-profile [<profile>]
```

### Description

The output of this command displays settings for a WLAN Hotspot 2.0 Query Protocol (H2QP) operating class profile.

### Syntax

| Parameter | Description                                                       |
|-----------|-------------------------------------------------------------------|
| <profile> | Name of Hotspot 2.0 Query Protocol (H2QP) operating class profile |

### Usage Guidelines

The values configured in this H2QP Operating Class profile list the channels on which the hotspot is capable of operating. It may be useful where, for instance, a mobile device discovers a hotspot in the 2.4 GHz band but finds it is dual-band and prefers the 5 GHz band.

### Examples

Issue this command without the optional <profile> parameter to display a list of all configured connection capability profiles. Include the <profile> parameter to display details for a specific profile.

The example below shows that the controller has two configured operating class profiles. The **References** column lists the number of other profiles with references to the operating class profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) (H2QP Connection Capability Profile "default") #show wlan hotspot h2qp-op-cl-profile
H2QP Operating Class Indication Profile List

Name References Profile Status
---- -
default 0
newopcl 1
Total:2
```

The following example displays the current configuration setting for the default H2QP operating class profile.

```
(host) (H2QP Connection Capability Profile "default") #show wlan hotspot h2qp-op-cl-profile
default
H2QP Operating Class Indication Profile "default"

Parameter Value

H2QP Operating Class (Valid Values 1-255) 1
```

The output of this command includes the following information:

| Parameter                                 | Description                                                                                                                         |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| H2QP Operating Class (Valid Values 1-255) | Displays the current operating class for the devices' BSS. The supported range for this field is 1-255, and the default value is 1. |

# show wlan hotspot h2qp-operator-friendly-name-profile

show wlan hotspot h2qp-operator-friendly-name-profile [<profile>]

## Description

The output of this command displays settings for a Hotspot 2.0 Query Protocol (H2QP) operator-friendly name profile.

## Syntax

| Parameter | Description                                  |
|-----------|----------------------------------------------|
| <profile> | Name of H2QP operator-friendly name profile. |

## Usage Guidelines

The operator-friendly name defined in this profile is a free-form text field that can identify the operator and also something about the location. Issue this command without the **<profile>** parameter to display the entire operator-friendly name profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has two configured operator-friendly name profiles. The **References** column lists the number of other profiles with references to the operator-friendly name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) (config)# show wlan hotspot h2qp-operator-friendly-name-profile
H2QP Operator Friendly Name Profile List

Name References Profile Status

default 0
operator1 8
Total:2
```

The following example displays the configuration settings for the profile **operator1**.

```
(host) (H2QP Operator Friendly Name Profile "operator1") #show wlan hotspot h2qp-operator-
friendly-name-profile operator1
H2QP Operator Friendly Name Profile "operator1"

Parameter Value

Operator Friendly Name Language Code eng
Operator Friendly Name CoffeeHouseGuest
```

The output of this command includes the following parameters:

| Parameter                            | Description                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operator Friendly Name Language Code | An ISO 639 language code that identifies the language used in the Operator Friendly Name field.                                                                                                                                                                                                    |
| Operator Friendly Name               | An operator-friendly name sent by devices using this profile. The name can be up to 64 alphanumeric characters, and can include special characters and spaces. If the name includes quotation marks ("), you must include a backslash character (\) before each quotation mark. (e.g. \"example\") |

## Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

# show wlan hotspot h2qp-wan-metrics-profile

show wlan hotspot h2qp-wan-metrics-profile [<profile-name>]

## Description

The output of this command displays settings for a Hotspot 2.0 Query Protocol (H2QP) WAN metrics profile.

## Syntax

| Parameter | Description                       |
|-----------|-----------------------------------|
| <profile> | Name of H2QP WAN metrics profile. |

## Usage Guidelines

The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about access network characteristics such as link status and the capacity and speed of the WAN link to the Internet. Issue this command without the **<profile>** parameter to display the entire WAN metrics profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has two configured WAN metrics profiles. The **References** column lists the number of other profiles with references to the WAN metrics profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(Host) (H2QP Connection Capability Profile "default") #show wlan hotspot h2qp-wan-metrics-profile
H2QP WAN Metrics Profile List

Name References Profile Status
---- -
default 0
fastwan 6
Total:2
```

The following example shows the current configuration settings for the profile fastwan.

```
(host) (config) #show wlan hotspot h2qp-wan-metrics-profile fastwan
H2QP WAN Metrics Profile "fastwan"

Parameter Value

H2QP WAN metrics link status link_up
H2QP WAN metrics symmetric WAN link Disabled
H2QP WAN metrics link at capacity Disabled
WAN Metrics uplink speed 1000
WAN Metrics downlink speed 1000
WAN Metrics uplink load 100
WAN Metrics downlink load 100
WAN Metrics load measurement duration 100
```

The output of this command includes the following information:

| Parameter                             | Description                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H2QP WAN metrics link status          | Indicates the status of the WAN Link by displaying one of the following values. The default link status is <b>reserved</b> , which indicates that the link status is unknown or unspecified. <ul style="list-style-type: none"> <li>link_down</li> <li>link_test</li> <li>link_up</li> <li>reserved</li> </ul> |
| H2QP WAN metrics symmetric WAN link   | This parameter indicates if the WAN Link has same speed in both the uplink and downlink directions.                                                                                                                                                                                                            |
| H2QP WAN metrics link at capacity     | This parameter indicates if the WAN Link has reached its maximum capacity. If this parameter is enabled, no additional mobile devices will be permitted to associate to the hotspot AP.                                                                                                                        |
| WAN Metrics uplink speed              | This parameter indicates the current WAN backhaul uplink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the uplink speed is unknown or unspecified.                                                                                                         |
| WAN Metrics down link speed           | This parameter indicates the current WAN backhaul downlink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.                                                                                                     |
| WAN Metrics uplink load               | The percentage of the WAN uplink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.                                                                                                                  |
| WAN Metrics downlink load             | The percentage of the WAN downlink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.                                                                                                                |
| WAN Metrics load measurement duration | Duration over which the downlink load is measured, in tenths of a second.                                                                                                                                                                                                                                      |

## Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |

## show wlan ht-ssid-profile

```
show wlan ht-ssid-profile [<profile>]
```

### Description

Show a list of all High-throughput SSID profiles, or display detailed configuration information for a specific High-throughput SSID profile.

### Syntax

| Parameter | Description                             |
|-----------|-----------------------------------------|
| <profile> | Name of a High-throughput SSID profile. |

### Usage Guidelines

Issue this command without the <profile> parameter to display the entire High-throughput SSID profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has two configured High-throughput SSID profiles. The **References** column lists the number of other profiles with references to the High-throughput SSID profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan ht-ssid-profile
High-throughput SSID profile List

Name References Profile Status

HT-profile1 16default2 1

Total:2
```

The following example shows configuration settings defined for the profile **default2**.

```
(host) #show wlan ht-ssid-profile default
High-throughput SSID profile "default2"

Parameter Value

40 MHz channel usage Enabled
BA AMSDU Enable Enabled
Temporal Diversity Enable Disabled
High throughput enable (SSID) Enabled
Legacy stations Allowed
Low-density Parity Check Enabled
Maximum number of spatial streams usable for STBC reception 1
Maximum number of spatial streams usable for STBC transmission 1
MPDU Aggregation Enabled
Max received A-MPDU size 65535 bytes
Max transmitted A-MPDU size 65535 bytes
Min MPDU start spacing 8 usec
Short guard interval in 20 MHz mode Enabled
Short guard interval in 40 MHz mode Enabled
```

The output of this command includes the following data columns:

| Parameter                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 40 MHz channel usage                                           | Shows if the profile enables or disables the use of 40 MHz channels.                                                                                                                                                                                                                                                                                                                                                              |
| BA AMSDU Enable                                                | Shows if the AP has enabled or disabled the ability to receive AMSDU in BA negotiation.                                                                                                                                                                                                                                                                                                                                           |
| Temporal Diversity Enable                                      | Shows if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries.                                                                                                                                                                 |
| High throughput enable (SSID)                                  | Shows if the profile enables or disables high-throughput (802.11n) features.                                                                                                                                                                                                                                                                                                                                                      |
| Legacy stations                                                | Allow or disallow associations from legacy (non-HT) stations. By default, this parameter is enabled (legacy stations are allowed).                                                                                                                                                                                                                                                                                                |
| Low-density Parity Check                                       | If enabled, the AP will advertise Low-density Parity Check (LDPC) support. LDPC improves data transmission over radio channels with high levels of background noise.                                                                                                                                                                                                                                                              |
| Maximum number of spatial streams usable for STBC reception    | Shows the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the W-AP90 series, W-AP130 Series, W-AP68, W-AP175 and W-AP105 only. The configured value will be adjusted based on AP capabilities.)<br><b>NOTE:</b> If transmit beamforming is enabled, STBC will be disabled for disabled for beamformed frames. |
| Maximum number of spatial streams usable for STBC transmission | Shows the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on W-AP90 series, W-AP175, W-AP130 Series and W-AP105 only. The configured value will be adjusted based on AP capabilities.)<br><b>NOTE:</b> If transmit beamforming is enabled, STBC will be disabled for disabled for beamformed frames.       |
| MPDU Aggregation                                               | Shows if the profile enables or disables MAC protocol data unit (MPDU) aggregation.                                                                                                                                                                                                                                                                                                                                               |
| Max received A-MPDU size                                       | Configured maximum size of a received aggregate MPDU, in bytes.                                                                                                                                                                                                                                                                                                                                                                   |
| Max transmitted A-MPDU size                                    | Configured maximum size of a transmitted aggregate MPDU, in bytes.                                                                                                                                                                                                                                                                                                                                                                |

| Parameter                           | Description                                                                                                                                                                                                                           |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Min MPDU start spacing              | Configured minimum time between the start of adjacent MPDUs within an aggregate MPDU, in microseconds.                                                                                                                                |
| Supported MCS set                   | Displays a list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20MHz vs. 40MHz) and the number of spatial streams used by the mesh node. |
| Short guard interval in 20 MHz mode | Shows if the profile enables or disables use of short (400ns) guard interval in 20 MHz mode.                                                                                                                                          |
| Short guard interval in 40 MHz mode | Shows if the profile enables or disables use of short (400ns) guard interval in 40 MHz mode.                                                                                                                                          |

## Command History

| Version       | Description                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.3   | Command introduced                                                                                                                                                                                                                                                                                                                                                                              |
| ArubaOS 3.3.1 | The <b>Legacy Stations</b> parameter was introduced                                                                                                                                                                                                                                                                                                                                             |
| ArubaOS 3.3.2 | De-aggregation of MAC Service Data Units (A-MSDUs) was introduced                                                                                                                                                                                                                                                                                                                               |
| ArubaOS 6.1   | <p>The following parameters were introduced:</p> <ul style="list-style-type: none"> <li>• Short guard interval in 20 MHz mode</li> <li>• Low-density Parity Check</li> <li>• Maximum number of spatial streams usable for STBC reception</li> <li>• Maximum number of spatial streams usable for STBC transmission</li> </ul> <p>The <b>allow weak encryption</b> parameter was deprecated.</p> |
| ArubaOS 6.2   | <p>The following parameters were introduced.</p> <ul style="list-style-type: none"> <li>• Transmit Beamforming Compressed Steering</li> <li>• Transmit Beamforming non Compressed Steering</li> <li>• Transmit Beamforming delayed feedback support</li> <li>• Transmit Beamforming immediate feedback support</li> <li>• Transmit Beamforming Sounding Interval</li> </ul>                     |

## Command Information

| Platforms                                                           | Licensing | Command Mode                      |
|---------------------------------------------------------------------|-----------|-----------------------------------|
| All platforms but operates with IEEE 802.11n compliant devices only |           | Config mode on master controllers |

## show wlan ssid-profile

```
show wlan ssid-profile [<profile>]
```

### Description

Show a list of all SSID profiles, or display detailed configuration information for a specific SSID profile.

### Syntax

| Parameter | Description              |
|-----------|--------------------------|
| <profile> | Name of an SSID profile. |

### Usage Guidelines

Issue this command without the <profile> parameter to display the entire SSID profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has six configured SSID profiles. The **References** column lists the number of other profiles with references to the SSIDs profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan ssid-profile
SSID Profile List

Name References Profile Status

coltrane-ssid-profile 1
corpl -ssid-profile 3
Remote 1
Secure-Profile2 0
test-ssid-profile 1
wizardtest-ssid-profile 1

Total:6
```

The following example shows configuration settings defined for the SSID Profile **Remote**.

```
(host) #show wlan ssid-profile remote

(host) #show wlan ssid-profile remote
SSID Profile "Remote"
(host) #show wlan ssid-profile remote

Parameter Value

SSID enable Enabled
ESSID aruba-ap
Encryption opensystem
Enable Management Frame Protection Disabled
Require Management Frame Protection Disabled
DTIM Interval 1 beacon periods
802.11a Basic Rates 6 12 24
802.11a Transmit Rates 6 9 12 18 24 36 48 54
```

```

802.11g Basic Rates 1 2
802.11g Transmit Rates 1 2 5 6 9 11 12 18 24 36 48 54
Station Ageout Time 1000 sec
Max Transmit Attempts 8
RTS Threshold 2333 bytes
Short Preamble Enabled
Max Associations 64
Wireless Multimedia (WMM) Disabled
Wireless Multimedia U-APSD (WMM-UAPSD) Powersave Enabled
WMM TSPEC Min Inactivity Interval 0 msec
Override DSCP mappings for WMM clients Disabled
DSCP mapping for WMM voice AC N/A
DSCP mapping for WMM video AC N/A
DSCP mapping for WMM best-effort AC N/A
DSCP mapping for WMM background AC N/A
Multiple Tx Replay Counters Disabled
Hide SSID Disabled
Deny_Broadcast Probes Disabled
Local Probe Request Threshold (dB) 0
Disable Probe Retry Enabled
Battery Boost Disabled
WEP Key 1 N/A
WEP Key 2 N/A
WEP Key 3 N/A
WEP Key 4 N/A
WEP Transmit Key Index 1
WPA Hexkey N/A
WPA Passphrase N/A
Maximum Transmit Failures 0
EDCA Parameters Station profile N/A
EDCA Parameters AP profile N/A
BC/MC Rate Optimization Disabled
Rate Optimization for delivering EAPOL frames Disabled
Strict Spectralink Voice Protocol (SVP) Disabled
High-throughput SSID Profile default
802.11g Beacon Rate default
802.11a Beacon Rate default
Advertise QBSS Load IE Disabled
Advertise Location Info Enabled
Advertise AP Name Disabled
802.11R Profile N/A
Enforce user vlan for open stations Enabled

```

The output of this command includes the following data columns:

| Parameter  | Description                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------|
| SSID       | Shows of the profile has enabled or disabled this SSID                                                                  |
| ESSID      | Name that uniquely identifies a wireless network. If the ESSID includes spaces, you must enclose it in quotation marks. |
| Encryption | The layer-2 authentication and encryption type used on this ESSID.                                                      |

| Parameter                                        | Description                                                                                                                                                       |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DTIM Interval                                    | The interval, in milliseconds, between the sending of Delivery Traffic Indication Messages (DTIMs) in the beacon.                                                 |
| 802.11a Basic Rates                              | List of supported 802.11a rates, in Mbps, that are advertised in beacon frames and probe responses.                                                               |
| 802.11a Transmit Rates                           | Set of 802.11a rates at which the AP is allowed to send data.                                                                                                     |
| 802.11g Basic Rates                              | List of supported 802.11b/g rates, in Mbps, that are advertised in beacon frames and probe responses.                                                             |
| 802.11g Transmit Rates                           | Set of 802.11b/g rates at which the AP is allowed to send data.                                                                                                   |
| Station Ageout Time                              | Time, in seconds, that a client is allowed to remain idle before being aged out.                                                                                  |
| Max Transmit Attempts                            | Maximum transmission failures allowed before the client gives up.                                                                                                 |
| RTS Threshold                                    | Wireless clients transmitting frames larger than this defined threshold must issue Request to Send (RTS) and wait for the AP to respond with Clear to Send (CTS). |
| Short Preamble                                   | Shows if the profile enables or disables short preamble for 802.11b/g radios                                                                                      |
| Max Associations                                 | Maximum number of wireless clients for the AP                                                                                                                     |
| Wireless Multimedia (WMM)                        | Shows if the profile enables or disables WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF)                                       |
| Wireless Multimedia U-APSD (WMM-UAPSD) Powersave | Shows if the profile enables or disables Wireless Multimedia (WMM) UAPSD powersave.                                                                               |
| WMM TSPEC Min Inactivity Interval                | Specifies the minimum inactivity time-out threshold of WMM traffic.                                                                                               |
| DSCP mapping for WMM voice AC                    | DSCP value used to map WMM voice traffic.                                                                                                                         |
| DSCP mapping for WMM video AC                    | DSCP value used to map WMM video traffic.                                                                                                                         |

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DSCP mapping for WMM best-effort AC | DSCP value used to map WMM best-effort traffic.                                                                                                                                                                                                                                                                                  |
| DSCP mapping for WMM background AC  | DSCP value used to map WMM background traffic.                                                                                                                                                                                                                                                                                   |
| 902i1 Compatibility Mode            | (For clients using NTT DoCoMo 902iL phones only) When enabled, the controller does not drop packets from the client if a small or old initialization vector value is received.                                                                                                                                                   |
| Hide SSID                           | Shows if the profile enables or disables hiding of the SSID name in beacon frames.                                                                                                                                                                                                                                               |
| Deny_Broadcast Probes               | When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID |
| Local Probe Response                | Shows if the profile enables or disables local probe response on the AP. If this option is enabled, the AP is responsible for sending 802.11 probe responses to wireless clients' probe requests. If this option is disabled, then the controller sends the 802.11 probe responses                                               |
| Disable Probe Retry                 | Shows if the profile enables or disables battery MAC level retries for probe response frames.                                                                                                                                                                                                                                    |
| Battery Boost                       | If enabled, this feature converts multicast traffic to unicast before delivery to the client, thus allowing you to set a longer DTIM interval.                                                                                                                                                                                   |
| WEP Key 1                           | Displays the Static WEP key associated with this key index.                                                                                                                                                                                                                                                                      |
| WEP Key 2                           | Displays the Static WEP key associated with this key index.                                                                                                                                                                                                                                                                      |
| WEP Key 3                           | Displays the Static WEP key associated with this key index.                                                                                                                                                                                                                                                                      |
| WEP Key 4                           | Displays the Static WEP key associated with this key index.                                                                                                                                                                                                                                                                      |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WEP Transmit Key Index                                 | Show the key index that specifies which static WEP key is to be used                                                                                                                                                                                                                                                      |
| WPA Hexkey                                             | WPA pre-shared key (PSK).                                                                                                                                                                                                                                                                                                 |
| WPA Passphrase                                         | WPA passphrase used to generate a pre-shared key (PSK).                                                                                                                                                                                                                                                                   |
| Maximum Transmit Failures                              | Maximum transmission failures allowed before the client gives up.                                                                                                                                                                                                                                                         |
| EDCA Parameters Station profile                        | Name of the enhanced distributed channel access (EDCA) Station profile that applies to this SSID.                                                                                                                                                                                                                         |
| EDCA Parameters AP profile                             | Name of the enhanced distributed channel access (EDCA) AP profile that applies to this SSID.                                                                                                                                                                                                                              |
| BC/MC Rate Optimization                                | Shows if the profile enables or disables scanning of all active stations currently associated to an AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate |
| Rate Optimization for delivering EAPOL frames Disabled | If this option is enabled, APs using this profile will use a more conservative rate for more reliable delivery of EAPOL frames.                                                                                                                                                                                           |
| Strict Spectralink Voice Protocol (SVP)                | Shows if the profile enables or disables strict Spectralink Voice Protocol (SVP).                                                                                                                                                                                                                                         |
| High-throughput SSID Profile                           | Name of the high-throughput SSID profile associated with this SSID profile.                                                                                                                                                                                                                                               |
| Advertise Location Info                                | APs that are part of this VAP will broadcast their GPS coordinates in the beacons and probe response frames as part of a vendor-specific Information Element.                                                                                                                                                             |
| Enforce user vlan for open stations                    | Shows the strict enforcement of data traffic only in user's assigned vlan (Open stations only).                                                                                                                                                                                                                           |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

# show wlan traffic-management-profile

show wlan traffic-management-profile [<profile>]

## Description

Show a list of all traffic management profiles, or display detailed configuration information for a specific traffic management profile.

## Syntax

| Parameter | Description                           |
|-----------|---------------------------------------|
| <profile> | Name of a Traffic Management profile. |

## Usage Guidelines

Issue this command without the <profile> parameter to display the entire Traffic Management profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has three configured Traffic Management profiles. The **References** column lists the number of other profiles with references to the Traffic Management profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan traffic-management-profile
Traffic management profile List

Name References Profile Status
---- -
mgmt1 3
mgmt2 2
Total:2
```

The following example shows configuration settings defined for the profile **mgmt1**.

```
(host) #show wlan traffic-management-profile mgmt1
Traffic management profile "default"

Parameter Value

Proportional BW Allocation N/A
Report interval 5 min
Station Shaping Policy default-access
```

The output of this command includes the following data columns:

| Parameter                  | Description                                                                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Proportional BW Allocation | Minimum bandwidth, as a percentage of available bandwidth, allocated to an SSID when there is congestion on the wireless network. An SSID can use all available bandwidth if no other SSIDs are active. |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Report interval        | Number of minutes between bandwidth usage reports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Station Shaping Policy | <p>Shows which of three possible Station Shaping policies is configured on the profile.</p> <ul style="list-style-type: none"> <li>• <b>default-access:</b> Traffic shaping is disabled, and client performance is dependent on MAC contention resolution. This is the default traffic shaping setting.</li> <li>• <b>fair-access:</b> Each client gets the same airtime, regardless of client capability and capacity. This option is useful in environments like a training facility or exam hall, where a mix of 802.11a/g, 802.11g and 802.11n clients need equal to network resources, regardless of their capabilities. The <b>bw-alloc</b> parameter of a traffic management profile allows you to set a minimum bandwidth to be allocated to a virtual AP profile when there is congestion on the wireless network. You must set traffic shaping to <b>fair-access</b> to use this bandwidth allocation value for an individual virtual AP.</li> <li>• <b>preferred-access:</b> High-throughput (802.11n) clients do not get penalized because of slower 802.11a/g or 802.11b transmissions that take more air time due to lower rates. Similarly, faster 802.11a/g clients get more access than 802.11b clients.</li> </ul> |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

# show wlan tsm-req-profile

show wlan tsm-req-profile

## Description

Shows configuration and other information about the parameters for the Transmit Stream/Category Measurement Request frames.

## Syntax

| Parameter      | Description                                                         |
|----------------|---------------------------------------------------------------------|
| <profile-name> | Name of this instance of the profile. name must be 1-63 characters. |

## Usage Guidelines

Issue this command without the <profile> parameter to display the entire TSM Request profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

For this profile to take effect, the 802.11K feature needs to be enabled.

## Examples

```
(host) #show wlan tsm-req-profile default
TSM Report Request Profile "default"

Parameter Value

Request Mode for TSM Report Request normal
Number of repetitions 65535
Duration Mandatory Enabled
Randomization Interval 0
Measurement Duration 25
Traffic ID 96
Bin 0 Range 200
```

The output of this command includes the following information:

| Parameter                           | Description                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Request mode for TSM Report Request | Shows the request mode for the Transmit Stream/Category Measurement Request frame.                                                  |
| Number of repetitions               | Shows the "Number of Repetitions" field in the TransmitStream/Category Measurement Request frame.                                   |
| Duration Mandatory                  | Shows the "Duration Mandatory" bit of the Measurement Request Mode field of the Transmit Stream/Category Measurement Request frame. |
| Randomization Interval              | Shows the Randomization Interval field in the Transmit Stream/Category Measurement Request frame.                                   |

| Parameter            | Description                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------|
| Measurement Duration | Shows the Measurement Duration field in the Transmit Stream/Category Measurement Request frame. |
| Traffic ID           | Shows the Traffic Identifier field in the Transmit Stream/Category Measurement Request frame.   |
| Bin 0 Range          | Shows the 'Bin 0 Range' field in the Transmit Stream/Category Measurement Request frame.        |

## Command History

This command is introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Enable mode on master or local controllers |

## show wlan virtual-ap

```
show wlan virtual-ap <profile-name>
```

### Description

Show a list of all Virtual AP profiles, or display detailed configuration information for a specific Virtual AP profile.

### Syntax

| Parameter      | Description                  |
|----------------|------------------------------|
| <profile-name> | Name of a Virtual AP profile |

### Usage Guidelines

Issue this command without the <profile> parameter to display the entire Virtual AP profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has six configured Virtual AP profiles. The **References** column lists the number of other profiles with references to the Virtual AP profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan virtual-ap
```

```
Virtual AP profile List
```

| Name                   | References | Profile Status |
|------------------------|------------|----------------|
| -----                  | -----      | -----          |
| coltrane-vap-profile   | 1          |                |
| default                |            |                |
| MegTest                |            |                |
| Remote                 | 1          |                |
| test-vap-profile       | 1          |                |
| wizardtest-vap-profile | 1          |                |
| Total: 6               |            |                |

The following example shows configuration settings defined for the profile **wizardtest-vap-profile**.

```
(host) #show wlan virtual-ap test-vap-profile
```

```
Virtual AP profile "wizardtest-vap-profile"
```

| Parameter         | Value       |
|-------------------|-------------|
| -----             | -----       |
| AAA Profile       | default     |
| 802.11K Profile   | default     |
| SSID Profile      | default     |
| Virtual AP enable | Enabled     |
| VLAN              | N/A         |
| Forward mode      | tunnel      |
| Allowed band      | all         |
| Band Steering     | Disabled    |
| Steering Mode     | prefer-5ghz |

|                                           |             |
|-------------------------------------------|-------------|
| Dynamic Multicast Optimization (DMO)      | Enabled     |
| Dynamic Multicast Optimization (DMO)      | Threshold 6 |
| Drop Broadcast and Multicast              | Disabled    |
| Convert Broadcast ARP requests to unicast | Enabled     |
| Authentication Failure Blacklist Time     | 3600 sec    |
| Blacklist Time                            | 3600 sec    |
| Deny inter user traffic                   | Disabled    |
| Deny time range                           | N/A         |
| DoS Prevention                            | Disabled    |
| HA Discovery on-association               | Disabled    |
| Mobile IP                                 | Enabled     |
| Preserve Client VLAN                      | Disabled    |
| Remote-AP Operation                       | standard    |
| Station Blacklisting                      | Enabled     |
| Strict Compliance                         | Disabled    |
| VLAN Mobility                             | Disabled    |
| FDB Update on Assoc                       | Disabled    |
| WMM Traffic Management Profile            | N/A         |
| Anyspot Profile                           | N/A         |

The output of this command includes the following data columns:

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AAA Profile       | Name of the AAA profile associated with this virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 802.11K Profile   | Name of an 802.11k profile associated with this virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SSID Profile      | Name of an SSID profile associated with this virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Virtual AP enable | Shows if the profile enables or disables the virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| VLAN              | The VLAN(s) into which users are placed in order to obtain an IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Forward mode      | <p>Forwarding mode defined on the profile:</p> <ul style="list-style-type: none"> <li>• <b>tunnel mode</b></li> <li>• <b>bridge mode</b></li> <li>• <b>split-tunnel mode</b></li> <li>• <b>decrypt-tunnel mode</b></li> </ul> <p>The forwarding mode controls whether data is tunneled to the controller using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the controller, and Internet access remains local).</p> |

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                      | When an AP is configured to use the decrypt-tunnel forwarding mode, that AP decrypts and decapsulates all 802.11 frames from a client and sends the 802.3 frames through the GRE tunnel to the controller, which then applies firewall policies to the user traffic. When the controller sends traffic to a client, the controller sends 802.3 traffic through the GRE tunnel to the AP, which then converts it to encrypted 802.11 and forwards to the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Band Steering                        | If enabled, ARM's band steering feature encourages dual-band capable clients to stay on the 5GHz band on dual-band APs. This frees up resources on the 2.4GHz band for single band clients like VoIP phones.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Steering Mode                        | <p>Band steering supports three different band steering modes.</p> <ul style="list-style-type: none"> <li>• <b>Force-5GHz:</b> When the AP is configured in <b>force-5GHz</b> band steering mode, the AP will try to force 5Ghz-capable APs to use that radio band.</li> <li>• <b>Prefer-5GHz (Default):</b> If you configure the AP to use <b>prefer-5GHz</b> band steering mode, the AP will try to steer the client to 5G band (if the client is 5G capable) but will let the client connect on the 2.4G band if the client persists in 2.4G association attempts.</li> <li>• <b>Balance-bands:</b> In this band steering mode, the AP tries to balance the clients across the two radios in order to best utilize the available 2.4G bandwidth. This feature takes into account the fact that the 5Ghz band has more channels than the 2.4 Ghz band, and that the 5Ghz channels operate in 40MHz while the 2.5Ghz band operates in 20MHz.</li> </ul> <p><b>NOTE:</b> Steering modes do not take effect until the band steering feature has been enabled. The band steering feature in ArubaOS versions 3.3.2-5.0 does not support multiple band-steering modes. The band-steering feature in these versions of ArubaOS functions the same way as the default <b>prefer-5GHz</b> steering mode available in ArubaOS 6.0 and later.</p> |
| Dynamic Multicast Optimization (DMO) | If enabled DMO techniques will be used to reliably transmit video data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dynamic Multicast Optimization (DMO) Threshold | Maximum number of high-throughput stations in a multicast group beyond which dynamic multicast optimization stops.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Drop Broadcast and Multicast                   | If enabled, the virtual AP will filter out broadcast and multicast traffic in the air.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Convert Broadcast ARP requests to unicast      | If enabled, all broadcast ARP requests are converted to unicast and sent directly to the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Authentication Failure Blacklist Time          | Time, in seconds, a client is blocked if it fails repeated authentication. An authentication failure blacklist time of 0 blocks failed users indefinitely.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Blacklist Time                                 | Number of seconds that a client is quarantined from the network after being blacklisted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Deny Inter User Traffic                        | <p>This option, when enabled, denies traffic between the clients using this virtual AP profile.</p> <p>The <b>firewall</b> command includes an option to deny all inter-user traffic, regardless of the Virtual AP profile used by those clients.</p> <p>If the global setting to deny inter-user traffic is enabled, all inter-user traffic between clients will be denied, regardless of the settings configured in the virtual AP profiles. If the setting to deny inter-user traffic is disabled globally but enabled on an individual virtual ap, only the traffic between untrusted users and the clients on that particular virtual AP will be blocked.</p> |
| Deny time range                                | Time range for which the AP will deny access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DoS Prevention                                 | If enabled, APs ignore deauthentication frames from clients. This prevents a successful deauth attack from being carried out against the AP. This does not affect third-party APs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| HA Discovery on-association                    | <p>If enabled, home agent discovery is triggered on client association instead of home agent discovery based on traffic from client. Mobility on association can speed up roaming and improve connectivity for clients that do not send many uplink packets to trigger mobility (VoIP clients). Best practices is to leave this parameter disabled as it increases IP mobility control traffic between controllers in the same mobility domain. Enable this parameter only when voice issues are observed in VoIP clients.</p> <p><b>NOTE:</b> <b>ha-disc-onassoc</b> parameter works only when IP mobility is enabled and configured on the controller.</p>       |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mobile IP            | Shows if the profile has enabled or disabled IP mobility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Preserve Client VLAN | This parameter allows clients to retain their previous VLAN assignment if the client disassociates from an AP and then immediately re-associates either with same AP or another AP on same controller.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Remote-AP Operation  | Shows when the virtual AP operates on a remote AP: <ul style="list-style-type: none"> <li>• <b>always</b>—Permanently enables the virtual AP (Bridge Mode only). This option can be used for non-802.1X bridge VAPs.</li> <li>• <b>backup</b>—Enables the virtual AP if the remote AP cannot connect to the controller (Bridge Mode only). This option can be used for non-802.1X bridge VAPs.</li> <li>• <b>persistent</b>—Permanently enables the virtual AP after the remote AP initially <b>connects</b> to the controller (Bridge Mode only). This option can be used for any (Open/PSK/802.1X) bridge VAPs.</li> <li>• <b>standard</b>—Enables the virtual AP when the remote AP connects to the controller. This option can be used for any (bridge/split-tunnel/tunnel/d-tunnel) VAPs.</li> </ul> |
| Station Blacklisting | Shows if the profile has enabled or disabled detection of denial of service (DoS) attacks, such as ping or SYN floods, that are not spoofed deauth attacks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Strict Compliance    | If enabled, the AP denies client association requests if the AP and client station have no common rates defined. Some legacy client stations which are not fully 802.11-compliant may not include their configured rates in their association requests. Such non-compliant stations may have difficulty associating with APs unless strict compliance is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Multi Association    | If enabled, this feature allows a station to be associated to multiple APs. If this feature is disabled, when a station moves to new AP it will be de authorized by the AP to which it was previously connected, deleting station context and flushing key caching information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Fast Roaming         | Shows if the AP has enabled or disabled fast roaming.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                      | Description                                                            |
|--------------------------------|------------------------------------------------------------------------|
| VLAN Mobility                  | Shows if the AP has enabled or disabled VLAN (Layer-2) mobility.       |
| WMM Traffic Management Profile | WMM Traffic Management Profile associated with this Virtual AP Profile |
| Anyspot profile                | Anyspot Profile associated with this Virtual AP Profile                |

## Command History

This command was introduced in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

## show wlan voip-cac-profile

```
show wlan voip-cac-profile [<profile>]
```

### Description

Show a list of all VoIP Call Admission Control profiles, or display detailed configuration information for a specific VoIP Call Admission Control profile.

### Syntax

| Parameter | Description                                   |
|-----------|-----------------------------------------------|
| <profile> | Name of a VoIP Call Admission Control profile |

### Usage Guidelines

Issue this command without the <profile> parameter to display the entire VoIP Call Admission Control profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

### Examples

The example below shows that the controller has three configured VoIP Call Admission Control profiles. The **References** column lists the number of other profiles with references to the VoIP Call Admission Control profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan voip-cac-profile
VoIP Call Admission Control profile List

Name References Profile Status

corp-voip 6
kgtest 0
QAlab-voip 1
Total:3
```

The following example shows configuration settings defined for the profile **QAlab-voip**.

```
(host) #show wlan voip-cac-profile
VoIP Call Admission Control profile "QAlab-voip "

Parameter Value

VoIP Call Admission Control Disabled
VoIP Bandwidth based CAC Disabled
VoIP Call Capacity 10
VoIP Bandwidth Capacity (kbps) 2000
VoIP Call Handoff Reservation 20 %
VoIP Send SIP 100 Trying Enabled
VoIP Disconnect Extra Call Disabled
VOIP TSPEC Enforcement Disabled
VOIP TSPEC Enforcement Period 1 sec
VoIP Drop SIP Invite and send status code (client) 486
VoIP Drop SIP Invite and send status code (server) 486
```

The output of this command includes the following data columns:

| Parameter                                          | Description                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VoIP Call Admission Control                        | Shows if the profile enables or disables WiFi VoIP Call Admission Control features.                                                                                                                                                                                                                                     |
| VoIP Bandwidth based CAC                           | Shows the desired call admission control (CAC) Mechanism: <ul style="list-style-type: none"> <li>• Disable - CAC is based on Call Counts</li> <li>• Enable - CAC should be based on Bandwidth.</li> </ul>                                                                                                               |
| VoIP Call Capacity                                 | Number of simultaneous calls that can be handled by one radio.                                                                                                                                                                                                                                                          |
| VoIP Bandwidth Capacity (kbps)                     | The maximum bandwidth that can be handled by one radio, in kbps.                                                                                                                                                                                                                                                        |
| VoIP Call Handoff Reservation                      | Percentage of call capacity reserved for mobile VoIP clients on call.                                                                                                                                                                                                                                                   |
| VoIP Send SIP 100 Trying                           | Shows if the profile enables or disables sending of <i>SIP 100 - trying</i> messages to a call originator to indicate that the call is proceeding.                                                                                                                                                                      |
| VoIP Disconnect Extra Call                         | If enabled, the controller disconnects calls that exceed the high capacity threshold by sending a deauthentication frame.                                                                                                                                                                                               |
| VOIP TSPEC Enforcement                             | Shows if the profile enables or disables validation of TSPEC requests for CAC.                                                                                                                                                                                                                                          |
| VOIP TSPEC Enforcement Period                      | Maximum time for the station to start the call after the TSPEC request                                                                                                                                                                                                                                                  |
| VoIP Drop SIP Invite and send status code (client) | Display the status code sent back to the client if the profile is configured to drop a SIP Invite: <ul style="list-style-type: none"> <li>• <b>480:</b> Temporary Unavailable</li> <li>• <b>486:</b> Busy Here</li> <li>• <b>503:</b> Service Unavailable</li> <li>• <b>none:</b> Don't send SIP status code</li> </ul> |
| VoIP Drop SIP Invite and send status code (server) | Display the status code sent back to the server if the profile is configured to drop a SIP Invite: <ul style="list-style-type: none"> <li>• <b>480:</b> Temporary Unavailable</li> <li>• <b>486:</b> Busy Here</li> </ul>                                                                                               |

|           | <ul style="list-style-type: none"> <li>• <b>503:</b> Service Unavailable</li> <li>• <b>none:</b> Don't send SIP status code</li> </ul> |

## Command History

This command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                           |
|---------------|-----------------------|--------------------------------------------------------|
| All platforms | Base operating system | Enable and Config mode on master or local controllers. |

# show wlan wmm-traffic-management-profile

show wlan wmm-traffic-management-profile [<profile-name>]

## Description

Display a list of all WMM traffic management profiles, or display detailed configuration information for a specific WMM traffic management profile.

## Syntax

| Parameter      | Description                                 |
|----------------|---------------------------------------------|
| <profile-name> | Name of the WMM traffic management profile. |

## Usage Guidelines

Issue this command without the <profile> parameter to display the entire WMM traffic management profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has two configured WMM traffic management profiles. The **References** column lists the number of other profiles with references to the WMM traffic management profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host) #show wlan wmm-traffic-management-profile
```

```
WMM Traffic management profile List
```

```

Name References Profile Status
---- -
default 3
test 2
```

```
Total:2
```

The following example shows configuration settings defined for the profile **test**.

```
(host) #show wlan traffic-management-profile test
```

```
WMM Traffic management profile "test"
```

```

Parameter Value

Enable Shaping Policy true
Voice Share 40 %
Video Share 43 %
Best-effort Share 10 %
Background Share 7 %
```

The output of this command includes the following data columns:

| Parameter             | Description                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------|
| Enable Shaping Policy | Displays if WMM based traffic shaping is enabled on the controller.                          |
| Voice Share           | Displays the bandwidth allocation in percentage (%) for voice access traffic category.       |
| Vimeo Share           | Displays the bandwidth allocation in percentage (%) for video access traffic category.       |
| Best-effort Share     | Displays the bandwidth allocation in percentage (%) for best effort access traffic category. |
| Background Share      | Displays the bandwidth allocation in percentage (%) for background access traffic category.  |

## show wms ap

```
show wms ap {<bssid>}|list|{stats [mon-mac <mon-mac> bssid <bssid>]}
```

### Description

Display information for APs currently monitored by the ArubaOS Wireless Management System (WMS).

### Syntax

| Parameter         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <bssid>           | Enter the AP's BSSID number in hexadecimal format (XX:XX:XX:XX:XX:XX). |
| list              | Show the AP Tree table for all APs.                                    |
| stats             | Show the AP Statistics table for all APs.                              |
| mon-mac <mon-mac> | Show the AP Tree table for an AP with the specified MAC address.       |
| bssid <bssid>     | Show the AP Tree table for an AP with the specified BSSID.             |

### Usage Guidelines

The WMS feature periodically sends statistics that it has collected for APs and Probes to the WMS process. When WMS receives an event message from an AM, it will save the event information along with the BSSID of the AP that generated the event in the WMS database. When WMS receives statistics from the AM, it updates its state, and the database.

### Examples

The command **show wms ap <bssid>** displays a list of AP MAC addresses and the BSSIDs seen by each AP.

```
(host)# show wms ap 00:1a:1e:88:01:e0
```

AP Info

The output of this command includes the following information:

| Column      | Description                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BSSID       | Basic Service Set Identifier for the AP. This is usually the AP's MAC address.                                                                                                                                                                                                                        |
| SSID        | The Service Set Identifier that identifies a wireless network.                                                                                                                                                                                                                                        |
| Channel     | Channel used by the AP's radio.                                                                                                                                                                                                                                                                       |
| Type        | A WMS AP type can be one of the following: <ul style="list-style-type: none"> <li>• soft-ap: A Dell Access Point (AP).</li> <li>• air-monitor: A Dell Air Monitor (AM).</li> </ul>                                                                                                                    |
| RAP_Type    | Indicates one of the following Rogue AP types: <ul style="list-style-type: none"> <li>• Valid (not a rogue AP)</li> <li>• Interfering</li> <li>• Rogue</li> <li>• Suspected Rogue</li> <li>• Disabled Rogue</li> <li>• Unclassified</li> <li>• Known Interfering</li> </ul>                           |
| Status      | If up, the AP is active. If down (or no information is shown) the AP is inactive.                                                                                                                                                                                                                     |
| Match MAC   | MAC address of a wired device that helped identify the AP as a rogue. If the AP has not been identified as a rogue, this column will display the MAC address 00:00:00:00:00:00.                                                                                                                       |
| Ageout      | An ageout time is the time, in minutes, that the client must remain unseen by any probes before it is eliminated from the database. If this column displays a - 1, the client has not yet aged out. Any other number indicates the number of minutes since the client has passed its ageout interval. |
| HT-type     | The type of high-throughput traffic sent by the AP: <ul style="list-style-type: none"> <li>• HT-20mhz: The AP radio uses a single 20 MHz channel</li> <li>• HT-40mhz: The AP radio uses a 40 MHz channel pair comprised of two adjacent 20 MHz channels.</li> </ul>                                   |
| HT-Sec-Chan | Secondary channel used for 40 MHz high-throughput transmissions.                                                                                                                                                                                                                                      |
| MAC         | MAC address of a probe that can see the specified AP.                                                                                                                                                                                                                                                 |
| IP          | IP address of a probe that can see the specified AP.                                                                                                                                                                                                                                                  |
| Name        | Name of the probe.                                                                                                                                                                                                                                                                                    |
| Type        | Displays the probe type: A WMS probe can be one of the following:                                                                                                                                                                                                                                     |

| Column  | Description                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------|
|         | <ul style="list-style-type: none"> <li>• soft-ap: A Dell Access Point (AP).</li> <li>• air-monitor: A Dell Air Monitor (AM).</li> </ul> |
| Status  | If up, the AP is active. If down (or no information is shown) the AP is inactive.                                                       |
| AP Type | AP model type.                                                                                                                          |

The example below shows received and transmitted data statistics for each BSSID seen by a monitoring AP.

```
(host)# show wms ap stats
```

```
AP Stats Table
```

```

```

## show wms channel

show wms channel stats

### Description

Display per-channel statistics for monitored APs.

### Syntax

No parameters.

### Example

This example shows per-channel statistics for monitored APs.

```
(host) #show wms channel stats
```

```
Channel Stats Table

Monitor-MAC Channel NumAP NumSta TotalPkt TotalByte Noise

## show wms client

```
show wms client <mac>|{list}|{probe <mac>}|{stats [mon-mac <mon-mac> mac <mac>]}
```

### Description

Display a list of client information for the clients that can be seen by monitoring APs.

### Syntax

| Parameter                   | Description                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <mac>                       | Show statistics for a client with the specified MAC address, including the BSSID of the AP to which that client is currently associated, and the MAC addresses of other monitoring APs that can see that client. |
| list                        | Show statistics for all monitored clients.                                                                                                                                                                       |
| probe <mac>                 | Specify a client's MAC address to show the BSSIDs of all probes that can see that client.                                                                                                                        |
| stats                       | Show the STA stats table, which displays data for all clients seen by each monitoring AP.                                                                                                                        |
| mon-mac <mon-mac> mac <mac> | Enter a monitoring AP's MAC address (<mon-mac>) and the MAC address of a client (<mac>) to show data for traffic received from and sent to a specific client as seen by a specific AP.                           |

### Example

The AP Info table in the example below shows that the client is associated to an AP with the BSSID **00:0b:86:cd:86:a0**. The Probe info table shows the MAC addresses of three other APs that can see the client.

```
(host) #show wms client 00:0e:35:29:9b:28
```

#### STA Info

```

MAC Type Status Ageout

00:0e:35:29:9b:28 valid up -1
```

#### AP Info

```

BSSID SSID Channel Type RAP_Type Status Match MAC Ageout

00:0b:86:cd:86:a0 MySSID 11 soft-ap valid up 00:00:00:00:00:00 -1
```

#### Probe Info

```

MAC IP Name Type Status Name AP Type

00:0b:86:a2:2b:50 192.168.2.10 0 soft-ap up LeftAP 61
00:0b:86:ad:94:40 192.168.2.5 0 soft-ap up 1.1.1 61
```

| Column    | Description                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAC       | MAC address of the client                                                                                                                                                                                                                                                                                     |
| Type      | Station type ( <b>valid</b> , <b>interfering</b> , or <b>disabled rogue client</b> )                                                                                                                                                                                                                          |
| Status    | If <b>up</b> , the client is active. If <b>down</b> (or no information is shown) the client is inactive.                                                                                                                                                                                                      |
| ageout    | An ageout time is the time, in minutes, that the client must remain unseen by any probes before it is eliminated from the database. If this column displays a - <b>1</b> , the client has not yet aged out. Any other number indicates the number of minutes since the client has passed its ageout interval. |
| BSSID     | BSSID of the AP to which the client is associated.                                                                                                                                                                                                                                                            |
| SSID      | Extended service set identifier (ESSID) of the BSSID.                                                                                                                                                                                                                                                         |
| RAP_Type  | Indicates one of the following Rogue AP types: <ul style="list-style-type: none"> <li>Valid (not a rogue AP)</li> <li>Interfering</li> <li>Rogue</li> <li>Disabled Rogue</li> <li>Suspected Rogue</li> <li>Unclassified</li> <li>Known Interfering</li> </ul>                                                 |
| Status    | If <b>up</b> , the AP is active. If <b>down</b> (or no information is shown) the AP is inactive.                                                                                                                                                                                                              |
| Match MAC | MAC address of a wired device that helped identify the AP as a rogue. If the AP has not been identified as a rogue, this column will display the MAC address 00:00:00:00:00:00.                                                                                                                               |
| Ageout    | An ageout time is the time, in minutes, that the client must remain unseen by any probes before it is eliminated from the database. If this column displays a - <b>1</b> , the client has not yet aged out. Any other number indicates the number of minutes since the client has passed its ageout interval. |
| MAC       | MAC address of a WMS probe.                                                                                                                                                                                                                                                                                   |
| IP        | IP address of a WMS probe.                                                                                                                                                                                                                                                                                    |
| Type      | A WMS AP type can be one of the following: <ul style="list-style-type: none"> <li><b>soft-ap</b>: Dell Access Point (AP).</li> <li><b>air-monitor</b>: Dell Air Monitor (AM).</li> </ul>                                                                                                                      |

| Column  | Description                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------|
| Status  | If <b>up</b> , the probe is active. If <b>down</b> (or no information is shown) the probe is inactive. |
| Name    | Name of the probe. If a name has not been defined for the probe, this column may display a zero (0).   |
| AP type | Model type of the probe.                                                                               |

The output of this command includes the following information:

## Command History

This command was introduced in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show wms counters

show wms counters [debug|event]

### Description

Show WMS event and debug counters. If you omit the optional **debug** and **events** parameters, the **show wms counters** command will display wms debug and events counters in a single table.

### Syntax

| Parameter | Description                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| debug     | Show show debug counters only                                                                                                                           |
| events    | Show events counters only. If you omit the debug and events parameters, the show wms counters will display debug and events counters in a single table. |

### Usage Guidelines

This command displays counters for database entries, messages and data structures. The counters displayed will vary for each controller; if the controller does not have an entry for a particular counter type, it will not appear in the output of this command

### Example

This example shows part of the output of the command **show wms counters**.

```
(host) #show wms counters
```

```

### Command History

This command was introduced in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show wms monitor-summary

show wms channel stats

### Description

Display the numbers of different AP and client types monitored over the last 5 minutes, 1 hour, and since the controller was last reset.

### Syntax

No parameters.

### Usage Guidelines

The WLAN management system (WMS) on the controller monitors wireless traffic to detect any new AP or wireless client station that tries to connect to the network. When an AP or wireless client is detected, it is classified and its classification is used to determine the security policies which should be enforced on the AP or client. Use the **show wms monitor-summary** command to view a quick summary of each classified AP and client type currently on the network.

If AP learning is enabled (with the wms general command), non-Dell APs connected on the same wired network as Dell APs are classified as valid APs. If AP learning is disabled, a non-Dell AP is classified as an unsecure or suspect-unsecure AP.

### Example

This example shows that the controller currently has 144 valid APs and 32 active valid clients, and verifies that the controller currently aware of a single disabled rogue AP.

```
(host) #show wms monitor-summary
```

WMS Monitor Summary

|                            | Last 5 Min | Last Hour | All |
|----------------------------|------------|-----------|-----|
| -                          | -----      | -----     | --- |
| Valid APs                  | 1          | 1         | 1   |
| Interfering APs            | 57         | 57        | 60  |
| Rogue APs                  | 3          | 3         | 3   |
| Manually Contained APs     | 0          | 0         | 0   |
| Unclassified APs           | 0          | 0         | 0   |
| Neighbor APs               | 0          | 0         | 0   |
| Suspected Rogue APs        | 138        | 138       | 139 |
| Valid Clients              | 0          | 0         | 0   |
| Interfering Clients        | 1          | 1         | 1   |
| Manually Contained Clients | 0          | 0         | 0   |

## show wms probe

show wms probe

### Description

Display detailed information for a list of WMS probes.

### Syntax

No parameters.

### Example

This example shows the Probe List table for WMS probes. The output below has been split into two tables to better fit in this document. In the actual command-line interface, this information appears in a single, long table.

```
(host) #show wms monitor-summary
```

WMS Monitor Summary

|                            | Last 5 Min | Last Hour | All |
|----------------------------|------------|-----------|-----|
| -                          | -----      | -----     | --- |
| Valid APs                  | 1          | 1         | 1   |
| Interfering APs            | 57         | 57        | 60  |
| Rogue APs                  | 3          | 3         | 3   |
| Manually Contained APs     | 0          | 0         | 0   |
| Unclassified APs           | 0          | 0         | 0   |
| Neighbor APs               | 0          | 0         | 0   |
| Suspected Rogue APs        | 138        | 138       | 139 |
| Valid Clients              | 0          | 0         | 0   |
| Interfering Clients        | 1          | 1         | 1   |
| Manually Contained Clients | 0          | 0         | 0   |

| Column          | Description                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monitor Eth MAC | Ethernet MAC address of a probe.                                                                                                                                             |
| BSSID           | Probe Radio BSSID.                                                                                                                                                           |
| PHY Type        | Radio PHY type: <ul style="list-style-type: none"><li>• 802.11A</li><li>• 802.11AHT-40Mbps</li><li>• 802.11AHT-20Mbps</li><li>• 802.11G</li><li>• 802,11GHT-20Mbps</li></ul> |
| IP              | IP address of the AP.                                                                                                                                                        |

| Column     | Description                                                                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IMS IP     | IP address of the AP's local controller.                                                                                                                                                         |
| Scan       | Shows if the Air Monitor is performing scanning.                                                                                                                                                 |
| Status     | If the scan column displays a status of Up, the AP or AM is active                                                                                                                               |
| Updates    | Number of updates the AP or AM sent to the WMS database since the controller was last reset.                                                                                                     |
| Reqs/Fails | Number of database update requests that have not yet been added into the database. and the number of failed database requests.                                                                   |
| Stats      | Total number of statistics updates sent to the database.                                                                                                                                         |
| Type       | A WMS AP type can be one of the following: <ul style="list-style-type: none"> <li>• <b>soft-ap</b>: A Dell Access Point (AP).</li> <li>• <b>air-monitor</b>: A Dell Air Monitor (AM).</li> </ul> |

The output of this command includes the following information:

## show wms rogue-ap

show wms rogue-ap <mac>

### Description

Display statistics for APs classified as rogues APs.

### Syntax

| Parameter | Description                |
|-----------|----------------------------|
| <mac>     | MAC address of a rogue AP. |

### Example

The output of this command shows statistics for a suspected Rogue AP, including how it was classified as a suspected rogue.

```
(host) #show wms rogue-ap 00:0b:86:d4:ca:12
```

```
Suspect Rogue AP Info
```

```

```

| Key              | Value                    |
|------------------|--------------------------|

| Helper Ap BSSID  | BSSID of the AP or AM that helped classify a rogue AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| AP name          | Names of APs that are able to see the specified MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Match Time       | Time the AP was identified as a rogue AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Confidence Level | <p>Shows the level of confidence that the AP was classified correctly for each match type. The suspected-rogue classification mechanism are:</p> <ul style="list-style-type: none"> <li>Each mechanism that causes a suspected-rogue classification is assigned a confidence level increment of 20%.</li> <li>AP classification rules have a configured confidence level.</li> <li>When a mechanism matches a previously unmatched mechanism, the confidence level increment associated with that mechanism is added to the current confidence level (the confidence level starts at zero).</li> <li>The confidence level is capped at 100%.</li> </ul> <p>If your controller reboots, your suspected-rogue APs are not checked against any new rules that were configured after the reboot. Without this restriction, all the mechanisms that classified your APs as suspected-rogue may trigger again causing the confidence level to surpass their cap of 100%. You can explicitly mark an AP as “interfering” to trigger all new rules to match against it.</p> |

## show wms routers

show wms routers <mac>

### Description

Show Learned Router Mac Information for WMS APs.

### Syntax

| Parameter | Description                                     |
|-----------|-------------------------------------------------|
| <mac>     | MAC address of a probe that can see the router. |

### Usage Guidelines

This command displays the MAC addresses of devices that have been determined to be routers by the listed APs. This output of this command will be blank if there is not any broadcast/multicast activity in an AP's subnet.

### Example

In the example below, a single WMS AP has learned MAC information for four different routers.

```
(host) #show wms routers

Router Mac 00:08:00:00:11:12 is Seen by APs

AP-Name

AP32
Router Mac 00:08:00:00:11:29 is Seen by APs

AP-Name

AP32
Router Mac 00:08:00:00:11:57 is Seen by APs

AP-Name

AP32
Router Mac 00:08:00:00:11:6e is Seen by APs

AP-Name

AP32
```

### Command History

This command was introduced in ArubaOS 3.0

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## show wms rules

```
show wms rules
 config
 state
 summary
```

### Description

Display the internal state and matching information of rules created using the [ids ap-classification-rule change](#) command.

### Syntax

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>config</code>  | Display the following information for each AP classification rule. <ul style="list-style-type: none"><li>• name</li><li>• ids</li><li>• match-ssid</li><li>• min-snr</li><li>• max-snr</li><li>• min-prcnt</li><li>• max-prcnt</li><li>• ssids</li><li>• enabled</li><li>• classify</li><li>• conf-incr</li><li>• flags</li><li>• match-cnt</li></ul> |
| <code>state</code>   | Display the following informatoin for each AP classification rule: <ul style="list-style-type: none"><li>• SSID Match Table</li><li>• SSID Exclude Table</li><li>• SNR Table</li><li>• Probe Count Table</li></ul>                                                                                                                                    |
| <code>summary</code> | Display an AP classification rules summary.                                                                                                                                                                                                                                                                                                           |

### Usage Guidelines

Issue this command to view existing AP classification rules. AP classification rule configuration is performed only on a master controller. If AMP is enabled via the mobility-manager command, then processing of the AP classification rules is disabled on the master controller. A rule is identified by its ASCII character string name (32 characters maximum). The AP classification rules have one of the following specifications:

- SSID of the AP

- SNR of the AP
- Discovered-AP-Count or the number of APs that can see the AP

## Example

The output in the example below shows that although two rules have been defined, neither have been enabled using the **ids ap-rule-matching rule-name <name>** command.

```
(host) (config) #show wms rules summary
```

```
AP Classification Rules Summary
```

```

Parameter Value

Num Rules 2
Num Active-Rules 0
Num SSID-to-match 0
Num SSID-to-exclude 0
Num SNR-bounds 0
Num Probe-Count-bounds 0
```

## Command History

This command was introduced in ArubaOS 6.1

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## show wms system

show wms system

### Description

Show the WMS system configuration and system state.

### Syntax

No parameters.

### Example

This example shows the WMS System Configuration and System State tables.

```
(host) #show wms system

System Configuration

Key Value
--- -
max-threshold 0
max-rbtree-entries 0
max-system-wm 1000
system-wm-update-interval 8

System State

Key Value
--- -
Max Threshold 25000
Current Threshold 230
Total AP Count 228
Total STA Count 5
MAX RB-tree Count 50000
Total Tree Count 195
Poll Count (Max) 1 (2)

Learned OUIs for Deployed APs

OUI

```

| Column            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max Threshold     | The maximum number of table entries allowed. If this table displays a zero (0), there is no configured limit.<br><b>NOTE:</b> If a configured maximum limit has reached, the controller will not create new WMS entries for monitored APs and monitored stations. If new APs are deployed after this limit is reached, those APs will not be marked as 'valid', which will impair the effectiveness of the Adaptive Radio Management feature. If there are new Rogue APs in the network, they will not be classified as a rogue. |
| Current Threshold | Current number of table entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Column            | Description                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total AP Count    | Total number of statistics entries for monitored APs in the AP table.                                                                                                                                                       |
| Total STA Count   | Total number of statistics entries for monitored stations in the Station table.                                                                                                                                             |
| MAX RB-tree Count | Maximum number of entries allowed in the statistics.                                                                                                                                                                        |
| Total Tree Count  | Total number of entries currently in the statistics tree. If this limit has been reached, the controller will not add entries with the RSSI information for APs, monitored APs and monitored clients that are seen by them. |
| Poll Count (Max)  | Current and maximum poll counts.                                                                                                                                                                                            |

The output of this command includes the following information:

## Command History

## show wms wired-mac

```
show wms wired-mac
 gw-mac [<mac>]
 monitored-ap-wm <mac>
 prop-eth-mac
 reg-ap-oui
 summary
 system-gw-mac
 system-wired-mac
 wireless-device}
```

### Description

Display a summary table of Wireless Management System (wms) wired MAC information. This command can display a list of APs aware of a specific gateway MAC address, or list the wired MAC addresses known to a single AP.

### Syntax

| Column                | Description                                                                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| gw-mac <mac>          | Show Gateway Wired Mac Information Collected from the APs. If you include the optional <b>&lt;mac&gt;</b> MAC address parameter, the output of this command will show information for that single MAC address only.                                                                                                                    |
| monitored-ap-wm <mac> | Show Monitored AP Wired Mac Information Collected from the APs. If you include the optional <b>&lt;mac&gt;</b> MAC address parameter, the output of this command will show information for that single MAC address only.                                                                                                               |
| prop-eth-mac <mac>    | Show Wired Mac Information Collected from the APs. If you include the optional <b>&lt;mac&gt;</b> MAC address parameter, the output of this command will show information for that single MAC address only.                                                                                                                            |
| reg-ap-oui <mac>      | Show Registered AP OUI Information Collected from the APs, including each registered OUI, and the time that OUI was last seen. If you include the optional <b>&lt;mac&gt;</b> MAC address parameter, the output of this command will show information for that single MAC address only.                                                |
| summary               | Display a wired MAC summary that includes the number of each of the following MAC types: <ul style="list-style-type: none"><li>• Registered AP OUIs</li><li>• Propagated Ethernet MACs.</li><li>• Potential Wireless Device MACs</li><li>• Monitored AP Wired MACs</li><li>• System Wired MACs</li><li>• System Gateway MACs</li></ul> |

| Column           | Description                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| system-gw-mac    | Show system gateway MAC information learned at the controller, including the age of each MAC address. If you include the optional <b>&lt;mac&gt;</b> MAC address parameter, the output of this command will show information for that single MAC address only. |
| system-wired-mac | Show system wired MAC information learned at the controller. If you include the optional <b>&lt;mac&gt;</b> MAC address parameter, the output of this command will show information for that single MAC address only.                                          |
| wireless-device  | Show Routers or potential wireless devices information, including the MAC address of the device, and the MAC address of the AP or controller that saw the device.                                                                                              |

## Example

This example shows the wired MAC summary.

```
(host) #show wms system

System Configuration

Key Value
--- -
max-threshold 0
max-rbtree-entries 0
max-system-wm 1000
system-wm-update-interval 8

System State

Key Value
--- -
Max Threshold 25000
Current Threshold 230
Total AP Count 228
Total STA Count 5
MAX RB-tree Count 50000
Total Tree Count 195
Poll Count (Max) 1(2)

Learned OUIs for Deployed APs

OUI

00:1a:1e:00:00:00
```

## show ip interface brief

show ip interface brief

### Description

View IP-related information on all interfaces in summary format.

### Syntax

No parameters.

### Example

```
(host) #show ip interface brief
```

| Interface | IP Address / IP Netmask      | Admin | Protocol |
|-----------|------------------------------|-------|----------|
| vlan 1    | 172.16.0.254 / 255.255.255.0 | up    | up       |
| vlan 2    | 10.4.62.9 / 255.255.255.0    | up    | up       |
| loopback  | unassigned / unassigned      | up    | up       |
| mgmt      | unassigned / unassigned      | down  | down     |

The following table details the columns and content in the show command.

| Column                 | Description                                                                       |
|------------------------|-----------------------------------------------------------------------------------|
| Interface              | List the interface and interface identification, where applicable.                |
| IP Address /IP Netmask | List the IP address and netmask for the interface, if configured.                 |
| Admin                  | States the administrative status of the interface.<br>Enabled—up<br>Disabled—down |
| Protocol               | Status of the IP on the interface.<br>Enabled—up<br>Disabled—down                 |

# shutdown

shutdown all

## Description

This command disables all interfaces on the controller.

## Usage Guidelines

This command stops all traffic through the physical ports on the controller. The console port remains active. Use this command only when you have physical access to the controller, so that you can continue to manage using the console port.

To shut down an individual interface, tunnel, or VLAN, use the `shutdown` option within the `interface` command. To restore the ports, use the `no shutdown` command.

## Example

The following example shuts down all physical interfaces on the controller.

```
(host) (config)#shutdown all
```

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Config mode on master or local controllers |

## snmp-server

```
snmp-server
 community <string>
 enable trap
 engine-id
 host IPv4/IPv6 Address|version {1 <name> udp-port <port>}|2c|{3 <name>} [inform] [interval
 <seconds>] [retrycount <number>] [udp-port <port>]}
 inform queue-length <size>
 source controller-ip
 stats
 trap enable|disable|{source [IPv4/IPv6 Address]}
 user <name> [auth-prot {md5|sha} <password>] [priv-prot {AES|DES} <password>]
```

### Description

This command configures SNMP parameters.

### Syntax

| Parameter   | Description                                                                                                                                                                                                                                                                                                                               | Range                 | Default  |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|----------|
| community   | Sets the read-only community string.                                                                                                                                                                                                                                                                                                      | —                     | —        |
| enable trap | Enables sending of SNMP traps to the configured host.                                                                                                                                                                                                                                                                                     | —                     | disabled |
| engine-id   | Sets the SNMP server engine ID as a hexadecimal number.                                                                                                                                                                                                                                                                                   | 24 characters maximum | —        |
| host        | Configures the IPv4/IPv6 Address address of the host to which SNMP traps are sent. This host needs to be running a trap receiver to receive and interpret the traps sent by the controller.                                                                                                                                               | —                     | —        |
| version     | Configures the SNMP version and security string for notification messages.                                                                                                                                                                                                                                                                | —                     | —        |
| inform      | Sends SNMP inform messages to the configured host.                                                                                                                                                                                                                                                                                        | —                     | disabled |
| inform      | Specifies the length for the SNMP inform queue.                                                                                                                                                                                                                                                                                           | 100-350               | 250      |
| stats       | Allows file-based statistics collection for MMS. The controller generates a file that contains statistics data used by MMS to display information in chart and graph formats.<br><br>File-based statistics collection is transparent to the user and increases the efficiency of transferring information between the controller and MMS. |                       | enabled  |

| Parameter | Description                                                                                                                                                                                               | Range   | Default  |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|----------|
| trap      | Source IP address of SNMP traps.                                                                                                                                                                          | —       | disabled |
| disable   | Disables an SNMP trap. You can get a list of valid trap names using the <code>show snmp trap-list</code> command.                                                                                         | —       | —        |
| enable    | Enables an SNMP trap.                                                                                                                                                                                     | —       | —        |
| source    | Enter the source IPv4/IPv6 Address address for sending traps.                                                                                                                                             | —       | —        |
| udp-port  | The port number to which notification messages are sent.                                                                                                                                                  | —       | 162      |
| user      | Configures an SNMPv3 user profile for the specified username.                                                                                                                                             | —       | —        |
| auth-prot | Authentication protocol for the user, either HMAC-MD5-98 Digest Authentication Protocol (MD5) or HMAC-SHA-98 Digest Authentication Protocol (SHA), and the password for use with the designated protocol. | MD5/SHA | SHA      |
| priv-prot | Privacy protocol for the user, either Advanced Encryption Standard (AES) or CBC-DES Symmetric Encryption Protocol (DES), and the password for use with the designated protocol.                           | AES/DES | DES      |

## Usage Guidelines

This command configures SNMP on the controller only. You configure SNMP-related information for APs in an SNMP profile which you apply to an AP group or to a specific AP. To configure SNMP hostname, contact, and location information for the controller, use the **hostname**, **syscontact**, and **syslocation** commands.

## Example

The following command configures an SNMP trap receiver:

```
(host) (config) #snmp-server host 191.168.1.1 version 2c 12345678
```

## Command History

| Release       | Modification                                      |

| All platforms | Base operating system | Config mode on master controllers |

## spanning-tree (Global Configuration)

spanning-tree

[forward-time <value> | hello-time <value> | max-age <value> | priority <value> | vlan range <WORD>]

RSTP is backward compatible with STP and is enabled by default. For ease of use, this command uses the spanning tree keyword.

### Description

This command is the global configuration for the Rapid Spanning Tree Protocol (RSTP) and Per VLAN Spanning Tree (PVST+). See [spanning-tree \(Configuration Interface\)](#) for details on the RSTP (config-if) command.

### Syntax

| Parameter         | Description                                                                                                                                                                                                                                                                                                           | Range   | Default    |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|------------|
| forward-time      | Specifies the time, in seconds, the port spends in the listening and learning state. During this time, the port waits to forward data packets.                                                                                                                                                                        | 4-30    | 15 seconds |
| hello-time        | Specifies the time, in seconds, between each bridge protocol data unit (BPDU) transmitted by the root bridge.                                                                                                                                                                                                         | 1-10    | 2 seconds  |
| max-age           | Specifies the time, in seconds, the root bridge waits to receive a hello packet before changing the STP topology.                                                                                                                                                                                                     | 6-40    | 20 seconds |
| priority          | Set the priority of a bridge to make it more or less likely to become the root bridge. The bridge with the lowest value has the highest priority.<br><br>When configuring the priority, remember the following:<br><br>The highest priority bridge is the root bridge.<br><br>The highest priority value is 0 (zero). | 0-65535 | 32768      |
| vlan range <WORD> | Enter the keywords <b>vlan range</b> followed by the range of VLAN ID's. Separate the VLAN IDs with a hyphen, comma or both to indicate the range.<br><br>For example: 2-3 or 2,4,6 or 2-6,11                                                                                                                         | —       | —          |

### Usage Guidelines

This command configures the global RSTP settings on the controller and is backward compatible with past versions of ArubaOS using STP.

By default, all interfaces and ports on the controller run RSTP as specified in 802.1w and 802.1D. The default RSTP values can be used for most implementations.

Use the `no spanning-tree` command to disable RSTP.

## Examples

The following command sets the time a port spends in the listening and learning state to 3 seconds:

```
spanning-tree forward-time 3
```

The following command sets the time the root bridge waits to transmit BPDUs to 4 seconds:

```
spanning-tree hello-time 4
```

The following command sets the time the root bridge waits to receive a hello packet to 30 seconds:

```
spanning-tree max-age 30
```

The following command sets the bridge priority to 10, making it more likely to become the root bridge:

```
spanning-tree priority 10
```

The follow command sets a spanning-tree VLAN range

```
spanning-tree vlan range 2-8,11
```

## Command History

| Release     | Modification                                          |
|-------------|-------------------------------------------------------|
| ArubaOS 6.0 | Added support for PVST+ and VLAN and VLAN Range       |
| ArubaOS 3.4 | Upgraded STP to RSTP with full backward compatibility |
| ArubaOS 1.0 | Introduced the Spanning Tree Protocol (STP)           |

## Command Information

| Platforms     | Licensing             | Command Mode           |
|---------------|-----------------------|------------------------|
| All platforms | Base operating system | Configuration (config) |

## spanning-tree mode

spanning-tree mode <rapid> | <rapid-pvst>

### Description

Set the spanning tree mode to either Rapid Spanning Tree (802.1w) or PVST+ (Per VLAN Spanning Tree).

### Syntax

| Parameter  | Description                                                           |
|------------|-----------------------------------------------------------------------|
| rapid      | Set the spanning tree mode to RSTP (Rapid Spanning Tree Protocol).    |
| rapid-pvst | Set the spanning tree mode to PVST+ (Per VLAN Spanning Tree protocol) |

### Usage Guidelines

Once the spanning tree mode is set, you can configure RSTP or PVST+.

### Command History

| Release     | Modification                                           |
|-------------|--------------------------------------------------------|
| ArubaOS 6.0 | PVST+ added                                            |
| ArubaOS 3.4 | Upgraded STP to RSTP with full backward compatibility. |

### Command Information

| Platform      | Licensing             | Command Mode                                      |
|---------------|-----------------------|---------------------------------------------------|
| All platforms | Base operating system | Configuration mode (config) on master controllers |

## spanning-tree (Configuration Interface)

```
spanning-tree
 cost <value>
 point-to-point
 port-priority <value>
 portfast
 vlan <vlan-id>
 cost <value>
 port-priority <value>
 vlan range <WORD>
```

RSTP is backward compatible with STP and is enabled by default. For clarity, this RSTP command uses the spanning tree keyword.

### Description

Dell's RSTP implementation interoperates with both PVST (Per VLAN Spanning Tree 802.1D) and Rapid-PVST (802.1w) implementation on industry-standard router/switches. Syntax

| Parameter             | Description                                                                                                                                                      | Range     | Default                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cost <value>          | Enter the spanning tree path cost. Use the cost values to determine the most favorable path to a particular destination; the lower the cost, the better the path | 1 - 65535 | Default: Based on Interface type: <ul style="list-style-type: none"><li>Fast Ethernet 10Mbps—100</li><li>Fast Ethernet 100Mbps—19</li><li>1 Gigabit Ethernet—4</li><li>10 Gigabit Ethernet—2</li></ul> |
| point-to-point        | Set the interface to a point-to-point                                                                                                                            | n/a       | Enabled                                                                                                                                                                                                |
| port-priority <value> | Change the spanning tree priority.                                                                                                                               | 0 - 255   | 128                                                                                                                                                                                                    |
| portfast              | Change from blocking to forwarding                                                                                                                               | n/a       | Disabled                                                                                                                                                                                               |
| vlan <vlan-id>        | Enter the keyword <b>vlan</b> followed by the VLAN-ID                                                                                                            | n/a       | —                                                                                                                                                                                                      |

| Parameter                                | Description                                                                                                                                                                                   | Range     | Default |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---------|
| <code>cost &lt;value&gt;</code>          | Enter the keyword <code>cost</code> followed by the cost value to change the interface's spanning tree path cost.                                                                             | 1 - 65535 |         |
| <code>port-priority &lt;value&gt;</code> | Change the spanning tree priority.                                                                                                                                                            | 0 - 255   | 128     |
| <code>vlan range &lt;WORD&gt;</code>     | Enter the keywords <b>vlan range</b> followed by the range of VLAN ID's. Separate the VLAN IDs with a hyphen, comma or both to indicate the range.<br><br>For example: 2-3 or 2,4,6 or 2-6,11 | —         | —       |

## Usage Guidelines

Dell supports global instances of RSTP and PVST+. Therefore, the ports on industry-standard routers/switches must be on the default or untagged VLAN for interoperability with controllers.

ArubaOS supports RSTP on the following interfaces:

- FastEthernet IEEE 802.3—`fastethernet`
- GigabitEthernet IEEE 802.3—`gigabitethernet`
- Port Channel ID—`port-channel`

In addition to port state changes, RSTP introduces port roles for all the interfaces.

| RSTP (802.1w) Port Role | Description                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------|
| Root                    | The port that receives the best BPDU on a bridge.                                                           |
| Designated              | The port can send the best BPDU on the segment to which it is connected.                                    |
| Alternate               | The port offers an alternate path, in the direction of root bridge, to that provided by bridge's root port. |
| Backup                  | The port acts as a backup for the path provided by a designated port in the direction of the spanning tree. |

## Example

The RSTP default values are adequate for most implementation. Use caution when making changes to the spanning tree values.

```
(host) (config-if) #spanning-tree cost 345

(host) (config-if) #spanning-tree point-to-point ?

(host) (config-if) #spanning-tree portfast ?
```

```
(host) (config-if) #spanning-tree vlan range 2-8,11
```

## spanning-tree vlan range (PVST+)

```
spanning-tree vlan range <WORD>
[forward-time <value> | hello-time <value> | max-age <value> | priority <value>]
```

### Description

Configure PVST+ on a range of VLANs.

### Syntax

| Parameter    | Description                                                                                                                                                                                                                                                                                                                  | Range   | Default    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|------------|
| <WORD>       | Enter a string representing the VLAN range                                                                                                                                                                                                                                                                                   | --      | --         |
| forward-time | Specifies the time, in seconds, the VLANs spends in the listening and learning state before transition to the forward state.                                                                                                                                                                                                 | 4-30    | 15 seconds |
| hello-time   | Set the time interval, in seconds, between transmission of BPDUs.                                                                                                                                                                                                                                                            | 1-10    | 2 seconds  |
| max-age      | Set the time interval for the PVST+ bridge to maintain configuration information before refreshing that information.                                                                                                                                                                                                         | 6-40    | 20 seconds |
| priority     | <p>Set the priority of a bridge to make it more or less likely to become the root bridge. The bridge with the lowest value has the highest priority.</p> <p>When configuring the priority, remember the following:</p> <p>The highest priority bridge is the root bridge.</p> <p>The highest priority value is 0 (zero).</p> | 0-65535 | 32768      |

### Example

The following command sets the time the VLAN range 2-3 spends in the listening and learning state to 3 seconds:

```
spanning-tree vlan range 2-3 forward-time 3
```

The following command sets the time the VLAN range 2-3 waits to transmit BPDUs to 4 seconds:

```
spanning-tree vlan range 2-3 hello-time 4
```

The following command sets the time the VLAN range 2-3 waits to receive a hello packet to 30 seconds:

```
spanning-tree vlan range 2-3 max-age 30
```

The following command sets the VLAN range 2-3 priority to 10, making it more likely to become the root bridge:

```
spanning-tree vlan range 2-3 priority 10
```

## Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.0 | Command introduced |

## Command Information

| Platforms     | Licensing             | Command Mode                |
|---------------|-----------------------|-----------------------------|
| All Platforms | Base operating system | Configuration Mode (config) |

## ssh

```
ssh disable_dsa | mgmt-auth {public-key [username/password] | username/password [public-key]}
```

### Description

This command configures SSH access to the controller.

### Syntax

| Parameter   | Description                                                                                                                                                  | Default               |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| disable_dsa | Disables DSA authentication for SSH. Only RSA authentication is used.                                                                                        | —                     |
| mgmt-auth   | Configures authentication method for the management user. You can specify username/password only, public key only, or both username/password and public key. | username/<br>password |

### Usage Guidelines

Public key authentication is supported using a X.509 certificate issued to the management client. If you specify public-key authentication, you need to load the client X.509 certificate into the controller and configure certificate authentication for the management user with the mgmt-user ssh-pubkey command.

### Example

The following commands configure SSH access using public key authentication only:

```
(host) (config) #ssh mgmt-auth public-key
 mgmt-user ssh-pubkey client-cert ssh-pubkey cli-admin root
```

### Command History

| Version     | Modification                                  |
|-------------|-----------------------------------------------|
| ArubaOS 3.0 | Command introduced                            |
| ArubaOS 3.1 | The <b>mgmt-auth</b> parameter was introduced |

### Command Information

## sso idp-profile

```
sso idp-profile <idp profile name>
 clone
 idp <urlname> <url>
 no
```

### Description

This command configures an SSO Identity Provider (IDP) profile for use with application Single Sign-On (SSO) with L2 Authentication.

### Syntax

| Parameter            | Description                                                 |
|----------------------|-------------------------------------------------------------|
| clone <profile name> | Copies the data from another SSO IDP profile                |
| idp <urlname> <url>  | Configures the name and URL of the controller's IDP server. |
| no                   | Deletes the command.                                        |

### Usage Guidelines

This command is used to configure an SSO IDP profile, which establishes the name and URL of the IDP server that the controller uses for application

The Dell ClearPass Policy Manager is the only device that can act as an IDP server for application SSO with a Dell controller.

### Example

```
sso idp-profile profile1
 idp url1 cppm128.arubanetworks.com/idp.login
```

### Command History

|---------------|------------------------|-----------------------------------|
| All platforms | Base operating system. | Config mode on master controllers |

## stm

```
add-blacklist-client <macaddr>
kick-off-sta <macaddr> <bssid>
purge-blacklist-clients
remove-blacklist-client <macaddr>
```

### Description

This command is used to manually disconnect a client from an AP or control the blacklisting of clients.

### Syntax

| Parameter                         | Description                                                                                                                                          |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| add-blacklist-client              | MAC address of the client to be added to the denial of service list.                                                                                 |
| kick-off-sta                      | When you use the kick-off-sta feature specify a client's MAC address and BSSID, the AP sends deauthorization frames to the station to disconnect it. |
| <macaddr>                         | MAC address of client to be disconnected.                                                                                                            |
| <bssid>                           | The associated BSSID of the client to be disconnected.                                                                                               |
| purge-blacklist-client            | Clear the entire client blacklist.                                                                                                                   |
| remove-blacklist-client <macaddr> | Specify the MAC address of a client to remove it from the denial of service list.                                                                    |

### Usage Guidelines

When you blacklist a client, the client is not allowed to associate with any AP in the network. If the client is connected to the network when you blacklist it, a deauthentication message is sent to force the client to disconnect. The blacklisted client is blacklisted for the duration specified in the virtual AP profile. The client blacklist supports up to 4,000 individual client entries.

The controller retains the client blacklist in the user database, so the information is not lost if the controller reboots. When you import or export the controller's user database, the client blacklist will be exported or imported as well.

### Example

The following command blacklists a client:

```
(host) #stm add-blacklist-client 00:01:6C:CC:8A:6D
```

## Command History

| Version     | Modification                                                                                                                              |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 1.0 | Command introduced.                                                                                                                       |
| ArubaOS 6.0 | The purge-client-blacklist parameter was introduced.<br>The <b>start-trace</b> and <b>stop-trace</b> parameters are no longer functional. |

## Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Enable mode on master or local controllers |

# support

support

## Description

This command, which should be used only in conjunction with Dell customer support, is for controller debugging purposes only.

## Syntax

No parameters.

## Usage Guidelines

This command is used by Dell customer support for debugging the controller. Do not use this command without the guidance of Dell customer support.

## Example

The following command allows Dell customer support to debug the controller:

```
(host) #support
```

## Command History

| Version     | Modification                                    |
|-------------|-------------------------------------------------|
| ArubaOS 2.4 | Command introduced as the <b>secret</b> command |
| ArubaOS 3.1 | Command renamed to <b>support</b>               |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

# syscontact

syscontact <syscontact>

## Description

This command configures the name of the system contact for the controller.

## Syntax

| Parameter  | Description                                                           |
|------------|-----------------------------------------------------------------------|
| syscontact | An alphanumeric string that specifies the name of the system contact. |

## Usage Guidelines

Use this command to enter the name of the person who acts as the system contact or administrator for the controller. You can use a combination of numbers, letters, characters, and spaces to create the name. To include a space in the name, use quotation marks to enclose the alphanumeric string. For example, to create the system contact name Lab Technician 1, enter "Lab Technician 1" at the prompt.

To change the existing name, enter the command with a different string. The new name takes affect immediately. To unconfigure the name, enter "" at the prompt.

## Example

The following command defines **LabTechnician** as the system contact name:

```
(host) (config) #syscontact LabTechnician
```

## Command History

This command was introduced in ArubaOS 3.1.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

# syslocation

syslocation <syslocation>

## Description

This command configures the name of the system location for the controller.

## Syntax

| Parameter   | Description                                                            |
|-------------|------------------------------------------------------------------------|
| syslocation | An alphanumeric string that specifies the name of the system location. |

## Usage Guidelines

Use this command to indicate the location of the controller. You can use a combination of numbers, letters, characters, and spaces to create the name. To include a space in the name, use quotation marks to enclose the text string.

To change the existing name, enter the command with a different string. To unconfigure the location, enter "" at the prompt.

## Example

The following command defines **SalesLab** as the location for the controller:

```
(host) # syslocation "Building 10, second floor, room 21E"
syscontact LabTechnician
```

## Command History

This command was introduced in ArubaOS 3.1.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## tar

```
tar clean {crash|flash|logs}| crash{kernel} | flash | logs {tech-support|user}}
```

### Description

This command archives a directory.

### Syntax

| Parameter    | Description                                                              |
|--------------|--------------------------------------------------------------------------|
| clean        | Removes a tar file                                                       |
| crash        | Removes crash.tar                                                        |
| flash        | Removes flash.tar.gz                                                     |
| logs         | Removes logs.tar                                                         |
| crash        | Archives the crash directory to crash.tar. A crash directory must exist. |
| kernel       | Archives the kernel crash directory to kernel_crash.tar.                 |
| flash        | Archives and compresses the /flash directory to flash.tar.gz.            |
| logs         | Archives the logs directory to log.tar.                                  |
| tech-support | Optionally, technical support information can be included.               |
| user         | Runs the user specific tech-support command.                             |

### Usage Guidelines

This command creates archive files in Unix tar file format.

### Example

The following command creates the log.tar file with technical support information:

```
tar logs tech-support
```

## Command History

| Version         | Description                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced.                                                                           |
| ArubaOS 6.4     | The <b>kernel</b> parameter was introduced.                                                   |
| ArubaOS 6.4.2.5 | The <b>show dot1x watermark history</b> was added as part of the <b>techsupport.log</b> file. |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

# telnet

telnet {cli|soe}

## Description

Enable telnet to the controller or to an AP through the controller.

## Syntax

| Parameter | Description                                     | Default  |
|-----------|-------------------------------------------------|----------|
| cli       | Enable telnet using the CLI.                    | Disabled |
| soe       | Enable telnet using Serial over Ethernet (SoE). | Disabled |

## Usage Guidelines

Use the **cli** option to enable telnet to the controller.

Use the **soe** option to enable telnet using the SoE protocol. This allows you to remotely manage an AP directly connected to the controller.

## Example

The following example enables telnet to the controller using the CLI.

```
(host) (config) #telnet cli
```

## Command History

The command was introduced in ArubaOS 1.0

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## threshold

```
threshold
 controlpath-cpu <percentage>
 controlpath-memory <percentage>
 datapath-cpu <percentage>
 no-of-APs <percentage>
 no-of-locals <percentage>
 total-tunnel-capacity <percentage>
 user-capacity <percentage>
 no ...
```

### Description

This command configures controller capacity thresholds which, when exceeded, will trigger alerts.

### Syntax

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| controlpath-cpu <percentage>    | <p>Set an alert threshold for controlpath CPU capacity. The &lt;percentage&gt; parameter is the percentage of the total controlpath CPU capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 80%.</p>                                                                                                   |
| controlpath-memory <percentage> | <p>Set an alert threshold for controlpath memory consumption. The &lt;percentage&gt; parameter is the percentage of the total memory capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 85%.</p>                                                                                                      |
| datapath-cpu <percentage>       | <p>Set an alert threshold for datapath CPU capacity. The &lt;percentage&gt; parameter is the percentage of the total datapath CPU capacity that must be exceeded before the alert is sent.</p> <p>The default threshold for this parameter is 30%.</p>                                                                                                         |
| no-of-APs <percentage>          | <p>The maximum number of APs that can be connected to a controller is determined by that controller's model type and installed licenses. Use this command to trigger an alert when the number of APs currently connected to the controller exceeds a specific percentage of its total AP capacity.</p> <p>The default threshold for this parameter is 80%.</p> |
| no-of-locals <percentage>       | <p>Set an alert threshold for the master controller's capacity to support branch and local controllers.</p>                                                                                                                                                                                                                                                    |

| Parameter                                             | Description                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                       | A master controller can support a combined total of 256 branch and local controllers. The <code>&lt;percentage&gt;</code> parameter is the percentage of the total master controller capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 80%. |
| <code>total-tunnel-capacity &lt;percentage&gt;</code> | Set an alert threshold for the controller's tunnel capacity. The <code>&lt;percentage&gt;</code> parameter is the percentage of the controller's total tunnel capacity that must be exceeded before the alert is sent.<br><br>The default threshold for this parameter is 80%                  |
| <code>user-capacity &lt;percentage&gt;</code>         | Set an alert threshold for the controller's user capacity. The <code>&lt;percentage&gt;</code> parameter is the percentage of the total resource capacity that must be exceeded before the alert is sent.<br><br>The default threshold for this parameter is 80%.                              |

## Usage Guidelines

The controller will send a *wlsxThresholdExceeded* SNMP trap and a syslog error message when the controller has exceeded a set percentage of the total capacity for that resource. A *wlsxThresholdCleared* SNMP trap and error message will be triggered if the resource usage drops below the threshold once again.

## Example

The following command configures a new alert threshold for datapath memory consumption:

```
(host) (config) #threshold datapath-cpu 90
```

If this threshold is exceeded then subsequently drops below the 90% threshold, the controller would send the following two syslog error messages.

```
Mar 10 13:13:58 nanny[1393]: <399816> <ERRS> |nanny| Resource 'Control-Path Memory' has gone
above 90% threshold, value : 93
Mar 10 13:16:58 nanny[1393]: <399816> <ERRS> |nanny| Resource 'Control-Path Memory' has come
below 90% threshold, value : 87
```

## Command History

The command was introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## time-range

```
time-range <name> absolute [end <mm/dd/yyyy> <hh:mm>] [[start <mm/dd/yyyy> <hh:mm>]
 time-range <name> periodic
 Daily <hh:mm> to <hh:mm>
 Friday <hh:mm> to <hh:mm>
 Monday <hh:mm> to <hh:mm>
 Saturday <hh:mm> to <hh:mm>
 Sunday <hh:mm> to <hh:mm>
 Thursday <hh:mm> to <hh:mm>
 Tuesday <hh:mm> to <hh:mm>
 Wednesday <hh:mm> to <hh:mm>
 Weekday <hh:mm> to <hh:mm>
 Weekend <hh:mm> to <hh:mm>
 no ...
```

### Description

This command configures time ranges.

### Syntax

| Parameter | Description                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| <name>    | Name of this time range. You can reference this name in other commands.                                               |
| absolute  | Specifies an absolute time range, with a specific start and/or end time and date.                                     |
| periodic  | Specifies a recurring time range. Specify the start and end time and Daily, Weekday, Weekend, or the day of the week. |
| no        | Negates any configured parameter.                                                                                     |

### Usage Guidelines

You can use time ranges when configuring session ACLs. Once you configure a time range, you can use it in multiple session ACLs.

### Example

The following command configures a time range for daytime working hours:

```
(host) (config) #time-range working-hours periodic
 weekday 7:30 to 18:00
```

### Command History

The command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing                                                    | Command Mode                      |
|---------------|--------------------------------------------------------------|-----------------------------------|
| All platforms | Next Generation Policy Enforcement Firewall (PEFNG) license. | Config mode on master controllers |

# tracpath

tracpath <global-address>

## Description

Traces the path of an IPv6 host.

## Syntax

| Parameter        | Description                          |
|------------------|--------------------------------------|
| <global-address> | The IPv6 global address of the host. |

## Usage Guidelines

Use this command to identify points of failure in your IPv6 network.

## Example

The following command traces the path of the specified IPv6 host.

```
(host) #tracpath 2005:d81f:f9f0:1001::14
```

## Command History

The command was introduced in ArubaOS 6.1.

## Command Information

| Platforms     | Licensing             | Command Mode                                                  |
|---------------|-----------------------|---------------------------------------------------------------|
| All platforms | Base operating system | User, Enable, and Config modes on local or master controllers |

# traceroute

```
traceroute <ipaddr>
 source
```

## Description

Trace the route to the specified IP address.

## Syntax

| Parameter       | Description                                                                  |
|-----------------|------------------------------------------------------------------------------|
| <ipaddr>        | The destination IP address.                                                  |
| source <ipaddr> | Sets the source IP address through which packets are sent for tracing route. |

## Usage Guidelines

Use this command to identify points of failure in your network.

## Example

The following command traces the route to the device identified by the IP address 10.1.2.3.

```
(host) (config) #traceroute 10.1.2.3
```

## Command History

| Release     | Modification                        |
|-------------|-------------------------------------|
| ArubaOS 2.0 | Command introduced                  |
| ArubaOS 6.3 | Introduced <b>source</b> parameter. |

## Command Information

| Platforms     | Licensing             | Command Mode                                                  |
|---------------|-----------------------|---------------------------------------------------------------|
| All platforms | Base operating system | User, Enable, and Config modes on local or master controllers |

## trusted

trusted all

### Description

This command makes all physical interfaces on the controller trusted ports.

### Syntax

| Parameter | Description                                |
|-----------|--------------------------------------------|
| all       | Makes all ports on the controller trusted. |

### Usage Guidelines

Trusted ports are typically connected to internal controlled networks. Untrusted ports connect to third-party APs, public areas, or any other network to which the controller should provide access control. When APs are attached directly to the controller, set the connecting port to be trusted.

By default, all ports on the controller are treated as trusted. You can use the **interface fastethernet** or **interface gigabitethernet** commands to make individual ports trusted.

### Example

The following command makes all ports trusted:

```
(host) (config) #trusted all
```

### Command History

The command was introduced in ArubaOS 2.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

# tunnel-group

```
tunnel-group <tungrpname>
 mode {l2|l3}
 no
 preemptive-failover
 tunnel <tunnel-id>
```

## Description

This command creates a tunnel-group to group a set of tunnels.

## Syntax

| Parameter           | Description                                                                                                                                                                                                                                                           | Default |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| mode {l2 l3}        | Set the type of tunnel-group.                                                                                                                                                                                                                                         | l3      |
| no                  | Negates any parameter configured.                                                                                                                                                                                                                                     | —       |
| preemptive-failover | When enabled, this option automatically redirects the traffic upon detecting an active tunnel with a higher precedence in the tunnel-group. When disabled, the traffic gets redirected to a higher precedence tunnel only when the tunnel carrying the traffic fails. | enabled |
| tunnel <tunnel-id>  | Adds the specified tunnel ID to the tunnel group. The range is 1-16777215.                                                                                                                                                                                            | —       |

## Usage Guidelines

Use this command to provide redundancy for L3 generic routing encapsulation (GRE) tunnels. This feature enables automatic redirection of the user traffic to a standby tunnel when the primary tunnel goes down.

To enable L3 GRE tunnel group, you must:

- configure a tunnel-group to group a set of tunnels.
- enable tunnel keepalives on all the tunnel interfaces assigned to the tunnel-group, and
- configure the session ACL with the tunnel-group as the redirect destination.

To enable L2 GRE tunnel group, you must:

- configure the member tunnel and add them to the appropriate VLAN.
- enable tunnel keepalives on the tunnel interface.
- configure the tunnel-group and set the group type to L2, and
- add the member tunnel to the group

You can configure up to 32 tunnel-groups on a controller with a maximum of 5 tunnels in each tunnel-group.

## Example

The following set of commands create a tunnel-group with tunnel IDs 10 and 20 as the members:

```
(host) (config) #tunnel-group tgroup1
(host) (config-tunnel-group) # mode 13
(host) (config-tunnel-group) # tunnel 10
(host) (config-tunnel-group) # tunnel 20
(host) (config-tunnel-group) #preemptive-failover
```

## Command History

| Version         | Modification                                                 |
|-----------------|--------------------------------------------------------------|
| ArubaOS 6.3     | Command introduced.                                          |
| ArubaOS 6.4.2.3 | The <b>mode</b> parameter was introduced.                    |
| ArubaOS 6.4.3.0 | The tunnel ID limit was changed from 2147483647 to 16777215. |

This command was introduced in ArubaOS 6.3

## Command Information

# tunnel-loop-prevention

tunnel-loop-prevention

## Description

This command prevents prevent forwarding loops between tunneled nodes on the controller.

The tunneled node loop prevention function appears on the WebUI as the “Enable Wired Access Concentrator Loop Prevention” option. It is located on the **Configuration > Advanced Services > Wired Access > Wired Access Concentration Configuration** pane.

## Syntax

No parameters.

## Usage Guidelines

This command prevents forwarding loops between tunnels from the tunneled nodes on the the controller.

To allow a tunneled node-connected machine to communicate with another controller that is a connected client on the same subnet, you must enable **broadcast-filter-arp**.

## Example

The following command prevents tunneled node forwarding:

```
(host) (config) #tunnel-loop-prevention
```

## Command History

| Release     | Modification                                                                 |
|-------------|------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                           |
| ArubaOS 6.1 | The command name changed from mux-loop-prevention to tunnel-loop-prevention. |

| All platforms | Requires the Policy Enforcement Firewall Next Generation (PEFNG)license. | Config mode on master controllers |

# tunnel-node-mtu

tunnel-node-mtu <mtu>

## Description

This command configures the MTU of a tunneled node.

## Syntax

| Parameter | Description                                                    |
|-----------|----------------------------------------------------------------|
| tnode-mtu | Value of the MTU for the tunneled nodes<br>Range: 1024 to 9216 |

## Usage Guidelines

A Dell controller can operate as a Wi-Fi controller, terminating GRE tunnels from tunneled node switches. As a Wi-Fi controller, the controller does not perform full Wi-Fi switching functions. Instead, it accepts traffic from ports designated as tunneled node ports, packages this traffic inside a GRE tunnel, and forwards the traffic back to a central controller for processing.

## Example

The following command configures the MTU of a controller for tunneled nodes:

```
(host) (config) #tunnel-node-mtu 1030
```

## Command History

The command was introduced in ArubaOS 6.2.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

# tunneled-node-address

tunneled-node-address <ipaddr>

## Description

This command configures the IP address of a tunneled node server.

## Syntax

| Parameter             | Description                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------|
| tunneled-node-address | IP address of the controller. This is the loopback or IP address of the controller acting as a tunneled node controller. |

## Usage Guidelines

A Dell controller can operate as a Wi-Fi controller, terminating GRE tunnels from tunneled node switches. As a Wi-Fi controller, the controller does not perform full Wi-Fi switching functions. Instead, it accepts traffic from ports designated as tunneled node ports, packages this traffic inside a GRE tunnel, and forwards the traffic back to a central controller for processing.

## Example

The following command configures the address of a controller for tunneled nodes:

```
(host) (config) #tunneled-node-address 192.168.1.245
```

## Command History

## upgrade

```
upgrade
 verify
 target add|del all|{host <ipaddr>}|{net <subnet>}
 target purge
```

### Description

Specify which local controllers using the centralized image upgrade feature should download the image from the image server, or verify the validity of an image on the upgrade server.

### Syntax

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| verify            | When you verify the upgrade image, the master controller attempts to connect to the file server, download the different images for each unique local controller and verify the validity of the image. Once controller images are verified as valid images by the master controller, the local controllers that are in the upgrade target list connect to the file server, download the appropriate image, and upgrade their software to the downloaded version                                                       |
| target<br>add del | Use this parameters to edit the list of controllers to be automatically upgraded with the centralized image upgrade feature. <ul style="list-style-type: none"><li>• <b>all</b>: Add all local controllers to or remove all local controllers from the target list</li><li>• <b>host &lt;ipaddr&gt;</b>: IPv4 address of a local controller to be added to or removed from the target list</li><li>• <b>net &lt;subnet&gt;</b>: Subnet of local controllers to be added to or removed from the target list</li></ul> |
| target<br>purge   | Clear the entire centralized image upgrade target list.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Usage Guidelines

This feature can be configured on a master controller only, and supports up to 100 simultaneous downloads.

### Example

```
(host)(config)# upgrade target add all
```

### Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.3 | Command introduced |

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| all platforms | Base operating system | Config mode on master controllers |

## upgrade-profile

```
auto-reboot
filepath <filepath>
max-downloads <1-100>
no ...
password <password>
protocol tftp|ftp|scp
serverip <ipaddr>
upgrade-enable
username <username>
```

### Description

The settings in this centralized image upgrade profile allow the master controller to automatically upgrade its associated local controllers by sending an image from an image server to one or more local controllers.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                              | Range | Default  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| auto-reboot         | Include this parameter to allow the local controllers to reboot after they download their new images.<br><br><b>NOTE:</b> If you enable this option, local controllers will reboot without saving any changes to their current configuration. If you have any unsaved configuration changes on your local controller that you want to retain, do not enable this option. | -     | Disabled |
| filepath            | file path to the location on the image server where the image file(s) reside.                                                                                                                                                                                                                                                                                            | -     | -        |
| max downloads       | Maximum number of local controllers that can simultaneously download a file from a file server. The centralized image downloading feature supports up to 100 simultaneous downloads. If this field is left blank, ArubaOS will use its default value of 10 downloads.                                                                                                    | 1-100 | 10       |
| password            | If you selected the FTP or SCP protocol for the Protocol type, enter the password that ArubaOS will use to connect to the image server.                                                                                                                                                                                                                                  | -     | -        |
| protocol            | Specify the protocol used to send the software upgrade from the image server to the local controller. <ul style="list-style-type: none"><li>• TFTP</li><li>• FTP</li><li>• SCP</li></ul>                                                                                                                                                                                 | -     | TFTP     |
| serverip            | IP address of the image server.                                                                                                                                                                                                                                                                                                                                          | -     | -        |
| upgrade-enable      | Issue the <b>upgrade-profile upgrade-enable</b> command to enable the centralized image upgrade feature.                                                                                                                                                                                                                                                                 | -     | Disabled |
| username <username> | If you specified FTP or SCP for the <b>protocol</b> parameter                                                                                                                                                                                                                                                                                                            | -     | -        |

| Parameter | Description                                                                  | Range | Default |
|-----------|------------------------------------------------------------------------------|-------|---------|
|           | field, enter the user name that ArubaOS uses to connect to the image server. |       |         |

## Usage Guidelines

This feature can be configured on a master controller only, and supports up to 100 simultaneous downloads.

## Example

```
(host) (config) # upgrade-profile
serverip 192.0.2.15
filepath /tftpboot
auto-reboot
upgrade-enable
```

## Command History

| Release     | Modification       |
|-------------|--------------------|
| ArubaOS 6.3 | Command introduced |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| all platforms | Base operating system | Config mode on master controllers |

## uplink

```
uplink {cellular priority <prior>}|disable|enable|{wired priority <prior>}|{wired vlan <id>}
```

### Description

Manage and configure the uplink network connection.

### Syntax

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                          | Range  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| cellular priority <prior> | Set the priority of the cellular uplink. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link.<br><br>Configuring the cellular link with a higher priority than your wired link priority will set your cellular link as the primary controller link. | 1-255  |
| enable                    | Enable the uplink manager.                                                                                                                                                                                                                                                                                                                                           | —      |
| disable                   | Disable the uplink manager.                                                                                                                                                                                                                                                                                                                                          | —      |
| wired priority <prior>    | Set the priority of the wired uplink. Each uplink type has an associated priority; wired ports having the highest priority by default.                                                                                                                                                                                                                               | 1-255  |
| wired vlan <id>           | Define the VLAN identification (ID) of the uplink VLAN . A maximim of four wired VLANs can be defined                                                                                                                                                                                                                                                                | 1-4094 |

### Usage Guidelines

The W-600 Series controllers supports multiple 3G cellular uplinks in addition to its standard wired ports, providing redundancy in the event of a connection failure. If a W-600 Series' wired link cannot access the internet, the controller can fail over to a secondary cellular link and continue routing traffic.

The uplink VLAN manager is enabled by default on branch controller uplinks. Master or local (non-branch) controllers using the PAN portal feature must issue the **uplink enable** command to enable the uplink manager.

## usb-printer

usb-printer [printer <printer-name> alias <alias-name>]

### Description

This command allows you to provide an alias to USB printers connected to W-650 series controllers.

### Syntax

| Parameter | Description                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| printer   | Enter the default printer name. To get the default printer name use the <b>show network-printer status</b> command. |
| alias     | Enter a new alias name for the printer.                                                                             |

### Example

The following command creates an alias for a printer:

```
(host) usb-printer printer usblp_HP_Officejet_Pro_L7500_MY872231FX alias HPOJ_L7500
(host) #show network-printer status
```

### Command History

This command was introduced in ArubaOS 3.4.

### Command Information

| Platforms                | Licensing             | Command Mode |
|--------------------------|-----------------------|--------------|
| W-600 Series controllers | Base operating system | Enable mode. |

## usb reclassify

```
usb reclassify <address>
```

### Description

Disconnect and reclassify an USB device.

### Syntax

| Parameter | Description                                                   |
|-----------|---------------------------------------------------------------|
| <address> | USB device address from the <a href="#">show usb</a> command. |

### Usage Guidelines

There's no way to power off an USB port on the W-600 Series controller, but you can re-initialize the device using the usb reclassify command. This command removes the modem from the USB device list, then detects it via the USB table.

### Command History

Introduced in ArubaOS 3.4.

### Command Information

| Platforms                | Licensing             | Command Mode                                |
|--------------------------|-----------------------|---------------------------------------------|
| W-600 Series controllers | Base operating system | Config mode on master and local controllers |

|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|------------|
|                            | <p>five web content reputation levels are pre-defined in ArubaOS.</p> <p><b>NOTE:</b> bandwidth contracts applied to a web content category or reputation will not be enforced unless web content classification is enabled using the <b>firewall web-content-classification</b> command.</p> | <p>risk</p> <ul style="list-style-type: none"> <li>• suspicious</li> <li>• trustworthy</li> </ul> |            |
| exclude<br>app appcategory | Excludes an application or application category from being configured as a bandwidth contract.                                                                                                                                                                                                | —                                                                                                 | —          |
| downstream                 | Applies the bandwidth contract to traffic from the controller to the client.                                                                                                                                                                                                                  | —                                                                                                 | —          |
| per-user                   | Specifies that bandwidth contract is assigned on a per-user basis instead of a per-role basis. For example, if two users are active on the network and both are part of the same role with a 500 Kbps bandwidth contract, then each user is able to use up to 500 Kbps.                       | —                                                                                                 | (per role) |
| upstream                   | Applies the bandwidth contract to traffic from the client to the controller.                                                                                                                                                                                                                  | —                                                                                                 | —          |
| captive-portal <STRING>    | Name of the captive portal profile configured with the <b>aaa authentication captive-portal</b> command.                                                                                                                                                                                      | —                                                                                                 | —          |
| check-for-accounting       | If disabled, RADIUS accounting is done for an authenticated users irrespective of the captive-portal profile in the role of an authenticated user. If enabled, accounting is not done as long as the user's                                                                                   | —                                                                                                 | enabled    |

| Parameter       | Description                                                                                                                                                                                                                                                                         | Range   | Default |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------|
|                 | role has a captive portal profile on it. Accounting will start when Auth/XML-Add/CoA changes the role of an authenticated user to a role which doesn't have captive portal profile.                                                                                                 |         |         |
| dialer          | If VPN is used as an access method, name of the VPN dialer configured with the <b>vpn-dialer</b> command. The user can login using captive portal and download the dialer. The dialer is a Windows application that configures the VPN client.                                      | —       | —       |
| dpi             | Role specific DPI configuration.                                                                                                                                                                                                                                                    | —       | —       |
| disable         | Disable role specific DPI configuration.                                                                                                                                                                                                                                            | —       | —       |
| max-sessions    | Maximum number of datapath sessions per user in this role.                                                                                                                                                                                                                          | 0-65535 | 65535   |
| no              | Negates any configured parameter.                                                                                                                                                                                                                                                   | —       | —       |
| policer-profile | Applies a policer profile to the user role.                                                                                                                                                                                                                                         | —       | —       |
| pool            | If VPN is used as an access method, specifies the IP address pool from which the user's IP address is assigned:<br><br>l2tp: When a user negotiates a Layer-2 Tunneling Protocol (L2TP)/ IPsec session, specifies an address pool configured with the <b>ip local pool</b> command. | —       | —       |

| Parameter                 | Description                                                                                                                                                       | Range                                                                                                | Default      |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|--------------|
|                           | pptp: When a user negotiates a Point-to-Point Tunneling Protocol (PPTP) session, specifies an address pool configured with the <b>pptp ip local pool</b> command. |                                                                                                      |              |
| <name>                    | Name of the L2TP or PPTP pool to be applied.                                                                                                                      | —                                                                                                    | —            |
| qos-profile               | Applies a QOS profile to the user role.                                                                                                                           | —                                                                                                    | —            |
| reauthentication-interval | Interval, in minutes or seconds, after which the client is required to reauthenticate.                                                                            | <ul style="list-style-type: none"> <li>• 0-4096 in minutes</li> <li>• 0-245760 in seconds</li> </ul> | 0 (disabled) |
| registration-role         | If enabled, a user is forced to do MAC-based authentication every time the user connects to the network.                                                          | —                                                                                                    | disabled     |
| session-acl <string>      | Session ACL configured with the <b>ip access-list session</b> command. You can specify both IPv4 and IPv6 ACLs.                                                   | —                                                                                                    | —            |
| ap-group                  | (Optional) AP group to which this ACL applies.                                                                                                                    | —                                                                                                    | —            |
| position                  | (Optional) Position of this ACL relative to other ACLs that you can configure for the user role. 1 is the top.                                                    | —                                                                                                    | (last)       |
| sso                       | Applies an SSO profile to the user role.                                                                                                                          | —                                                                                                    | —            |
| stateful-kerberos         | Applies a stateful Kerberos profile to the user role.                                                                                                             | —                                                                                                    | —            |
| stateful-ntlm             | Apply stateful NTLM authentication to the specified user role                                                                                                     |                                                                                                      |              |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Range | Default |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| traffic-control-profile <STRING> | Apply the Lync traffic control priority profile to the user-role.<br><b>NOTE:</b> For the string value, enter the profile name that you created using <b>app lync traffic-control</b> command.                                                                                                                                                                                                                                                                  | —     | —       |
| via                              | Applies a VIA connection profile to the user role.                                                                                                                                                                                                                                                                                                                                                                                                              | —     | —       |
| vlan                             | Identifies the VLAN ID or VLAN name to which the user role is mapped. This parameters works only when using Layer-2 authentication such as 802.1X or MAC address, ESSID, or encryption type role mapping because these authentications occur before an IP address is assigned. If a user authenticates using a Layer-3 mechanism such as VPN or captive portal this parameter has no effect.<br><b>NOTE:</b> VLAN IDs and VLAN names cannot be listed together. | —     | —       |
| voip-profile                     | Applies a VOIP profile to the user role.                                                                                                                                                                                                                                                                                                                                                                                                                        | —     | —       |
| web-cc disable                   | Disable web content classification for this user role. User role bandwidth contracts associated with web content classification categories and reputation types will not enforced unless web content classification is enabled using the <b>firewall web-content-classification</b> command.                                                                                                                                                                    | —     | —       |
| wispr                            | Apply WISPr authentication to the specified user role.                                                                                                                                                                                                                                                                                                                                                                                                          | —     | —       |

## Usage Guidelines

Every client in a user-centric network is associated with a user role. All wireless clients start in an initial role. From the initial role, clients can be placed into other user roles as they pass authentication.

## Example

The following command configures a user role:

```
(host) (config) #user-role new-user
 dialer default-dialer
 pool pptp-pool-1
```

## Command History

| Version         | Modification                                                                                                                                                                                |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced                                                                                                                                                                          |
| ArubaOS 3.4.1   | The <b>stateful-ntlm</b> and <b>wispr</b> parameters were introduced.                                                                                                                       |
| ArubaOS 6.1     | The <b>ipv6 session-acl</b> parameter was removed. The <b>session-acl</b> parameter is common for both IPv4 and IPv6 ACLs.                                                                  |
| ArubaOS 6.4     | The <b>bandwidth-contract app</b> , <b>bandwidth-contract appcategory</b> , <b>bandwidth-contract exclude</b> , <b>traffic-control-profile</b> , and <b>sso</b> parameters were introduced. |
| ArubaOS 6.4.1.0 | The <b>check-for-accounting</b> parameter was introduced.                                                                                                                                   |
| ArubaOS 6.4.2.0 | The <b>web-cc-category</b> , <b>web-cc-reputation</b> and <b>web-cc disable</b> parameters were introduced.                                                                                 |

| All platforms | This command requires the PEFNG license. | Config mode on master controllers |

## valid-network-oui-profile

```
valid-network-oui-profile
no
oui <oui>
```

### Description

This command allows you to add a new OUI to the controller

### Syntax

| Parameter | Description                                                            | Range | Default |
|-----------|------------------------------------------------------------------------|-------|---------|
| no        | Negates any configured parameter.                                      | —     | —       |
| oui <oui> | The new OUI to be added. Use the aa:bb:cc format to input the new OUI. | —     | —       |

### Usage Guidelines

This command adds a new OUI to the controller. The new OUI must be entered in a aa:bb:cc format.

### Example

The following command adds a new OUI to the controller.

```
(host) (config) #valid-network-oui-profile
(host) (Valid Equipment OUI profile) #
(host) (Valid Equipment OUI profile) #oui 00:11:22
This should only be used when adding equipment with a new OUI. Are you sure you
want to proceed? [y/n]: y
```

### Command History

|----------------------------|-----------------------|-----------------------------------|
| Available on all platforms | Base operating system | Config mode on master controllers |

## vlan-bwcontract-explist

vlan-bwcontract-explist mac <mac>

### Description

Use this command to add entries to or remove entries from the MAC exception list for bandwidth contracts on broadcast/multicast traffic.

### Syntax

| Parameter | Description                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------|
| <mac>     | MAC address of a protocol that should be added to or removed from the exception list for bandwidth contracts. |

### Usage Guidelines

Bandwidth contracts on a VLAN can limit broadcast and multicast traffic. ArubaOS version 6.0 and later includes an internal exception list to allow broadcast and multicast traffic using the VRRP, LACP, OSPF, PVST and STP protocols. To remove per-vlan bandwidth contract limits on an additional broadcast or multicast protocol, add the MAC address for that broadcast/multicast protocol to the Vlan Bandwidth Contracts MAC Exception List.

### Example

The following command adds the MAC address for CDP (Cisco Discovery Protocol) and VTP (Virtual Trunking Protocol) to the list of protocols that are not limited by VLAN bandwidth contracts.

```
(host) (config) #vlan-bwcontract-explist mac 01:00:0C:CC:CC:CC
```

### Command History

Command introduced in ArubaOS 6.0.

### Command Information

| Platforms     | Licensing             | Command Mode                               |
|---------------|-----------------------|--------------------------------------------|
| All platforms | Base operating system | Config mode on master or local controllers |

## vlan-name

vlan-name <name> [assignment {even|hash}]

### Description

This command creates a named VLAN on the controller and given an assignment type.

### Syntax

| Parameter  | Description                                                                                                           | Range           |
|------------|-----------------------------------------------------------------------------------------------------------------------|-----------------|
| <name>     | Name of the VLAN.                                                                                                     | 1–32 characters |
| assignment | Sets the assignment type. This determines how a VLAN assignment is handled by the controller.                         | —               |
| even       | Sets the assignment type as even. The Even assignment type is based on an even distribution of VLAN pool assignments. | —               |
| hash       | Sets the assignment type as hash. The hash type means that the VLAN assignment is based on the station MAC address.   | —               |

### Usage Guidelines

Create a named VLAN so you can set up a VLAN pool. A VLAN pool consists of a set of VLAN IDs which are grouped together to efficiently manage multi-controller networks from a single location.

---

VLAN pooling should *not* be used with static IP addresses.

---

The Even VLAN assignment type maintains a dynamic latest usage level of each VLAN ID. Therefore, as users age out, the number of available addresses increases. This leads to a more even distribution of addresses.

The Even type is only supported in tunnel and decrypt tunnel forwarding modes. It is not supported in split or bridge modes and it is not allowed for VLAN pools that are configured directly under a virtual AP. It can only be used under named VLANs. If a VLAN is given an Even assignment in bridge mode, a message displays indicating that the Hash assignment is automatically used instead to retrieve the VLAN ID.

---

L2 Mobility is not compatible with the existing implementation of the Even VLAN pool assignment type.

---

### Example

The following command creates a VLAN named **mygroup** with the assignment type “even” on the controller:

```
(host) (config) #vlan-name mygroup assignment even
```

### Related Commands

```
(host) (config) #show vlan
```

## vlan

vlan <id> [<description>] | [<name> <vlan-ids>] | [range <range>] | [wired aaa-profile <profile>]

### Description

This command creates a VLAN ID or a range of VLAN IDs on the controller.

### Syntax

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                  | Range                                                         | Default                              |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|--------------------------------------|
| <id>                        | Identification number for the VLAN.                                                                                                                                                                                                                                                                                                                                          | 2-4094                                                        | 1                                    |
| <description>               | Description of a VLAN ID.                                                                                                                                                                                                                                                                                                                                                    | 1-32 characters; cannot begin with a numeric character        | VLAN000 x, where x is the ID number. |
| <name>                      | (Optional) Identification name of the VLAN. The VLAN name was created using the <b>vlan-name</b> command.                                                                                                                                                                                                                                                                    | 1-32 characters; a name cannot begin with a numeric character | VLAN<id>                             |
| <vlan-ids>                  | (Optional) List of VLAN IDs that are associated with this VLAN. If two or more IDs are listed, the VLAN needs to be specified first as a VLAN pool using the <b>vlan-name</b> command.                                                                                                                                                                                       | Existing VLAN IDs                                             | 1                                    |
| range <range>               | Create a range of multiple VLAN IDs by specifying the beginning and ending VLAN ID separated by a hyphen.<br><br>For example, 55-58                                                                                                                                                                                                                                          | 2-4094                                                        | —                                    |
| wired aaa-profile <profile> | Assign an AAA profile to a VLAN to enable role-based access for wired clients connected to an untrusted VLAN or port on the controller. This parameter applies to wired clients only.<br><br>Note that this profile will only take effect if the VLAN and/or the port on the controller is untrusted. If both the port and the VLAN are trusted, no AAA profile is assigned. | —                                                             | —                                    |

## Usage Guidelines

Use the **interface vlan** command to configure the VLAN interface, including an IP address. Use the **vlan-name** command to create a named VLAN to set up a VLAN pool. A VLAN pool consists of a set of VLAN IDs which are grouped together to efficiently manage multi-controller networks from a single location.

To enable role-based access for wired clients connected to an untrusted VLAN and/or port on the controller, you must use the **wired aaa-profile** parameter to specify the wired AAA profile you would like to apply to that VLAN. If you do not specify a per-VLAN wired AAA profile, traffic from clients connected to an untrusted wired port or VLAN will use the global wired AAA profile, if configured.

## Example

The following command creates VLAN ID 27 with the description **myvlan** on the controller.

```
(host) (config) #vlan 27 myvlan
```

The following command associates the VLAN IDs 5, 12 and 100 with VLAN guestvlan on the controller.

```
vlan guestvlan 5,12,100
```

The following command creates VLAN IDs 200-300, 302, 303-400.

```
(host) (config) #vlan range 200-300,302, 303-400
```

## voice alg-based-cac

```
voice alg-based-cac
 disable
 enable
```

### Description

This command is used to enable or disable VoIP signaling based Call Admission Control (CAC).

### Syntax

| Parameter | Description                       |
|-----------|-----------------------------------|
| disable   | Disable VoIP signaling based CAC. |
| enable    | Enable VoIP signaling based CAC.  |

### Usage Guidelines

When call admission control in the VoIP CAC profile is enabled along with voice ALG based CAC, the controller does call admission control based on VoIP signaling and Traffic Specification (TSpec) messages (if handset supports TSpec), with precedence given to TSpec messages. When call admission control in the VoIP CAC profile is enabled while the voice ALG based CAC is disabled, the controller does call admission control based on TSpec signaling messages. If the handset does not support TSpec, call admission control is not applied.

### Example

The following example disables VoIP signaling based CAC:

```
(host) (config) #voice alg-based-cac disable
```

### Command History

## voice dialplan-profile

```
voice dialplan-profile <profile>
 clone <source>
 dialplan {<sequence> <pattern> <action>}
 no...
```

### Description

This command allows you to create a dial plan profile and configure dial plans to the profile.

### Syntax

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <profile>  | Name of this instance of the dial plan profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| clone      | Name of the existing dial plan profile from which parameter values are copied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| dialplan   | Configures a dialplan with the sequence, pattern, and action specified for the profile. You can configure upto 20 dialplans for a profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <sequence> | A number that positions the dial plan in the list of dial plans configured in the controller. The range is 100 - 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <pattern>  | <p>A digit pattern or the number of digits that will be dialed by the user. You can specify the digit pattern using 'X', 'Z', 'N', '[ ]' and '.'.</p> <ul style="list-style-type: none"><li>• X is a wild card that represents any character from 0 to 9.</li><li>• Z is a wild card that represents any character from 1 to 9.</li><li>• N is a wild card that represents any character from 2 to 9.</li><li>• [ ] is a wild card that represents the number or the range specified in the brackets.</li><li>• . (period) is a wild card that represents any-length digit strings.</li></ul> |
| <action>   | <p>A prefix code that is automatically prefixed to the dialed number. This is specified as &lt;prefix-code&gt;%e. Examples of dial plans are:</p> <ul style="list-style-type: none"><li>• 9%e: The number 9 is prefixed to the dialed number.</li><li>• 91%e: The number 91 is prefixed to the dialed number.</li></ul>                                                                                                                                                                                                                                                                       |

### Usage Guidelines

You can configure dial plans on the controller that are required by the local EPABX system to provide outgoing PSTN call facility from a SIP device.

---

Dial plan can be configured only for SIP over UDP.

---

## Example

The following command creates a dial plan for the dial plan profile, *local*:

```
(host) (config) #voice dialplan-profile local
(host) (Dialplan Profile "local") #dialplan 300 Z. 91%e
```

## Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

## Command Information

| Platforms     | Licensing                               | Command Mode                     |
|---------------|-----------------------------------------|----------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on master controller |

## voice logging

```
voice logging
 client mac <client mac>
no ...
```

### Description

This command allows you to enable logging for a voice client.

### Syntax

| Parameter  | Description                                                      |
|------------|------------------------------------------------------------------|
| client mac | MAC address of the voice client to be enabled for voice logging. |

### Usage Guidelines

You can enable voice logging for a specific voice client based on the MAC address of the client to troubleshoot any voice issues.

### Example

The following command enables voice logging on the client with the MAC address 11:22:33:44:55:67:

```
(host) (config) #voice logging
(host) (VoIP Logging) #client-mac 11:22:33:44:55:67
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

### Command Information

| Platforms     | Licensing                               | Command Mode                     |
|---------------|-----------------------------------------|----------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on master controller |

## voice real-time-config

```
voice real-time-config
 config-enable
 no...
```

### Description

This command enables the controller to analyze the call quality of the voice calls based on the RTP media streams.

### Syntax

| Parameter     | Description                                                                                           | Default |
|---------------|-------------------------------------------------------------------------------------------------------|---------|
| config-enable | Enables the controller to analyze the call quality of the voice calls based on the RTP media streams. | enabled |

### Usage Guidelines

You can enable the controller to compute and display the call quality parameters such as Jitter, delay, packet loss, and R-value directly from the RTP media stream of the voice calls. **config-enable** enables the controller to analyze the call quality of the voice calls based on the RTP media streams.

### Example

The following command enables the controller to analyze the RTP media streams for call quality reports:

```
(host) (config) #voice real-time-config
(host) (Configure Real-Time Analysis) #config-enable
```

### Command History

| Version         | Description                                       |
|-----------------|---------------------------------------------------|
| ArubaOS 6.0     | Command introduced.                               |
| ArubaOS 6.4.3.0 | The default value was changed to <b>enabled</b> . |

### Command Information

| Platforms     | Licensing                               | Command Mode                     |
|---------------|-----------------------------------------|----------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on master controller |

## voice rtcp-inactivity

`voice rtcp-inactivity {enable | disable}`

### Description

This command enables or disables the RTCP inactivity timer.

### Syntax

| Parameter | Description                         |
|-----------|-------------------------------------|
| enable    | Enables the RTCP inactivity timer.  |
| disable   | Disables the RTCP inactivity timer. |

### Usage Guidelines

You can enable the RTCP inactivity timer to clear a voip session if an on-hold client moves out of the coverage area.

### Example

The following command enables the RTCP inactivity timer:

```
(host) (config) #voice rtcp-inactivity enable
```

### Command History

| Version     | Description                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| ArubaOS 5.0 | The <b>rtcp-inactivity</b> parameter was introduced to the <code>voip</code> command.                               |
| ArubaOS 6.0 | This was part of the <code>voip</code> command in the earlier version. <code>voip</code> command is now deprecated. |

### Command Information

| Platforms     | Licensing                               | Command Mode                     |
|---------------|-----------------------------------------|----------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on master controller |

## voice sip

```
voice sip
 dialplan-profile <dial-plan profile>
 no...
 session-expiry <session-expiry>
 session-timer
```

### Description

This command allows you to enable SIP session timer and associate a dial plan profile to the SIP ALG.

### Syntax

| Parameter         | Description                                                                                                     | Default  |
|-------------------|-----------------------------------------------------------------------------------------------------------------|----------|
| dial-plan profile | Name of the existing Dial plan profile to be associated to the SIP ALG.                                         | _        |
| session-expiry    | Timeout value in seconds for the session timer. The range is 240 - 1200 seconds.                                | 300 sec  |
| session-timer     | If enabled, the SIP session is terminated when no session refresh request is received within the timeout value. | disabled |

### Usage Guidelines

You can configure the SIP settings such as enabling the session timer and associating a dial plan profile to the SIP ALG. **session-timer** acts as a keep alive mechanism for the SIP sessions using the periodic session refresh requests from the user agents. The interval for the session refresh requests is determined through a negotiation mechanism. If a session refresh request is not received within the negotiated interval, the session is terminated. **session-expiry** is the timeout interval of the session timer configured on the SIP ALG.

### Example

The following command enables session timer on the SIP ALG:

```
(host) (config) #voice sip
(host) (SIP settings) #session-timer
```

The following command sets the timeout value of the session timer to 400 seconds on the SIP ALG:

```
(host) (SIP settings) #session-expiry 400
```

The following command associates the dial plan profile, *default* to the SIP ALG:

```
(host) (SIP settings) #dialplan-profile default
```

### Command History

| Version     | Description         |
|-------------|---------------------|
| ArubaOS 6.0 | Command introduced. |

## Command Information

| Platforms     | Licensing                               | Command Mode                     |
|---------------|-----------------------------------------|----------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on master controller |

## voice sip-midcall-req-timeout

voice sip-midcall-req-timeout {enable | disable}

### Description

This command enables or disables the SIP mid-call request timer.

### Syntax

| Parameter | Description                             |
|-----------|-----------------------------------------|
| enable    | Enables the SIP mid-call request timer. |
| disable   | Disables the timer.                     |

### Usage Guidelines

You can enable the SIP mid-call request timer on the controller to clear the voip session if there is no response to a SIP mid-call request.

### Example

The following command enables the SIP mid-call request timer:

```
(host) (config) #voice sip-mid-call-req-timeout enable
```

### Command History

| Version     | Description                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| ArubaOS 5.0 | The <b>sip-midcall-req-timeout</b> parameter was introduced to the <code>voip</code> command.                       |
| ArubaOS 6.0 | This was part of the <code>voip</code> command in the earlier version. <code>voip</code> command is now deprecated. |

### Command Information

| Platforms     | Licensing                               | Command Mode                     |
|---------------|-----------------------------------------|----------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on master controller |

## voice test

```
voice test force_send_delts sta <sta-mac> tid <tid_number>
```

### Description

This command allows a user to manually send Delete Traffic Stream (DELTS) management frames.

### Syntax

| Parameter    | Description                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <sta-mac>    | The MAC address of the client station to which the DELTS are sent                                                                                                                                           |
| <tid_number> | The traffic stream id. The valid range for this parameter is 0 to 7. If the traffic stream ID is not specified and there are multiple live traffic streams, multiple DELTS will be sent out to the station. |

### Usage Guidelines

Issue this command to send DELTS for a live traffic stream, even if the client is not a voice client.

### Example

The following command sends DELTS to a station with the MAC address *08:00:69:02:01:FA*.

```
(host) (config) #voice test force_send_delts sta <08:00:69:02:01:FA> tid 6
```

### Command History

This command was introduced in ArubaOS 6.1.

### Command Information

| Platforms     | Licensing                               | Command Mode                                |
|---------------|-----------------------------------------|---------------------------------------------|
| All platforms | This command requires the PEFNG license | Config mode on a master or local controller |

## vpdn group l2tp

```
vpdn group l2tp
 client configuration {dns|wins} <ipaddr1> [<ipaddr2>]
 disable|enable
 l2tp tunnel hello <seconds>
 no ...
 ppp authentication {CACHE-SECURID|CHAP|EAP|MSCHAP|MSCHAPv2|PAP}
 ppp securid cache <minutes>
```

### Description

This command configures an L2TP/IPsec VPN connection.

### Syntax

| Parameter            | Description                                                                                                                                                                                    | Range   | Default    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|------------|
| client configuration | Configures parameters for the remote clients.                                                                                                                                                  | —       | —          |
| dns                  | Configures a primary and optional secondary DNS server.                                                                                                                                        | —       | —          |
| wins                 | Configures a primary and optional secondary WINS server.                                                                                                                                       | —       | —          |
| disable enable       | Disables or enables termination of L2TP clients.                                                                                                                                               | —       | enabled    |
| l2tp tunnel hello    | Configures L2TP tunneling hello timeout, in seconds.                                                                                                                                           | 10-1440 | 60 seconds |
| no                   | Negates any configured parameter.                                                                                                                                                              | —       | —          |
| ppp authentication   | Enables the protocols for PPP authentication. This list should match the L2TP configuration configured with the <b>vpn-dialer</b> command on the controller.                                   | —       | —          |
| CACHE-SECURID        | The controller caches Secure ID tokens so that the user does not need to reauthenticate each time a network connection is lost.                                                                | —       | —          |
| CHAP                 | Use CHAP with PPP authentication.                                                                                                                                                              | —       | —          |
| EAP                  | Use EAP-TLS with PPP authentication. Specify this protocol for Windows IPsec VPN clients that use Common Access Card (CAC) Smart Cards that contain user information and digital certificates. | —       | —          |
| MSCHAP               | Use MSCHAP with PPP authentication.                                                                                                                                                            | —       | —          |
| MSCHAPv2             | Use MSCHAPv2 with PPP authentication. This is the default for L2TP                                                                                                                             | —       | —          |

| Parameter   | Description                                                                                                           | Range    | Default      |
|-------------|-----------------------------------------------------------------------------------------------------------------------|----------|--------------|
| PAP         |                                                                                                                       | —        | —            |
| ppp securid | If CACHE-SECURID is configured for PPP authentication, this specifies the time, in minutes, that the token is cached. | 15-10080 | 1440 minutes |

## Usage Guidelines

L2TP/IPsec relies on the PPP connection process to perform user authentication and protocol configuration. You specify the protocol used for PPP authentication and whether SecureID tokens are cached on the controller. Client addresses are assigned from a pool configured with the **ip local pool** command.

## Example

The following command configures virtual private dial-in networking:

```
(host) (config) #vpdn group l2tp
ppp authentication PAP
client configuration dns 10.1.1.2
client configuration wins 10.1.1.2
```

## Command History

The command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## vpdn group pptp

```
vpdn group pptp
 client configuration {dns|wins} <ipaddr1> [<ipaddr2>]
 disable|enable
 no ...
 ppp authentication {MSCHAP|MSCHAPv2}
 pptp echo <seconds>
```

### Description

This command configures a PPTP VPN connection.

### Syntax

| Parameter            | Description                                                                                                                                                                                            | Range  | Default    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|------------|
| client configuration | Configures parameters for the remote clients.                                                                                                                                                          | —      | —          |
| dns                  | Configures a primary and optional secondary DNS server.                                                                                                                                                | —      | —          |
| wins                 | Configures a primary and optional secondary WINS server.                                                                                                                                               | —      | —          |
| disable enable       | Disables or enables termination of PPTP clients.                                                                                                                                                       | —      | enabled    |
| no                   | Negates any configured parameter.                                                                                                                                                                      | —      | —          |
| ppp authentication   | Enables the protocols for PPP authentication. This list should match the PPTP configuration configured with the <b>vpn-dialer</b> command on the controller.                                           | —      | —          |
| MSCHAP               | Use MSCHAP with PPP authentication.                                                                                                                                                                    | —      | —          |
| MSCHAPv2             | Use MSCHAPv2 with PPP authentication. This is the default for L2TP                                                                                                                                     | —      | —          |
| pptp echo            | Time, in seconds, that the controller waits for a PPTP echo response from the client before considering the client to be down. The client is disconnected if it does not respond within this interval. | 10-300 | 60 seconds |

### Usage Guidelines

PPTP connections require user-level authentication through a PPP authentication protocol (MSHCApV2 is the currently-supported method.) Client addresses are assigned from a pool configured with the **ppptp** command.

## Example

The following command configures virtual private dial-in networking:

```
vpdn group pptp
 ppp authentication MSCHAPv2
 client configuration dns 10.1.1.2
 client configuration wins 10.1.1.2
```

## Command History

The command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## vpn-dialer

```
vpn-dialer <name>
 enable dnetclear|l2tp|pptp|securid_newpinmode|wirednowifi
 ike {authentication {pre-share <key>|rsa-sig}|encryption {3des|des}|
 group {1|2}|hash {md5|sha}|lifetime [<seconds>]}
 ipsec {encryption {esp-3des|esp-des}|hash {esp-md5-hmac|esp-sha-hmac}|
 lifetime [<seconds>]|pfs {group1|group2}}
 no {enable...|ipsec...|ppp...}
 ppp authentication {cache-securid|chap|mschap|mschapv2|pap}
```

### Description

This command configures the VPN dialer.

### Syntax

| Parameter          | Description                                                                                                                                                                                       | Range                     | Default   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|-----------|
| <name>             | Name that identifies this VPN dialer configuration.                                                                                                                                               | —                         | —         |
| enable             | Enables dialer operations:                                                                                                                                                                        | —                         | —         |
| dnetclear          | Enables “split tunneling” functionality so that traffic destined for the internal network is tunneled while traffic for the Internet is not. This option is not recommended for security reasons. | —                         | disabled  |
| l2tp               | Allows the dialer to negotiate a Layer-2 Tunneling Protocol (L2TP)/IPsec tunnel with the controller.                                                                                              | —                         | enabled   |
| pptp               | Allows the dialer to negotiate a Point-to-Point Tunneling Protocol (PPTP) with the controller.                                                                                                    | —                         | disabled  |
| securid_newpinmode | Supports SecurID new and next pin mode.                                                                                                                                                           | —                         | disabled  |
| wirednowifi        | Allows the dialer to detect when a wired network connection is in use, and shuts down the wireless interface.                                                                                     | —                         | disabled  |
| ike                | Configures internet key exchange (IKE) protocol. This configuration must match the IKE policy configured with the <b>crypto isakmp policy</b> command on the controller.                          | —                         | —         |
| authentication     | Specifies whether preshared keys or RSA signatures are used for IKE authentication.                                                                                                               | pre-share<br> <br>rsa-sig | pre-share |

| Parameter          | Description                                                                                                                                                            | Range                       | Default       |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|---------------|
| encryption         | Specifies the IKE encryption protocol, either DES or 3DES.                                                                                                             | 3des   des                  | 3des          |
| group              | Specifies the Diffie-Hellman group, either 1 or 2.                                                                                                                     | 1   2                       | 2             |
| hash               | Specifies the HASH algorithm, ether SHA or MD5.                                                                                                                        | md5   sha                   | sha           |
| lifetime           | Specifies how long an IKE security association lasts, in seconds.                                                                                                      | 300-86400                   | 28800 seconds |
| ipsec              | Configures IPsec. This configuration must match the IPsec parameters configured with the <b>crypto dynamic-map</b> and <b>crypto ipsec</b> commands on the controller. | —                           | —             |
| encryption         | Specifies the encryption type for IPsec, either DES or 3DES.                                                                                                           | esp-3des   esp-des          | esp-3des      |
| hash               | Specifies the hash algorithm used by IPsec, either MD5 or SHA.                                                                                                         | esp-md5-hmac   esp-sha-hmac | esp-sha-hmac  |
| lifetime           | Specifies how long an IPsec security association lasts, in seconds.                                                                                                    | 300-86400                   | 7200 seconds  |
| pfs                | Specifies the IPsec Perfect Forward Secrecy (PFS) mode, either group 1 or group 2.                                                                                     | group1   group2             | group2        |
| no                 | Negates any configured parameter.                                                                                                                                      | —                           | —             |
| ppp authentication | Enables the protocols for PPP authentication. This list should match the L2TP or PPTP configuration configured with the <b>vpdn</b> command on the controller.         | —                           | —             |
| cache-securid      | The controller caches Secure ID tokens so that the user does not need to reauthenticate each time a network connection is lost.                                        | —                           | disabled      |
| chap               | Use CHAP with PPP authentication.                                                                                                                                      | —                           | enabled       |
| mschap             | Use MSCHAP with PPP authentication.                                                                                                                                    | —                           | enabled       |
| mschapv2           | Use MSCHAPv2 with PPP authentication.                                                                                                                                  | —                           | enabled       |
| pap                | Use PAP with PPP authentication.                                                                                                                                       | —                           | enabled       |

## Usage Guidelines

A VPN dialer is a Windows application that configures a Windows client for use with the VPN services in the controller. When VPN is used as an access method, a user can login using captive portal and download a VPN dialer. You can customize a VPN dialer for a user role configured with the **user-role** command. After the user authenticates via captive portal, a link appears to allow download of the VPN dialer if a dialer is configured for the user role.

## Example

The following command configures a VPN dialer:

```
(host) (config) #vpn-dialer default-dialer
 ike authentication pre-share f00xYz123BcA
```

## Command History

The command was introduced in ArubaOS 3.0.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## vrrp

```
vrrp <id>
 advertise <interval>
 authentication <password>
 description <text>
 holdtime <secs>
 ip address <ipaddr>
 no...
 preempt
 priority <level>
 shutdown
 tracking interface {fastethernet <slot>/<port>|gigabitethernet <slot>/<port>}
 {sub <value>}
 tracking master-up-time <duration> add <value>
 tracking vlan <vlanid> {sub <value>}
 tracking vrrp-master-state <vrid> add <value>
 vlan <vlanid>
vrrp ipv6 <id>
 advertise <interval>
 description <text>
 holdtime <secs>
 ipv6 address <ipaddr>
 no...
 preempt
 priority <level>
 shutdown
 tracking interface {fastethernet <slot>/<port>|gigabitethernet <slot>/<port>}
 {sub <value>}
 tracking master-up-time <duration> add <value>
 tracking vlan <vlanid> {sub <value>}
 tracking vrrp-master-state <vrid> add <value>
 vlan <vlanid>
```

## Description

This command configures the Virtual Router Redundancy Protocol (VRRP).

## Syntax

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                        | Range | Default |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
| id        | <p>Number that uniquely identifies the VRRP instance, also known as the VRID. This number should match the VRID on the other member of the redundant pair.</p> <p>For ease in administration, you should configure this with the same value as the VLAN ID.</p> <p>After you configure the VRID, the command platform enters VRRP mode. From here, you can access the remaining VRRP commands.</p> | 1-255 | —       |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Range           | Default              |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------|
| <code>advertise</code>             | Specifies the time, in seconds, between successive VRRP advertisements sent by the current <i>master</i> .<br><br>Best practices are to use the default value.                                                                                                                                                                                                                                                                                                                                                    | 1-60 seconds    | 1 second (1s=1000ms) |
| <code>authentication</code>        | Configure an optional password of up to eight characters to be used to authenticate VRRP peers in their advertisements.<br><br>The password must be the same on both members of the redundant pair.<br><br>The password is sent in plain-text and therefore should not be treated as a security measure. Rather, the purpose of the password is to guard against misconfigurations in the event that other VRRP devices exist on the same network.<br><br><b>Note:</b> This parameter is supported only for IPv4. | 8 characters    | —                    |
| <code>description</code>           | Configure an optional text string to describe the VRRP instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1-80 characters | —                    |
| <code>holdtime &lt;secs&gt;</code> | The VRRP virtual router does not begin listening to advertisements until the holdtime expires. If your deployment includes a VRRP master with preemption disabled and an uplink switch is running RSTP, a higher value will prevent the VRRP master from regaining the master state after it reboots.                                                                                                                                                                                                             | 30-120 seconds. | 45 seconds.          |
| <code>ip address</code>            | Configure the virtual IP address that will be owned by the elected VRRP <i>master</i> . Use the same IP address on each member of the redundant pair.<br><br>This IP address will be redundant - it will be active on the VRRP master, and will become active on the VRRP backup in the event that the VRRP master fails.                                                                                                                                                                                         | —               | —                    |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Range        | Default  |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------|
|              | The IP address must be unique; the IP address cannot be the loopback address of the controller. Only IPv4 address formats are supported.                                                                                                                                                                                                                                                                                                                                                                                            |              |          |
| ipv6 address | <p>Configure the virtual IPv6 address that will be owned by the elected VRRP <i>master</i>. Use the same IPv6 address on each member of the redundant pair.</p> <p>This IPv6 address will be redundant - it will be active on the VRRP master, and will become active on the VRRP backup in the event that the VRRP master fails.</p> <p>The IPv6 address must be unique; the IPv6 address cannot be the loopback address of the controller. Only IPv6 address formats are supported.</p>                                           | —            | —        |
| no           | Negates all configured VRRP parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | —            | —        |
| preempt      | <p>Preempt mode allows a controller to take over the role of master if it detects a lower priority controller currently acting as master.</p> <p>Best practices are to use the default value to avoid excessive interruption to users or “flapping” if a problematic controller is cycling up and down.</p>                                                                                                                                                                                                                         | —            | disabled |
| delay        | <p>Delay value in seconds.</p> <p>Specifying a value enables the delay timer. The timer is triggered when the VRRP state moves out of backup or init state to become a master. This is applicable only if router pre-emption is enabled.</p> <p>When the timer is triggered, it delays the router for a specified period of time before taking over the master router. In the mean time, if there is an advertisement from another VRRP master (existing master), the router stops the timer and does not transition to master.</p> | 0-60 seconds | 0        |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                 | Range          | Default                |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|------------------------|
| priority                         | <p>Defines the priority level of the VRRP instance for the controller. This value is used in the election mechanism for the master.</p> <p>A higher number specifies a higher priority.</p> <p>The default priority setting is adequate for most networks.</p>                                                              | 100            | 1-255                  |
| shutdown                         | <p>Administratively shutdown VRRP. When down, VRRP is not active, although the controller maintains the configuration information.</p> <p>To start the VRRP instance, use <b>no shutdown</b>.</p>                                                                                                                           | —              | enabled (VRRP is down) |
| tracking interface               | <p>Configures VRRP tracking based on Layer-2 interface state transitions. You can configure this on Fast Ethernet or Gigabit Ethernet interfaces.</p> <p>You can track a combined maximum of 16 VLAN and Layer-2 interfaces.</p>                                                                                            | —              | —                      |
| <slot>                           | <slot> is always 1.                                                                                                                                                                                                                                                                                                         | —              | —                      |
| <port>                           | Number assigned to the network interface embedded in the controller. Port numbers start at 0 from the left-most position.                                                                                                                                                                                                   | —              | —                      |
| sub                              | <p>Decreases the priority of the VRRP instance by the specified amount. When the interface comes up again, the value is restored to the previous priority level.</p> <p>The combined priority and tracking vales cannot exceed 255.</p> <p>If the priority value exceeds 255, the controller displays an error message.</p> | 0-255          | —                      |
| tracking master-up-time duration | Monitors how long the controller has been master for the VRRP instance.                                                                                                                                                                                                                                                     | 0-1440 minutes | —                      |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                             | Range  | Default |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|---------|
| tracking master-up-time add | <p>Instructs the controller to add the specified value to the existing priority level.</p> <p>The combined priority and tracking values cannot exceed 255.</p> <p>If the priority value exceeds 255, the controller displays an error message similar to the following:</p> <p>Error: Vrrp 30 priority + tracking value exceeds 255</p> | 0-255  | —       |
| tracking vlan               | <p>Configures VRRP tracking based on VLAN state transitions.</p> <p>You can track a combined maximum of 16 VLAN and Layer-2 interfaces.</p>                                                                                                                                                                                             | —      | —       |
| sub                         | <p>Decreases the priority of the VRRP instance by the specified amount. When the VLAN comes up again, the value is restored to the previous priority level.</p> <p>The combined priority and tracking values cannot exceed 255.</p> <p>If the priority value exceeds 255, the controller displays an error message.</p>                 | 0-255  | —       |
| vrrp-master-state           | Specifies the VRID to use for tracking the state of the VRRP master controller.                                                                                                                                                                                                                                                         | 1-255  | —       |
| vrrp-master-state add       | <p>Instructs the controller to add the specified value to the existing priority level.</p> <p>The combined priority and tracking values cannot exceed 255.</p> <p>If the priority value exceeds 255, the controller displays an error message similar to the following:</p> <p>Error: Vrrp 30 priority + tracking value exceeds 255</p> | 0-255  | —       |
| vlan                        | Specifies the VLAN ID of the VLAN on which VRRP will run.                                                                                                                                                                                                                                                                               | 1-4094 | —       |

## Usage Guidelines

Use this command to set parameters for VRRP on the controller. The default VRRP parameters can be left for most implementations.

You can use a combination of numbers, letters, and characters to create the authentication password and the VRRP description. To include a space in the password or description, enter quotation marks around the string. For example, to create the password Floor 1, enter "Floor 1" at the prompt.

To change the existing password or description, enter the command with a different string. The new password or description takes affect immediately.

To unconfigure the existing password or description, enter "" at the prompt. If you update the password on one controller, you must update the password on the redundant member pair.

## Interface Tracking

You can track multiple VRRP instances to prevent asymmetric routing and dynamically change the VRRP master to adapt to changes in the network. VRRP interface tracking can alter the priority of the VRRP instance based on the state of a particular VLAN or Layer-2 interface. The priority of the VRRP instance can increase or decrease based on the operational state of the specified interface. For example, interface transitions (up/down events) can trigger a recomputation of the VRRP priority, which can change the VRRP master depending on the resulting priority. You can track a combined maximum of 16 interfaces.

---

You must enable preempt mode to allow a controller to take over the role of master if it detects a lower priority controller currently acting as master

---

## Example

The following command configures a priority of 105 for VRRP ID (VRID) 30:

```
(host) (config) #vrrp 30
 priority 105
```

The following commands configure VLAN interface tracking and assumes the following:

- You have two controllers, a primary and a backup.
- The configuration highlights the parameters for interface tracking. You may have other parameters configured for VRRP.

| Primary Configuration                                                                                                                                                                                                                                                                                       | Backup Configuration                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre> vrp 10   vlan 10   ip address 10.200.22.254   priority 105   preempt   tracking vlan 20 sub 10  vrp 20   vlan 20   ip address 10.200.22.254   preempt   priority 105   tracking vlan 10 sub 10  vrp 30   vlan 30   ip address 10.200.22.254   preempt   priority 105   tracking vlan 20 sub 10 </pre> | <pre> vrp 10   vlan 10   ip address 10.200.22.254   priority 100   preempt   tracking vlan 20 sub 10  vrp 20   vlan 20   ip address 10.200.22.254   preempt   priority 100   tracking vlan 10 sub 10  vrp 30   vlan 30   ip address 10.200.22.254   preempt   priority 100   tracking vlan 20 sub 10 </pre> |

If VLAN 20 goes down, VRRP 20 automatically fails over, VRRP 10 and VRRP 30 would drop their priority to 95, causing a failover to the backup controller. Once VLAN 20 comes back up, the primary controller restores the VRRP priority to 105 for all VRRP IDs and resumes the master VRRP role.

## Command History

## web-cc

web-cc global-bandwidth-contract

web-cc-category <category-name> downstream|upstream kbits|mbits <bandwidth>

web-cc-reputation high-risk|low-risk|moderate-risk|suspicious|trustworthy

downstream|upstream kbits|mbits <1-2000>

### Description

This command defines global bandwidth contracts for HTTP traffic matching a predefined web content category or reputation type.

### Syntax

| Parameter                                                                             | Description                                                                                                                                                                                                                         | Range                                   | Default |
|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|---------|
| web-cc-category<br><category-name>                                                    | Specify a web content category to apply a bandwidth contract to that category type. To see the full list of available web content categories, issue the command <b>show web-cc categories</b> .                                     | —                                       | —       |
| downstream upstream                                                                   | Specify <b>downstream</b> to apply the bandwidth contract to downstream traffic from the controller. Specify <b>upstream</b> to apply the contract to upstream traffic to the controller.                                           | —                                       | —       |
| kbits mbits                                                                           | Select kbits to define the contract bandwidth in kilobits/second. Select mbits to define the contract in megabits/second.                                                                                                           | —                                       | —       |
| bandwidth                                                                             | Define the contract value. If you are defining the bandwidth value in kilobits/second, the supported range is 256-2,000,000 kbits. If you are defining the bandwidth value in megabits/second, the supported range is 1-2000 mbits. | 256-2,000,000 kbits<br><br>1-2000 mbits | —       |
| web-cc-reputation<br>high-risk low-risk <br>moderate-risk sus-<br>picious trustworthy | Define a bandwidth contract for traffic associated with one of five predefined reputation types. Session access control lists (ACLs) can be applied to these risk categories using the ip access-list session command.              | —                                       | —       |

### Usage Guidelines

The web content classification feature classifies all (HTTP) web traffic on the network. Dell Inc. uses the Webroot® classification categories and risk reputation levels, URL database and URL cloud look-up service to classify the web traffic. You can create firewall policies and bandwidth contracts based upon these web traffic classification and reputation types.

### Example

The following example creates a 100 megabit/second bandwidth contract for a category called **music**.

(host) (config) #web-cc global-bandwidth-contract web-cc-category music downstream mbits 100

### Description

This command configures the controller's web server.

### Syntax

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                               | Range             | Default |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|---------|
| bypass-cp-landing-page | Disables the bypass captive portal landing page. On disabling this feature, non-browser apps continue to request Captive Portal login page from the controller.<br><b>NOTE:</b> This increases the load of the <b>httpd</b> process of the controller.<br><b>NOTE:</b> The landing page contains the meta-refresh tag to reload the page using real browser applications. | —                 | enabled |
| captive-portal-cert    | Specifies the name of the server certificate associated with captive portal. Use the <b>show crypto-local pki ServerCert</b> command to see the server certificates installed in the controller.                                                                                                                                                                          | —                 | default |
| ciphers                | Configures the strength of the cipher suite:<br><br><b>high:</b> encryption keys larger than 128 bits<br><br><b>low:</b> 56 or 64 bit encryption keys<br><br><b>medium:</b> 128 bit encryption keys<br><br><b>NOTE:</b> This command is not available in FIPS software images because ciphers are pre-configured only to acceptable values.                               | high, low, medium | high    |

| Parameter                                                              | Description                                                                                                                                                                                                                                                         | Range                                 | Default                     |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-----------------------------|
| idp-cert                                                               | Specifies the IDP certificate name configured in the controller                                                                                                                                                                                                     | —                                     | —                           |
| mgmt-auth                                                              | Specifies the authentication method for the management user; you can choose to use either username/password or certificates, or both username/password and certificates.                                                                                            | username/<br>password,<br>certificate | username/<br>password       |
| no                                                                     | Negates any configured parameter.                                                                                                                                                                                                                                   | —                                     | —                           |
| session-timeout <session-timeout>                                      | Specifies the amount of time after which the WebUI session times out and requires login for continued access.                                                                                                                                                       | 30-3600<br>seconds                    | 900<br>seconds              |
| ssl-protocol                                                           | Specifies the Secure Sockets Layer (SSL) or Transport Layer Security (TLS) protocol version used for securing communication with the web server: <ul style="list-style-type: none"> <li>• TLS v1</li> <li>• TLS v1.1</li> <li>• TLS v1.2</li> </ul>                 | —                                     | tlsv1<br>tlsv1.1<br>tlsv1.2 |
| switch-cert                                                            | Specifies the name of the server certificate associated with WebUI access. Use the <b>show crypto-local pki ServerCert</b> command to see the server certificates installed in the controller.                                                                      | —                                     | default                     |
| web-https-port-443                                                     | Enables WebUI access on the HTTPS port (443). When you connect to the WebUI using https (tcp port 443), the controller continues using port 443 and no longer redirects to port 4343.                                                                               | —                                     | —                           |
| web-lync-listen-port<br>{http <listen-port>} <br>{https <listen-port>} | Configures the port number on which Lync Network Diagnostic (LND), a Microsoft® plug-in, sends HTTP/HTTPS messages to Dell controller.<br><b>NOTE:</b> Disable the media classification ACL before using this feature. ## Usage Guidelines

There is a default server certificate installed in the controller. However this certificate does not guarantee security in production networks. Best practices are to replace the default certificate with a custom certificate issued for your site by a trusted Certificate Authority (CA). See the *Dell Networking W-Series ArubaOS User Guide* for more information about how to generate a Certificate Signing Request (CSR) to submit to a CA and how to import the signed certificate received from the CA into the controller. After importing the signed certificate into the controller, use the **web-server profile** command to specify the certificate for captive portal or WebUI access. If you need to specify a different certificate for captive portal or WebUI access, use the **no** command to revert back to the default certificate before you specify the new certificate (see the Example section).

You can use client certificates to authenticate management users. If you specify certificate authentication, you need to configure certificate authentication for the management user with the **mgmt-user webui-cacert** command.

## Example

The following commands configure WebUI access with client certificates only, and specify the server certificate for the controller:

```
(host) (config) #web-server profile
(host) (Web Server Configuration) #mgmt-auth certificate
(host) (Web Server Configuration) #switch-cert ServerCert1
(host) (Web Server Configuration) #!
(host) (config) #mgmt-user webui-cacert test_string serial 1111 admin root
```

To specify a different server certificate, use the **no** command to revert back to the default certificate *before* you specify the new certificate:

```
(host) (config) #web-server profile
(host) (Web Server Configuration) #mgmt-auth certificate
(host) (Web Server Configuration) #switch-cert ServerCert1
(host) (Web Server Configuration) #no switch-cert
(host) (Web Server Configuration) #switch-cert ServerCert2
```

## whitelist-db cpsec add

```
whitelist-db cpsec add mac-address <name>
 ap-group <ap_group>
 ap-name <ap_name>
 description <description>
```

### Description

Add an AP entry to the campus AP whitelist.

### Syntax

| Parameter                 | Description                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| mac-address <name>        | MAC address of the AP you want to enter into the campus AP whitelist database.                                                 |
| ap-group <ap_group>       | (Optional) Name of the AP group.<br><b>NOTE:</b> If the AP group is not entered, a campus AP boots with "default" as AP group. |
| ap-name <ap_name>         | (Optional) Name of the AP.<br><b>NOTE:</b> If the AP name is not entered, a campus AP boots with its MAC address as AP name.   |
| description <description> | (Optional) Brief description of the AP. If the description includes spaces, enclose the description in quotation marks.        |

### Usage Guidelines

You can manually add entries to the campus AP whitelist to grant valid APs secure access to the network.

### Example

The following command creates a new campus AP whitelist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) #whitelist-db cpsec add mac-address 00:16:CF:AF:3E:E1
 ap-group default
 ap-name W-AP225
 description "W-AP225 in lobby"
```

## whitelist-db cpsec delete

```
whitelist-db cpsec delete mac-address <mac-address>
```

### Description

Remove an individual AP entry to the campus AP whitelist.

### Syntax

| Parameter                 | Description                                                            |
|---------------------------|------------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the AP you want to remove from the campus AP whitelist. |

### Usage Guidelines

Use this command to remove an individual whitelist entries for an AP that has been either removed from the network, or is no longer a candidate for automatic certificate provisioning. If the AP whose entry you deleted is still connected to the network and the control plane security feature is configured to send certificates to all APs (or a range of addresses that include that AP), then the controller will send the AP another certificate, and the AP will reappear in the campus whitelist. To permanently revoke a certificate from an invalid or suspected rogue AP, use the command [whitelist-db cpsec revoke](#).

### Example

The following command removes an AP with the MAC address 10:14:CA:AF:3E:E1 from the campus AP whitelist.:

```
(host) (config) #whitelist-db cpsec delete mac-address 10:14:CA:AF:3E:E1
```

## whitelist-db cpsec-local-switch-list

```
whitelist-db cpsec-local-switch-list
 del mac-address <mac-address>
 purge
```

### Description

Delete a local controller from the local switch whitelist.

### Syntax

| Parameter                                        | Description                                                 |
|--------------------------------------------------|-------------------------------------------------------------|
| <code>del mac-address &lt;mac-address&gt;</code> | Remove a single controller from the local switch whitelist. |
| <code>purge</code>                               | Clear all entries from the local switch whitelist           |

### Usage Guidelines

If your deployment includes both master and local controllers, then the campus AP whitelist on each controller contains an entry for every AP on the network, regardless of the controller to which it is connected. The master controller also maintains a whitelist of local controllers with APs using control plane security. When you change a campus AP whitelist on any controller, that controller contacts the master controller to check the local switch whitelist, then contacts every other controller on the local switch whitelist to notify it of the change.

If you ever remove a local controller from the network, you must also remove the local controller from the local switch whitelist. If the local switch whitelist contains entries for local controllers no longer on the network, then a campus AP whitelist entry can be marked for deletion but will not be physically deleted, as the controller will be waiting for an acknowledgement from another controller no longer on the network. Any unused local controller entries in the local switch whitelist can significantly increase network traffic and reduce controller memory resources.

### Example

The following command removes a local controller from the local switch whitelist:

```
(host) (config) #whitelist-db cpsec-local-switch-list del mac-address 00:1E:33:CA:D2:51
```

| All platforms | Base operating system | Config mode on master controllers |

## whitelist-db cpsec-master-switch-list

```
whitelist-db cpsec-master-switch-list
 del mac-address <mac-address>
 purge
```

### Description

Delete a master controller from the master switch whitelist.

### Syntax

| Parameter                                        | Description                                                         |
|--------------------------------------------------|---------------------------------------------------------------------|
| <code>del mac-address &lt;mac-address&gt;</code> | Remove a single master controller from the master switch whitelist. |
| <code>purge</code>                               | Clear all entries from the master switch whitelist                  |

### Usage Guidelines

Each local controller using the control plane security feature has a master switch whitelist which contains the IP and MAC addresses of its master controller. If your network has a redundant master controller, then this whitelist will contain more than one entry.

**The master switch whitelist rarely needs to be purged.** Although you can delete an entry from the master switch whitelist, you should do so only if you have removed a master switch from the network. Deleting a valid master controller from the master switch whitelist can cause errors in your network.

### Example

The following command removes a master controller from the master switch whitelist

```
(host) (config) #whitelist-db cpsec-master-switch-list del mac-address 00:1E:33:CA:D2:51
```

| cert-type<br>{factory-cert switch-cert}                       | (Optional) Type of certificate used by an AP. <ul style="list-style-type: none"><li>• <b>factory-cert:</b> AP uses a factory-installed certificate.</li><li>• <b>switch-cert:</b> AP uses a controller-signed certificate.</li></ul>                                                  |
| description <description>                                     | (Optional) Brief description of an AP. If the description includes spaces, enclose the description in quotation marks.                                                                                                                                                                |
| mode {disable enable}                                         | (Optional) Mode of an AP. <ul style="list-style-type: none"><li>• <b>disable:</b> Disables an AP in the campus AP whitelist. A disabled AP cannot contact a controller over a secure connection.</li><li>• <b>enable:</b> Enables a disabled AP in the campus AP whitelist.</li></ul> |
| revoke-text <revoke-text>                                     | (Optional) Brief description why an AP was revoked.                                                                                                                                                                                                                                   |
| state<br>{approved-ready-for-cert <br>certified-factory-cert} | (Optional) State of an AP. <ul style="list-style-type: none"><li>• <b>approved-ready-for-cert:</b> AP is approved and is ready to receive a certificate.</li><li>• <b>certified-factory-cert:</b> AP is certified and has a factory-installed certificate.</li></ul>                  |

## Example

The following command changes the AP group, AP name, certificate type, description, mode, revoke text, and state of an AP with MAC address 00:1E:37:CB:D4:52:

```
(host) #whitelist-db cpsec modify mac-address 00:1E:37:CB:D4:52
 ap-group default
 ap-name ap-225
 cert-type factory-cert
 description "AP-225 in lobby"
 mode disable
 revoke-text "Maintenance"
 state approved-ready-for-cert
```

# whitelist-db cpsec purge

whitelist-db cpsec purge

## Description

Clear the campus AP whitelist.

## Syntax

No parameters.

## Usage Guidelines

Use this command to clear all entries in the entire campus AP whitelist. If your network includes both master and local controllers, then each campus AP whitelist is synchronized across all controllers. If you purge the entire campus AP whitelist on one controller, that action will clear the campus AP whitelist on every controller in the network. To delete an individual entry in the campus AP whitelist, use the command [whitelist-db cpsec delete](#).

## Example

The following command remove all APs from the campus AP whitelist:

```
(host) (config) #whitelist-db cpsec purge
```

| All platforms | Base operating system. | Config mode on master or local controllers |

## whitelist-db cpsec revoke

```
whitelist-db cpsec revoke mac-address <mac-address> revoke-text <revoke-text>
```

### Description

Revoke a certificate from an AP in the campus AP whitelist.

### Syntax

| Parameter                 | Description                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the AP you want to remove from the cpsec whitelist database.                                                                                                   |
| revoke-text <revoke-text> | A brief description why the AP's certificate was revoked, up to 64 alphanumeric characters. If this comment includes spaces, you must enclose the comment in quotation marks. |

### Usage Guidelines

Use this command to revoke a certificate from a invalid or suspected rogue AP.

### Example

The following command revokes a certificate from an AP. This command does not delete a whitelist entry for a revoked AP, but marks its entry with the revoked state.

```
(host) (config) #whitelist-db cpsec revoke mac-address 00:1E:37:CA:D4:51
revoke-text "revoking cert from a rogue AP."
```

| All platforms | Base operating system. | Config mode on master or local controllers |

## whitelist-db rap add

```
whitelist-db rap add mac-addr <mac-address>
 ap-group <ap-group>
 ap-name <ap-name>
 description <description>
 full-name <full-name>
 mode enable|disable
 remote-ip <ip-addr>
```

### Description

Add an AP entry to the remote AP whitelist.

### Syntax

| Parameter                 | Description                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the AP you want to enter into the remote AP whitelist database.                                |
| ap-group <ap-group>       | AP group of the remote AP.                                                                                    |
| ap-name <ap-name>         | Name of the Remote AP.                                                                                        |
| description <description> | Description of the remote AP. If the description includes spaces, it must be enclosed within quotation marks. |
| full-name <full-name>     | Name of the client using the remote AP.                                                                       |
| remote-ip <ip-addr>       | IP address used to assign a static inner IP address for the remote AP.                                        |

### Usage Guidelines

You can manually add entries to the remote AP whitelist to grant valid remote APs secure access to the network.

### Example

The following command creates a new remote AP whitelist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) (config) #whitelist-db rap add mac-address 00:16:CF:AF:3E:E1
```

### Related Commands

| All platforms | Base operating system. | Config mode on master or local controllers |

## whitelist-db rap del

```
whitelist-db rap del mac-addr <mac-address>
```

### Description

Remove an AP entry from the remote AP whitelist.

### Syntax

| Parameter                 | Description                                                                     |
|---------------------------|---------------------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the AP you want to remove from the remote AP whitelist database. |

### Usage Guidelines

You can manually remove entries from the remote AP whitelist to revoke a remote AP's secure access to the network. If you want to temporarily revoke an AP's access without removing the entry from the whitelist, use the command [whitelist-db rap revoke](#).

### Example

The following command revokes and deletes a remote AP whitelist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) (config) #whitelist-db rap del mac-address 00:16:CF:AF:3E:E1
```

### Related Commands

| All platforms | Base operating system. | Config mode on master or local controllers |

## whitelist-db rap modify

```
whitelist-db rap modify mac-addr <mac-address>
 ap-group <ap-group>
 ap-name <ap-name>
 description <description>
 full-name <full-name>
 mode enable|disable
 remote-ip <ip-addr>
```

### Description

Remove an AP entry from the remote AP whitelist.

### Syntax

| Parameter                 | Description                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the remote AP whose whitelist database entry you want to modify.                               |
| ap-group <ap-group>       | AP group of the remote AP.                                                                                    |
| ap-name <ap-name>         | Name of the Remote AP.                                                                                        |
| description <description> | Description of the remote AP. If the description includes spaces, it must be enclosed within quotation marks. |
| full-name <full-name>     | Name of the client using the remote AP.                                                                       |
| mode enable disable       | Enable or disable the remote AP without deleting it from the database.                                        |
| remote-ip <ip-addr>       | IP address used to assign a static inner IP address for the remote AP.                                        |

### Usage Guidelines

You can manually remove entries from the remote AP whitelist to revoke a remote AP's secure access to the network.

### Example

The following command modifies a remote AP whitelist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) (config) #whitelist-db rap modify mac-address 00:16:CF:AF:3E:E1
 description "AP moved to second floor"
```

## whitelist-db rap revoke

```
whitelist-db rap revoke mac-address <mac-address> revoke-comment <comment>
```

### Description

Revoke a certificate from an AP in the remote AP whitelist.

### Syntax

| Parameter                 | Description                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mac-address <mac-address> | MAC address of the AP you want to remove from the remote AP whitelist database.                                                                                               |
| revoke-comment <comment>  | A brief description why the AP's certificate was revoked, up to 64 alphanumeric characters. If this comment includes spaces, you must enclose the comment in quotation marks. |

### Usage Guidelines

Use this command to revoke a certificate from a invalid or suspected rogue AP.

### Example

The following command revokes a certificate from an AP. This command does not delete a whitelist entry for a revoked AP, but marks its entry with the revoked state.

```
(host) (config) #whitelist-db rap revoke mac-address 00:1E:37:CA:D4:51
revoke-comment "revoking cert from a rogue RAP."
```

|---------------|------------------------|--------------------------------------------|
| All platforms | Base operating system. | Config mode on master or local controllers |

## whitelist-db rap-local-switch-list

```
whitelist-db rap-local-switch-list
 del mac-addr <mac-address>
 purge
```

### Description

Delete a local controller from the local switch table used by the remote AP whitelist

### Syntax

| Parameter                                        | Description                                             |
|--------------------------------------------------|---------------------------------------------------------|
| <code>del mac-address &lt;mac-address&gt;</code> | Remove a single controller from the local switch table. |
| <code>purge</code>                               | Clear all controllers from the local switch table       |

### Usage Guidelines

If your deployment includes both master and local controllers, then the remote AP whitelist on each controller contains an entry for every remote AP on the network, regardless of the controller to which it is connected. The master controller also maintains a whitelist of local controllers with remote AP. When you change a remote AP whitelist on any controller, that controller contacts the master controller to check the local switch whitelist, then contacts every other controller on the local switch whitelist to notify it of the change.

If you ever remove a local controller from the network, you must also remove the local controller from the local switch whitelist. If the local switch whitelist contains entries for local controllers no longer on the network, then a remote AP whitelist entry can be marked for deletion but will not be physically deleted, as the controller will be waiting for an acknowledgment from another controller no longer on the network. Any unused local controller entries in the local switch whitelist can significantly increase network traffic and reduce controller memory resources.

### Example

The following command removes a local controller from the local switch whitelist table:

```
(host) (config) #whitelist-db rap-local-switch-list del mac-address 00:16:CF:AF:3E:E1
```

### Related Commands

| Command                              | Description                                | Mode                                       |
|--------------------------------------|--------------------------------------------|--------------------------------------------|
| <a href="#">whitelist-db rap add</a> | Add an entry into the remote AP whitelist. | Config mode on master or local controllers |

### Command History

This command was introduced in ArubaOS 6.3.

## Command Information

| Platforms     | Licensing              | Command Mode                               |
|---------------|------------------------|--------------------------------------------|
| All platforms | Base operating system. | Config mode on master or local controllers |

## whitelist-db rap-master-switch-list

```
whitelist-db rap-master-switch-list
 del mac-addr <mac-address>
 purge
```

### Description

Delete a master controller from the master switch table used by the remote AP whitelist.

### Syntax

| Parameter                                        | Description                                                         |
|--------------------------------------------------|---------------------------------------------------------------------|
| <code>del mac-address &lt;mac-address&gt;</code> | Remove a single master controller from the master switch whitelist. |
| <code>purge</code>                               | Clear all controllers from the Registered Master Switch table.      |

### Usage Guidelines

Each local controller with remote APs managed through a remote AP whitelist has a master switch whitelist which contains the IP and MAC addresses of its master controller. If your network has a redundant master controller, then this whitelist will contain more than one entry.

**The master switch whitelist rarely needs to be purged.** Although you can delete an entry from the master switch whitelist, you should do so only if you have removed a master switch from the network. Deleting a valid master controller from the master switch whitelist can cause errors in your network.

### Example

The following command removes a master controller from the master switch whitelist table:

```
(host) (config) #whitelist-db rap-master-switch-list del mac-address 00:16:CF:AF:3E:E1
```

### Related Commands

# whoami

whoami

## Description

This command displays information about the current user logged into the controller.

## Syntax

No parameters.

## Usage Guidelines

Use this command to display the name and role of the user who is logged into the controller for this session.

## Example

The following command displays information about the user logged into the controller:

```
(host) #whoami
```

## Command History

This command was available in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode                                            |
|---------------|-----------------------|---------------------------------------------------------|
| All platforms | Base operating system | Enable and Config modes on master and local controllers |

## wlan anyspot-profile

```
wlan anyspot-profile <profile-name>
 clone <profile-name>
 enable-anyspot
 exclude-ssid <exclude-ssid>
 exclude-wildcard <exclude-wildcard>
 no
 preset-ssid <preset-ssid>
```

### Description

The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.

### Syntax

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clone <profile-name>                | Make a copy of an existing anyspot profile.                                                                                                                                                                                                                                                                                                                                                                   |
| enable-anyspot                      | Issue this command to enable the anyspot feature. Note that you must associate the anyspot profile with a virtual AP profile for the settings to take effect.                                                                                                                                                                                                                                                 |
| exclude-ssid <exclude-ssid>         | An anyspot-enabled radio will not respond to client probe requests using an ESSID in the <b>Exclude ESSID</b> lists. To add an ESSID to the list, enter the full name of the ESSID, then click <b>Add</b> . To remove an ESSID from the list, select it and click <b>Delete</b> . ESSIDs from neighboring APs will automatically appear in this list as long as the anyspot-enabled AP can detect that ESSID. |
| exclude-wildcard <exclude-wildcard> | An anyspot-enabled radio will not respond to client probe requests using an ESSID in the <b>Exclude ESSID</b> list. To exclude ESSIDs that partially match a text string, enter that string then click <b>Add</b> . To remove a matching string from the list, select it and click <b>Delete</b> .                                                                                                            |
| no                                  | Remove or negate any configured parameter.                                                                                                                                                                                                                                                                                                                                                                    |
| preset-ssid <preset-ssid>           | The anyspot-enabled AP will not send an ESSID in beacons, but if a client sends a probe request without an ESSIDs (that is, the probe request is not looking for a specific network) then the anyspot-enabled AP will respond to the probe request with an ESSID from this list.                                                                                                                              |

### Usage Guidelines

When an AP is configured to use this feature, the anyspot AP radio hides its configured ESSID in beacons, and compiles a list of other ESSIDs from detected neighboring APs. If the client sends a probe request without a specified ESSID, the anyspot AP will respond with a preconfigured ESSID.

When a client searches for a preferred network, that client sends the SSID of the preferred network in the probe request. The anyspot AP checks to see if there is a neighboring AP using that ESSID that can respond the

client's request. If no matching network is found, the anyspot AP sends a response to the client using the SSID from the client request. If the client is authorized to connect to the anyspot AP, that client associates to AP. Once connected to the anyspot AP, the client recognizes the ESSID to which it is connected as one associated with its preferred network, and does not send out any further probe requests.

## Example

The following command defines a ESSID to be returned in probe requests that do not contain an ESSID, as well as two ESSIDs that should be excluded from anyspot responses, in the event that a client is probing for one of these excluded ESSIDs.

```
wlan anyspot-profile anyspot1
 preset SSID companyguest
 exclude-ssid corp_dev_essid
 exclude-ssid corp_voip_essid
```

## Command History

| request-info <request-info>   | This option is used to indicate the contents of the Request Information IE that could be present in the Beacon Report Request frame. The Request Information IE is present for all Measurement Modes except the 'Beacon Table' mode. It consists of a list of Element IDs that should be included by the client in the response frame. | Any valid element ID in the x/y/z format. For example, 0/21/22. | —        |
| rpt-condition <rpt-condition> | This option is used to indicate the value for the "Reporting Condition" field in the Beacon Reporting Information sub-element present in the Beacon Report Request frame.                                                                                                                                                              | 0 - 255                                                         | 0        |
| rpt-detail                    | This option is used to indicate the value for the "Detail" field in the Reporting Detail sub-element present in the Beacon Report Request frame.                                                                                                                                                                                       | —                                                               | Disabled |
| ssid <ssid>                   | A unique character string (sometimes referred to as a network name), consisting of no more than 32 characters. The SSID is case-sensitive (for example, WLAN-01).                                                                                                                                                                      | —                                                               | —        |

## Usage Guidelines

The Beacon Report Request profile is configured under the 802.11K profile.

## Example

The following commands configure the parameters under the bcn-rpt-req-profile.

```
(host) (config) #wlan bcn-rpt-req-profile default
(host) (Beacon Report Request Profile "default") #channel 9
(host) (Beacon Report Request Profile "default") #interface 1
(host) (Beacon Report Request Profile "default") #no measure-dur-mandatory
(host) (Beacon Report Request Profile "default") #measure-duration 100
(host) (Beacon Report Request Profile "default") #measure-mode active-all-ch
(host) (Beacon Report Request Profile "default") #random-interval 100
(host) (Beacon Report Request Profile "default") #reg-class 12

(host) (Beacon Report Request Profile "default") #rpt-condition 2
(host) (Beacon Report Request Profile "default") #no rpt-detail
(host) (Beacon Report Request Profile "default") #request-info 0/21/22
(host) (Beacon Report Request Profile "default") #ssid aruba-ap
```

## Command History

This command is introduced in ArubaOS 6.2.

 inner-eap
 inner-eap-type
 no
 non-broadcasting-connection
 range-connect
 ssid-profile
```

### Description

You can push WLAN profiles to users computers that use the Microsoft Windows Wireless Zero Config (WZC) service to configure and maintain their wireless networks. After the WLAN profiles are pushed to user computers, they are automatically displayed as an ordered list in the preferred networks.

### Syntax

| Parameter                | Description                                                                                                                                                                                                                                                                                           | Default |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| auth-as-computer         | Authenticate with domain credentials.                                                                                                                                                                                                                                                                 |         |
| auth-as-guest            | Authenticate as a guest user.                                                                                                                                                                                                                                                                         |         |
| clone                    | Copy settings from another WLAN client profile.                                                                                                                                                                                                                                                       |         |
| eap-cert                 | If you select EAP type as certificate, you can use one of the following options: <ul style="list-style-type: none"><li>• mschapv2-use-windows-credentials</li><li>• use-smartcard</li><li>• simple-certificate-selection</li><li>• use-different-name</li><li>• validate-server-certificate</li></ul> | —       |
| eap-cert-connect-only-to | Comma separated list of servers.                                                                                                                                                                                                                                                                      |         |
| eap-peap                 | Configure EAP-PEAP settings.                                                                                                                                                                                                                                                                          |         |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Default      |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| eap-peap-connect-only-to    | Comma separated list of servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |              |
| eap-type                    | Enter a EAP type used by client to connect to wireless network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | EAP-PEAP     |
| enable-8021x                | Select this option to enable 802.1x authentication for this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Enabled      |
| ieap-cert-connect-only      | Command separated list of servers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |              |
| inner-eap                   | Enter the inner EAP type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | EAP-MSCHAPv2 |
| inner-eap-type              | Specify one of the following: <ul style="list-style-type: none"> <li>mschapv2-use-windows-credentials: Automatically use the Windows logon name and password (and domain if any)</li> <li>use-smartcard: Use a smart card</li> <li>simple-certificate-selection: Use a certificate on the users computer or use a simple certificate selection method (recommended)</li> <li>validate-server-certificate: Validate the server certificate</li> <li>use-different-name: Use a different user name for the connection (and not the CN on the certificate)</li> </ul> |              |
| no                          | Negate and reset all configuration settings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |              |
| non-broadcasting-connection | Connect even if WLAN is not broadcasting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Disabled     |
| range-connect               | Automatically connect to this WLAN if in range.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |              |
| ssid-profile                | Enter the name of the SSID profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |              |

### Description

Configure a 802.11k radio profile.

### Syntax

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Default      |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <profile-name>       | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | "default"    |
| ap-chan-rpt-11a      | This value is sent in the 'Channel' field of the AP channel reports on the 'A' radio. You can specify values in the range 34 to 165.                                                                                                                                                                                                                                                                                                                                                                                                                                | 36           |
| ap-chan-rpt-11bg     | This value is sent in the 'Channel' field of the AP channel reports on the 'BG' radio. You can specify values in the range 1 to 14.                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1            |
| bcn-measurement-mode | Configures an <b>active</b> , <b>beacon-table</b> or <b>passive</b> beacon measurement mode for the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | beacon-table |
| active               | <p>Enables <b>active</b> beacon measurement mode. In this mode, the client sends a probe request to the broadcast destination address on all supported channels, sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.</p> <p><b>NOTE:</b> If the station doesn't support active measurement mode, it returns a Beacon Measurement Report with the <i>Incapable</i> bit set in the <i>Measurement Report Mode</i> field.</p> | —            |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Default    |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| beacon-table         | <p>Enables <b>beacon-table</b> beacon measurement mode. In this mode, the client measures beacons and returns a report with stored beacon information for any supported channel with the requested SSID and BSSID. The client does not perform any additional measurements. This is the default beacon measurement mode.</p> <p><b>NOTE:</b> If a station doesn't support beacon-table able measurement mode, it returns a Beacon Measurement Report with the <i>Incapable</i> bit set in the <i>Measurement Report Mode</i> field.</p> | —          |
| passive              | <p>Enables <b>passive</b> beacon measurement mode. In this mode, the client sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.</p> <p><b>NOTE:</b> If a station doesn't support passive measurement mode, it returns a Beacon Measurement Report with the <i>Incapable</i> bit set in the <i>Measurement Report Mode</i> field.</p>                                                           | —          |
| clone <profile-name> | Copy settings from another specified 802.11k profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | —          |
| bcn-req-chan-11a     | This value is sent in the 'Channel' field of the beacon requests on the 'A' radio. You can specify values in the range 34 to 165.                                                                                                                                                                                                                                                                                                                                                                                                       | 36         |
| bcn-req-chan-11bg    | This value is sent in the 'Channel' field of the Beacon Requests on the 'BG' radio. You can specify values in the range 1 to 14.                                                                                                                                                                                                                                                                                                                                                                                                        | 1          |
| bcn-req-time         | <p>This option configures the time duration between two consecutive beacon requests sent to a dot11K client. By default, the beacon requests are sent to a dot11K client every 60 seconds. However, if a different value is required, the <code>bcn-req-time</code> option can be used.</p> <p>This permits values in the range from 10 seconds to 200 seconds.</p>                                                                                                                                                                     | 60 seconds |
| dot11k-enable        | Enables the 802.11K feature. This feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Disabled   |
| force-dissasoc       | <p>This feature allows the AP to forcefully disassociate “on-hook” voice clients (clients that are not on a call) after period of inactivity.</p> <p>Without the forced disassociation feature, if an AP has reached its call admission control limits and an on-hook voice client wants to start a new call, that client may be denied. If forced disassociation is enabled, those clients can associate to a neighboring AP that can fulfil their QoS requirements.</p> <p>This feature is disabled by default.</p>                   | Disabled   |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Default    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| handover-trigger-profile | Name of the handover trigger profile associated with this 802.11k profile. If the handover trigger feature is enabled in the handover trigger profile, the controller will initiate the handover of a voice client (for example: dual mode handsets) roaming at the edge of Wi-Fi coverage to an alternate carrier or connection. The handover trigger is initiated if the Wi-Fi signal strength reported by the voice client (received from all APs) is equal to or less than the threshold value.<br><br>You must enable dot11k before using this command. |            |
| lm-req-time              | This option configures the time duration between two consecutive link measurement requests sent to an dot11K client. By default, link measurement requests are sent to a dot11K client every 61 seconds. However, you can use the <code>lm-req-time</code> option to specify different time interval.<br><br>This permits values in the range from 10 seconds to 200 seconds.                                                                                                                                                                                | 61 seconds |
| no                       | Negates or removes any configured parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |            |
| rrm-ie-profile           | RRM IE Settings Profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |            |
| tsm-req-profile          | TSM Report Request Settings Profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |
| tsm-req-time             | This option configures the time duration between two consecutive transmit stream measurement requests sent to a dot11K client. By default, the transmit stream measurement requests are sent to a dot11K client every 90 seconds. However, you can use the <code>tsm-req time</code> option to specify a different time interval.<br><br>This permits values in the range from 10 seconds to 200 seconds.                                                                                                                                                    | 90 seconds |

## Usage Guidelines

In a 802.11k network, if the AP with the strongest signal is reaches its maximum capacity, clients may connect to an under utilized AP with a weaker signal. A 802.11k profile can assigned to each virtual AP.

## Example

The following command enables the 802.11k feature on the 802.11k profile and configures the beacon measurement mode and specifies the time interval for beacon, link, and transmit stream measurement requests.

```
(host) (config) #wlan dot11k-profile default
(host) (802.11K Profile "default") #dot11k-enable
(host) (802.11K Profile "default") #bcn-measurement-mode beacon-table
(host) (802.11K Profile "default") #bcn-req-time 60
(host) (802.11K Profile "default") #lm-req-time 60
(host) (802.11K Profile "default") #tsm-req-time 90
```

### Description

This command configures an 802.11r radio profile.

### Syntax

| Parameter      | Description                                                                                                                                                                                                                | Range    | Default   |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-----------|
| <profile-name> | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                    | —        | "default" |
| clone          | Name of an existing dot11r-profile from which the parameter values are copied.                                                                                                                                             | —        | —         |
| mob-domain-id  | An ID that uniquely identifies the mobility domain.                                                                                                                                                                        | 1-65535  | 1         |
| dot11r         | Enables the Fast BSS Transition capability.                                                                                                                                                                                | —        | Disabled  |
| no             | Negates or removes any configured parameter.                                                                                                                                                                               |          | —         |
| key-duration   | The r1 key timeout value in seconds for decrypt-tunnel or bridge mode.                                                                                                                                                     | 60-86400 | 3600      |
| key-assignment | The list of neighbor APs for decrypt-tunnel or bridge mode. <ul style="list-style-type: none"><li>static: Get neighbor AP list from ARM or VBR.</li><li>dynamic: Use all APs from ap-group as the neighbor list.</li></ul> | —        | —         |
|                |                                                                                                                                                                                                                            |          |           |

### Usage Guidelines

You can enable and configure Fast BSS Transition on a per Virtual AP basis. You must create an 802.11r profile and associate that with the Virtual AP profile through an SSID profile.

### Example

The following set of commands enable the 802.11r capability on the 802.11r profile, configures the Fast BSS mobility domain ID, and specifies the r1 key time-out value.

```
(host) (config) #wlan dot11r-profile default
(host) (802.11r Profile "default") #fastbss-transition
```

```
(host) (802.11r Profile "default") #fastbss-mob-domain-id 25
(host) (802.11r Profile "default") #r1key_validity_duration 2500
```

Configure a mobility domain ID that uniquely identifies a mobility domain using the following command:

```
(host) (802.11r Profile "default") #mob-domain-id <1-65535>
```

The default value is 1.

Configure the r1 key timeout value in seconds for decrypt-tunnel or bridge mode using the following command:

```
(host) (802.11r Profile "default") #key_duration <60-86400>
```

The default value is 3600 seconds.

Apply the 802.11r profile to an SSID profile using the following command:

```
(host) (config) #wlan ssid-profile voice dot11r-profile voice-enterprise
```

You can advertise the 802.11r capability on the Virtual AP profile by applying the SSID profile. Use the following command to apply the SSID profile to the Virtual AP profile:

```
(host) (config) #wlan virtual-ap voice-AP ssid-profile voice
```

## Command History

This command was introduced in ArubaOS 6.3.

## wlan edca-parameters-profile

```
wlan edca-parameters-profile {ap|station} <profile-name>
 {background | best-effort | video | voice}
 [acm] [aifsn <number>] [ecw-max <exponent>] [ecw-min <exponent>] [txop <number>]
 [clone <profile-name>]
```

### Description

This command configures an enhanced distributed channel access (EDCA) profile for APs or for clients (stations).

### Syntax

| Parameter      | Description                                                                                                                                                                                                                       | Range  | Default      |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------|
| <profile-name> | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                           | —      | “default”    |
| background     | Configures the background queue.                                                                                                                                                                                                  | —      | —            |
| best-effort    | Configures the best-effort queue.                                                                                                                                                                                                 | —      | —            |
| video          | Configures the video queue.                                                                                                                                                                                                       | —      | —            |
| voice          | Configures the voice queue.                                                                                                                                                                                                       | —      | —            |
| acm            | Specifies mandatory admission control. The client reserves the access category through traffic specification (TSPEC) signaling. Enter 1 to enable, 0 to disable.                                                                  | 0, 1   | 0 (disabled) |
| aifsn          | Arbitrary inter-frame space number.                                                                                                                                                                                               | 1-15   | 0            |
| ecw-max        | The exponential (n) value of the maximum contention window size, as expressed by $2^n-1$ . A value of 4 computes to $2^4-1 = 15$ .                                                                                                | 1-15   | 0            |
| ecw-min        | The exponential (n) value of the minimum contention window size, as expressed by $2^n-1$ . A value of 4 computes to $2^4-1 = 15$ .                                                                                                | 0-15   | 0            |
| txop           | Transmission opportunity, in units of 32 microseconds. Divide the desired transmission duration by 32 to determine the value to configure. For example, for a transmission duration of 3008 microseconds, enter 94 ( $3008/32$ ). | 0-2047 | 0            |
| clone          | Name of an existing EDCA profile from which parameter values are copied.                                                                                                                                                          | —      | —            |

## Usage Guidelines

EDCA profiles are specific either to APs or clients. You apply an EDCA profile to a specific SSID profile. use this command only under the guidance of your Dell technical support representative.

The following are the default values configured for APs:

| Access Category | ecw-min | ecw-max | aifsn | txop | acm |
|-----------------|---------|---------|-------|------|-----|
| best-effort     | 4       | 6       | 3     | 0    | No  |
| background      | 4       | 10      | 7     | 0    | No  |
| video           | 3       | 4       | 1     | 94   | No  |
| voice           | 2       | 3       | 1     | 47   | No  |

The following are the default values configured for clients:

| Access Category | ecw-min | ecw-max | aifsn | txop | acm |
|-----------------|---------|---------|-------|------|-----|
| best-effort     | 4       | 10      | 3     | 0    | No  |
| background      | 4       | 10      | 7     | 0    | No  |
| video           | 3       | 4       | 2     | 94   | No  |
| voice           | 2       | 3       | 2     | 47   | No  |

## Example

The following command configures an EDCA profile for APs:

```
(host) (config) #wlan edca-parameters-profile ap edcal
best-effort ecw-min 15 ecw-max 15 aifsn 15 txop 100 acm 1
```

## Command History

| Version       | Description                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.1   | Command introduced.                                                                                                                                               |
| ArubaOS 3.4.1 | License requirements changed in ArubaOS 3.4.1, so the command requires the PEF license instead of the Voice Services Module license required in earlier versions. |

This command was introduced in ArubaOS 3.1.

## wlan handover-trigger-profile

```
wlan handover-trigger-profile <profile-name>
 clone <source>
 handover-threshold <handover-threshold>
 handover-trigger
no
```

### Description

Configure a handover trigger profile to ensure QoS for voice calls.

### Syntax

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Range           | Default   |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-----------|
| <profile-name>                             | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                                                                                                                                                                                                                                                                      | —               | "default" |
| clone <source>                             | Creates a copy of the Handover Trigger Profile specified as the <source>. <source> is the name of an existing Handover Trigger Profile from which parameter values are copied.                                                                                                                                                                                                                                                                                               | —               | —         |
| handover-threshold<br><handover-threshold> | If the best signal strength (-dbm) of a WiFi signal received by a voice client from all the APs is equal to or lesser than this threshold value, the handover trigger feature initiates the handover process.. Threshold values can be specified in the range 20 to 70.                                                                                                                                                                                                      | 20 – 70<br>-dBm | 50 -dBm   |
| handover-trigger                           | Issue this command to enable the handover trigger feature. If enabled, the controller will initiate the handover of a voice client (for example: dual mode handsets) roaming at the edge of Wi-Fi coverage to an alternate carrier or connection. The handover trigger is initiated if the Wi-Fi signal strength reported by the voice client (received from all APs) is equal to or less than the threshold value.<br><br>You must enable dot11k before using this command. | —               | Enabled   |
| no                                         | Negates any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                            | —               | —         |

### Usage Guidelines

The handover-trigger profile is a part of the 802.11K profile. It is used to configure the parameters for the “Wi-Fi Edge Detection and Handover of Voice Clients” feature. It is mandatory to enable the 802.11K feature before enabling the “Wi-Fi Edge Detection and Handover of Voice Clients” feature.

### Example

The following command enables the handover trigger feature and sets the handover threshold at -20dbm.

```
(host) (config) #wlan handover-trigger-profile default
(host) (Handover Trigger Profile "default") #handover-trigger
```

```
(host) (Handover Trigger Profile "default") #handover-threshold 20
```

### Command History

This command was introduced in ArubaOS 6.2.

## Usage Guidelines

Hotspot 2.0 is a Wi-Fi Alliance specification based upon the 802.11u protocol that provides wireless clients with a streamlined mechanism to discover and authenticate to suitable networks, and allows mobile users the ability to roam between partner networks without additional authentication.

Access Network Query Protocol (ANQP) and Hotspot 2.0 Query Protocol (H2QP) profiles define the information in the 802.11u Information Elements (IEs) to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP and H2QP profile to be associated with the advertisement profile.

Values configured in the ANQP profiles will not be sent to clients unless you:

1. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)
2. Enable the hotspot feature within that Hotspot profile (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

## Example

The following command associates the ANQP domain name profile **anqp-dom-1** to the advertisement profile **network1**.

```
wlan hotspot advertisement-profile network1
 anqp-domain-name-profile anqp-dom-1
```

## Related Commands

Use the following commands to configure the Hotspot feature.

| Command                                                                                                       | Description                                                                                                                                                                                                       |

| 3gpp_plmn5           | The Public Land Mobile Networks (PLMN) value of the fifth-highest priority network.<br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).  |
| 3gpp_plmn6           | The Public Land Mobile Networks (PLMN) value of the sixth-highest priority network.<br>The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).  |
| clone <profile-name> | Make a copy of an existing 3GPP profile.                                                                                                                                                      |

| Parameter | Description                                                                            |
|-----------|----------------------------------------------------------------------------------------|
| enable    | Issue this command to enable this profile. ANQP 3GPP profiles are disabled by default. |
| no        | Remove an existing parameter.                                                          |

## Usage Guidelines

The 3GPP Cellular Network Profile defines an ANQP information element (IE) to be sent in a Generic Advertisement Service (GAS) query response from an AP in a hotspot with a roaming relationship with a cellular operator. The 3GPP Mobile Country Code (MCC) and the 12-bit Mobile Network Code data in the IE can help the client select a 3GPP network.

Values configured in this profile will not be sent to clients unless you:

1. Associate the 3GPP Cellular Network profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-3gpp-nwk-profile <profile-name>`)
2. Associate the ANQP advertisement profile with a Hotspot profile. (`"wlan hotspot h2-profile advertisement-profile <profile-name>"`)
3. Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

## Example

The following command defines 3GPP data for the 3GPP profile cellcorp1.

```
wlan hotspot anqp-3gpp-nwk-profile cellcorp1
 enable
 3gpp_plmn1 310026
 3gpp_plmn2 208000
 3gpp_plmn3 208001
```

## Command History

This command was introduced in ArubaOS 6.

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot anqp-domain-name-profile

```
wlan hotspot anqp-domain-name-profile <profile-name>
 clone <profile-name>
 domain-name <domain-name>
 no ...
```

### Description

This command defines the domain name to be sent in an Access Network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

### Syntax

| Parameter                 | Description                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------|
| clone <profile-name>      | Make a copy of an existing ANQP domain name profile.                                         |
| domain-name <domain-name> | Domain name of the hotspot operator. This alphanumeric string must be 32 characters or less. |
| no                        | Remove an existing parameter.                                                                |

### Usage Guidelines

Use this command to configure a domain name in the ANQP Domain Name profile. If a client uses the Generic Advertisement Service (GAS) to post an ANQP query to an Access Point, the AP will return an ANQP Information Element with the domain name configured in this profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Domain Name profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-domain-name-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name> )
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable )

### Example

The following command defines a domain name for the ANQP domain name profile domain1.

```
wlan hotspot anqp-domain-name-profile domain1
 domain-name example.com
```

### Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot anqp-ip-addr-avail-profile

```
wlan hotspot anqp-ip-addr-avail-profile <profile-name>
 clone <profile-name>
 ipv4-addr-avail availability-unknown|not-available|port-restricted|port-restricted-double-
nated|port-restricted-single-nated|private-double-nated|private-single-nated
 ipv6-addr-avail available|availability-unknown|not-available
 no ...
```

### Description

This command defines available IP address types to be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

### Syntax

| Parameter                    | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| clone <profile-name>         | Make a copy of an existing ANQP IP Address Availability profile.                                    |
| ipv4-addr-avail              | Indicate the availability of an IPv4 network.                                                       |
| availability-unknown         | Network availability cannot be determined.                                                          |
| not-available                | Network is not available.                                                                           |
| port-restricted              | Network has some ports restricted ( for example, the network blocks port 110 to restrict POP mail). |
| port-restricted-double-nated | Network has some ports restricted and multiple routers performing network address translation.      |
| port-restricted-single-nated | Network has some ports restricted and a single router performing network address translation.       |
| private-double-nated         | Network is a private network with multiple routers doing network address translation.               |
| private-single-nated         | Network is a private network a single router doing network address translation.                     |
| public                       | Network is a public network.                                                                        |
| ipv6-addr-avail              | Indicate the availability of an IPv6 network.                                                       |
| available                    | An IPv6 network is available.                                                                       |
| availability-unknown         | Network availability cannot be determined.                                                          |

| Parameter     | Description                   |
|---------------|-------------------------------|
| not-available | Network is not available.     |
| no            | Remove an existing parameter. |

## Usage Guidelines

The IP Address Availability information configured using this command provides clients with information about the availability of IP address versions and types which could be allocated to those clients after they associate to the hotspot AP.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP IP Address Availability profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-ip-addr-avail-profile <profile-name> )`
2. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name> )`
3. Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable )`

## Example

The following command configures an AP using this profile to advertise a public IPv4 network.

```
wlan hotspot anqp-ip-addr-avail-profile default
 ipv4-addr-avail public
 ipv6-addr-avail not-available
```

## Command History

This command was introduced in ArubaOS 6.4

no ...
```

### Description

This command defines a Network Access Identifier (NAI) realm whose information can be sent as an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

### Syntax

| Parameter                               | Description                                                                                                                                                                                                                                                                |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clone <profile-name>                    | Make a copy of an existing NAI Realm profile.                                                                                                                                                                                                                              |
| nai-home-realm                          | Mark the realm in this profile as the NAI Home Realm.                                                                                                                                                                                                                      |
| nai-realm-auth-id-1 nai-realm-auth-id-2 | Use the <b>nai-realm-auth-id-1</b> command to send the one of the following authentication methods for the primary NAI realm ID.<br><br>Use the <b>nai-realm-auth-id-2</b> command to send the one of the following authentication methods for the secondary NAI realm ID. |
| credential-type                         | The specified authentication ID uses credential authentication.                                                                                                                                                                                                            |
| expanded-eap                            | The specified authentication ID uses the expanded EAP authentication method.                                                                                                                                                                                               |
| expanded-inner-eap                      | The specified authentication ID uses the expanded inner EAP authentication method.                                                                                                                                                                                         |
| inner-auth-eap                          | The specified authentication ID uses inner EAP authentication type.                                                                                                                                                                                                        |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| non-eap-inner-auth                            | The specified authentication ID uses non-EAP inner authentication type.                                                                                                                                                                                                                                                      |
| tunneled-eap-credential-type                  | The specified authentication ID uses the tunneled EAP credential type.                                                                                                                                                                                                                                                       |
| nai-realm-auth-value-1 nai-realm-auth-value-2 | <p>Use the <b>nai-realm-auth-value-1</b> command to select an authentication value for the authentication method specified by <b>nai-realm-auth-id-1</b>.</p> <p>Use the <b>nai-realm-auth-value-2</b> command to select the authentication value for the authentication method specified by <b>nai-realm-auth-id-2</b>.</p> |

| eap-sim               | EAP for GSM Subscriber Identity Modules                                                                   |
| eap-tls               | EAP-Transport Layer Security                                                                              |
| eap-ttls              | EAP-Tunneled Transport Layer Security                                                                     |
| generic-token-card    | EAP Generic Token Card (EAP-GTC)                                                                          |
| identity              | EAP Identity type                                                                                         |
| notification          | The hotspot realm uses EAP Notification messages for authentication.                                      |
| one-time-password     | Authentication with a single-use password.                                                                |

| Parameter                       | Description                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| peap                            | Protected Extensible Authentication Protocol                                                                                                                                                             |
| peap-mschapv2                   | Protected Extensible Authentication Protocol with Microsoft Challenge Handshake Authentication Protocol version 2                                                                                        |
| nai-realm-encoding <0-255>      | Issue this command if the NAI realm named defined by <a href="#">nai-realm-name &lt;nai-realm-name&gt;</a> is a UTF-8 formatted character string that is not formatted in accordance with IETF RFC 4282. |
| nai-realm-name <nai-realm-name> | Name of the NAI realm. The realm name is often the domain name of the service provider.                                                                                                                  |
| no                              | Negate or remove any existing parameter                                                                                                                                                                  |

## Usage Guidelines

An AP's NAI Realm profile identifies and describes a NAI realm accessible using the AP, and the method that this NAI realm uses for authentication. These settings configured in this profile determine the NAI realm elements that are included as part of a GAS Response frame.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP NAI Realm profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name>anqp-nai-realm-profile <profile-name>`)
2. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profileadvertisement-profile <profile-name>`)
3. Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name>hotspot-enable`)

## Example

```
wlan hotspot anqp-nai-realm-profile home
 enable
 nai-realm-name corp-hotspot.com
 nai-realm-auth-id-1 credential-type
 nai-realm-auth-value-1 cred-cert
 nai-home-realm
!
wlan hotspot anqp-nai-realm-profile non-home
 nai-realm-name corp-hotspot-roam.com
 nai-realm-eap-method eap-sim
 nai-realm-auth credential-type
```

## Command History

This command was introduced in ArubaOS 6.4

|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot anqp-nwk-auth-profile

```
wlan hotspot anqp-nwk-auth-profile <profile-name>
 clone <profile-name>
 no ...
 nwk-auth-type acceptance|dns-redirection|http-https-redirection|online-enroll
 url <url>
```

### Description

This command configures an ANQP Network Authentication profile to define authentication type being used by the hotspot network.

### Syntax

| Parameter              | Description                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clone <profile-name>   | Make a copy of an existing ANQP Network Authentication profile.                                                                                                                        |
| no                     | Negate any existing parameter.                                                                                                                                                         |
| nwk-auth-type          | Network Authentication Type being used by the hotspot network.                                                                                                                         |
| acceptance             | Network requires the user to accept terms and conditions.<br><b>NOTE:</b> This option requires you to specify a redirection URL string as an IP address, FQDN or URL.                  |
| dns-redirection        | Additional information on the network is provided through DNS redirection.<br><b>NOTE:</b> This option requires you to specify a redirection URL string as an IP address, FQDN or URL. |
| http-https-redirection | Additional information on the network is provided through HTTP/HTTPS redirection.                                                                                                      |
| online-enroll          | Network supports online enrollment.                                                                                                                                                    |
| url                    | URL, IP address, or FQDN used by the hotspot network for the <b>acceptance</b> or <b>dns-redirection</b> network authentication types.                                                 |

### Usage Guidelines

When you enable the [asra](#) option in the WLAN hotspot profile, the settings you configure in the Network Authentication profile are sent in the GAS response to the client.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Network Authentication profile an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-nwk-auth-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable )

## Example

The following command configures the default Network Authorization profile to use DNS redirection.

```
wlan hotspot anqp-nwk-auth-profile default
 nwk-auth-type dns-redirection redirect-url http://www.example.com/redirect.html
```

## Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot anqp-roam-cons-profile

```
wlan hotspot anqp-roam-cons-profile <profile-name>
 clone <profile-name>
 no ...
 roam-cons-oi <roam-cons-oi>
 roam-cons-oi-len <roam-cons-oi-len>
```

### Description

This command configures the Roaming Consortium OI information to be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

### Syntax

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clone <profile-name>                | Make a copy of an existing ANQP Roaming Consortium profile.                                                                                                                                                                                                                                                                             |
| no                                  | Negate any existing parameter.                                                                                                                                                                                                                                                                                                          |
| roam-cons-oi <roam-cons-oi>         | Send the specified roaming consortium OI in a GAS query response. The OI must be a hexadecimal number 3-5 octets in length.                                                                                                                                                                                                             |
| roam-cons-oi-len <roam-cons-oi-len> | Length of the OI. The value of the <b>roam-cons-oi-len</b> parameter must equal upon the number of octets of the <b>roam-cons-oi</b> field. <ul style="list-style-type: none"><li>• <b>0</b>: 0 Octets in the OI (Null)</li><li>• <b>3</b>: OI length is 24-bit (3 Octets)</li><li>• <b>5</b>: OI length is 36-bit (5 Octets)</li></ul> |

### Usage Guidelines

Organization Identifiers (OIs) are assigned to service providers when they register with the IEEE registration authority. The Roaming Consortium Information Elements (IEs) contain information identifying the network and service provider, whose security credentials can then be used to authenticate with the AP transmitting this element.

Use the [wlan hotspot anqp-roam-cons-profile](#) command to define the OI for the hotspot service provider in the ANQP Roaming Consortium profile. Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Roaming Consortium profile an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-roam-cons-profile <profile-name> )
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name> )
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable )

To identify additional Roaming consortium OIs used by the service provider's top three roaming partners, configure the [roam-cons-oi-1](#), [roam-cons-oi-2](#) or [roam-cons-oi-3](#) parameters in the Hotspot Profile.

## Example

The following command defines the roaming consortium OI and OI length in the ANQP roaming consortium profile:

```
wlan hotspot anqp-roam-cons-profile profile1
 roam-cons-oi 506F9A
 roam-cons-oi-len 3
```

## Command History

This command was introduced in ArubaOS 6.4

## wlan hotspot anqp-venue-name-profile

```
wlan hotspot anqp-venue-name-profile <profile-name>
 clone
 no
 venue-group outdoor|reserved|utility-misc|vehicular|assembly|business educational|factory-
or-industrial|institutional|mercantile|residential| storage|unspecified
 venue-language <language>
 venue-name <venue-name>
 venue-type <venue-type>
```

### Description

This command defines venue information be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

### Syntax

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clone                       | Make a copy of an existing ANQP Venue Name profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| no                          | Negates any existing parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| venue-group                 | <p>Specify one of the following venue groups to be advertised in the ANQP Information Elements (IEs) from APs associated with this profile. The default setting is unspecified.</p> <ul style="list-style-type: none"><li>• assembly</li><li>• business</li><li>• educational</li><li>• factory-or-industrial</li><li>• institutional</li><li>• mercantile</li><li>• outdoor</li><li>• reserved</li><li>• residential</li><li>• storage</li><li>• unspecified</li><li>• Utility-Misc</li><li>• Vehicular</li></ul> |
| venue-language <venue-name> | An ISO 639 language code that identifies the language used in the Venue Name field.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| venue-name <venue-name>     | Venue name to be advertised in the ANQP IEs from APs associated with this profile. If the venue name includes spaces, the name must be enclosed in quotation marks, e.g. "Midtown Shopping Center".                                                                                                                                                                                                                                                                                                                |

| Parameter               | Description                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| venue-type <venue-type> | Specify a venue type to be advertised in the IEs from APs associated with this hotspot profile. The complete list of supported venue types is described in <a href="#">Venue Types on page 2294</a> . |

## Usage Guidelines

Use this command to configure the venue group and venue type in an ANQP Venue Name profile. If a client uses the Generic Advertisement Service (GAS) to post an ANQP query to an Access Point, the AP will return ANQP Information Elements with the values configured in this profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Venue Name profile with an ANQP Advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-venue-name-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

## Venue Types

The following list describes the different venue types that may be configured in a hotspot profile:

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Example

The following command defines an ANQP Venue Name profile for a shopping mall.

```
wlan hotspot anqp-venue-name-profile Mallprofile1
venue-group mercantile
venue-name Westgate Shopping Center
venue-type mercantile-shopping-mall
```

## Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot h2qp-conn-capability-profile

```
wlan hotspot h2qp-conn-capability-profile <profile>
 clone
 esp
 icmp
 no
 tcp-ftp
 tcp-http
 tcp-pptp-vpn
 tcp-ssh
 tcp-tls-vpn
 tcp-voip
 udp-ike2-4500
 udp-ike2-500
 udp-ipsec-vpn
 udp-voip
```

### Description

Define a Hotspot 2.0 Query Protocol (H2QP) profile that advertises hotspot protocol and port capabilities.

### Syntax

| Parameter     | Description                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------|
| clone         | Make a copy of an existing hotspot connection capability profile.                                           |
| esp           | Include this parameter to enable the Encapsulating Security Payload (ESP) port used by IPsec VPNs. (port 0) |
| icmp          | Indicates that the ICMP port is enabled and available. (port 0)                                             |
| no            | Negates any existing parameter, returning it to its default disabled value.                                 |
| tcp-ftp       | Include this parameter to enable the FTP port. (port 20)                                                    |
| tcp-http      | Include this parameter to enable the HTTP port. (port 80)                                                   |
| tcp-pptp-vpn  | Include this parameter to enable the PPTP port used by IPsec VPNs. (port 1723)                              |
| tcp-ssh       | Include this parameter to enable the SSH port. (port 22)                                                    |
| tcp-tls-vpn   | Include this parameter to enable the TCP TLS port used by VPNs. (port 80)                                   |
| tcp-voip      | Include this parameter to enable the TCP VoIP port. (port 5060)                                             |
| udp-ike2-4500 | Include this parameter to enable the IKEv2. (port 4500)                                                     |

| Parameter     | Description                                                                  |
|---------------|------------------------------------------------------------------------------|
| udp-ike2-500  | Include this parameter to enable the IKEv2. (port 500)                       |
| udp-ipsec-vpn | Include this parameter to enable the IPsec VPN port. (ports 500, 4500 and 0) |
| no            | Negates any existing parameter, returning it to its default disabled value.  |
| udp-voip      | Include this parameter to enable the UDP VoIP port. (port 5060)              |

## Usage Guidelines

The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about the IP protocols and associated port numbers that are available and open for communication.

Values configured in this profile will not be sent to clients unless you:

1. Associate the H2QP profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> h2qp-conn-cap-profile <profile-name>`)
2. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)
3. Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

## Example

The following example allows the H2QP connection capability profile to advertise the availability of ICMP, HTTP and VOIP ports.

```
(host) (config)# wlan hotspot h2qp-conn-capability-profile Wan1
icmp
http
voip
enable
```

## Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot h2qp-op-cl-profile

```
wlan hotspot h2qp-op-cl-profile <profile>
 clone
 no
 op-cl <1-255>
```

### Description

This command defines a Hotspot 2.0 Query Protocol (H2QP) profile that defines the Operating Class to be sent in the ANQP IE.

### Syntax

| Parameter | Description                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| clone     | Makes a copy of an existing hotspot operating class profile.                                                                  |
| no        | Negates any existing parameter, returning it to its default disabled value.                                                   |
| op-cl     | Configures the operating class for the devices' BSS. The supported range for this field is 1-255, and the default value is 1. |

### Usage Guidelines

The values configured in this H2QP Operating Class profile define the channels on which the hotspot is capable of operating. It may be useful where, for instance, a mobile device discovers a hotspot in the 2.4 GHz band but finds it is dual-band and prefers the 5 GHz band. For a definition of these global operating classes, refer to Table E-4 of IEEE Std 802.11-2012, Annex E.

Values configured in this profile will not be sent to clients unless you:

1. Associate the H2QP profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> h2qp-op-cl-profile <profile-name> )
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name> )
3. Enable the hotspot feature within that Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable )

### Example

The following example configures and enables a profile with the default operating class value.

```
(host)(config)#wlan hotspot h2qp-op-cl-profile
 op-cl 1
 enable
```

### Command History

This command was introduced in ArubaOS 6.4

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Config mode on master controllers |

## wlan hotspot h2qp-operator-friendly-name-profile

```
wlan hotspot h2qp-operator-friendly-name-profile <profile>
 clone
 no
 op-fr-name <op-fr-name>
 op-lang-code <op-lang-code>
```

### Description

This command defines a Hotspot 2.0 Query Protocol (H2QP) operator-friendly name profile.

### Syntax

| Parameter      | Description                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clone          | Makes a copy of an existing operator-friendly name profile.                                                                                                                                                                                                                                        |
| no             | Negates any existing parameter.                                                                                                                                                                                                                                                                    |
| <op-fr-name>   | An operator-friendly name sent by devices using this profile. The name can be up to 64 alphanumeric characters, and can include special characters and spaces. If the name includes quotation marks ("), you must include a backslash character (\) before each quotation mark. (e.g. \"example\") |
| <op-lang-code> | An ISO 639 language code that identifies the language used in the op-fr-name field.                                                                                                                                                                                                                |

### Usage Guidelines

The operator-friendly name configured in this profile is a free-form text field that can identify the operator and also something about the location.

Values configured in this profile will not be sent to clients unless you:

1. Associate the H2QP operator-friendly name profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name>h2qp-operator-friendly-profile <profile-name>`)
2. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)
3. Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name>hotspot-enable`)

### Example

The example below shows that the controller has two configured operator friendly name profiles. The **References** column lists the number of other profiles with references to the operator friendly name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) (config)# wlan hotspot h2qp-operator-friendly-name-profile
 op-fr-name my_hotspot
 op-lang-code <op-lang-code>
```

## Command History

This command was introduced in ArubaOS 6.4

## wlan hotspot h2qp-wan-metrics-profile

```
wlan hotspot h2qp-wan-metrics-profile <profile-name>
at-capacity
clone
downlink-load
downlink-speed
load-dur
no
symm-link
uplink-load
uplink-speed
wan-metrics-link-status link_down|link_test|link_up|reserved
```

### Description

Create a Hotspot 2.0 Query Protocol (H2QP) profile that specifies the hotspot WAN status and link metrics.

### Syntax

| Parameter              | Description                                                                                                                                                                                                                                         | Range                     | Default            |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|--------------------|
| at_capacity            | Use the <b>at_capacity</b> parameter to indicate that the WAN Link has reached its maximum capacity. If this parameter is enabled, no additional mobile devices will be permitted to associate with the hotspot AP.                                 | enabled<br>disabled       | disabled           |
| clone <profile>        | Make a copy of an existing H2QP profile.                                                                                                                                                                                                            | -                         | -                  |
| downlink_load <load>   | The percentage of the WAN downlink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.                                                     | 1-100                     | 0<br>(unspecified) |
| downlink_speed <speed> | Use the <b>downlink_speed &lt;speed&gt;</b> parameter to indicate the current WAN backhaul downlink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified. | 0 -<br>2,147,483,647 Kbps | 0<br>(unspecified) |
| load_dur <load_dur>    | Duration over which the downlink load is measured, in tenths of a second.                                                                                                                                                                           | 0 and 65535               | 0 (unspecified)    |
| no                     | Negate any existing parameter                                                                                                                                                                                                                       | -                         | -                  |
| symm_link              | Use the <b>symm_link</b> parameter to indicate that the WAN Link has same speed in both the uplink and downlink directions.                                                                                                                         | enabled<br>disabled       | disabled           |

| Parameter               | Description                                                                                                                                                                                                                             | Range                                                                                                             | Default         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|-----------------|
| uplink_load <speed>     | The percentage of the WAN uplink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.                                           | 1-100                                                                                                             | 0 (unspecified) |
| uplink_speed <speed>    | Use the <b>uplink &lt;speed&gt;</b> parameter to indicate the current WAN backhaul uplink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the uplink speed is unknown or unspecified. | 0 - 2,147,483,647 kbps                                                                                            | 0 (unspecified) |
| wan_metrics_link_status | Define the status of the WAN Link by configuring one of the following values. The default link status is <b>reserved</b> , which indicates that the link status is unknown or unspecified.                                              | <ul style="list-style-type: none"> <li>link_down</li> <li>link_test</li> <li>link_up</li> <li>reserved</li> </ul> | reserved        |
| link_down               | WAN link is down.                                                                                                                                                                                                                       | -                                                                                                                 | -               |
| link_test               | WAN link is currently in a test state.                                                                                                                                                                                                  | -                                                                                                                 | -               |
| link_up                 | WAN link is up.                                                                                                                                                                                                                         | -                                                                                                                 | -               |
| reserved                | This parameter is reserved by the Hotspot 2.0 specification, and cannot be configured. This is the default link status.                                                                                                                 | -                                                                                                                 | -               |

## Usage Guidelines

The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about access network characteristics such as link status and the capacity and speed of the WAN link to the Internet. Issue this command without the **<profile>** parameter to display the entire WAN metrics profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

## Examples

The example below shows that the controller has three configured WAN metrics profiles. The **References** column lists the number of other profiles with references to the operator-friendly name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) (config) #show wlan hotspot h2qp-wan-metrics-profile
H2QP WAN Metrics Profile List

Name References Profile Status

default 0
WanFastlink
```

Total:1

### Description

This command configures a hotspot profile for an 802.11u public access service provider.

### Syntax

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addtl-roam-cons-ois<br><addtl-roam-cons-ois> | Number of additional roaming consortium Organization Identifiers (OIs) advertised by the AP. This feature supports up to three additional OIs, which are defined using the <a href="#">roam-cons-oi-1</a> , <a href="#">roam-cons-oi-2</a> and <a href="#">roam-cons-oi-3</a> parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| advertisement-profile<br><profile-name>      | Advertisement profile associated with this hotspot profile. If this parameter is not changed, the hotspot profile uses with the <b>default</b> advertisement profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| advertisement-protocol                       | Select one of the following advertisement protocol types to be used by the AP. <ul style="list-style-type: none"> <li>• <b>anqp</b>: Access Network Query Protocol (ANQP)</li> <li>• <b>emergency</b>: Emergency Alert System( EAS)</li> <li>• <b>mih-cmd-event</b>: Media Independent Handover (MIH) Command and Event Services Capability Discovery</li> <li>• <b>mih-info</b>: Media Independent Handover (MIH) Information Service. This option allows handovers between differing kinds of wireless access protocols and technologies, allowing access points on different IP subnets to communicate with each other at the link level while maintaining session continuity.</li> <li>• <b>rsvd</b>: Reserved for future use.</li> </ul>            |
| asra                                         | Issue the asra (Additional Steps Required for Access) subcommand if any additional steps are required for network access. If this parameter is enabled, the AP will send the following Information Elements (IEs) in response to the client's ANQP query. <ul style="list-style-type: none"> <li>• Venue Name</li> <li>• Domain Name List</li> <li>• Network Authentication Type</li> <li>• Roaming Consortium List</li> <li>• NAI Realm List</li> </ul> <p><b>NOTE:</b> If asra is enabled, the advertisement profile for this hotspot must reference an enabled network authentication type profile. For more information on enabling an network authentication type profile, see <a href="#">wlan hotspot anqp-nwk-auth-profile on page 2289</a>.</p> |
| clone <profile-name>                         | Makes a copy of an existing hotspot profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| comeback-mode                                | By default, ANQP information is obtained from a GAS Request and Response. If you enable the comeback-mode option, advertisement information is obtained using a GAS Request and Response, as well as a Comeback-Request and Comeback-Response. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| gas-comeback-delay <delay>                   | At the end of the GAS comeback delay interval, the client may attempt to retrieve the query response using a Comeback Request Action frame. The supported range is 100-2000 milliseconds, and the default value is 500 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grp-frame-block                                              | This option configures the Downstream Group Addressed Forwarding (DGAF) Disabled Mode. If this feature is enabled, it ensures that the AP does not forward downstream group-addressed frames. It is disabled by default, allowing the AP to forward downstream group-addressed frames.                                                                                                                                                                                                                                                                                              |
| hessid                                                       | This optional parameter devices an AP's homogenous ESS identifier (HESSID), which is that device's MAC address in colon-separated hexadecimal format.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| hotspot-enable                                               | Enables or disables the hotspot. When this feature is enabled, the Information Elements (IEs) for this hotspot are included in beacons and probe responses from the AP.<br><br>This setting is disabled by default.                                                                                                                                                                                                                                                                                                                                                                 |
| internet                                                     | If you issue the <b>internet</b> parameter, the AP sends an Information Element (IE) indicating that the network allows internet access. By default, a hotspot profile does not advertise network internet access.                                                                                                                                                                                                                                                                                                                                                                  |
| no                                                           | Negates or removes any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| p2p-cross-connect                                            | Issue this command to advertise support for P2P Cross Connections. This setting is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| p2p-dev-mgmt                                                 | Issue this command to advertise support for P2P device management. This setting is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| pame-bi                                                      | This option enables the Pre-Association Message Exchange BSSID Independent (PAME-BI) bit, which is used by an AP to indicate whether the AP indicates that the Advertisement Server can return a query response that is independent of the BSSID used for the GAS Frame exchange.                                                                                                                                                                                                                                                                                                   |
| query-response-length-limit<br><query-response-length-limit> | Generic Advertisement Service (GAS) enables advertisement services that lets clients query multiple 802.11 networks at once, while also allowing the client to learn more about a network's 802.11 infrastructure before associating.<br><br>If a client transmits a GAS Query using a GAS Initial Request frame, the responding AP will provide the query response (or information on how to receive the query response) in a GAS Initial Response frame.<br><br>This parameter sets the maximum length of the GAS query response, in octets. The supported range is 1-255 octets. |
| radius_cui                                                   | Include this parameter to enable the Chargeable-User-Identity RADIUS attribute defined by RFC 4372. Home networks can use this attribute to identify a user for the roaming transactions that take place outside of that home network.                                                                                                                                                                                                                                                                                                                                              |
| radius_loc_data                                              | Include this parameter to enable the Location Data RADIUS attribute defined by RFC 5580. Enabling this parameter allows the RADIUS server to use location data.                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| time-error                | The standard deviation of error in time value estimate, in milliseconds. The default value is 0 milliseconds, and the supported range is 0- 2,147,483,647 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| time-zone                 | <p>The time zone in which the AP is operating, in the format <code>&lt;std&gt;&lt;offset&gt;[dst[offset] [,start[/time],end[/time]]</code></p> <p>Where the <code>&lt;std&gt;</code> string specifies the abbreviation of the time zone, <code>&lt;dst&gt;</code> is the abbreviation of the timezone in daylight savings time, and the <code>&lt;offset&gt;</code> string specifies the time value you must add to the local time to arrive at UTC.</p> <p><b>NOTE:</b> For complete details on configuring the timezone format, refer to section 8.3 of IEEE Std 1003.1, 2004 Edition.</p>                                                                                                                                                                                                                                                         |
| venue-group <venue-group> | <p>Specify one of the following venue groups to be advertised in the IEs from APs associated with this hotspot profile. The default setting is <b>unspecified</b>.</p> <ul style="list-style-type: none"> <li>• <b>assembly</b></li> <li>• <b>business</b></li> <li>• <b>educational</b></li> <li>• <b>factory-or-industrial</b></li> <li>• <b>institutional</b></li> <li>• <b>mercantile</b></li> <li>• <b>outdoor</b></li> <li>• <b>reserved</b></li> <li>• <b>residential</b></li> <li>• <b>storage</b></li> <li>• <b>unspecified</b></li> <li>• <b>Utility-Misc</b></li> <li>• <b>Vehicular</b></li> </ul> <p><b>NOTE:</b> This parameter only defines the venue group advertised in the IEs from hotspot APs. To define the venue group to be included in ANQP responses, use <a href="#">anqp-venue-name-profile &lt;profile-name&gt;</a>.</p> |
| venue-type <venue-type>   | <p>Specify a venue type to be advertised in the IEs from APs associated with this hotspot profile. The complete list of supported venue types is described in <a href="#">Venue Types on page 2310</a></p> <p><b>NOTE:</b> This parameter only defines the venue type advertised in the IEs from hotspot APs. To define the venue type to be included in ANQP responses, use <a href="#">anqp-venue-name-profile &lt;profile-name&gt;</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                       |

## Usage Guidelines

Hotspot 2.0 is a Wi-Fi Alliance specification based upon the 802.11u protocol that provides wireless clients with a streamlined mechanism to discover and authenticate to suitable networks, and allows mobile users the ability to roam between partner networks without additional authentication.

ArubaOS 6.3 supports Hotspot 2.0 with enhanced network discovery and selection. Clients can receive general information about the network identity, venue and type via management frames from the Dell AP. Clients can

also query APs for information about the network's available IP address type (IPv4 or IPv6), roaming partners, and supported authentication methods, and receive that information in Information Elements from the AP.

## Generic Advertisement Service (GAS) Queries

An Organization Identifier (OI) is a unique identifier assigned to a service provider when it registers with the IEEE registration authority. Starting with ArubaOS 6.3, an AP can include its service provider OI in beacons and probe responses to clients. If a client recognizes an AP's OI, it will attempt to associate to that AP using the security credentials corresponding to that service provider.

If the client does *not* recognize the AP's OI, that client can send a Generic Advertisement Service (GAS) query to the AP to request more information more about the network before associating.

## ANQP Information Elements

ANQP Information Elements (IEs) are additional data that can be sent from the AP to the client to identify the AP's network and service provider. If a client requests this information via a GAS query, the hotspot AP then sends the ANQP Capability list in the GAS Initial Response frame indicating support for the following IEs:

- **Venue Name:** defined using the [wlan hotspot anqp-venue-name-profile](#) command.
- **Domain Name:** defined using the [wlan hotspot anqp-domain-name-profile](#) command.
- **Network Authentication Type:** defined using the [wlan hotspot anqp-nwk-auth-profile](#) command.
- **Roaming Consortium List:** defined using the [wlan hotspot anqp-roam-cons-profile](#) command.
- **NAI Realm:** defined using the [wlan hotspot anqp-nai-realm-profile](#) command.
- **Cellular Network Data:** defined using the [wlan hotspot anqp-3gpp-nwk-profile](#) command.
- **Connection Capability:** defined using the [wlan hotspot h2qp-conn-capability-profile](#) command.
- **Operator Class:** defined using the [wlan hotspot h2qp-op-cl-profile](#) command.
- **Operator Friendly Name:** defined using the [wlan hotspot h2qp-operator-friendly-name-profile](#) command.
- **WAN Metrics:** defined using the [wlan hotspot h2qp-wan-metrics-profile](#).

## Roaming Consortium OIs

Organization Identifiers (OIs) are assigned to service providers when they register with the IEEE registration authority. You can specify the OI for the hotspot's service provider in the ANQP Roaming Consortium profile using the [wlan hotspot anqp-roam-cons-profile](#) command. This Hotspot profile also allows you to define and send up to three additional roaming consortium OIs for the service provider's top three roaming partners. To send this additional data to clients, you must specify the number of roaming consortium elements a client can query using the **addtl-roam-cons-ois <1-3>** parameter, then define those elements using the following parameters:

- **roam-cons-oi-1** and **roam-cons-len 1**
- **roam-cons-oi-2** and **roam-cons-len 2**
- **roam-cons-oi-3** and **roam-cons-len 3**

The configurable values for each additional OI include the Organization Identifier itself, the OI length, and the venue group and venue type associated with those OIs.

## Venue Types

The following list describes the different venue types that may be configured in a hotspot profile:

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Example

The following command configures a hotspot profile with one additional roaming consortium OI for the service provider's top roaming partner.

```
wlan hotspot hs2-profile profile2
 venue-group mercantile
 venue-type mercantile-shopping-mall
 addtl-roam-cons-ois
 roam-cons-len 3
 roam-cons-oi1 415B8C
 hotspot-enable
```

## Related Commands

Use the following commands to configure the Hotspot feature.

### Description

This command configures a high-throughput SSID profile.

### Syntax

| Parameter       | Description                                                                              | Range | Default   |
|-----------------|------------------------------------------------------------------------------------------|-------|-----------|
| <profile-name>  | Name of this instance of the profile. The name must be 1-63 characters.                  | —     | “default” |
| 40MHz-enable    | Enables or disables the use of this high-throughput SSID in 40 MHz mode.                 | —     | enabled   |
| 80MHz-enable    | Enables or disables the use of 80 MHz channels on Very High Throughput (VHT) APs.        | —     | enabled   |
| ba-amsdu-enable | Enable/Disable Receive AMSDU in BA negotiation.                                          | —     | enabled   |
| clone           | Name of an existing high-throughput SSID profile from which parameter values are copied. | —     | —         |

| Parameter               | Description                                                                                                                                                                                                                      | Range                           | Default |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|---------|
| high-throughput-enable  | Determines if this high-throughput SSID allows high-throughput (802.11n) stations to associate.<br><br>Enabling high-throughput in an ht-ssid-profile enables Wi-Fi Multimedia (WMM) base features for the associated SSID.      | —                               | enabled |
| ldpc                    | If enabled, the AP will advertise Low-density Parity Check (LDPC) support. LDPC improves data transmission over radio channels with high levels of background noise.                                                             | —                               | enabled |
| legacy-stations         | Controls whether or not legacy (non-HT) stations are allowed to associate with this SSID. By default, legacy stations are allowed to associate.<br><br>This setting has no effect on a BSS in which HT support is not available. | —                               | enabled |
| max-rx-a-mpdu-size      | Controls the maximum size, in bytes, of an Aggregated-MAC Packet Data Unit (A-MPDU) that can be received on this high-throughput SSID.                                                                                           | 8191<br>16383<br>32767<br>65535 | 65535   |
| 8191                    | Maximum size of 8191 bytes.                                                                                                                                                                                                      | —                               | —       |
| 16383                   | Maximum size of 16383 bytes.                                                                                                                                                                                                     | —                               | —       |

| mpdu-agg                | Enables or disables MAC protocol data unit (MPDU) aggregation.<br><br>High-throughput APs are able to send aggregated MAC protocol data units (MDPUs), which allow an AP to receive a single block acknowledgment instead of multiple ACK signals. This option, which is enabled by default, reduces network traffic overhead by effectively eliminating the need to initiate a new transfer for every MPDU. | —                          | enabled |

| short-guard-intvl-20MHz | Enables or disables use of short guard interval in 20 MHz mode of operation.                                                                                                                                                                                                                                                                                                                                 | —                          | enabled |
| short-guard-intvl-40MHz | Enables or disables use of short guard interval in 40 MHz mode of operation.                                                                                                                                                                                                                                                                                                                                 | —                          | enabled |
| short-guard-intvl-80MHz | Enables or disables use of short guard interval in 80 MHz mode of operation.                                                                                                                                                                                                                                                                                                                                 | —                          | enabled |
| stbc-rx-streams         | Controls the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the W-AP90 series, W-AP130 Series, W-AP68, W-AP175 and W-AP105 only. The configured value will be adjusted based on AP capabilities.)<br><b>NOTE:</b> If transmit beamforming is enabled, STBC                              | 0-1                        | 1       |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Range          | Default        |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|----------------|
|                             | will be disabled for disabled for beamformed frames.                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                |
| stbc-tx-streams             | Controls the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on W-AP90 series, W-AP175, W-AP130 Series and W-AP105 only. The configured value will be adjusted based on AP capabilities.)<br><b>NOTE:</b> If transmit beamforming is enabled, STBC will be disabled for disabled for beamformed frames.                                            | 0-1            | 1              |
| supported-mcs-set           | Comma-separated list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this high-throughput SSID.                                                                                                                                                                                                                                                                                                                                           | 0-23           | 0-23           |
| temporal-diversity          | Shows if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries.                                                                                                                                                                                                         | —              | disabled       |
| very-high-throughput-enable | Enable or disable support for Very High Throughput (802.11ac ) on the SSID.                                                                                                                                                                                                                                                                                                                                                                                               | —              | enabled        |
| vht-supported-mcs-map       | Modulation Coding Scheme (MCS) values or ranges of values for spatial streams 1 through 3. Valid values for the maximum MCS settings are 7, 8, 9 or a dash (-) if a spatial stream is not supported. If a MCS is not valid for a particular combination of bandwidth and number of spatial streams, it will not be used.                                                                                                                                                  | 7, 8, 9, or -  | Default: 9,9,9 |
| vht-txbf-explicit-enable    | Enable or disable VHT Explicit Transmit Beamforming for the W-AP220 Series . When this feature is enabled, the AP requests information about the MIMO channel and uses that information to transmit data over multiple transmit streams using a calculated steering matrix. The result is higher throughput due to improved signal at the beamformee (the receiving client). If this parameter is disabled, all other transmit beamforming settings will not take effect. | —              | Enabled        |
| vht-txbf-sounding-interval  | Time interval in seconds between channel information updates between the AP and the beamformee client. (W-AP220 Series only)                                                                                                                                                                                                                                                                                                                                              | 1-1000 seconds | 25 seconds     |

## Usage Guidelines

The ht-ssid profile configures the high-throughput SSID. Stations are not allowed to use HT with TKIP standalone encryption, although TKIP can be provided in mixed-mode BSSIDs that support HT. HT is disabled on a BSSID if the encryption mode is standalone TKIP or WEP.

You can also use this profile to configure explicit transmit beamforming for W-AP130 Series access points. When this feature is enabled, the AP coordinates the signals sent from each antenna so the signals focus on the receiver, improving radio range and performance. The W-AP130 Series AP can advertise transmit beamforming

capabilities in beacon, probe response and association responses in the HT capabilities IE, then use the compressed or noncompressed beamforming report from clients to form a steering matrix. The AP ensures that the steering matrix stays current by updating and recalibrating the steering matrix at regular intervals.

By default, W-AP130 Series access points support both compressed and non-compressed steering information from clients. If you have many clients that can send only non-compressed steering reports, best practices are to retain the default settings, allowing the AP to support both types of steering reports. If all (or nearly all) of the AP's clients are capable of sending compressed steering reports, best practices are to disable non-compressed steering in the AP's HT SSID profile.

De-aggregation of MAC Service Data Units (A-MSDUs) is supported on W-3000 Series controllers, W-7200 Series, and the W-6000M3 with a maximum frame transmission size of 4k bytes; however, this feature is always enabled and is not configurable. Aggregation is not currently supported.

## Example

The following command configures the maximum size of a received aggregate MPDU to be 8191 bytes for the high-throughput SSID named "htcorpnet:"

```
(host) (config) #wlan ht-ssid-profile htcorpnet
max-rx-a-mpdu-size 8191
```

 no
 pwr-constraint-ie
 qbss-load-ie
 quiet-ie
 tpc-report-ie
```

### Description

Configure an radio resource management RRM IE profile to define the information elements advertised by an AP with 802.11k support enabled.

### Syntax

| Parameter               | Description                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bss-aac-ie              | The AP will advertise in beacon and probe responses the BSS Available Admission Capacity (ACC) IE, which contains information about the admission capabilities for each User Priority / Access Category                                                        |
| clone                   | Copy the settings of an existing RRM IE profile.                                                                                                                                                                                                               |
| country-ie              | The AP will advertise in beacon and probe responses the device's regulatory domain.                                                                                                                                                                            |
| enabled-capabilities-ie | The AP will advertise in beacon and probe responses support for radio measurements in a device.                                                                                                                                                                |
| no ...                  | Disables the transmission of an IE in this profile.                                                                                                                                                                                                            |
| pwr-constraint-ie       | The AP will advertise in beacon and probe responses the regulatory maximum transmit power for that current channel.                                                                                                                                            |
| qbss-load-ie            | The AP will advertise in beacon and probe responses the QoS Basic Service Set (QBSS) Load IE, which contains information on the current station count, channel utilization and available admission capacity levels in the QBSS                                 |
| quiet-ie                | The AP will advertise in beacon and probe responses the Quiet IE, which is used to silence the channel for measurement purposes. When an AP uses a quiet IE to schedule a quiet interval, stations may not transmit on that channel during the quiet interval. |
| tpc-report-ie           | The AP will advertise in beacon and probe responses information about its transmit power controls.                                                                                                                                                             |

### Usage Guidelines

ArubaOS supports RRM Information Elements (IEs) for APs with 802.11k support enabled. All IEs are sent by default.

## Example

The following command prevents the AP from advertising the country IE.

```
(host) (config) #wlan rrm-ie-profile default
(host) (Handover Trigger Profile) #no country-ie
```

## Related commands

[wlan dot11k-profile](#) <profile> dot11k-enable

## Description

This command configures an SSID profile.

## Syntax

|                          | Description                                                                                                                                                                                                                                                                                                                                                                               | Range                                      | Default                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|-----------------------------------|
| <profile-name>           | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                                                                                                                                                                                   | —                                          | “default”                         |
| 902il-compatibility-mode | (For clients using NTT DoCoMo 902iL phones only) When enabled, the controller does not drop packets from the client if a small or old initialization vector value is received. (When TKIP or AES is used for encryption and TSPEC is enabled, the phone resets the value of the initialization vector after add/delete TSPEC.)<br><b>NOTE:</b> This parameter requires the PEFNG license. | —                                          | disabled                          |
| a-basic-rates            | List of supported 802.11a rates, in Mbps, that are advertised in beacon frames and probe responses.                                                                                                                                                                                                                                                                                       | 6, 9, 12, 18, 24, 36, 48, 54 Mbps          | 6, 12, 24 Mbps                    |
| a-beacon-rate            | Sets the beacon rate for 802.11a (use for Distributed Antenna System (DAS) only). Using this parameter in normal operation may cause connectivity problems.                                                                                                                                                                                                                               | default, 6, 9, 12, 18, 24, 36, 48, 54 Mbps | minimum valid rate                |
| a-tx-rates               | Set of 802.11a rates at which the AP is allowed to send data. The actual transmit rate depends on what the client is able to handle, based on information sent at the time of association and on the current error/loss rate of the client.                                                                                                                                               | 6, 9, 12, 18, 24, 36, 48, 54 Mbps          | 6, 9, 12, 18, 24, 36, 48, 54 Mbps |
| advertise-ap-name        | If enabled, APs that are part of this VAP will broadcast the AP Name information in the beacons frames.                                                                                                                                                                                                                                                                                   | —                                          | —                                 |
| advertise-location       | If enabled, APs that are part of this VAP will broadcast their GPS coordinates in the beacons and probe response frames as part of a vendor-specific Information Element.                                                                                                                                                                                                                 | —                                          | disabled                          |
| ageout                   | Time, in seconds, that a client is allowed to remain idle before being aged out.                                                                                                                                                                                                                                                                                                          |                                            | 1000 seconds                      |

|                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Range | Default  |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| battery-boost           | <p>Converts multicast traffic to unicast before delivery to the client, thus allowing you to set a longer DTIM interval. The longer interval keeps associated wireless clients from activating their radios for multicast indication and delivery, leaving them in power-save mode longer and thus lengthening battery life.</p> <p><b>NOTE:</b> This parameter requires the PEFNG license. This parameter should not be enabled if you plan on using the Push-To-Talk feature for Polycom SpectraLink devices.</p> | —     | disabled |
| clone                   | Name of an existing SSID profile from which parameter values are copied.                                                                                                                                                                                                                                                                                                                                                                                                                                            | —     | —        |
| deny-bcast              | When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID.                                                                                                                                                                                   | —     | disabled |
| disable-probe-retry     | Enable or disable battery MAC level retries for probe response frames. By default this parameter is enabled, which mean that MAC level retries for probe response frames is disabled.                                                                                                                                                                                                                                                                                                                               |       | Enabled  |
| dot11r-profile          | Associates the dot11r-profile with the SSID profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                | —     | —        |
| dtim-period             | Specifies the interval, in milliseconds, between the sending of Delivery Traffic Indication Messages (DTIMs) in the beacon. This is the maximum number of beacon cycles before unacknowledged network broadcasts are flushed. When using wireless clients that employ power management features to sleep, the client must revive at least once during the DTIM period to receive broadcasts.                                                                                                                        |       | 1        |
| eapol-rate-opt          | Use a more conservative rate for more reliable delivery of EAPOL frames.                                                                                                                                                                                                                                                                                                                                                                                                                                            | —     | enabled  |
| edca-parameters-profile | <p>Name of the enhanced distributed channel access (EDCA) profile that applies to this SSID.</p> <p><b>NOTE:</b> This parameter requires the</p>                                                                                                                                                                                                                                                                                                                                                                    | —     | —        |

|                        | Description                                                                                                                                                                                                                                   | Range                                                | Default                                        |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|------------------------------------------------|
|                        | PEFNG license. Configure this parameter only under the guidance of your Dell representative.                                                                                                                                                  |                                                      |                                                |
| ap sta                 | Assigns the specified EDCA profile to AP or station (client).                                                                                                                                                                                 | —                                                    | —                                              |
| enforce-user-vlan      | Strict enforcement of data traffic only in user's assigned vlan (Open stations only).                                                                                                                                                         | —                                                    | —                                              |
| ssid                   | Name that uniquely identifies a wireless network. The ESSID can be up to 31 characters. If the ESSID includes spaces, you must enclose it in quotation marks.                                                                                 | —                                                    | aruba-ap                                       |
| g-basic-rates          | List of supported 802.11b/g rates that are advertised in beacon frames and probe responses.                                                                                                                                                   | 1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54 Mbps       | 1, 2 Mbps                                      |
| g-beacon-rate          | Sets the beacon rate for 802.11g (use for Distributed Antenna System (DAS) only). Using this parameter in normal operation may cause connectivity problems.                                                                                   | default, 1,2,5, 6 9, 11, 12, 18, 24, 36, 48, 54 Mbps | minimum valid rate                             |
| g-tx-rates             | Set of 802.11b/g rates at which the AP is allowed to send data. The actual transmit rate depends on what the client is able to handle, based on information sent at the time of association and on the current error/loss rate of the client. | 1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54 Mbps       | 1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54 Mbps |
| hide-ssid              | Enables or disables hiding of the SSID name in beacon frames. Note that hiding the SSID does very little to increase security.                                                                                                                | —                                                    | disabled                                       |
| ht-ssid-profile        | Name of high-throughput SSID profile to use for configuring high-throughput support. See <a href="#">wlan ht-ssid-profile on page 2314</a> .                                                                                                  | —                                                    | "default"                                      |
| local-probe-req-thresh | APs will not respond to client probe requests if the SNR value in the probe request is less than the specified threshold value.                                                                                                               | 0-100                                                | 0                                              |
| max-clients            | Maximum number of wireless clients for the AP.                                                                                                                                                                                                | 0-256                                                | 64                                             |

|                | Description                                                                                                                                                                                                                                                                                                                                                                                                                  | Range                                      | Default        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|----------------|
| max-retries    | Maximum number of retries allowed for the AP to send a frame.                                                                                                                                                                                                                                                                                                                                                                | 0-15                                       | 4              |
| max-tx-fail    | The AP assumes the client has left and should be deauthorized when the AP detects this number of consecutive frames were not delivered because the <b>max-retries</b> threshold was exceeded.                                                                                                                                                                                                                                | 0 - 2,147,483,647                          | 0              |
| mcast-rate-opt | Enables or disables scanning of all active stations currently associated to an AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate.<br><b>NOTE:</b> Do not enable this parameter unless instructed to do so by your Dell technical support representative. | —                                          | disabled       |
| mfp-capable    | When enabled, the SSID supports management frame protection (MFP) capable clients and traditional clients.                                                                                                                                                                                                                                                                                                                   | —                                          | disabled       |
| mfp-required   | When enabled, the SSID only supports MFP capable clients.                                                                                                                                                                                                                                                                                                                                                                    | —                                          | disabled       |
| multicast-rate | When configured, chooses the rate for video multicast frames.                                                                                                                                                                                                                                                                                                                                                                | default, 6, 9, 12, 18, 24, 36, 48, 54 Mbps | default        |
| no             | Negates any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                            | —                                          | —              |

| wpa2-tkip        | WPA2 with TKIP encryption and dynamic keys using 802.1x.                                                                                                                                                                                                       | —     | —       |
| xSec             | Encryption and tunneling of Layer-2 traffic between the controller and wired or wireless clients, or between controllers. To use xSec encryption, you must use a RADIUS authentication server. For clients, you must install the Funk Odyssey client software. | —     | —       |

|                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Range | Default    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------|
|                  | Requires installation of the xSec license. For xSec between controllers, you must install an xSec license in each controller.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |            |
| qbss-load-enable | <p>Enables the AP to advertise the QBSS load element. The element includes the following parameters that provide information on the traffic situation:</p> <ul style="list-style-type: none"> <li>• <b>Station count:</b> The total number of stations associated to the QBSS.</li> <li>• <b>Channel utilization:</b> The percentage of time (normalized to 255) the channel is sensed to be busy. The access point uses either the physical or the virtual carrier sense mechanism to sense a busy channel.</li> <li>• <b>Available admission capacity:</b> The remaining amount of medium time (measured as number of 32us/s) available for a station via explicit admission control.</li> </ul> <p>The QAP uses these parameters to decide whether to accept an admission control request. A wireless station uses these parameters to choose the appropriate access points.</p> <p><b>NOTE:</b> For 802.11n APs, ensure that either wmm or high throughput is enabled.</p> | —     | disabled   |
| rts-threshold    | Wireless clients transmitting frames larger than this threshold must issue Request to Send (RTS) and wait for the AP to respond with Clear to Send (CTS). This helps prevent mid-air collisions for wireless clients that are not within wireless peer range and cannot detect when other wireless clients are transmitting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       | 2333 bytes |
| short-preamble   | Enables or disables short preamble for 802.11b/g radios. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using short preamble. To use only long preamble, disable short preamble. Legacy client devices that use only long preamble generally can be updated to support short preamble.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | —     | enabled    |

|                           | Description                                                                                                                                                                                           | Range       | Default        |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|----------------|
| ssid-enable               | Enables/disables this SSID.                                                                                                                                                                           | —           | enabled        |
| strict-svp                | Enable Strict Spectralink Voice Protocol (SVP)                                                                                                                                                        | —           | disabled       |
| wepkey1 - wepkey4         | Static WEP key associated with the key index. Can be 10 or 26 hex characters in length.                                                                                                               | —           | —              |
| weptxkey                  | Key index that specifies which static WEP key is to be used. Can be 1, 2, 3, or 4.                                                                                                                    | 1, 2, 3, 4  | 1              |
| wmm                       | Enables or disables WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF). WMM provides prioritization of specific traffic relative to other traffic in the network.     | —           | disabled       |
| wmm-be-dscp               | DSCP value used to map WMM best-effort traffic.                                                                                                                                                       | 0-63        | —              |
| wmm-bk-dscp               | DSCP used to map WMM background traffic.                                                                                                                                                              | 0-63        | —              |
| wmm-override-dscp-mapping | Overrides the default DSCP mappings in the SSID profile with the ToS value. This setting is useful when you want to set a non-default ToS value for a specific traffic.                               | —           | disabled       |
| wmm-ts-min-inact-int      | Specifies the minimum inactivity time-out threshold of WMM traffic. This setting is useful in environments where low inactivity interval time-outs are advertised, which may cause unwanted timeouts. | 0-3,600,000 | 0 milliseconds |
| wmm-uapsd                 | Enable Wireless Multimedia (WMM) UAPSD powersave.                                                                                                                                                     | —           | enabled        |
| wmm-vi-dscp               | DSCP used to map WMM video traffic.                                                                                                                                                                   | 0-63        | —              |
| wmm-vo-dscp               | DSCP used to map WMM voice traffic.                                                                                                                                                                   | 0-63        | —              |
| wpa-hexkey                | WPA pre-shared key (PSK).                                                                                                                                                                             | —           | —              |
| wpa-passphrase            | WPA passphrase with which to generate a pre-shared key (PSK).                                                                                                                                         | —           | —              |

## Usage Guidelines

The SSID profile configures the SSID. Default WMM mappings exist for all SSIDs. After you customize an WMM mapping and apply it to the SSID, the controller overwrites the default mapping values and uses the user-configured values.

### Suite-B cryptography

The opmode parameters for Suite-B encryption, **wpa2-aes-gcm-128** and **wpa2-aes-gcm-256**, require the ACR license. Note, however, that not all controllers support Suite-B encryption. The table below describes the controller support for Suite-B encryption in ArubaOS.

| Controller    | Serial Number Prefix         | ACR License Support |
|---------------|------------------------------|---------------------|
| W-7200 Series | All serial numbers supported | Yes                 |
| W-600 Series  | All serial numbers supported | Yes                 |
| W-3000 Series | FC                           | Yes                 |
| W-3000 Series | F                            | No                  |
| W-6000M3 card | AK                           | Yes                 |
| W-6000M3 card | A                            | No                  |

To determine the serial number prefix for your controller, issue the CLI command **show inventory** and note the prefix before the system serial number. The serial number prefix in the example below appears in **bold**.

```
(host) #show inventory
Supervisor Card slot : 0
System Serial# : AK0093676
SC Assembly# : 2010052B (Rev:02.01)
SC Serial# : F01629529 (Date:03/29/10)
SC Model# : W-3600-US
```

### Multicast Rate Optimization

The Multicast Rate Optimization feature dynamically selects the rate for sending broadcast/multicast frames on any BSS. This feature determines the optimal rate for sending broadcast and multicast frames based on the lowest of the unicast rates across all associated clients.

When the Multicast Rate Optimization option ([mcast-rate-opt](#)) is enabled, the controller scans the list of all associated stations in that BSS and finds the lowest transmission rate as indicated by the rate adaptation state for each station. If there are no associated stations in the BSS, it selects the lowest configured rate as the transmission rate for broadcast and multicast frames.

This feature is disabled by default. Multicast Rate Optimization applies to broadcast and multicast frames only. 802.11 management frames are not affected by this feature and will be transmitted at the lowest configured rate.

The Multicast Rate Optimization feature should only be enabled on a BSS where all associated stations are sending or receiving unicast data. If there is no unicast data to or from a particular station, then the rate adaptation state may not accurately reflect the current sustainable transmission rate for that station. This could result in a higher packet error rate for broadcast/multicast packets at that station.

## Example

The following command configures an SSID for WPA2 AES authentication:

```
(host) (config) #wlan ssid-profile corpnet
 essid Corpnet
 opmode wpa2-aes
```

## Command History

| Release         | Modification                                                                                                                                                                                    |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced                                                                                                                                                                              |
| ArubaOS 3.2     | The <b>wmm-ts-min-inact-int</b> parameter was introduced. The <b>wpa2-preauth</b> parameter was removed,                                                                                        |
| ArubaOS 3.3     | Support for the high-throughput IEEE 802.11n standard was introduced including the <b>ht-ssid-profile</b> parameter and various rate changes.                                                   |
| ArubaOS 3.3.1   | Support for configurable WMM AC mapping was introduced including the <b>wmm-be-dscp</b> , <b>wmm-bk-dscp</b> , <b>wmm-vi-dscp</b> , and <b>wmm-vo-dscp</b> parameters.                          |
| ArubaOS 3.4     | The <b>deny-bcast</b> and <b>disable-probe-retry</b> parameters were introduced. The <b>drop-mcast</b> parameter was deprecated.                                                                |
| ArubaOS 3.4.1   | License requirements changed in ArubaOS 3.4.1, so the command required the PEF license instead of the Voice Services Module license required in earlier versions.                               |
| ArubaOS 6.1     | The <b>opmode</b> options <b>wpa2-aes-gcm-128</b> and <b>wpa2-aes-gcm-256</b> were introduced. These parameters require the ACR license.<br><br>The <b>qbss-load-enable</b> option is included. |
| ArubaOS 6.1.4.1 | The <b>advertise-ap-name</b> parameter was added.                                                                                                                                               |
| ArubaOS 6.2     | The <b>advertise-location</b> and <b>enforce-user-vlan</b> parameters were added.                                                                                                               |
| ArubaOS 6.3     | <ul style="list-style-type: none"><li>• The <b>dot11r-profile</b> parameter was added.</li><li>• The <b>opmode bSec 256</b> parameter was added.</li></ul>                                      |
| ArubaOS 6.4     | <ul style="list-style-type: none"><li>• The <b>mfp-capable</b> and <b>mfp-required</b> parameters were added.</li><li>• The <b>eapol-rate-opt</b> parameter was enabled by default.</li></ul>   |
| ArubaOS 6.4.2.0 | The description of the <b>multicast-rate</b> parameter is changed to denote the rate for video multicast frames.                                                                                |

## wlan traffic-management-profile

```
wlan traffic-management-profile <profile-name>
 bw-alloc virtual-ap <virtual-ap> share <percent>
 clone <profile-name>
 no ...
 report-interval <minutes>
 shaping-policy default-access|fair-access|preferred-access
```

### Description

This command configures a traffic management profile.

### Syntax

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                              | Range                                                     | Default        |

|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
|           | <p>environments like a training facility or exam hall, where a mix of 802.11a/g, 802.11g and 802.11n clients need equal to network resources, regardless of their capabilities. The <b>bw-alloc</b> parameter of a traffic management profile allows you to set a minimum bandwidth to be allocated to a virtual AP profile when there is congestion on the wireless network. You must set traffic shaping to <b>fair-access</b> to use this bandwidth allocation value for an individual virtual AP.</p> <ul style="list-style-type: none"> <li>• <b>preferred-access:</b> High-throughput (802.11n) clients do not get penalized because of slower 802.11a/g or 802.11b transmissions that take more air time due to lower rates. Similarly, faster 802.11a/g clients get more access than 802.11b clients.</li> </ul> |       |         |

## Usage Guidelines

The traffic management profile allows you to allocate bandwidth to SSIDs. When you enable the band-steering feature, an AP keeps track of all BSSIDs active on a radio, all clients connected to the BSSID, and 802.11a/g, 802.11b, or 802.11n capabilities of each client. Every sampling period, airtime is allocated to each client, giving it opportunity to get and receive traffic. The specific amount of airtime given to an individual client is determined by;

- Client capabilities (802.11a/g, 802.11b or 802.11n)
- Amount of time the client spent receiving data during the last sampling period
- Number of active clients in the last sampling period
- Activity of the current client in the last sampling period

The **bw-alloc** parameter of a traffic management profile allows you to set a minimum bandwidth to be allocated to a virtual AP profile when there is congestion on the wireless network. You must set traffic shaping to fair-access to use this bandwidth allocation value for an individual virtual AP.

## Example

The following command configures a traffic management profile that allocates bandwidth to the corpnet virtual AP:

```
(host) (config) #wlan traffic-management-profile best
 bw-alloc virtual-ap corpnet share 75
```

| <profile-name>          | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                                                 | —      | “default” |
| bin0-range <bin0-range> | This value is used to set the 'Bin 0 Range' field in the Transmit Stream/Category Measurement Request frame. Bin 0 Range indicates the delay range of the first bin (Bin 0) of the Transmit Delay Histogram, expressed in units of TUs. | 0- 255 | 6         |
| clone <source>          | Creates a copy of the Transmit Stream Measurement Request Report Request Profile.<br><br><source> is the name of an existing TSM Profile from which parameter values are copied.                                                        | —      | —         |
| dur-mandatory           | This parameter is used to set the "Duration Mandatory" bit of the Measurement Request Mode field of the Transmit Stream/Category Measurement Request frame.                                                                             | —      | Enabled   |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Range   | Default |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------|
| <code>measure-duration &lt;measure-duration&gt;</code> | This parameter is used to set the Measurement Duration field in the Transmit Stream/Category Measurement Request frame. The Measurement Duration is set to the duration of the requested measurement. It is expressed in units of TUs. When the request mode for the Transmit Stream/Category Measurement Request frame is set to "triggered", the Measurement Duration field should be set to 0.                                                                                                                                                          | 0-65535 | 9776    |
| <code>no</code>                                        | Negates any configured parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | —       | —       |
| <code>num-repeats &lt;num-repeats&gt;</code>           | This parameter is used to set the "Number of Repetitions" field in the Transmit Stream/Category Measurement Request frame. The Number of Repetitions field contains the requested number of repetitions for all the Measurement Request elements in this frame. A value of zero in the Number of Repetitions field indicates Measurement Request elements are executed once without repetition. A value of 65535 in the Number of Repetitions field indicates Measurement Request elements are repeated until the measurement is cancelled or superseded.  | 0-65535 | 65535   |
| <code>random-interval &lt;random-interval&gt;</code>   | This parameter is used to set the Randomization Interval field in the Transmit Stream/Category Measurement Request frame. The Randomization Interval is used to specify the desired maximum random delay in the measurement start time. It is expressed in units of TUs (Time Units). When the request mode for the Transmit Stream/Category Measurement Request frame is set to "triggered", the Randomization Interval is not used and is set to 0. A Randomization Interval of 0 in a measurement request indicates that no random delay is to be used. | 0-65535 | 0       |
| <code>request-mode {normal   triggered}</code>         | This parameter is used to determine the request mode for the Transmit Stream/Category Measurement Request frame. There are two options for this field: <ul style="list-style-type: none"> <li>normal</li> </ul>                                                                                                                                                                                                                                                                                                                                            | —       | normal  |

| Parameter               | Description                                                                                                                                                                                                                                               | Range | Default |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|---------|
|                         | <ul style="list-style-type: none"> <li>triggered</li> </ul>                                                                                                                                                                                               |       |         |
| traffic-id <traffic-id> | The parameter is used to set the Traffic Identifier field in the Transmit Stream/Category Measurement Request frame. The Traffic Identifier field contains the TID subfield. The TID subfield indicates the TC or TS for which traffic is to be measured. | 0-255 | 96      |

## Usage Guidelines

The tsm-req-profile is a part of the 802.11K profile. It is used to configure the parameters for the Transmit Stream/Category Measurement frames. It takes effect only when the 802.11K feature is enabled.

## Example

```
(host) (config) # wlan tsm-req-profile default
(host) (TSM Report Request Profile "default") #bin0-range 1
(host) (TSM Report Request Profile "default") #dur-mandatory
(host) (TSM Report Request Profile "default") #measure-duration 25
(host) (TSM Report Request Profile "default") #num-repeats 0
(host) (TSM Report Request Profile "default") #random-interval 0
(host) (TSM Report Request Profile "default") #request-mode normal
(host) (TSM Report Request Profile "default") #traffic-id 96
```

## Command History

This command is introduced in ArubaOS 6.2.

### Description

This command configures a virtual AP profile.

### Syntax

| Parameter      | Description                                                             | Range   | Default   |
|----------------|-------------------------------------------------------------------------|---------|-----------|
| <profile-name> | Name of this instance of the profile. The name must be 1-63 characters. | —       | "default" |
| aaa-profile    | Name of the AAA profile that applies to this virtual AP.                | —       | "default" |
| allowed-band   | The band(s) on which to use the virtual AP:                             | a/g/all | all       |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Range                   | Default  |

|                             | <p>a—802.11a band only (5 GHz)</p> <p>g—802.11b/g band only (2.4 GHz)</p> <p>all—both 802.11a and 802.11b/g bands (5 GHz and 2.4 GHz)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                         |          |
| anyspot-profile             | Anyspot Profile associated with this Virtual AP Profile. The anysspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.                                                                                                                                                                                                                                                                                                                                                                                                                                                           | —                       | —        |
| auth-failure-blacklist-time | Time, in seconds, a client is blocked if it fails repeated authentication. A value of 0 blocks a client indefinitely.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0-2,147,483,647 seconds | 0        |
| band-steering               | <p>ARM's band steering feature can encourage or require dual-band capable clients to stay on the 5GHz band on dual-band APs. This frees up resources on the 2.4GHz band for single band clients like VoIP phones.</p> <p>Band steering reduces co-channel interference and increases available bandwidth for dual-band clients, because there are more channels on the 5GHz band than on the 2.4GHz band. Dual-band 802.11n-capable clients may see even greater bandwidth improvements, because the band steering feature will automatically select between 40MHz or 20MHz channels in 802.11n networks. This feature is disabled by default, and must be enabled in a Virtual AP profile.</p> | —                       | disabled |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Range                   | Default               |

|                               | <p>The band steering feature supports three steering modes, which can be configured via the <a href="#">steering-mode</a> parameter:</p> <p>Band steering can be configured on both campus APs and remote APs that have a virtual AP profile set to tunnel, decrypt-tunnel, split-tunnel or bridge forwarding mode. Note, however, that if a campus or remote APs has virtual AP profiles configured in bridge or split-tunnel forwarding mode but no virtual AP in tunnel mode, those APs will gather information about 5G-capable clients independently and will not exchange this information with other APs that also have bridge or split-tunnel virtual APs only.</p> |                         |                       |
| <code>blacklist</code>        | Enables detection of denial of service (DoS) attacks, such as ping or SYN floods, that are not spoofed deauth attacks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                       | enabled               |
| <code>blacklist-time</code>   | Number of seconds that a client is quarantined from the network after being blacklisted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 0-2,147,483,647 seconds | 3600 seconds (1 hour) |
| <code>broadcast-filter</code> | Filter out broadcast and multicast traffic in the air.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | —                       | disabled              |
| <code>all</code>              | <p>Filter out broadcast and multicast traffic in the air.</p> <p><b>NOTE:</b> Do not enable this option for virtual APs configured in bridge forwarding mode. This configuration parameter is only intended for use for virtual APs in tunnel mode. In tunnel mode, all packets travel to the controller, so the controller is able to drop all broadcast traffic. When a virtual AP is configured to use bridge forwarding mode, most data traffic stays local</p>                                                                                                                                                                                                         | —                       | enabled               |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Range | Default  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
|           | <p>to the AP, and the controller is not able to filter out that broadcast traffic.</p> <p><b>IMPORTANT:</b> If you enable this option, you must also enable the <b>Broadcast-Filter ARP</b> parameter in the stateful firewall configuration to prevent ARP requests from being dropped. Note also that although a virtual AP profile can be replicated from a master controller to local controllers, stateful firewall settings do not. If you select the <b>broadcast-filter all</b> option for a Virtual AP Profile on a master controller, you must enable the <b>broadcast-filter arp</b> setting on each individual local controller.</p>                                                                                                                                                                         |       |          |
| arp       | <p>If enabled, all broadcast ARP requests are converted to unicast and sent directly to the client. You can check the status of this option using the <b>show ap active</b> and the <b>show datapath tunnel</b> command. If enabled, the output will display the letter <b>a</b> in the flags column.</p> <p>Do not enable this option for virtual APs configured in bridge forwarding mode. This configuration parameter is only intended for use for virtual APs in tunnel mode. In tunnel mode, all packets travel to the controller, so the controller is able to convert ARP requests directed to the broadcast address into unicast. When a virtual AP is configured to use bridge forwarding mode, most data traffic stays local to the AP, and the controller is not able to convert that broadcast traffic.</p> | —     | disabled |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Range | Default  |

|                 | <p>and responses, and process all 802.11e and 802.11k action frames.</p> <p><b>NOTE:</b> Virtual APs in bridge or split-tunnel mode using static WEP should use key slots 2-4 on the controller. Key slot 1 should only be used with Virtual APs in tunnel mode.</p>                                                                                                                                                                                                                                                                                                                                                                                   |       |          |
| ha-disc-onassoc | <p>If enabled, home agent discovery is triggered on client association instead of home agent discovery based on traffic from client. Mobility on association can speed up roaming and improve connectivity for clients that do not send many uplink packets to trigger mobility (VoIP clients). Best practices is to leave this parameter disabled, as it increases IP mobility control traffic between controllers in the same mobility domain. Enable this parameter only when voice issues are observed in VoIP clients.</p> <p><b>NOTE:</b> ha-disc-onassoc parameter works only when IP mobility is enabled and configured on the controller.</p> | —     | disabled |
| hs2-profile     | Enables or disables a hotspot profile. This is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | —     | enabled  |
| mobile-ip       | Enables or disables IP mobility on a virtual AP. This is enabled by default. L3 mobility service is active on a VAP only if <b>router mobile</b> is also enabled on the controller.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | —     | enabled  |

| multi-association | Enables or disables multi-association for this virtual AP. When enabled, this feature allows a station to be associated to multiple APs. If this feature is disabled, when a station moves to new AP it will be de authorized by the AP to which it was previously connected, deleting station context and flushing key caching information.                                                                                                                                                                                                                                                                                             | —                                             | disabled |
| no                | Negates any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | —                                             | —        |
| outer-vlan        | List of VLANs that can be used for QinQ outer vlan in this virtual AP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | —                                             | —        |
| preserve-vlan     | This parameter allows clients to retain their previous VLAN assignment if the client disassociates from an AP and then immediately re-associates either with same AP or another AP on same controller.                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                               |          |

|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|----------|
|                   | feature in these versions of ArubaOS functions the same way as the default <b>prefer-5GHz</b> steering mode available in ArubaOS 6.0 and later.                                                                                                                                                                                                                    |                               |          |
| strict-compliance | If enabled, the AP denies client association requests if the AP and client station have no common rates defined. Some legacy client stations which are not fully 802.11-compliant may not include their configured rates in their association requests. Such non-compliant stations may have difficulty associating with APs unless strict compliance is disabled. | —                             | disabled |
| vap-enable        | Enable or disable the virtual AP.                                                                                                                                                                                                                                                                                                                                  | —                             | enabled  |
| vlan              | The VLAN(s) into which users are placed in order to obtain an IP address. Enter VLANs as a comma-separated list of existing VLAN IDs or VLAN names. A mixture of names and numeric IDs are not allowed.<br><b>NOTE:</b> You must add an existing VLAN ID to the Virtual AP profile.                                                                                |                               | 1        |
| vlan-mobility     | VLAN mobility retains the client VLAN on roaming irrespective of the VAP VLAN, provided the user VLANs are extended.<br><br>VLAN mobility and mobile IP are mutually exclusive.<br><br>VLAN mobility does not re-use user firewall sessions on roaming as the sessions will have to be recreated locally on the roamed controller.                                 | —                             | disabled |
| wan-operation     | Specify the wan-operation to enable Virtual AP depending on the state of the WAN link.                                                                                                                                                                                                                                                                             | always/<br>backup/<br>primary | always   |

| Parameter                      | Description                                                                               | Range | Default |
|--------------------------------|-------------------------------------------------------------------------------------------|-------|---------|
| wmm-traffic-management-profile | Specify the WMM Traffic Management Profile to be associated with this Virtual AP Profile. | —     | —       |

## Usage Guidelines

Wireless LAN profiles configure WLANs in the form of virtual AP profiles. A virtual AP profile contains an SSID profile which defines the WLAN and an AAA profile which defines the authentication for the WLAN. You can configure and apply multiple instances of virtual AP profiles to an AP group or to an individual AP.

A named VLAN can be deleted although it is configured in a virtual AP profile. If this occurs the virtual AP profiles becomes invalid. If the named VLAN is added back later the virtual AP becomes valid again.

Beginning with ArubaOS 6.1.3.2, the **broadcast-filter arp** parameter is enabled by default. Behaviors associated with these settings are enabled upon upgrade to ArubaOS 6.1.3.2. If your controller supports clients behind a wireless bridge or virtual clients on VMware devices, you must disable the broadcast-filter arp setting to allow those clients to obtain an IP address. In previous releases of ArubaOS, the virtual AP profile included two unique broadcast filter parameters; the **broadcast-filter all** parameter, which filtered out all broadcast and multicast traffic in the air except DHCP response frames (these were converted to unicast frames and sent to the corresponding client) and the **broadcast-filter arp** parameter, which converted broadcast ARP requests to unicast messages sent directly to the client.

Starting with ArubaOS 6.1.3.2, the **broadcast-filter arp** setting includes the additional functionality of broadcast-filter all parameter, where DHCP response frames are sent as unicast to the corresponding client. This can impact DHCP discover/requested packets for clients behind a wireless bridge and virtual clients on VMware devices. Disable the broadcast-filter arp setting using the **wlan virtual-ap <profile> no broadcast-filter arp** command to resolve this issue and allow clients behind a wireless bridge or VMware devices to receive an IP address.

In ArubaOS 6.2 and later, if there is only one VLAN defined, then the controller will send IPv6 router advertisements (RAs) as usual. If, however, there are multiple VLANs, then the controller will automatically convert 802.11 multicast frames to unicast. This conversion prevents RA frames from being sent with a multicast key to all clients on the BSSID, which could lead to clients having multiple IPv6 addresses.

## Example

The following command configures a virtual AP:

```
wlan virtual-ap corpnet
 vlan 1
 aaa-profile corpnet
```

## Command History

| Release         | Modification                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0     | Command introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ArubaOS 3.2     | Support for the split tunneling option and the rap-operation parameter was introduced.                                                                                                                                                                                                                                                                                                                                                                                           |
| ArubaOS 3.3     | In support of the IEEE 802.11n standard, a change to the allowed-band parameter was introduced.                                                                                                                                                                                                                                                                                                                                                                                  |
| ArubaOS 3.3.2   | <ul style="list-style-type: none"> <li>Support for the <b>ha-disc-onassoc</b> parameter was introduced.</li> <li>The <b>band-steering</b> parameter was introduced but is not a released feature in ArubaOS 3.3.2. Do not <b>use band-steering</b> without proper guidance from Dell technical support.</li> <li>Support for the <b>voip-proxy-arp</b> parameter was introduced.</li> </ul>                                                                                      |
| ArubaOS 3.4     | <ul style="list-style-type: none"> <li>The <b>voip-proxy-arp</b> parameter was renamed to <b>broadcast-filter-arp</b> and it does not require a Voice license.</li> <li>The <b>fast-roaming</b> parameter was renamed to <b>multi-association</b>.</li> </ul>                                                                                                                                                                                                                    |
| ArubaOS 5.0     | The <b>decrypt-tunnel</b> forwarding mode was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ArubaOS 6.0     | The <b>steering-mode balance-bands force-5ghz prefer-5ghz</b> parameters were introduced.                                                                                                                                                                                                                                                                                                                                                                                        |
| ArubaOS 6.1     | <ul style="list-style-type: none"> <li>The <b>deny inter user traffic</b> and <b>Disable conversion multicast RA packets to unicast</b> parameters were introduced.</li> <li>The <b>multi-association</b> parameter was deprecated.</li> <li>The <b>Multicast Optimization for Video</b> and <b>Multicast Optimization Threshold</b> parameter were renamed to <b>Dynamic Multicast Optimization (DMO)</b> and <b>Dynamic Multicast Optimization (DMO) Threshold</b>.</li> </ul> |
| ArubaOS 6.2     | The <b>outer-vlan</b> and <b>fdb-update-on-assoc</b> parameters were introduced, and the <b>disable-ra-mcast-to-ucast</b> parameter was deprecated.                                                                                                                                                                                                                                                                                                                              |
| ArubaOS 6.3     | The <b>hs2-profile</b> and <b>outer-vlan</b> parameters were introduced.                                                                                                                                                                                                                                                                                                                                                                                                         |
| ArubaOS 6.4.3.0 | The <b>wan-operation</b> parameter was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                               |

 wmm_tspeg_enforcement_period <seconds>
```

### Description

This command configures a Voice over IP (VoIP) call admission control (CAC) profile.

### Syntax

| Parameter              | Description                                                                                                                                                                                             | Range        | Default   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|-----------|
| <profile-name>         | Name of this instance of the profile. The name must be 1-63 characters.                                                                                                                                 | —            | “default” |
| bandwidth-cac          | Select the desired call admission control (CAC) Mechanism: <ul style="list-style-type: none"><li>• Disable - CAC is based on Call Counts</li><li>• Enable - CAC should be based on Bandwidth.</li></ul> | —            | disabled  |
| bandwidth-capacity     | Define the maximum bandwidth that can be handled by one radio, in kbps. The default value is 2000 kbps (2 Mbps)                                                                                         | —            | —         |
| <bandwidth-capacity>   | Maximum bandwidth that can be handled by one radio, in kbps. The default value is 2000 kbps (2 Mbps)                                                                                                    | 1-60000<br>0 | 2000      |
| call-admission-control | Enables or disables WiFi VoIP Call Admission Control features.                                                                                                                                          | —            | disabled  |
| call-capacity          | Number of simultaneous calls that can be handled by one radio.                                                                                                                                          | 2-8000       | 10        |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                       | Range | Default  |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|----------|
| call-handoff-reservation                  | Percentage of call capacity reserved for mobile VoIP clients on call.                                                                                                                                                                                                                                                                                                                                             | 0-100 | 20%      |
| clone                                     | Name of an existing VoIP CAC profile from which parameter values are copied.                                                                                                                                                                                                                                                                                                                                      | —     | —        |
| disconnect-extra-call                     | Disconnects calls that exceed the high capacity threshold by sending a deauthentication frame.                                                                                                                                                                                                                                                                                                                    | —     | disabled |
| no                                        | Negates any configured parameter.                                                                                                                                                                                                                                                                                                                                                                                 | —     | —        |
| send-sip-100-trying                       | Enables sending of SIP 100 - trying messages to a call originator to indicate that the call is proceeding. This is useful when the SIP invite may be redirected through a number of servers before reaching the controller.                                                                                                                                                                                       | —     | enabled  |
| send-sip-status-code client server <code> | Use this parameter with the <b>client</b> or <b>server</b> options to drop a SIP Invite and send status code back to the client or server. You must also include one of the following codes: <ul style="list-style-type: none"> <li>• <b>480</b>: Temporary Unavailable</li> <li>• <b>486</b>: Busy Here</li> <li>• <b>503</b>: Service Unavailable</li> <li>• <b>none</b>: Don't send SIP status code</li> </ul> | —     | 486      |
| wmm_tspec_enforcement                     | Enables validation of TSPEC requests for CAC.                                                                                                                                                                                                                                                                                                                                                                     | —     | disabled |
| wmm_tspec_enforcement_period              | Maximum time for the station to start the call after the TSPEC request.                                                                                                                                                                                                                                                                                                                                           | 1-100 | 1 second |

## Usage Guidelines

The VoIP CAC profile prevents any single AP from becoming congested with voice calls.

## Example

The following command enables VoIP CAC:

```
(host) (config) #wlan voip-cac-profile cac1
 call-admission-control
 disconnect-extra-call
```

## Command History

## wlan wmm-traffic-management-profile

```
wlan wmm-traffic-management-profile <profile-name>
 background <share>
 best-effort <share>
 clone <source>
 enable-shaping
 no
 video <share>
 voice <share>
```

### Description

This command configures bandwidth shaping for WMM access categories.

---

The bandwidth shaping is applied on down-link traffic only.

---

### Syntax

| Parameter           | Description                                                                                    | Range | Default  |
|---------------------|------------------------------------------------------------------------------------------------|-------|----------|
| background <share>  | Bandwidth allocation in percentage (%) for WMM background access traffic category.             | 1-99  | 5        |
| best-effort <share> | Bandwidth allocation in percentage (%) for WMM best effort access traffic category.            | 1-99  | 5        |
| clone <source>      | Copy configuration from another WMM Traffic management profile.                                | —     | —        |
| enable-shaping      | Enable a bandwidth shaping policy so that the allocated bandwidth share is appropriately used. | —     | disabled |
| no                  | Negate any configured parameter.                                                               | —     | —        |
| video <share>       | Bandwidth allocation in percentage (%) for video access traffic category.                      | 1-99  | 55       |
| voice <share>       | Bandwidth allocation in percentage (%) for voice access traffic category.                      | 1-99  | 35       |

### Usage Guidelines

After you configure the WMM traffic management profile, apply it to the virtual AP profile. For WMM traffic management to take effect, you must enable **fair-access** or **preferred-access** parameter under [wlan traffic-management-profile](#).

### Example

The following command configures a WMM traffic management profile:

```
(host) (config) #wlan wmm-traffic-management-profile test
(host) (WMM Traffic management profile "test") #enable-shaping
(host) (WMM Traffic management profile "test") #background 7
(host) (WMM Traffic management profile "test") #best-effort 10
```

```
(host) (WMM Traffic management profile "test") #voice 40
(host) (WMM Traffic management profile "test") #video 43
```

Apply the WMM traffic management profile to the virtual AP profile.

```
(host) (config) #wlan virtual-ap employee
(host) (Virtual AP profile "employee") #wmm-traffic-management-profile test
```

Enable the **fair-access** or **preferred access** parameter under **wlan traffic-management-profile**.

```
(host) (config) #wlan traffic-management-profile test
(host) (Traffic management profile "test") #shaping-policy fair-access
```

OR

```
(host) (Traffic management profile "test") #shaping-policy preferred-access
```

Apply the traffic management profile to an ap group.

```
(host) (config) #ap-group default
(host) (AP group "default") #dot11a-traffic-mgmt-profile test
```

## wms ap

wms ap <bssid> mode {interfering|manually-contained|neighbor|rogue|suspected-rogue|valid}

### Description

This command allows you to classify an AP into one of several categories.

### Syntax

| Parameter          | Description                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <bssid>            | BSSID of the AP.                                                                                                                                                                       |
| mode               | Classify the AP into one of the following categories.                                                                                                                                  |
| interfering        | An AP seen in the RF environment but is not connected to the wired network.                                                                                                            |
| manually-contained | Manually enable denial of service from this AP                                                                                                                                         |
| neighbor           | An neighboring AP whose BSSID is known.                                                                                                                                                |
| suspected-rogue    | A suspected rogue AP that is plugged into the wired side of the network but may not be an unauthorized device. Automatic shutdown of rogue APs does not apply to these devices.        |
| rogue              | A rogue AP that is unauthorized and is plugged into the wired side of the network. You can configure automatic shutdown of rogue APs in the IDS unauthorized device detection profile. |
| valid              | An AP that is part of the enterprise providing WLAN service.                                                                                                                           |

### Usage Guidelines

If AP learning is enabled (with the wms general learn-ap enable command), non-Dell APs connected on the same wired network as Dell APs are classified as valid APs. If AP learning is disabled, a non-Dell AP is classified as an unsecure or suspect-unsecure AP.

### Example

The following command classifies an interfering AP as a known-interfering AP:

```
(host) #wms ap 01:00:00:00:00:00 mode known-interfering
```

## Command History

| Release     | Modification                                         |
|-------------|------------------------------------------------------|
| ArubaOS 3.0 | Introduced                                           |
| ArubaOS 6.0 | Renamed the modes and deprecated the DoS mode.       |
| ArubaOS 6.1 | The <b>suspected-rogue</b> parameter was introduced. |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## wms clean-db

wms clean-db

### Description

This command deletes the WMS database.

### Syntax

| Parameter | Description              |
|-----------|--------------------------|
| clean-db  | Cleans the WMS database. |

### Usage Guidelines

This command deletes all entries from the WMS database. Do not use this command unless instructed to do so by a Dell representative.

### Example

The following command cleans the WMS database:

```
(host) #wms clean-db
WMS Database will be deleted. Do you want to proceed with this action [y/n]:
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## wms client

```
wms client <macaddr> mode {manually-contain|interfering|valid}
```

### Description

This command allows you to classify a wireless client into one of several categories.

### Syntax

| Parameter        | Description                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------|
| client           | MAC address of the client.                                                                    |
| mode             | Classify the client into one of the following categories:                                     |
| manually-contain | Manually enable denial of service to this client.                                             |
| interfering      | Setting the client mode to <i>interfering</i> makes it part of clients outside the enterprise |
| valid            | A client that is part of the enterprise.                                                      |

### Usage Guidelines

ArubaOS can automatically determine client classification based on client behavior, but this command allows you to explicitly classify a client. The classification of a client is used in certain policy enforcement features. For example, if **protect-valid-sta** is enabled in the IDS Unauthorized Device Profile, then clients that are classified as valid cannot connect to non-valid APs.

### Example

The following command classifies a client as valid:

```
(host) #wms client 00:00:A4:34:C9:B3 mode valid
```

### Command History

| Release     | Modification                                                                                                                                |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ArubaOS 3.0 | Command introduced                                                                                                                          |
| ArubaOS 6.1 | The following parameters were deprecated<br>dos<br>neighbor<br>The following parameters were introduced:<br>manually-contain<br>interfering |

## Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## wms export-class

wms export-class <filename>

### Description

This command exports classification information into a file.

### Syntax

| Parameter  | Description                                                               |
|------------|---------------------------------------------------------------------------|
| <filename> | Name of the file into which you want to export classification information |

### Usage Guidelines

This command writes classification data into comma separated values (CSV) files—one for APs and one for clients. You can import these files into the Dell Mobility Manager system.

### Example

The following command exports classification data into an AP and a client file:

```
(host) #wms export-class class
```

Exported data to class\_ap.csv and class\_sta.csv

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## wms export-db

wms export-db <filename>

### Description

This command exports the WMS database to a specified file.

### Syntax

| Parameter  | Description                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <filename> | Name of the file into which you want to export the database. The filename plus any extensions must be no longer than 32 characters and may contain only keyboard characters. |

### Usage Guidelines

The file is exported as an ASCII text file. If you have configured the controller for operation with DellIMMS, this command will fail and an error will be returned.

### Example

The following command exports the WMS database to a file:

```
(host) #wms export-db database
```

```
Exported WMS DB to database
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## wms import-db

```
wms import-db <filename>
```

### Description

This command imports the specified file into the WMS database.

### Syntax

| Parameter  | Description                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <filename> | Name of the file into which you want to import into the database. The filename plus any extensions must be no longer than 32 characters and may contain only keyboard characters. |

### Usage Guidelines

The imported file replaces the WMS database. The imported file must be a valid WMS database file that you previously exported using the **wms export-db** command.

### Example

The following command imports the WMS database from a file:

```
(host) #wms import-db database
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## wms reinit-db

wms reinit-db

### Description

This command reinitializes the WMS database to its factory defaults.

### Syntax

No parameters.

### Usage Guidelines

When you use this command, there is no automatic backup of the current database. If an MMS server is configured on the controller (See [mobility-manager on page 650](#)), this command will fail and return an error.

### Example

The following command reinitializes the WMS database:

```
(host) #wms reinit-db
WMS Database will be re-initialized. Do you want to proceed with this action [y/n]:
```

### Command History

This command was introduced in ArubaOS 3.0.

### Command Information

| Platforms     | Licensing             | Command Mode                      |
|---------------|-----------------------|-----------------------------------|
| All platforms | Base operating system | Enable mode on master controllers |

## write

```
write {erase [all] | memory | terminal}
```

### Description

This command saves the running configuration to memory or displays the running configuration on the screen. This command can also be used to erase the running configuration and return the controller to factory defaults.

### Syntax

| Parameter             | Description                                                                                                                                                                                                                                                                          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>erase</code>    | Erases the running system configuration file. Rebooting the controller resets it to the factory default configuration. If you specify <code>all</code> , the configuration and all data in the controller databases (including the license, WMS, and internal databases) are erased. |
| <code>memory</code>   | Saves the current system configuration to memory. Any configuration changes made during this session will be made permanent.                                                                                                                                                         |
| <code>terminal</code> | Displays the current system configuration.                                                                                                                                                                                                                                           |

### Usage Guidelines

Configuration changes made using the CLI affect only the current session. You must save your changes for them to be retained across system reboots. Changes are lost if the system reboots before saving the changes. To save your configuration changes, use the `write memory` command.

If you use the `write erase` command, the license key management database on the controller is not affected. If you use the `write erase all` command, all databases on the controller are deleted, including the license key management database. If you reset the controller to the factory default configuration, perform the Initial Setup as described in the *Dell Networking W-Series ArubaOS Quick Start Guide*.

If you use the `write terminal` command, all of the commands used to configure the controller appear on the terminal. If paging is enabled, there is a pause mechanism that stops the output from printing continuously to the terminal. To navigate through the output, use any of the commands displayed at the bottom of the output, as described in below. If paging is disabled, the output prints continuously to the terminal. For more information about the `paging` command, see [paging on page 673](#).

| Key      | Description                   |
|----------|-------------------------------|
| Q        | Exit the display.             |
| U        | Page up through the output.   |
| spacebar | Page down through the output. |

| Key | Description                           |
|-----|---------------------------------------|
| /   | Enter a text string to search for.    |
| N   | Repeat the text string to search for. |

## Example

The following command saves your changes so they are retained after a reboot:

```
(host) #write memory
```

The following command deletes the running configuration and databases and returns the controller to the factory default settings:

```
(host) #write erase
```

## Command History

This command was introduced in ArubaOS 1.0.

## Command Information

| Platforms     | Licensing             | Command Mode            |
|---------------|-----------------------|-------------------------|
| All platforms | Base operating system | Enable and Config modes |

The Dell Networking W-Series ArubaOS command-line interface offers different levels of user access by differentiating between different command modes.

When you first log in to the CLI, you start your session in *User* mode, which provides only limited access for basic operational testing. You must enter an additional password to access *Enable* mode, which allows you to issue show commands run certain management functions. Configuration commands can only be issued in *Configuration* mode. You can access Config mode by entering **configure terminal** at the command prompt. You can exit your current command mode and return to a lower-level command mode at any time by entering **exit** at the command prompt.

The following sections describes how to access each command mode, the command prompt for each mode, and links to its available commands.

## User mode

You always begin a CLI session in user mode, the command mode with the lowest level of user access. The command prompt for a user mode session is a greater-than (>) symbol:

(host) >

The following commands are available in user mode.

- enable
- exit
- help
- logout
- ping
- tracepath
- traceroute

## Enable Mode

To move from user mode to enable mode, you must enter the command **enable**, press **Enter**, then enter config mode password that was defined during the controller's initial setup process. (The default password is **enable**.) Users in enable mode may return to user mode at any time by entering the command **exit**.

The command prompt for a CLI session in enable mode is a pound (#) symbol:

(host) #

To view a list of commands available in enable mode, access the CLI in enable mode and enter a question mark (?):

(host) #?

Some top-level commands have different sets of subcommands available in Enable or Config mode. To view a list of available subcommands in Enable mode, access the CLI in Enable mode, enter the top level command, then enter a question mark (?). For example, the following example shows which aaa commands are available in Enable mode:

|                |                                          |
|----------------|------------------------------------------|
| (host) #aaa ?  |                                          |
| authentication | Authentication                           |
| inservice      | Bring authentication server into service |
| ipv6           | Internet Protocol Version 6              |
| query-user     | Query User                               |
| test-server    | Test authentication server               |
| user           | User commands                            |

## Config Mode

To move from enable mode to config mode, enter the command **config terminal**. Users in config mode may return to enable mode at any time by entering the command **exit**.

When you are in config mode, **(config)** appears before the # prompt:

(host) (config) #

Some top-level commands have different sets of subcommands available in Enable or Config mode. To view a list of available subcommands in Config mode, access the CLI in Config mode, enter the top level command, then enter a question mark (?). For example, the following example shows which aaa commands are available in Config mode:

|                        |                                                         |
|------------------------|---------------------------------------------------------|
| (host) (config) #aaa ? |                                                         |
| alias-group            | Configure an Alias Group                                |
| authentication         | Authentication                                          |
| authentication-server  | Authentication Servers                                  |
| bandwidth-contract     | Configure bandwidth contract (256 Kbps - 2 Gbps)        |
| derivation-rules       | Configure rules to derive user role or vlan             |
| dns-query-interval     | Set DNS query interval                                  |
| password-policy        | Password policy for locally configured management users |
| profile                | Configure an AAA Profile                                |
| radius-attributes      | Configure RADIUS attribute                              |
| server-group           | Configure a Server Group                                |
| tacacs-accounting      | Configure accounting                                    |
| timers                 | Configure authentication timers                         |
| user                   | User commands                                           |

## Configuration Sub-modes

Some Config mode commands can enter you into a sub-mode with a limited number of available commands specific to that mode. When you are in a configuration sub-mode, the (config) that appears before the command prompt will change to indicate your current mode; e.g (config-if) for config-interface mode, and (config-tunnel) for config-tunnel mode.

You can exit a sub-command mode and return to the basic configuration mode at any time by entering the [exit](#) command.
