2. Blocks and Functionality

Figure 2-1. Block Diagram

Figure 2-1. shows the CYT2B7 architecture block diagram, giving a simplified view of the interconnection between subsystems and blocks. CYT2B7 has four major subsystems: CPU, system resources, peripherals, and I/O^[4, 5]. The color-coding shows the lowest power mode where the particular block is still functional.

CYT2B7 provides extensive support for programming, testing, debugging, and tracing of both hardware and firmware.

Debug-on-chip functionality enables in-system debugging using the production device. It does not require special interfaces, debugging pods, simulators, or emulators.

The JTAG interface is fully compatible with industry-standard third-party probes such as I-jet, J-Link, and GHS.

The debug circuits are enabled by default.

CYT2B7 provides a high level of security with robust flash protection and the ability to disable features such as debug.

Additionally, each device interface can be permanently disabled for applications concerned with phishing attacks from a maliciously reprogrammed device or attempts to defeat security by starting and interrupting flash programming sequences. All programming, debug, and test interfaces are disabled when maximum device security is enabled.

4. GPIO STD supporting 2.7 V to 5.5 V V_{DDIO} range.
5. GPIO_ENH supporting 2.7 V to 5.5 V V_{DDIO} range with higher currents at lower voltages.

3. Functional Description

3.1 CPU Subsystem

3.1.1 CPU

The CYT2B7 CPU subsystem contains a 32-bit Arm Cortex-M0+ CPU with MPU, and a 32-bit Arm Cortex-M4F CPU with MPU, and single-precision FPU. This subsystem also includes P-/M-DMA controllers, a cryptographic accelerator, 1088 KB of code-flash, 96 KB of work-flash, 128 KB of SRAM, and 32 KB of ROM.

The Cortex-M0+ CPU provides a secure, un-interruptible boot function. This guarantees that, following completion of the boot function, system integrity is valid and privileges are enforced. Shared resources (flash, SRAM, peripherals, and so on) can be accessed through bus arbitration, and exclusive accesses are supported by an inter-processor communication (IPC) mechanism using hardware semaphores.

3.1.2 DMA Controllers

CYT2B7 has three DMA controllers: P-DMA0 with 16 general-purpose and 73 dedicated channels, P-DMA1 with 8 general-purpose and 25 dedicated channels, and M-DMA0 with four channels. P-DMA is used for peripheral-to-memory and memory-to-peripheral data transfers and provides low latency for a large number of channels. Each P-DMA controller uses a single data-transfer engine that is shared by the associated channels. General purpose channels have a rich interconnect matrix including P-DMA cross triggering which enables demanding data-transfer scenarios. Dedicated channels have a single triggering input (such as an ADC channel) to handle common transfer needs. M-DMA is used for memory-to-memory data transfers and provides high memory bandwidth for a small number of channels. M-DMA uses a dedicated data-transfer engine for each channel. They support independent accesses to peripherals using the AHB multi-layer bus.

3.1.3 Flash

CYT2B7 has 1088 KB (960 KB with a 32-KB sector size, and 128 KB with an 8-KB sector size) of code-flash with an additional work-flash of up to 96 KB (72 KB with 2-KB sector size, and 24 KB with 128-B sectors size). Work-flash is optimized for reprogramming many more times than code-flash. Code-flash supports Read-While-Write (RWW) operation allowing flash to be updated while the CPU is active. Both the code-flash and work-flash areas support dual-bank operation for over-the-air (OTA) programming.

3.1.4 SRAM

CYT2B7 has 128 KB of SRAM with two independent controllers. The first controller, SRAM0, provides DeepSleep retention in 32-KB increments, while SRAM1 is selectable between fully retained and not retained.

3.1.5 ROM

CYT2B7 has 32-KB ROM that contains boot and configuration routines. This ROM enables secure boot and authentication of user flash to guarantee a secure system.

3.1.6 Cryptography Accelerator for Security

The cryptography accelerator implements (3)DES block cipher, AES block cipher, SHA hash, cyclic redundancy check, pseudo random number generation, true random number generation, galois/counter mode, and a vector unit to support asymmetric key cryptography such as RSA and ECC.

Depending on the part number, this block is either completely or partially available or not available at all. See [Ordering Information](#) for more details.

3.2 System Resources

3.2.1 Power System

The power system ensures that the supply voltage levels meet the requirements of each power mode, and provides a full-system reset when these levels are not valid. Internal power-on reset (POR) guarantees full-chip reset during the initial power ramp.

Three Brown-Out Detection (BOD) circuits monitor the external supply voltages (V_{DD0} , V_{DDA} , V_{CCD}). The BOD on V_{DD0} and V_{CCD} are initially enabled and cannot be disabled. The BOD on V_{DDA} is initially disabled and can be enabled by the user. For the external supplies V_{DD0} and V_{DDA} , BOD circuits are software configurable with two settings; a 2.7-V minimum voltage that is robust for all internal signaling and a 3.0-V minimum voltage, which is also robust for all I/O specifications (which are guaranteed at 2.7 V). The BOD on V_{CCD} is provided as a safety measure and is not a robust detector.

Three overvoltage detection (OVD) circuits are provided for monitoring external supplies (V_{DD0} , V_{DDA} , V_{CCD}), and overcurrent detection circuits (OCD) for monitoring internal and external regulators. OVD thresholds on V_{DD0} and V_{DDA} are configurable with two settings; a 5.0-V and 5.5-V maximum voltage. Two voltage-detection circuits are provided to monitor the external supply voltage (V_{DD0}) for falling and rising levels, each configurable for one of the 26 selectable levels.

All BOD, OVD, and OCD circuits on V_{DD0} and V_{CCD} generate a reset, because these protect the CPUs and fault logic. The BOD and OVD circuits on V_{DDA} can be configured to generate either a reset, or a fault.

3.2.2 Regulators

CYT2B7 contains two regulators that provide power to the low-voltage core transistors: DeepSleep and core internal. These regulators accept a 2.7–5.5-V V_{DD0} supply and provide a low-noise 1.1-V supply to various parts of the device. These regulators are automatically enabled and disabled by hardware and firmware when switching between power modes. The core internal and core external regulators operate in active mode, and provide power to the CPU subsystem and associated peripherals.

DeepSleep

The DeepSleep regulator is used to maintain power to a small number of blocks when in DeepSleep mode. These blocks include the ILO and WDT timers, BOD detector, SCB0, SRAM memories, Smart I/O, and other configuration memories. The DeepSleep regulator is enabled when in DeepSleep mode, and the core internal regulator is disabled. It is disabled when XRES_L is asserted (LOW) and when the core internal regulator is disabled.

Core internal

The core internal regulator supports load currents up to 150 mA, and is operational during the device start-up (boot process), and in Active/Sleep modes.

3.2.3 Clock System

The CYT2B7 clock system provides clocks to all subsystems that require them, and glitch-free switching between different clock sources. In addition, the clock system ensures that no metastable conditions occur.

The clock system for CYT2B7 consists of the 8-MHz IMO, two ILOs, three watchdog timers, a PLL, an FLL, five clock supervisors (CSV), a 3.988- to 33.34 MHz ECO, and a 32.768-kHz WCO.

The clock system supports two main clock domains: CLK_HF, and CLK_LF.

- CLK_HF_x are the Active mode clocks. Each can use any of the high frequency clock sources including IMO, EXT_CLK, ECO, FLL, or PLL
- CLK_LF is a DeepSleep domain clock and provides a reference clock for the MCWDT or RTC modules. The reference clock for the CLK_LF domain is either disabled or selectable from ILO0, ILO1, or WCO

Table 3-1. CLK_HF Destinations

Name	Description
CLK_HF0	CPUSS clocks, PERI, and AHB infrastructure
CLK_HF1	Event Generator, also available in HSIOM as an output

IMO Clock Source

The IMO is the frequency reference in CYT2B7 when no external reference is available or enabled. The IMO operates at a frequency of 8 MHz $\pm$ 1%. The internal trim settings for the IMO can be dynamically updated to provide a tolerance <1%.

ILO Clock Source

An ILO is a low-power oscillator, nominally 32.768 kHz, which generates clocks for a watchdog timer when in DeepSleep mode. There are two ILOs to ensure clock supervisor (CSV) capability in DeepSleep mode. ILO-driven counters can be calibrated to the IMO, WCO, or ECO to improve their accuracy. ILO1 is also used for clock supervision.

PLL and FLL

A PLL or FLL may be used to generate high-speed clocks from the IMO, the ECO, or EXT_CLK. The FLL provides a much faster lock than the PLL (5 μ s instead of 35 μ s) in exchange for a small amount ($\pm$ 2%) of frequency error^[6].

Clock Supervisor (CSV)

Each CSV allows one clock (reference) to supervise the behavior of another clock (monitored). Each CSV has counters for both the monitored and reference clocks. Parameters for each counter determine the frequency of the reference clock as well as the upper and lower frequency limits of the monitored clock. If the frequency range comparator detects a stopped clock or a clock outside the specified frequency range, an abnormal state is signaled and either a reset or an interrupt is generated.

Note

6. Operation of reference-timed peripherals (like a UART) with an FLL-based reference is not recommended due the allowed frequency error.

EXT_CLK

One of the two GPIO_STD I/Os can be used to provide an external clock input of up to 80 MHz. This clock can be used as the source clock for either the PLL or FLL, or can be used directly by the CLK_HF domain.

ECO

The ECO provides high-frequency clocking using an external crystal connected to the ECO_IN and ECO_OUT pins. It supports fundamental mode (non-overtone) quartz crystals, in the range of 3.988 to 33.34 MHz. When used in conjunction with the PLL, it generates CPU and peripheral clocks up to device's maximum frequency. ECO accuracy depends on the selected crystal. If the ECO is disabled, the associated pins can be used for any of the available I/O functions.

WCO

The WCO is a low-power, watch-crystal oscillator intended for real-time-clock applications. It requires an external 32.768-kHz crystal connected to the WCO_IN and WCO_OUT pins. The WCO can also be configured as a clock reference for CLK_LF, which is the clock source for the MCWDT and RTC.

3.2.4 Reset

CYT2B7 can be reset from a variety of sources, including software. Reset events are asynchronous and guarantee reversion to a known state. The reset cause (POR, BOD, OVD, overcurrent, XRES_L, WDT, MCWDT, software reset, fault, CSV, Hibernate wakeup, debug) is recorded in a register, which is sticky through reset and allows software to determine the cause of the reset. An XRES_L pin is available for external reset.

3.2.5 Watchdog Timers

CYT2B7 has one watchdog timer (WDT) and two multi-counter watchdog timers (MCWDT).

The WDT is a free-running counter clocked only by ILO0, which allows it to be used as a wakeup source from Hibernate. Watchdog operation is possible during all power modes. To prevent a device reset from a WDT timeout, the WDT must be serviced during a configured window. A watchdog reset is recorded in the reset cause register.

An MCWDT is available for each of the CPU cores. These timers provide more capabilities than the WDT, and are only available in Active, Sleep, and DeepSleep modes. These timers have multiple counters that can be used separately or cascaded to trigger interrupts and/or resets. They are clocked from ILO0 or the WCO.

3.2.6 Power Modes

CYT2B7 has the following six power modes:

- **Active** – all peripherals are available
- **Low-Power Active (LPACTIVE)** – Low-power profile of Active mode where all peripherals and the CPUs are available, but with limited capability
- **Sleep** – all peripherals except the CPUs are available
- **Low-Power Sleep (LPSLEEP)** – Low-power profile of Sleep mode where all peripherals except the CPUs are available, but with limited capability
- **DeepSleep** – only peripherals which work with CLK_LF are available
- **Hibernate** – the device and I/Os are in High-Z state, the device resets on wakeup

3.3 Peripherals

3.3.1 Peripheral Clock Dividers

Integer and fractional clock dividers are provided for peripheral and timing purposes.

Table 3-2. Clock Dividers

Divider	Count	Description
div_8	32	Integer divider, 8 bits
div_16	16	Integer divider, 16 bits
div_24_5	8	Fractional divider, 24.5 bits (24 integer bits, 5 fractional bits)

3.3.2 Peripheral Protection Unit

The Peripheral Protection Unit (PPU) controls and monitors unauthorized access from all masters (CPU, P-/M-DMA, Crypto, and any enabled debug interface) to the peripherals. It allows or restricts data transfers on the bus infrastructure. The access rules are enforced based on specific properties of a transfer, such as an address range for the transfer and access attributes (such as read/write, user/privilege, and secure/non-secure).

3.3.3 12-bit SAR ADC

CYT2B7 contains three 1-Msps SAR ADCs. These ADCs can be clocked at up to 26.67 MHz and provide a 12-bit result in 26 clock cycles.

The references for all three SAR ADCs come from a dedicated pair of inputs: VREFH and VREFL⁷.

CYT2B7 devices support up to 85 logical ADC channels, and external inputs from up to 67 I/Os. Each ADC also supports six internal connections for diagnostic and monitoring purposes. The number of ADC channels (per ADC and package type) are listed in [Table 1-1](#).

Each ADC has a sequencer, which autonomously cycles through the configured channels (sequencer scan) with zero-switching overhead (that is, the aggregate sampling bandwidth, when clocked at 26.67 MHz, is equal to 1 Msps whether it is for a single

channel or distributed over several channels). The sequencer switching is controlled through a state machine or firmware. The sequencer prioritizes trigger requests, enables the appropriate analog channel, controls ADC sampling, initiates ADC data conversion, manages results, and initiates subsequent conversions for repetitive or group conversions without CPU intervention.

Each SAR ADC has an analog multiplexer used to connect the signals to be measured to the ADC. It has 32 GPIO STD inputs, one special GPIO STD input for motor-sense, and six additional inputs to measure internal signals such as a band-gap reference, a temperature sensor, and power supplies. The device supports synchronous sampling of one motor-sense channel on each of the three ADCs.

CYT2B7 has one temperature sensor that is shared by all three ADCs. The temperature sensor must only be sampled by one ADC at a time. Software post processing is required to convert the temperature sensor reading into kelvin or Celsius values.

To accommodate signals with varying source impedances and frequencies, it is possible to have different sample times programmed for each channel. Each ADC also supports range comparison, which allows fast detection of out-of-range values without having to wait for a sequencer scan to complete and for the CPU firmware to evaluate the measurement for out-of-range values.

The ADCs are not usable in DeepSleep and Hibernate modes as they require a high-speed clock. The ADC input reference voltage VREFH range is 2.7 V to V_{DDA} and VREFL is V_{SSA} .

3.3.4 Timer/Counter/PWM Block (TCPWM)

The TCPWM block consists of 16-bit (75 channels) and 32-bit (four channels) counters with a user-programmable period. Twelve of the 16-bit counters include extra features to support motor control operations. Each TCPWM counter contains a capture register to record the count at the time of an event, a period register (used to either stop or auto-reload the counter when its count is equal to the period register), and compare registers to generate signals that are used as PWM duty-cycle outputs.

Each counter within the TCPWM block supports several functional modes such as timer, capture, quadrature, PWM, PWM with dead-time insertion (PWM_DT, 8-bit), pseudo-random PWM (PWM_PR), and shift-register.

In motor-control applications, the counter within the TCPWM block supports enhanced quadrature mode with features such as asymmetric PWM generation, dead-time insertion (16-bit), and association of different dead times for PWM output signals.

The TCPWM block also provides true and complement outputs, with programmable offset between them, to allow their use as deadband complementary PWM outputs. The TCPWM block also has a kill input (only for the PWM mode) to force outputs to a predetermined state; for example, this may be used in motor-drive systems when an overcurrent state is detected and the PWMs driving the FETs need to be shut off immediately (no time for software intervention).

Note

7. VREF_L prevents IR drops in the VSSIO and VSSA paths from impacting the measurements. VREF_L, when properly connected, reduces or removes the impact of IR drops in the VSSIO and VSSA paths from measurements.

3.3.5 Serial Communication Blocks (SCB)

CYT2B7 contains eight serial communication blocks, each configurable to support I²C, UART, or SPI.

I²C Interface

An SCB can be configured to implement a full I²C master (capable of multi-master arbitration) or slave interface. Each SCB configured for I²C can operate at speeds of up to 1 Mbps (Fast-mode Plus^[8]) and has flexible buffering options to reduce the interrupt overhead and latency of the CPU. In addition, each SCB supports FIFO buffering for receive and transmit data, which, by increasing the time for the CPU to read the data, reduces the need for clock stretching. The I²C interface is compatible with Standard, Fast-mode, and Fast-mode Plus devices as specified in the NXP I²C-bus specification and user manual (UM10204). The I²C-bus I/O is implemented with GPIO in open-drain modes^[9, 10].

UART Interface

When configured as a UART, each SCB provides a full-featured UART with maximum signalling rate determined by the configured peripheral-clock frequency and over-sampling rate. It supports infrared interface (IrDA) and SmartCard (ISO 7816) protocols, which are minor variants of the UART protocol. It also supports the 9-bit multiprocessor mode that allows the addressing of peripherals connected over common Rx and Tx lines. Common UART functions such as parity, number of stop bits, break detect, and frame error are supported. FIFO buffering of transmit and receive data allows greater CPU service latencies to be tolerated.

The LIN protocol is supported by the UART. LIN is based on a single-master multi-slave topology. There is one master node and multiple slave nodes on the LIN bus. The SCB UART supports only LIN slave functionality. Compared to the dedicated LIN blocks, an SCB/UART used for LIN requires a higher level of software interaction and increased CPU load.

SPI Interface

The SPI configuration supports full Motorola SPI, TI Synchronous Serial Protocol (SSP, essentially adds a start pulse that is used to synchronize SPI-based codecs), and National Microwire (a half-duplex form of SPI). The SPI interface can use the FIFO. The SPI interface operates with up to a 12.5-MHz SPI Clock. SCB also supports EZSPI^[11] mode.

SCB0 supports the following additional features:

- Operable as a slave in DeepSleep mode
- I²C slave EZ (EZI2C^[12]) mode with up to 256-B data buffer for multi-byte communication without CPU intervention
- I²C slave externally-clocked operations
- Command/response mode with a 512-B data buffer for multi-byte communication without CPU intervention

Notes

8. I/Os drive level does not support the full bus capacitance in Fast-mode Plus speeds.
9. This is not 100% compliant with the I²C-bus specification; I/Os are not over-voltage tolerant, do not support the 20-mA sink requirement of Fast-mode Plus, and violate the leakage specification when no power is applied.
10. Only Port 0 with the slew rate control enabled meets the minimum fall time requirement.
11. The Easy SPI (EZSPI) protocol is based on the Motorola SPI operating in any mode (0, 1, 2, or 3). It allows communication between master and slave reduces the need for CPU intervention.
12. The Easy I²C (EZI2C) protocol is a unique communication scheme built on top of the I²C protocol by Cypress. It uses a meta protocol around the standard I²C protocol to communicate to an I²C slave using indexed memory transfers. This reduces the need for CPU intervention.

3.3.6 CAN FD

CYT2B7 supports two CAN FD controller blocks, each supporting three CAN FD channels. All CAN FD controllers are compliant with the ISO 11898-1:2015 standard; an ISO 16845:2015 certificate is available. It also implements the time-triggered CAN (TTCAN) protocol specified in ISO 11898-4 (TTCAN protocol levels 1 and 2) completely in hardware.

All functions concerning the handling of messages are implemented by the Rx and Tx handlers. The Rx handler manages message acceptance filtering, transfer of received messages from the CAN core to a message RAM, and provides receive-message status. The Tx handler is responsible for the transfer of transmit messages from the message RAM, to the CAN core, and provides transmit-message status.

3.3.7 Local Interconnect Network (LIN)

CYT2B7 contains up to eight LIN channels. Each channel supports transmission/reception of data following the LIN protocol according to ISO standard 17987. Each LIN channel connects to an external transceiver through a 3-pin interface (including an enable function) and supports master and slave functionality. Each channel also supports classic and enhanced checksum, along with break detection during message reception and wake-up signaling. Break detection, sync field, checksum calculations, and error interrupts are handled in hardware.

3.3.8 One-Time-Programmable (OTP) eFuse

CYT2B7 contains a 1024-bit OTP eFuse memory that can be used to store and access a unique and unalterable identifier or serial number for each device. eFuses are also used to control the device life-cycle (manufacturing, programming, normal operation, end-of-life, and so on) and the security state. Of the 1024 bits, 192 are available for user purposes.

3.3.9 Event Generator

The event generator supports generation of interrupts and triggers in Active mode and interrupts in DeepSleep mode. The event generators are used to trigger a specific device operation (execution of an interrupt handler, a SAR ADC conversion, and so on) and to provide a cyclic wakeup mechanism from DeepSleep mode. They provide CPU-free triggers for device functions, and reduce CPU involvement in triggering device functions, thus reducing overall power consumption and processing overhead.

3.3.10 Trigger Multiplexer

CYT2B7 supports connecting various peripherals using trigger signals. Triggers are used to inform a peripheral of the occurrence of an event or change of state. These triggers are used to affect or initiate some action in other peripherals. The trigger multiplexer is used to route triggers from a source peripheral to a destination. Triggers provide active logic functionality and are typically supported in Active mode.

3.4 I/Os

CYT2B7 has up to 152 programmable I/Os.

The I/Os are organized as logical entities called ports, which are a maximum of 8 bits wide. During power-on, Hibernate, and reset, the I/Os are forced to the High-Z state.

Every I/O can generate an interrupt (if enabled) and each port has an interrupt request (IRQ) and interrupt service routine (ISR) associated with it.

I/O port power source mapping is listed in [Table 3-3](#). The associated supply determines the V_{OH} , V_{OL} , V_{IH} , and V_{IL} levels when configured for CMOS and Automotive thresholds.

Table 3-3. I/O Port Power Source

Supply	Ports
VDDD	P0, P1, P2, P3, P4, P5, P16, P17, P18, P19, P20, P21, P22, P23
VDDIO_1	P6, P7, P8, P9 ^[13]
VDDIO_2	P10, P11, P12, P13, P14, P15

3.4.1 Port Nomenclature

Px.y describes a particular bit “y” available within an I/O port “x.”

For example, P4.2 reads “port 4, bit 2”.

Each I/O implements the following:

- Programmable drive mode
 - High impedance
 - Resistive pull-up
 - Resistive pull-down
 - Open drain with strong pull-down
 - Open drain with strong pull-up
 - Strong pull-up or pull-down
 - Weak pull-up or pull-down

CYT2B7 has two types of programmable I/Os: GPIO standard and GPIO Enhanced.

■ GPIO Standard (GPIO_STD)

Supports standard automotive signaling across the 2.7-V to 5.5-V V_{DDIO} range. GPIO Standard I/Os have multiple configurable drive levels, drive modes, and selectable input levels.

■ GPIO Enhanced (GPIO_ENH)

Supports extended functionality automotive signalling across the 2.7-V to 5.5-V V_{DDIO} range with higher currents at lower voltages (full I²C timing support, slew-rate control).

Both GPIO_STD and GPIO_ENH implement the following:

- Configurable input threshold (CMOS, TTL, or Automotive)
- Hold mode for latching previous state (used for retaining the I/O state in DeepSleep mode)
- Analog input mode (input and output buffers disabled)

3.4.2 Smart I/O

Smart I/O allows Boolean operations on signals going to the I/O from the subsystems of the chip or on signals coming into the chip. CYT2B7 has five Smart I/O blocks. Operation can be synchronous or asynchronous and the blocks operate in all device power modes except for the Hibernate mode.

Note

13. The I/Os in VDDIO_1 domain are referred to the VDDD domain in 64-LQFP package.

Most pins have alternate functionality, as specified in [Table 11-1](#).

Port 11 has the following additional features,

- Ability to pass full-level analog signals to the SAR without clipping to V_{DD} in cases where $V_{DD} < V_{DDA}$
- Ability to simultaneously capture all three ADC signals with highest priority (ADC[0:2]_M)
- Lower noise, for the most sensitive sensors

Notes

18. HCon refers to High Speed I/O matrix connection reference as per [Table 10-1](#).

19. DeepSleep ordering (DS #0, DS #1, DS #2) does not have any impact on choosing any alternate functions; the HSIOM module handles the individual alternate function assignment.

20. All port pin functions available in DeepSleep mode are also available in Active mode.

Notes

21. I/O pins that support an oscillator function (WCO or ECO) must be configured for high-impedance if the oscillator is enabled.

 22. This I/O has increased leakage to ground when the V_{DD} supply is below the POR threshold.

25. Active Mode ordering (ACT#0, ACT#1, and so on) does not have any impact on configuring alternate functions; the HSIOM module handles the alternate function assignments.

22. Peripheral Protection Unit Fixed Structure Pairs

Protection pair is a pair PPU structures, a master and a slave structure. The master structure protects the slave structure, and the slave structure protects resources such as peripheral registers, or the peripheral itself.

25. Development Support

CYT2B7 has a rich set of documentation, programming tools, and online resources to assist during the development process. Visit www.cypress.com to find out more.

25.1 Documentation

A suite of documentation supports CYT2B7 to ensure that you can find answers to your questions quickly. This section contains a list of some of the key documents.

25.1.1 Software User Guide

A step-by-step guide for using the sample driver library along with third-party IDEs such as IAR EWARM and GHS Multi.

25.1.2 Technical Reference Manual

The Technical Reference Manual (TRM) contains all the technical detail needed to use a CYT2B7 device, including a complete description of all registers. The TRM is available in the documentation section at www.cypress.com.

25.2 Tools

CYT2B7 is supported on third-party development tool ecosystems such as IAR and GHS. CYT2B7 is also supported by Cypress programming utilities for programming, erasing, or reading using Cypress' MiniProg4 or Segger J-link. More details are available in the documentation section at www.cypress.com.

26. Electrical Specifications

26.1 Absolute Maximum Ratings

Use of this device under conditions outside the min and max limits listed in [Table 26-1](#) may cause permanent damage to the device. Exposure to conditions within the limits of [Table 26-1](#) but beyond those of normal operation for extended periods of time may affect device reliability. The maximum storage temperature is 150 °C in compliance with JEDEC Standard JESD22-A103, High Temperature Storage Life. When operated under conditions within the limits of [Table 26-1](#) but beyond those of normal operation, the device may not operate to specification.

Power considerations

The average chip-junction temperature, T_J , in °C, may be calculated using Equation 1:

$$T_J = T_A + (P_D \times \theta_{JA}) \quad \text{Equation. 1}$$

Where:

T_A is the ambient temperature in °C.

θ_{JA} is the package junction-to-ambient thermal resistance, in °C/W.

P_D is the sum of P_{INT} and P_{IO} ($P_D = P_{INT} + P_{IO}$).

P_{INT} is the chip internal power. ($P_{INT} = V_{DD} \times I_{DD} + V_{DDA} \times I_A$)

P_{IO} represents the power dissipation on input and output pins; user determined.

For most applications, $P_{IO} < P_{INT}$ and may be neglected.

On the other hand, P_{IO} may be significant if the device is configured to continuously drive external modules and/or memories.

Notes

31. These parameters are based on the condition that $V_{SSD} = V_{SSA} = 0.0$ V.

32. The I/Os in V_{DDIO_1} domain are referred to the V_{DD} domain in 64-LQFP package.

33. A current-limiting resistor must be provided such that the current at the I/O pin does not exceed rated values at any time, including during power transients. Refer to [Figure 26-1](#) for more information on the recommended circuit.

34. V_{DDIO} and V_{DD} must be sufficiently loaded or protected to prevent them from being pulled out of the recommended operating range by the clamp current.

35. When the conditions of [42], [43], and SID18A/B/C/D are met, $|I_{CLAMP_ABS}|$ supersedes V_{IA_ABS} and V_{I1_ABS} .

36. The definition of "closer" depends on the package. In LQFP packaging, "closest" is determined by counting pins. For example, in a 176-LQFP package, P17.4 (pin 120) is closer to the V_{DDP} on pin 110 than on pin 132. Ports 11 and 21 should not be used for injection currents. The impact of injection currents is only defined for GPIO_STD/GPIO_ENH type I/Os.

26.2 Device-Level Specifications
Table 26-2. Recommended Operating Conditions

Spec ID	Parameter	Description	Min	Typ	Max	Units	Details/Conditions
Recommended Operating Conditions							
SID40	V_{DDDD} , V_{DDA} , V_{DDIO_1} , V_{DDIO_2}	Power supply voltage ^[40]	2.7 ^[41]	–	5.5 ^[42]	V	
SID40A	$V_{DDIO_1_EFP}$	Power supply voltage for eFuse programming ^[43]	3	–	5.5	V	
SID41	C_{S1}	Smoothing capacitor ^[44, 45]	3.76	–	11	μF	

Notes

39. +B is the positive battery voltage around 45 V.
40. V_{DDDD} , V_{DDIO_1} , V_{DDIO_2} , and V_{DDA} do not have any sequencing limitation and can establish in any order. These supplies (except for V_{DDA} and V_{DDIO_2}) are independent in voltage level. For example, $V_{DDIO_1} = 5.0$ V, $V_{DDDD} = 3.3$ V, and $V_{DDA} = V_{DDIO_2} = 4.0$ V are supported, as is any other combination of voltages between 2.7 V and 5.5 V inclusive. The presence of V_{DDA} without V_{DDDD} can cause some leakage from V_{DDA} . However, the device does not drive any analog or digital output.
41. 3.0 V $\pm$ 10% is supported with a lower BOD setting option for V_{DDDD} and V_{DDA} . This setting provides robust protection for internal timing but BOD reset occurs at a voltage below the specified operating conditions. A higher BOD setting option is available (consistent with down to 3.0 V) and guarantees that all operating conditions are met.
42. 5.0 V $\pm$ 10% is supported with a higher OVD setting option for V_{DDDD} and V_{DDA} . This setting provides robust protection for internal and interface timing, but OVD reset occurs at a voltage above the specified operating conditions. A lower OVD setting option is available (consistent with up to 5.0 V) and guarantees that all operating conditions are met.
43. eFuse programming must be executed with the part in a “quiet” state, with minimal activity (preferably only JTAG or a single LIN/CAN channel on V_{DDDD} domain, no activity on V_{DDIO_1}).
44. Smoothing capacitor, C_{S1} is required per chip (not per V_{CCD} pin). The V_{CCD} pins must be connected together to ensure a low-impedance connection (see the requirement in Figure 26-2. and Table 26-3).
45. Capacitors used for power supply decoupling or filtering are operated under a continuous DC-bias. Many capacitors used with DC power across them provide less than their target capacitance, and their capacitance is not constant across their working voltage range. When selecting capacitors for use with this device, ensure that the selected components provide the required capacitance under the specific operating conditions of temperature and voltage used in your design. While the temperature coefficient is normally found within a parts catalog (such as, X7R, C0G, Y5V), the matching voltage coefficient may only be available on the component datasheet or direct from the manufacturer. Use of components that do not provide the required capacitance under the actual operating conditions may cause the device to operate to less than datasheet specifications.

Figure 26-2.Smoothering Capacitor

Smoothing capacitor should be placed as close as possible to the V_{CCD} pin marked in the [Table 26-3](#).

$$1 \text{ LSB (Ideal value)} = (V_{REFH} - V_{REFL}) / 4096 \quad [\text{V}]$$

N: A/D converter digital output value
 V_{NT} (Ideal value): $V_{REFL} + 0.5 \text{ LSB}$ [V]
 V_{FST} (Ideal value): $V_{REFH} - 1.5 \text{ LSB}$ [V]
 V_{NT} : Voltage at which the digital output changes from $N - 1$ to N

26.7.2 Calculating the Impact of Neighboring Pins

The three ADC specifications based on SID19A, SID19B, and SID19C, can be used to calculate the pin leakage and resulting ADC offset caused by injection current using the below formula:

$$I_{LEAK} = I_{INJECTED} \times CLAMP_COUPLING_RATIO$$

$$V_{ERROR} = I_{LEAK} \times (R_{CLAMP_INTERNAL} + R_{SOURCE})$$

$$Code\ Error = V_{ERROR} \times 2^{12} / V_{REF}$$

Where:

$I_{INJECTED}$ is the injected current in mA.

I_{LEAK} is the calculated leakage current in mA.

V_{ERROR} is the voltage error calculated due to leakage currents in V.

V_{REF} is the ADC reference voltage in V.

Figure 26-5. Integral and Differential Linearity Errors

$$\text{Integral linearity error of digital output } N = (V_{NT} - \{1 \text{ LSb} \times (N - 1) + V_{ZT}\}) / 1 \text{ LSb} \quad [\text{LSb}]$$

$$\text{Differential linearity error of digital output } N = (V_{(N+1)T} - V_{NT} - 1 \text{ LSb}) / 1 \text{ LSb} \quad [\text{LSb}]$$

$$1 \text{ LSb} = (V_{FST} - V_{ZT}) / 4094 \quad [\text{V}]$$

V_{ZT} : Voltage for which digital output changes from 0x000 to 0x001

V_{FST} : Voltage for which digital output changes from 0xFFE to 0xFFFF.

Figure 26-6.ADC Equivalent Circuit for Analog Input

R_{EXT} : Source impedance
 C_{EXT} : On-PCB capacitance
 C_{IN} : I/O pad or Input capacitance
 R_{VIN} : ADC equivalent input resistance
 C_{VIN} : ADC equivalent input capacitance
 K : Constant for sampling accuracy $K = \ln(\text{abs}(4096/\text{LSb}_{\text{SAMPLE}}))$

Sampling Time (t_{SAMPLE}) requirement is shown in the following equation
 $t_{\text{SAMPLE}} > K \times \{ C_{VIN} \times (R_{VIN} + R_{EXT}) + (C_{IN} + C_{EXT}) \times R_{EXT} \}$ [seconds]

$K = \text{value of } 9.0 \text{ is recommended to get } \pm 0.5 \text{ LSb sampling accuracy at } 12\text{-bit (LSb}_{\text{SAMPLE}} = \pm 0.5)$

29.1 Bootloading or End-of-line Programming

- Triggered at device startup, if a trigger condition is applied
- Either CAN or LIN communication may be used
- Bootloader polls for the communication on CAN or LIN at separate time frames, until the overall 300-second timeout is reached
- If a bootloader command is received on either communication interface, the polling stops and bootloader starts using this interface

1. Crypto LSL1, LSR1, LSL1_WITH_CARRY, & LSR1_WITH_CARRY instructions may work incorrectly in certain scenarios	
Problem Definition	LSL1, LSR1, LSL1_WITH_CARRY, & LSR1_WITH_CARRY instructions should ignore the value in IW[3:0] (shift by 1 instruction does not use these fields). But because of a HW issue, shift does not work if the register data field pointed by IW[3:0] is '0' (destination data is same as source data).
Parameters Affected	NA
Trigger Condition(s)	Using LSL1, LSR1, LSL1_WITH_CARRY, & LSR1_WITH_CARRY instructions
Scope of Impact	The shift does not happen (destination data is same as source data).

Workaround	IW[3:0] should be pointed to a dummy register where the data field of the register is non-zero value (rsrc0->data[12:0]). Since stack pointer(r15) points to a non-zero value (to use the LSL1 instruction you must have allocated at least one register, so that SP will not be zero), it is safe to use r15 as rsrc0. <pre>static __forceinline void LSL1 (int rdst, int rsrc1) { AHB_WRITE_W (MMIO_CRYPT0_INSTR_FF_WR, (CRYPTO_VU_LSL_OPC << 24) (rdst << 12) (rsrc1 << 4) 15); }</pre> This software workaround applies to other instructions such as LSR1, LSL1_WITH_CARRY & LSR1_WITH_CARRY as well.
Fix Status	No silicon fix planned. Use workaround.

2. Crypto MEM_BUF may be corrupted

Problem Definition	The SRAM in the Crypto block is 8 KB but the address decode is wired to create four 8-KB images of the SRAM within a 32-KB address space. Writes to memory space above the initial 8-KB image will corrupt SRAM contents.
Parameters Affected	NA
Trigger Condition(s)	Any write to address between 0x40108000 and 0x4010FFFF
Scope of Impact	CRYPTO MEM_BUF may be corrupted
Workaround	The software should ensure that there is no access beyond 8 KB MEM_BUF address range from either MMIO writes or address overflows while executing CRYPTO operations
Fix Status	No silicon fix planned. Use workaround.

3. ConfigureFmInterrupt API assumes a parameter with 8 bytes boundary, but actual boundary is 4 bytes

Problem Definition	STATUS_ADDR_PROTECTED will be returned if the ConfigureFmInterrupt API is called with arguments stored in SRAM with 4-byte boundary (available SRAM or protected boundary SRAM).
Parameters Affected	NA
Trigger Condition(s)	Call ConfigureFmInterrupt API with arguments stored in SRAM at 4 bytes boundary of available SRAM or protected boundary of SRAM.
Scope of Impact	ConfigureFmInterrupt API will fail by returning STATUS_ADDR_PROTECTED error status when called with argument having 4 bytes boundary of available SRAM or protected boundary of SRAM.
Workaround	Allow 4 bytes margin (that is, assume that the API parameter size is 8 and store the arguments) for ConfigureFmInterrupt API parameter.
Fix Status	No silicon fix planned. Use workaround.

4. SMPU/MPU/PPU protection region size is limited to 2 GB

Problem Definition	If SMPU/MPU/PPU protection block size is configured for 4 GB (PROT_SMPU_SMPU_STRUCT_ATT0.REGION.SIZE = 31), then during protection check in SROM, the value of the internal uint32 variable will overflow (4G = 0x1 0000 0000). Therefore, SROM assumes the protection size equals zero, and no protection will be applied.
Parameters Affected	NA
Trigger Condition(s)	Configure SMPU/MPU/PPU to protect with region size equal to 4 GB or the region size with value 31u.
Scope of Impact	If SMPU/MPU/PPU is configured to protect region size of 4 GB, then SROM software does not apply any protection as per the request.
Workaround	Use two protection blocks of region size equal to 2 GB if 4-GB region size protection is required.
Fix Status	No silicon fix planned. Use workaround.

5. DirectExecute API may return error if called with arguments placed in SRAM memory

Problem Definition	If DirectExecute API is called in the master PC (other than PC0 or PC1) with arguments in SRAM_SCRATCH_ADDR, then the API will return STATUS_ADDR_PROTECTED status.
Parameters Affected	NA
Trigger Condition(s)	Call DirectExecute API with arguments in SRAM_SCRATCH_ADDR and master PC configured > 1.
Scope of Impact	DirectExecute API, if called with master PC configured > 1 and arguments in SRAM_SCRATCH_ADDR, the API will return STATUS_ADDR_PROTECTED.
Workaround	Call DirectExecute API with master PC0 or PC1, if arguments are stored in SRAM memory.
Fix Status	No silicon fix planned. Use workaround.

6. CAN FD RX FIFO top pointer feature does not function as expected

Problem Definition	The RX FIFO top pointer function calculates the address for received messages in Message RAM by hardware. This address should restart back from the start address after reading all messages of RX FIFO n size (n: 0 or 1). However, the address does not restart back from the start address when RX FIFO n size is set to 1 (CANFD_CH_RXFnC.FnS = 0x01). This results in CPU/DMA reading messages from the wrong address in Message RAM.
Parameters Affected	NA
Trigger Condition(s)	RX FIFO top pointer function is used when RX FIFO n size is set to 1 element (CANFD_CH_RXFnC.FnS = 0x01).
Scope of Impact	Received message cannot be correctly read by using the RX FIFO top pointer function, when RX FIFO n size is set to 1 element.
Workaround	Any of the following. 1) Set RX FIFO n size to 2 or more when using the RX FIFO top pointer function. 2) Do not use the RX FIFO top pointer function when RX FIFO n size is set to 1 element. Instead of reading received messages from the RX FIFO top pointer, read directly from the Message RAM.
Fix Status	No silicon fix planned. Use workaround.

7. CAN FD debug message handling state machine does not reset to Idle state when CANFD_CH_CCCR.INIT is set	
Problem Definition	If either of the CANFD_CH_CCCR.INIT bits is set by the Host or when the M_TTCAN module enters BusOff state, the debug message handling state machine stays in its current state instead of being reset to Idle state. Configuring the CANFD_CH_CCCR.CCE bit does not change CANFD_CH_RXF1S.DMS.
Parameters Affected	NA
Trigger Condition(s)	Either of the CANFD_CH_CCCR.INIT bits is set by the Host or when the M_TTCAN module enters BusOff state.
Scope of Impact	The errata is limited to the use case when the Debug on CAN functionality is active. Normal operation of the CAN module is not affected, in which case the debug message handling state machine always remains in Idle state. In the described use case, the debug message handling state machine is stopped and remains in the current state signaled by the CANFD_CH_RXF1S.DMS bit. If CANFD_CH_RXF1S.DMS is set to 0b11, the DMA request remains active.
Workaround	In case the debug message handling state machine stops while CANFD_CH_RXF1S.DMS is 0b01 or 0b10, it can be reset to Idle state by hardware reset or by reception of debug messages after CANFD_CH_CCCR.INIT is reset to zero.
Fix Status	No silicon fix planned. Use workaround.

8. TPIU Peripheral ID mismatch	
Problem Definition	TPIU peripheral ID indicates that it is M3-TPIU instead of M4-TPIU.
Parameters Affected	NA
Trigger Condition(s)	When the debugger reads PID registers for component identification.
Scope of Impact	The only impact is that the debuggers read the TPIU as M3-TPIU.
Workaround	No specific workaround required. Debuggers can use trace features.
Fix Status	No fix planned

9. Limitation of the memory hole in SCB register space	
Problem Definition	The memory hole [offset address: 0x1000 to 0xFFFF] inside the SCB register space is not aligned to the below defined spec. Since the offset address bits [15:12] are ignored and treated as 4'b0000, write/read access to the offset address [0x1000 to 0xFFFF] will actually happen to [0x0000 to 0x0FFF]. - Access to address gaps in mapped memory space: writes are ignored and any read returns a zero.
Parameters Affected	NA
Trigger Condition(s)	Access to the memory hole [offset address: 0x1000 to 0xFFFF] in SCB register space
Scope of Impact	The memory hole [offset address: 0x1000 to 0xFFFF] in the SCB register space is not aligned to other IP registers.
Workaround	Do not access to the memory hole [offset address: 0x1000 to 0xFFFF] in SCB register space.
Fix Status	No fix planned

10. WDT service can be missed	
Problem Definition	If WDT service happens within 4 ILO clock cycles before DeepSleep entry, it clears the counter but does not fully complete an internal handshake. A service after DeepSleep wakeup may then be missed if it occurs less than 2 ILO clock cycles after the processor resumes clocking. After this time, the internal handshake is complete and servicing works normally.
Parameters Affected	NA
Trigger Condition(s)	Service WDT within 4 ILO clock cycles before DeepSleep entry and within 2 ILO clock cycles of processor clock resuming
Scope of Impact	WDT service after DeepSleep wakeup may be ignored and WDT continues counting. This can cause unintended WARN_ACTION or UPPER_ACTION, including interrupt, fault, and/or reset.
Workaround	Wait 130 μ s or more after DeepSleep wakeup. (for example, to measure 130 μ s, software can read WDT_CNT register at wake up and make sure that WDT_CNT was incremented of 4 units before servicing WDT). Afterwards, write '1' to WDT service (WDT_SERVICE.SERVICE) after waiting until WDT service (WDT_SERVICE.SERVICE) reads '0'.
Fix Status	No silicon fix planned. Use workaround.
